Subnet / IP Range	Enter `10.10.10.0/24`. Include the netmask or specify a specific range.
Interface	Select **internal**. This is the interface on this FortiGate unit that will be handling with this traffic.

3. Define an address name for the IP address and netmask of the private network behind the remote peer.
4. Create another address. Enter the following information, and select **OK**.

Name	Enter `branch_1_internal`. A meaningful name for the private network behind the `branch_1` peer.
Type	Select **IP/Netmask**.
Subnet / IP Range	Enter `192.168.1.0/24`. Include the netmask or specify a specific range.
Interface	Select **any**. The interface on this FortiGate unit that will be handling with this traffic. If you are unsure, or multiple interfaces may be handling this traffic use `any`.

Creating branch_1 route-based security policies

Define an ACCEPT security policy to permit communications between the source and destination addresses. See Defining VPN security policies on page 1.

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information, and select **OK**.

Name	Enter an appropriate name for the policy.
Incoming Interface	Select **internal**. The interface that connects to the private network behind the `branch_1` FortiGate unit.
Outgoing Interface	Select **branch_1**. The VPN Tunnel (IPsec Interface) you configured earlier.
Source	Select **branch_1_internal**. The address name that you defined for the private network behind this FortiGate unit.
Destination Address	Select **branch_2_internal**. The address name that you defined for the private network behind the `branch_2` peer.
Action	Select **ACCEPT**.
NAT	Disable **NAT**.
Comments	Internal -> branch2

To permit the remote client to initiate communication, you need to define a security policy for communication in that direction.

3. Select **Create New**.
4. Enter the following information, and select **OK**.

Name	Enter an appropriate name for the policy.
Incoming Interface	Select **branch_1**. The VPN Tunnel (IPsec Interface) you configured earlier.
Outgoing Interface	Select **internal**. The interface that connects to the private network behind this FortiGate unit.
Source	Select **branch_2_internal**. The address name that you defined for the private network behind the `branch_2` remote peer.
Destination Address	Select **branch_1_internal**. The address name that you defined for the private network behind this FortiGate unit.
Action	Select **ACCEPT**.
NAT	Disable **NAT**.
Comments	branch_2 -> Internal

Creating branch_1 policy-based security policies

A policy-based security policy allows you the flexibility to allow inbound or outbound traffic or both through this single policy.

This policy-based IPsec VPN security policy allows both inbound and outbound traffic

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information, and select **OK**.

Incoming Interface	Select **internal**. The interface that connects to the private network behind this FortiGate unit.
Outgoing Interface	Select **wan1**. The FortiGate unit's public interface.
Source	Select **branch_1_internal**. The address name that you defined for the private network behind this FortiGate unit.
Destination Address	Select **branch_2_internal**. The address name that you defined for the private network behind the remote peer.
Action	Select **IPsec**. Under **VPN Tunnel**, select **branch_1** from the drop-down list. The name of the Phase 1 tunnel. Select **Allow traffic to be initiated from the remote site**.

3. Place this security policy in the policy list above any other policies having similar source and destination addresses.

Results

Once both ends are configured, you can test the VPN tunnel.

To test the VPN initiated by branch_2

1. On branch_2, go to **Monitor > IPsec Monitor**.
   All IPsec VPN tunnels will be listed on this page, no matter if they are connected or disconnected.
2. Select the tunnel listed for branch_2, and select the status column for that entry.
   The status will say **Bring Up** and remote port, incoming and outgoing data will all be zero. This indicates an inactive tunnel. When you right-click and select **Bring Up**, the FortiGate will try to set up a VPN session over this tunnel. If it is successful, Bring Up will change to Active, and the arrow icon will change to a green up arrow icon.
3. If this does not create a VPN tunnel with increasing values for incoming and outgoing data, you need to start troubleshooting:

To test the VPN initiated by branch_1

1. On branch_1, go to **Monitor > IPsec Monitor**.
2. Select the tunnel listed for branch_1, and select the status column.
   The difference between branch_2 and branch_1 at this point is that the tunnel entry for branch-1 will not have a remote gateway IP address. It will be resolved when the VPN tunnel is started.
3. If this does not create a VPN tunnel with increasing values for incoming and outgoing data, you need to start troubleshooting.

Some troubleshooting ideas include:

- If there was no entry for the tunnel on the monitor page, check the Auto Key (IKE) page to verify the Phase 1 and Phase 2 entries exist.
- Check the security policy or policies, and ensure there is an outgoing policy as a minimum.
- Check that you entered a local ID in the Phase 1 configuration, and that branch_1 has the same local ID.
- Ensure the local DNS server has an up-to-date DNS entry for exmaple.com.

For more information, see Troubleshooting on page 1.

FortiClient dialup-client configuration

The FortiClient Endpoint Security application is an IPsec VPN client with antivirus, antispam and firewall capabilities. This section explains how to configure dialup VPN connections between a FortiGate unit and one or more FortiClient Endpoint Security applications.

FortiClient users are usually mobile or remote users who need to connect to a private network behind a FortiGate unit. For example, the users might be employees who connect to the office network while traveling or from their homes.

For greatest ease of use, the FortiClient application can download the VPN settings from the FortiGate unit to configure itself automatically.

The following topics are included in this section:

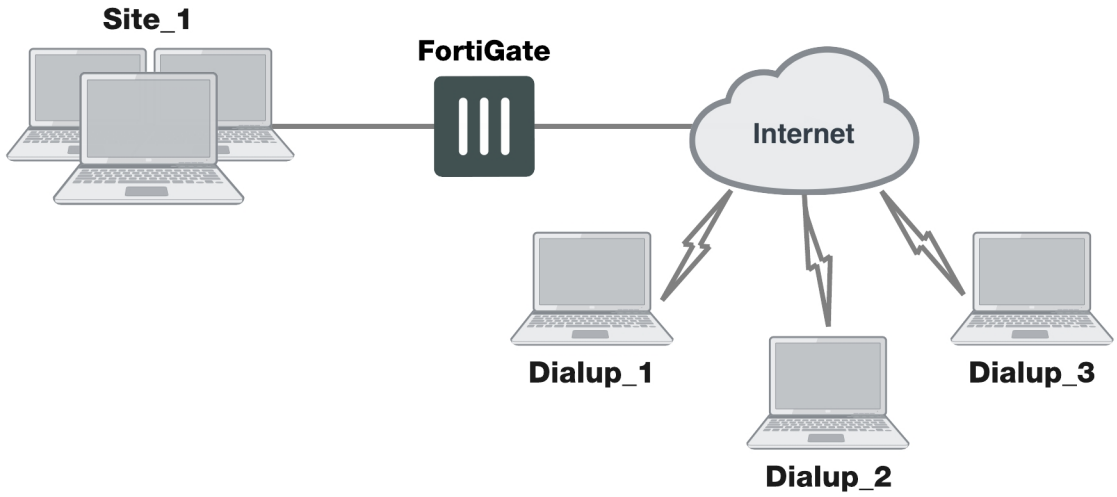
Configuration overview

Dialup users typically obtain dynamic IP addresses from an ISP through Dynamic Host Configuration Protocol (DHCP) or Point-to-Point Protocol over Ethernet (PPPoE). Then, the FortiClient Endpoint Security application initiates a connection to a FortiGate dialup server.

By default the FortiClient dialup client has the same IP address as the host PC on which it runs. If the host connects directly to the Internet, this is a public IP address. If the host is behind a NAT device, such as a router, the IP address is a private IP address. The NAT device must be NAT traversal (NAT-T) compatible to pass encrypted packets (see Phase 1 parameters on page 1967). The FortiClient application also can be configured to use a virtual IP address (VIP). For the duration of the connection, the FortiClient application and the FortiGate unit both use the VIP address as the IP address of the FortiClient dialup client.

The FortiClient application sends its encrypted packets to the VPN remote gateway, which is usually the public interface of the FortiGate unit. It also uses this interface to download VPN settings from the FortiGate unit. See Automatic configuration of FortiClient dialup clients on page 2042.

Example FortiClient dialup-client configuration



Peer identification

The FortiClient application can establish an IPsec tunnel with a FortiGate unit configured to act as a dialup server. When the FortiGate unit acts as a dialup server, it does not identify the client using the Phase 1 remote gateway address. The IPsec tunnel is established if authentication is successful and the IPsec security policy associated with the tunnel permits access. If configured, the FortiGate unit could also require FortiClient registration, that is, the remote user would be required to have FortiClient installed before connection is completed.

Automatic configuration of FortiClient dialup clients

The FortiClient application can obtain its VPN settings from the FortiGate VPN server. FortiClient users need to know only the FortiGate VPN server IP address and their username and password on the FortiGate unit.

The FortiGate unit listens for VPN policy requests from clients on TCP port 8900. When the dialup client connects:

- The client initiates a Secure Sockets Layer (SSL) connection to the FortiGate unit.
- The FortiGate unit requests a user name and password from the FortiClient user. Using these credentials, it authenticates the client and determines which VPN policy applies to the client.
- Provided that authentication is successful, the FortiGate unit downloads a VPN policy to the client over the SSL connection. The information includes IPsec Phase 1 and Phase 2 settings, and the IP addresses of the private networks that the client is authorized to access.
- The client uses the VPN policy settings to establish an IPsec Phase 1 connection and Phase 2 tunnel with the FortiGate unit.

FortiClient-to-FortiGate VPN configuration steps

Configuring dialup client capability for FortiClient dialup clients involves the following general configuration steps:

1. If you will be using VIP addresses to identify dialup clients, determine which VIP addresses to use. As a precaution, consider using VIP addresses that are not commonly used.
2. Configure the FortiGate unit to act as a dialup server. See Configure the FortiGate unit on page 1.

3. If the dialup clients will be configured to obtain VIP addresses through DHCP over IPsec, configure the FortiGate unit to act as a DHCP server or to relay DHCP requests to an external DHCP server.
4. Configure the dialup clients. See Configure the FortiClient Endpoint Security application on page 1.

Using virtual IP addresses

When the FortiClient host PC is located behind a NAT device, unintended IP address overlap issues may arise between the private networks at the two ends of the tunnel. For example, the client's host might receive a private IP address from a DHCP server on its network that by co-incidence is the same as a private IP address on the network behind the FortiGate unit. A conflict will occur in the host's routing table and the FortiClient Endpoint Security application will be unable to send traffic through the tunnel. Configuring virtual IP (VIP) addresses for FortiClient applications prevents this problem.

Using VIPs ensures that client IP addresses are in a predictable range. You can then define security policies that allow access only to that source address range. If you do not use VIPs, the security policies must allow all source addresses because you cannot predict the IP address for a remote mobile user.

The FortiClient application must not have the same IP address as any host on the private network behind the FortiGate unit or any other connected FortiClient application. You can ensure this by reserving a range of IP addresses on the private network for FortiClient users. Or, you can assign FortiClient VIPs from an uncommonly used subnet such as 10.254.254.0/24 or 192.168.254.0/24.

You can reserve a VIP address for a particular client according to its device MAC address and type of connection. The DHCP server then always assigns the reserved VIP address to the client. For more information about this feature, see the "dhcp reserved-address" section in the "system" chapter of the FortiGate CLI Reference.

On the host computer, you can find out the VIP address that the FortiClient Endpoint Security application is using. For example, in Windows command prompt, type `ipconfig /all`

On Linux or Mac OS X, type `ifconfig` in a terminal window. The output will also show the IP address that has been assigned to the host Network Interface Card (NIC).

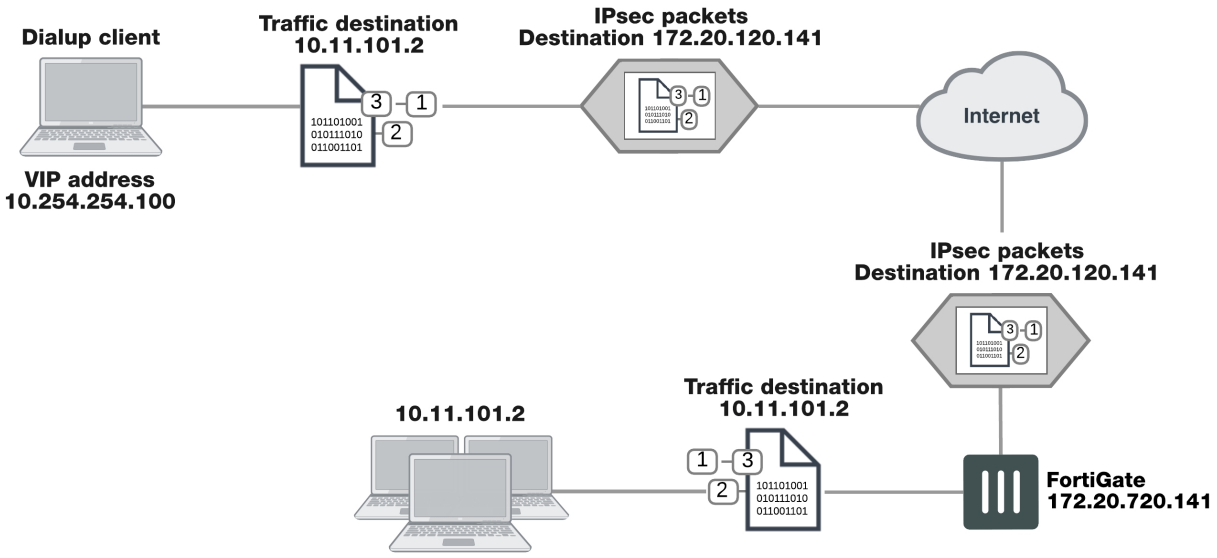
It is best to assign VIPs using DHCP over IPsec. The FortiGate dialup server can act as a DHCP server or relay requests to an external DHCP server. You can also configure VIPs manually on FortiClient applications, but it is more difficult to ensure that all clients use unique addresses.

If you assign a VIP on the private network behind the FortiGate unit and enable DHCP-IPsec (a Phase 2 advanced option), the FortiGate unit acts as a proxy on the local private network for the FortiClient dialup client. Whenever a host on the network behind the dialup server issues an ARP request for the device MAC address of the FortiClient host, the FortiGate unit answers the ARP request on behalf of the FortiClient host and forwards the associated traffic to the FortiClient host through the tunnel. For more information, see Phase 2 parameters on page 1985.

FortiGate units fully support RFC 3456. The FortiGate DHCP over IPsec feature can be enabled to allocate VIP addresses to FortiClient dialup clients using a FortiGate DHCP server.

The figure below shows an example of a FortiClient-to-FortiGate VPN where the FortiClient application is assigned a VIP on an uncommonly used subnet. The diagram also shows that while the destination for the information in the encrypted packets is the private network behind the FortiGate unit, the destination of the IPsec packets themselves is the public interface of the FortiGate unit that acts as the end of the VPN tunnel.

IP address assignments in a FortiClient dialup-client configuration



Assigning VIPs by RADIUS user group

If you use XAuth authentication, you can assign users the virtual IP address stored in the Framed-IP-Address field of their record on the RADIUS server. (See RFC 2865 and RFC 2866 for more information about RADIUS fields.) To do this:

- Set the DHCP server **IP Assignment Mode** to **User-group defined method**. This is an Advanced setting. See Configuring a DHCP server on a FortiGate interface on page 2048.
- Create a new firewall user group and add the RADIUS server to it.
- In your Phase 1 settings, configure the FortiGate unit as an XAuth server and select from **User Group** the new user group that you created. For more information, see Phase 1 parameters on page 1967.
- Configure the FortiClient application to use XAuth. See Configuration overview on page 2041.

FortiClient dialup-client infrastructure requirements

- To support policy-based VPNs, the FortiGate dialup server may operate in either NAT mode or transparent mode. NAT mode is required if you want to create a route-based VPN.
- If the FortiClient dialup clients will be configured to obtain VIP addresses through FortiGate DHCP relay, a DHCP server must be available on the network behind the FortiGate unit and the DHCP server must have a direct route to the FortiGate unit.
- If the FortiGate interface to the private network is not the default gateway, the private network behind the FortiGate unit must be configured to route IP traffic destined for dialup clients back (through an appropriate gateway) to the FortiGate interface to the private network. As an alternative, you can configure the IPsec security policy on the FortiGate unit to perform inbound NAT on IP packets. Inbound NAT translates the source addresses of inbound decrypted packets into the IP address of the FortiGate interface to the local private network.

Configuring the FortiGate unit

Configuring the FortiGate unit to establish VPN connections with FortiClient Endpoint Security users involves the following steps:

- Configure the VPN settings
- If the dialup clients use automatic configuration, configure the FortiGate unit as a VPN policy server
- If the dialup clients obtain VIP addresses by DHCP over IPsec, configure an IPsec DHCP server or relay

The procedures in this section cover basic setup of policy-based and route-based VPNs compatible with FortiClient Endpoint Security. A route-based VPN is simpler to configure.

The IPsec VPN Wizard greatly simplifies IPsec VPN tunnel creation for route-based tunnels.

To configure FortiGate unit VPN settings to support FortiClient users, you need to:

- Configure the FortiGate Phase 1 VPN settings
- Configure the FortiGate Phase 2 VPN settings
- Add the security policy

On the local FortiGate unit, define the Phase 1 configuration needed to establish a secure connection with the FortiClient peer. See Phase 1 parameters on page 1967.

1. Go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit **Network** (full configuration options are only available once you click the **Convert To Custom Tunnel** button).
3. Enter these settings in particular:

Remote Gateway	Select **Dialup User**.
IP Address	Enter the IP address of the remote peer.
Interface	Select the interface through which clients connect to the FortiGate unit.
Mode Config	When enabled, further options become available: • **Client Address Range** • **Subnet Mask** • **Use System DNS** • **DNS Server** • **Enable IPv4 Split Tunnel**
Authentication Method	Select **Pre-shared Key**.
Pre-shared Key	Enter the pre-shared key. This must be the same preshared key provided to the FortiClient users.
Peer option	Select **Any peer ID**.

4. Edit **Authentication** and enter the following information:

Method	Select **Pre-shared Key**.

Pre-shared Key	Enter the pre-shared key. This must be the same preshared key provided to the FortiClient users.
Peer Options	Set **Accept Types** to **Any peer ID**.

5. Define the Phase 2 parameters needed to create a VPN tunnel with the FortiClient peer. See Phase 2 parameters on page 1985. Enter these settings in particular:

Name	Enter a name to identify this Phase 2 configuration.
Phase 1	Select the name of the Phase 1 configuration that you defined.
Advanced	Select to configure the following optional setting.
DHCP-IPsec	Select if you provide virtual IP addresses to clients using DHCP.

6. Define names for the addresses or address ranges of the private networks that the VPN links. These addresses are used in the security policies that permit communication between the networks. For more information, see Defining policy addresses on page 1.

   Enter these settings in particular:
   - Define an address name for the individual address or the subnet address that the dialup users access through the VPN.
   - If FortiClient users are assigned VIP addresses, define an address name for the subnet to which these VIPs belong.

4. Define security policies to permit communication between the private networks through the VPN tunnel. Route-based and policy-based VPNs require different security policies. For detailed information about creating security policies, see Defining VPN security policies on page 1.

If the security policy, which grants the VPN Connection is limited to certain services, DHCP must be included, otherwise the client won't be able to retrieve a lease from the FortiGate's (IPsec) DHCP server, because the DHCP Request (coming out of the tunnel) will be blocked.

Route-based VPN security policies

Define an ACCEPT security policy to permit communications between the source and destination addresses.

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter these settings in particular:

Name	Enter an appropriate name for the policy.
Incoming Interface	Select the VPN Tunnel (IPsec Interface) you configured in Step "Configuration overview" on page 2041.
Outgoing Interface	Select the interface that connects to the private network behind this FortiGate unit.
Source	Select **all**.

Destination Address	Select **all**.
Action	Select **ACCEPT**.
NAT	Disable **NAT**.

If you want to allow hosts on the private network to initiate communications with the FortiClient users after the tunnel is established, you need to define a security policy for communication in that direction.

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter these settings in particular:

Incoming Interface	Select the interface that connects to the private network behind this FortiGate unit.
Outgoing Interface	Select the interface that connects to the private network behind this FortiGate unit.
Source	Select **all**.
Destination Address	Select **all**.
Action	Select **ACCEPT**.
NAT	Disable **NAT**.

Policy-based VPN security policy

Define an IPsec security policy to permit communications between the source and destination addresses.

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter these settings in particular:

Incoming Interface	Select the interface that connects to the private network behind this FortiGate unit.
Outgoing Interface	Select the FortiGate unit's public interface.
Source	Select the address name that you defined in Step "Configuration overview" on page 2041 for the private network behind this FortiGate unit.
Destination Address	If FortiClient users are assigned VIPs, select the address name that you defined for the VIP subnet. Otherwise, select **all**.
Action	Select **IPsec**. Under **VPN Tunnel**, select the name of the Phase 1 configuration that you created in Step "Configuration overview" on page 2041 from the drop-down list. Select **Allow traffic to be initiated from the remote site**.

Place VPN policies in the policy list above any other policies having similar source and destination addresses.

Configuring the FortiGate unit as a VPN policy server

When a FortiClient application set to automatic configuration connects to the FortiGate unit, the FortiGate unit requests a user name and password. If the user supplies valid credentials, the FortiGate unit downloads the VPN settings to the FortiClient application.

You must do the following to configure the FortiGate unit to work as a VPN policy server for FortiClient automatic configuration:

1. Create user accounts for FortiClient users.
2. Create a user group for FortiClient users and the user accounts that you created in step 1.
3. Connect to the FortiGate unit CLI and configure VPN policy distribution as follows:

```
config vpn ipsec forticlient
   edit <policy_name>
      set phase2name <tunnel_name>
      set usergroupname <group_name>
      set status enable
   end
```

`<tunnel_name>` must be the Name you specified in the step 2 of Configuration overview on page 2041.
`<group_name>` must be the name of the user group your created for FortiClient users.

Configuring DHCP services on a FortiGate interface

If the FortiClient dialup clients are configured to obtain a VIP address using DHCP, configure the FortiGate dialup server to either:

- Relay DHCP requests to a DHCP server behind the FortiGate unit (see Configuring DHCP relay on a FortiGate interface on page 2048 below).
- Act as a DHCP server (see Configuring a DHCP server on a FortiGate interface on page 2048).

Note that DHCP services are typically configured during the interface creation stage, but you can return to an interface to modify DHCP settings if need be.

Configuring DHCP relay on a FortiGate interface

1. Go to **Network > Interfaces** and select the interface that you want to relay DHCP.
2. Enable **DHCP Server**, and create a new DHCP **Address Range** and **Netmask**.
3. Open the **Advanced...** menu and set **Mode** to **Relay**.
4. Enter the **DHCP Server IP**.
5. Select **OK**.

Configuring a DHCP server on a FortiGate interface

1. Go to **Network > Interfaces** and select the interface that you want to act as a DHCP server.
2. Enable **DHCP Server**, and create a new DHCP **Address Range** and **Netmask**.
3. Set **Default Gateway** to **Specify**, and enter the IP address of the default gateway that the DHCP server assigns to DHCP clients.
4. Set **DNS Server** to **Same as System DNS**. If you want to use a different DNS server for VPN clients, select **Specify** and enter an IP address in the available field.
5. Open the **Advanced...** menu and set **Mode** to **Server**.
6. Select **OK**.

Configure the FortiClient Endpoint Security application

The following procedure explains how to configure the FortiClient Endpoint Security application to communicate with a remote FortiGate dialup server using the VIP address that you specify manually. These procedures are based on FortiClient 5.4.1.

Configuring FortiClient

This procedure explains how to configure the FortiClient application manually using the default IKE and IPsec settings. For more information, refer to the FortiClient Administration Guide.

1. Go to **Remote Access** and select the **Settings** icon.
2. Select **Add a new connection**, set the new VPN connection to **IPsec VPN**, and complete following information:

Connection Name	Enter a descriptive name for the connection.
Remote Gateway	Enter the IP address or the fully qualified domain name (FQDN) of the remote gateway.
Authentication Method	Select **Pre-shared Key** and enter the pre-shared key in the field provided.
Authentication (XAuth)	Extended Authentication (XAuth) increases security by requiring additional user authentication in a separate exchange at the end of the VPN Phase 1 negotiation. The FortiGate unit challenges the user for a user name and password. It then forwards the user's credentials to an external RADIUS or LDAP server for verification. Implementation of XAuth requires configuration at both the FortiGate unit and the FortiClient application.

3. Select **OK**.

Adding XAuth authentication

For information about configuring a FortiGate unit as an XAuth server, see Phase 1 parameters on page 1967. The following procedure explains how to configure the FortiClient application.

Note that XAuth is not compatible with IKE version 2.

For more information on configuring XAuth authentication, see the FortiClient Administration Guide.

FortiGate dialup-client configurations

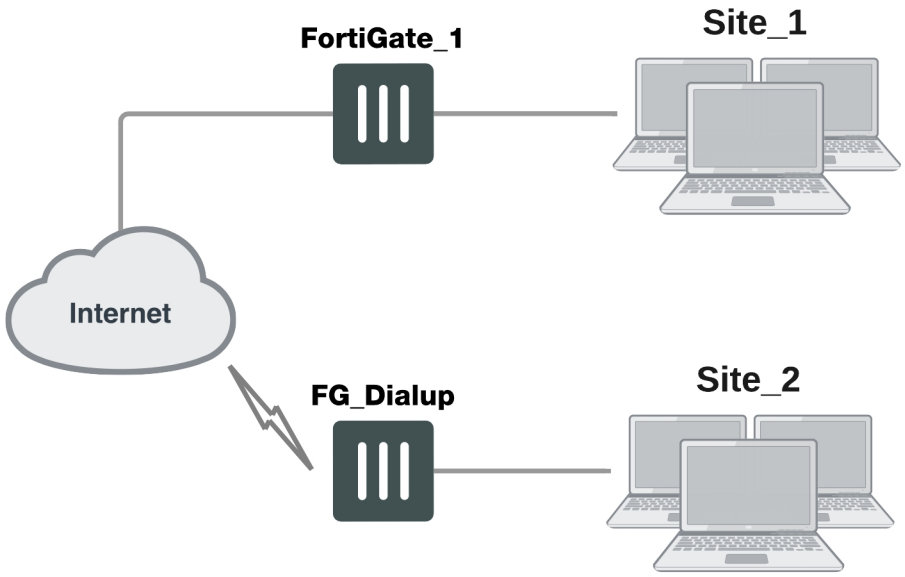
This section explains how to set up a FortiGate dialup-client IPsec VPN. In a FortiGate dialup-client configuration, a FortiGate unit with a static IP address acts as a dialup server and a FortiGate unit having a dynamic IP address initiates a VPN tunnel with the FortiGate dialup server.

The following topics are included in this section:

Configuration overview

A dialup client can be a FortiGate unit. The FortiGate dialup client typically obtains a dynamic IP address from an ISP through the Dynamic Host Configuration Protocol (DHCP) or Point-to-Point Protocol over Ethernet (PPPoE) before initiating a connection to a FortiGate dialup server.

Example FortiGate dialup-client configuration



In a dialup-client configuration, the FortiGate dialup server does not rely on a Phase 1 remote gateway address to establish an IPsec VPN connection with dialup clients. As long as authentication is successful and the IPsec security policy associated with the tunnel permits access, the tunnel is established.

Several different ways to authenticate dialup clients and restrict access to private networks based on client credentials are available. To authenticate FortiGate dialup clients and help to distinguish them from FortiClient dialup clients when multiple clients will be connecting to the VPN through the same tunnel, best practices dictate that you assign a unique identifier (local ID or peer ID) to each FortiGate dialup client. For more information, see Phase 1 parameters on page 1967.

Whenever you add a unique identifier (local ID) to a FortiGate dialup client for identification purposes, you must select Aggressive mode on the FortiGate dialup server and also specify the identifier as a peer ID on the FortiGate dialup server. For more information, see Phase 1 parameters on page 1967.

Users behind the FortiGate dialup server cannot initiate the tunnel because the FortiGate dialup client does not have a static IP address. After the tunnel is initiated by users behind the FortiGate dialup client, traffic from the private network behind the FortiGate dialup server can be sent to the private network behind the FortiGate dialup client.

Encrypted packets from the FortiGate dialup client are addressed to the public interface of the dialup server. Encrypted packets from the dialup server are addressed either to the public IP address of the FortiGate dialup client (if the dialup client connects to the Internet directly), or if the FortiGate dialup client is behind a NAT device, encrypted packets from the dialup server are addressed to the public IP address of the NAT device.

If a router with NAT capabilities is in front of the FortiGate dialup client, the router must be NAT-T compatible for encrypted traffic to pass through the NAT device. For more information, see Phase 1 parameters on page 1967.

When the FortiGate dialup server decrypts a packet from the FortiGate dialup client, the source address in the IP header may be one of the following values, depending on the configuration of the network at the far end of the tunnel:

- If the FortiGate dialup client connects to the Internet directly, the source address will be the private IP address of a host or server on the network behind the FortiGate dialup client.
- If the FortiGate dialup client is behind a NAT device, the source address will be the public IP address of the NAT device.

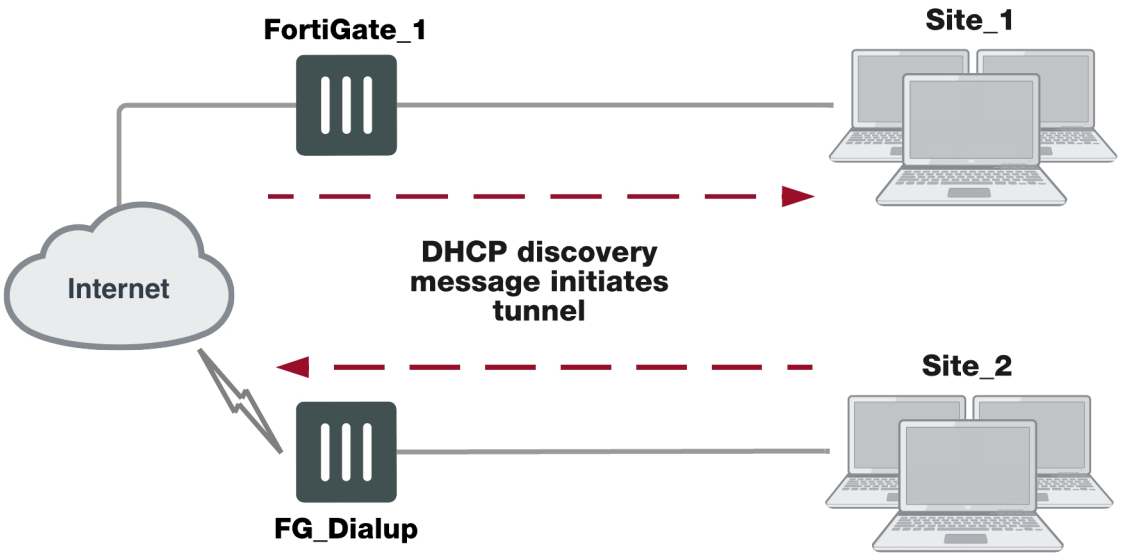
In some cases, computers on the private network behind the FortiGate dialup client may (by co-incidence) have IP addresses that are already used by computers on the network behind the FortiGate dialup server. In this type of situation (ambiguous routing), conflicts may occur in one or both of the FortiGate routing tables and traffic destined for the remote network through the tunnel may not be sent.

In many cases, computers on the private network behind the FortiGate dialup client will most likely obtain IP addresses from a local DHCP server behind the FortiGate dialup client. However, unless the local and remote networks use different private network address spaces, unintended ambiguous routing and IP-address overlap issues may arise.

To avoid these issues, you can configure FortiGate DHCP relay on the dialup client instead of using a DHCP server on the network behind the dialup client. The FortiGate dialup client can be configured to relay DHCP requests from the local private network to a DHCP server that resides on the network behind the FortiGate dialup server. You configure the FortiGate dialup client to pass traffic from the local private network to the remote network by enabling FortiGate DHCP relay on the FortiGate dialup client interface that is connected to the local private network.

Afterward, when a computer on the network behind the dialup client broadcasts a DHCP request, the dialup client relays the message through the tunnel to the remote DHCP server. The remote DHCP server responds with a private IP address for the computer. To avoid ambiguous routing and network overlap issues, the IP addresses assigned to computers behind the dialup client cannot match the network address space used by the private network behind the FortiGate dialup server.

Preventing network overlap in a FortiGate dialup-client configuration



When the DHCP server resides on the private network behind the FortiGate dialup server, the IP destination address specified in the IPsec security policy on the FortiGate dialup client must refer to that network.

You must add a static route to the DHCP server FortiGate unit if it is not directly connected to the private network behind the FortiGate dialup server; its IP address does not match the IP address of the private network. Also, the destination address in the IPsec security policy on the FortiGate dialup client must refer to the DHCP server address. The DHCP server must be configured to assign a range of IP addresses different from the DHCP server's local network, and also different from the private network addresses behind the FortiGate dialup server. See Routing on page 1.

FortiGate dialup-client infrastructure requirements

The requirements are:

- The FortiGate dialup server must have a static public IP address.
- NAT mode is required if you want to create a route-based VPN.
- The FortiGate dialup server may operate in either NAT mode or transparent mode to support a policy-based VPN.
- Computers on the private network behind the FortiGate dialup client can obtain IP addresses either from a DHCP server behind the FortiGate dialup client, or a DHCP server behind the FortiGate dialup server.
  - If the DHCP server resides on the network behind the dialup client, the DHCP server must be configured to assign IP addresses that do not match the private network behind the FortiGate dialup server.
  - If the DHCP server resides on the network behind the FortiGate dialup server, the DHCP server must be configured to assign IP addresses that do not match the private network behind the FortiGate dialup client.

Configuring the server to accept FortiGate dialup-client connections

The procedures in this section assume that computers on the private network behind the FortiGate dialup client obtain IP addresses from a local DHCP server. The assigned IP addresses do not match the private network behind the FortiGate dialup server.

In situations where IP-address overlap between the local and remote private networks is likely to occur, FortiGate DHCP relay can be configured on the FortiGate dialup client to relay DHCP requests to a DHCP server behind the FortiGate dialup server. For more information, see To configure DHCP relay on a FortiGate interface on page 1.

Configuring dialup client capability for FortiGate dialup clients involves the following general configuration steps:

- Determine which IP addresses to assign to the private network behind the FortiGate dialup client, and add the IP addresses to the DHCP server behind the FortiGate dialup client. Refer to the software supplier's documentation to configure the DHCP server.
- Configure the FortiGate dialup server. See Configuration overview on page 2050.
- Configure the FortiGate dialup client. See Configuration overview on page 2050.

Before you begin, optionally reserve a unique identifier (peer ID) for the FortiGate dialup client. The dialup client will supply this value to the FortiGate dialup server for authentication purposes during the IPsec Phase 1 exchange. In addition, the value will enable you to distinguish FortiGate dialup-client connections from FortiClient dialup-client connections. The same value must be specified on the dialup server and on the dialup client.

In circumstances where multiple remote dialup VPN tunnels exist, each tunnel must have a peer ID set.

At the FortiGate dialup server, define the Phase 1 parameters needed to authenticate the FortiGate dialup client and establish a secure connection. See Phase 1 parameters on page 1967.

1. Go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit **Network** (full configuration options are only available once you click the **Convert To Custom Tunnel** button).
3. Enter these settings in particular:

Remote Gateway	Select **Dialup User**.
Interface	Select the interface through which clients connect to the FortiGate unit.

4. Edit **Authentication** and enter the following information:

Mode	If you will be assigning an ID to the FortiGate dialup client, select **Aggressive**.
Peer Options	If you will be assigning an ID to the FortiGate dialup client, set **Accept Types** to **This peer ID** and type the identifier that you reserved for the FortiGate dialup client into the adjacent field.

5. Define the Phase 2 parameters needed to create a VPN tunnel with the FortiGate dialup client. See Phase 2 parameters on page 1985. Enter these settings in particular:

Name	Enter a name to identify this Phase 2 configuration.
Phase 1	Select the name of the Phase 1 configuration that you defined.

6. Define names for the addresses or address ranges of the private networks that the VPN links. See Defining policy addresses on page 1. Enter these settings in particular:
   - Define an address name for the server, host, or network behind the FortiGate dialup server.
   - Define an address name for the private network behind the FortiGate dialup client.
4. Define the security policies to permit communications between the private networks through the VPN tunnel. Route-based and policy-based VPNs require different security policies. For detailed information about creating security policies, see Defining VPN security policies on page 1.

Route-based VPN security policy

Define an ACCEPT security policy to permit communications between hosts on the private network behind the FortiGate dialup client and the private network behind this FortiGate dialup server. Because communication cannot be initiated in the opposite direction, there is only one policy.

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter these settings in particular:

Name	Enter an appropriate name for the policy.
Incoming Interface	Select the VPN tunnel (IPsec interface) created in Step 1.
Outgoing Interface	Select the interface that connects to the private network behind this FortiGate unit.
Source	Select **all**.
Destination Address	Select **all**.
Action	Select **ACCEPT**.
NAT	Disable **NAT**.

Policy-based VPN security policy

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter these settings in particular:

Name	Enter an appropriate name for the policy.
Incoming Interface	Select the interface that connects to the private network behind this FortiGate unit.
Outgoing Interface	Select the FortiGate unit's public interface.
Source	Select the address name that you defined for the private network behind this FortiGate unit.

Destination Address	Select the address name that you defined.
Action	Select **IPsec**. Under **VPN Tunnel**, select the name of the Phase 1 configuration that you created in Step "Configuration overview " on page 2050 from the drop-down list. Select **Allow traffic to be initiated from the remote site**.

3. To prevent traffic from the local network from initiating the tunnel after the tunnel has been established, you need to disable the outbound VPN traffic in the CLI

```
config firewall policy
   edit <policy_number>
      set outbound disable
end
```

Place the policy in the policy list above any other policies having similar source and destination addresses.

If configuring a route-based policy, configure a default route for VPN traffic on this interface.

Configuring the FortiGate dialup client

At the FortiGate dialup client, define the Phase 1 parameters needed to authenticate the dialup server and establish a secure connection. See Phase 1 parameters on page 1967.

1. Go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit **Network** (full configuration options are only available once you click the **Convert To Custom Tunnel** button).
3. Enter these settings in particular:

Remote Gateway	Select **Static IP Address**.
IP Address	Type the IP address of the dialup server's public interface.
Interface	Select the interface that connects to the public network.
Mode	The FortiGate dialup client has a dynamic IP address, select **Aggressive**.
Advanced	Select to view the following options.
Local ID	If you defined a peer ID for the dialup client in the FortiGate dialup server configuration, enter the identifier of the dialup client. The value must be identical to the peer ID that you specified previously in the FortiGate dialup server configuration.

4. Edit **Authentication** and enter the following information:

Mode	The FortiGate dialup client has a dynamic IP address, select **Aggressive**.

5. Edit **Phase 1 Proposal** and enter the following information:

Local ID	If you defined a peer ID for the dialup client in the FortiGate dialup server configuration, enter the identifier of the dialup client. The value must be identical to the peer ID that you specified previously in the FortiGate dialup server configuration.

6. Define the Phase 2 parameters needed to create a VPN tunnel with the dialup server. See Phase 2 parameters on page 1985. Enter these settings in particular:

Name	Enter a name to identify this Phase 2 configuration.
Phase 1	Select the name of the Phase 1 configuration that you defined.

7. Define names for the addresses or address ranges of the private networks that the VPN links. See Defining policy addresses on page 1. Enter these settings in particular:
   - Define an address name for the server, host, or network behind the FortiGate dialup server.
   - Define an address name for the private network behind the FortiGate dialup client.
4. Define security policies to permit communication between the private networks through the VPN tunnel. Route-based and policy-based VPNs require different security policies. For detailed information about creating security policies, see Defining VPN security policies on page 1.

Route-based VPN security policy

Define an ACCEPT security policy to permit communications between hosts on the private network behind this FortiGate dialup client and the private network behind the FortiGate dialup server. Because communication cannot be initiated in the opposite direction, there is only one policy.

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter these settings in particular:

Name	Enter an appropriate name for the policy.
Incoming Interface	Select the interface that connects to the private network behind this FortiGate unit.
Outgoing Interface	Select the VPN tunnel (IPsec interface) created in Step 1.
Source	Select **all**.
Destination Address	Select **all**.
Action	Select **ACCEPT**.
NAT	Disable **NAT**.

Policy-based VPN security policy

Define an IPsec security policy to permit communications between the source and destination addresses.

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter these settings in particular:

Incoming Interface	Select the interface that connects to the private network behind this FortiGate unit.
Outgoing Interface	Select the FortiGate unit's public interface.
Source	Select the address name that you defined for the private network behind this FortiGate unit.
Destination Address	Select the address name that you defined for the private network behind the dialup server.
Action	Select **IPsec**. Under **VPN Tunnel**, select the name of the Phase 1 configuration that you created in Step "Configuration overview " on page 2050 from the drop-down list. Clear **Allow traffic to be initiated from the remote site** to prevent traffic from the remote network from initiating the tunnel after the tunnel has been established.

Place the policy in the policy list above any other policies having similar source and destination addresses.

Supporting IKE Mode Config clients

IKE Mode Config is an alternative to DHCP over IPsec. A FortiGate unit can be configured as either an IKE Mode Config server or client. This chapter contains the following sections:

IKE Mode Config overview

Dialup VPN clients connect to a FortiGate unit that acts as a VPN server, providing the client the necessary configuration information to establish a VPN tunnel. The configuration information typically includes a virtual IP address, netmask, and DNS server address.

IKE Mode Config is available only for VPNs that are route-based, also known as interface-based. A FortiGate unit can function as either an IKE Configuration Method server or client. IKE Mode Config is configurable only in the CLI.

Automatic configuration overview

VPN configuration for remote clients is simpler if it is automated. Several protocols support automatic configuration:

- The Fortinet FortiClient Endpoint Security application can completely configure a VPN connection with a suitably configured FortiGate unit given only the FortiGate unit's address. This protocol is exclusive to Fortinet. For more information, see FortiClient dialup-client configurations on page 1.
- DHCP over IPsec can assign an IP address, Domain, DNS and WINS addresses. The user must first configure IPsec parameters such as gateway address, encryption and authentication algorithms.
- IKE Mode Config can configure host IP address, Domain, DNS and WINS addresses. The user must first configure IPsec parameters such as gateway address, encryption and authentication algorithms. Several network equipment vendors support IKE Mode Config, which is described in the ISAKMP Configuration Method document draft-dukes-ike-mode-cfg-02.txt.

This chapter describes how to configure a FortiGate unit as either an IKE Mode Config server or client.

IKE Mode Config method

IKE Mode Config is configured with the CLI command `config vpn ipsec phase1-interface`. The `mode-cfg` variable enables IKE Mode Config. The `type` field determines whether you are creating an IKE Mode Config server or a client. Setting `type` to `dynamic` creates a server configuration, otherwise the configuration is a client.

Creating an IKE Mode Config client

If the FortiGate unit will connect as a dialup client to a remote gateway that supports IKE Mode Config, the relevant `vpn ipsec phase1-interface` variables are as follows:

Variable	Description
`ike-version 1`	IKE v1 is the default for FortiGate IPsec VPNs. IKE Mode Config is also compatible with IKE v2 (RFC 4306). Use syntax `ike-version 2`.
`mode-cfg enable`	Enable IKE Mode Config.
`type {ddns | static}`	If you set `type` to `dynamic`, an IKE Mode Config server is created.
`assign-ip {enable | disable}`	Enable to request an IP address from the server.
`interface <interface_name>`	This is a regular IPsec VPN field. Specify the physical, aggregate, or VLAN interface to which the IPsec tunnel will be bound.
`proposal <encryption_combination>`	This is a regular IPsec VPN field that determines the encryption and authentication settings that the client will accept. For more information, see Phase 1 parameters on page 1967.
`ip-version <4 | 6>`	This is a regular IPsec VPN field. By default, IPsec VPNs use IPv4 addressing. You can set `ip-version` to `6` to create a VPN with IPv6 addressing.

For a complete list of available variables, see the CLI Reference.

IKE Mode Config client example - CLI

In this example, the FortiGate unit connects to a VPN gateway with a static IP address that can be reached through Port 1. Only the port, gateway and proposal information needs to be configured. All other configuration information will come from the IKE Mode Config server.

```
config vpn ipsec phase1-interface
   edit vpn1
      set ip-version 4
      set type static
      set remote-gw <gw_address>
      set interface port 1
      set proposal 3des-sha1 aes128-sha1
      set mode-cfg enable
      set assign-ip enable
   end
```

Creating an IKE Mode Config server

If the FortiGate unit will accept connection requests from dialup clients that support IKE Mode Config, the following `vpn ipsec phase1-interface` settings are required before any other configuration is attempted:

Variable	Description
`ike-version 1`	IKE v1 is the default for FortiGate IPsec VPNs. IKE Mode Config is also compatible with IKE v2 (RFC 4306). Use syntax `ike-version 2`.
`mode-cfg enable`	Enable IKE Mode Config.
`type dynamic`	Any other setting creates an IKE Mode Config client.
`interface <interface_name>`	This is a regular IPsec VPN field. Specify the physical, aggregate, or VLAN interface to which the IPsec tunnel will be bound.
`proposal <encryption_combination>`	This is a regular IPsec VPN field that determines the encryption and authentication settings that the server will accept. For more information, see Phase 1 parameters on page 1967.
`ip-version <4 | 6>`	This is a regular IPsec VPN field. By default, IPsec VPNs use IPv4 addressing. You can set `ip-version` to `6` to create a VPN with IPv6 addressing.

IKE Mode Config server example - CLI

In this example, the FortiGate unit assigns IKE Mode Config clients addresses in the range of 10.11.101.160 through 10.11.101.180. DNS and WINS server addresses are also provided. The public interface of the FortiGate unit is Port 1.

When IKE Mode-Configuration is enabled, multiple server IPs can be defined in IPsec Phase 1.

The `ipv4-split-include` variable specifies a firewall address that represents the networks to which the clients will have access. This destination IP address information is sent to the clients.

Only the CLI fields required for IKE Mode Config are shown here. For detailed information about these variables, see the FortiGate CLI Reference.

```
config vpn ipsec phase1-interface
edit "vpn-p1"
   set type dynamic
   set interface "wan1"
   set xauthtype auto
   set mode aggressive
   set mode-cfg enable
   set proposal 3des-sha1 aes128-sha1
   set dpd disable
   set dhgrp 2
   set xauthexpire on-rekey
   set authusrgrp "FG-Group1"
   set ipv4-start-ip 10.10.10.10
   set ipv4-end-ip 10.10.10.20
   set ipv4-dns-server1 1.1.1.1
   set ipv4-dns-server2 2.2.2.2
   set ipv4-dns-server3 3.3.3.3
   set ipv4-wins-server1 4.4.4.4
   set ipv4-wins-server2 5.5.5.5
```

```
    set domain "fgt1c-domain"
    set banner "fgt111C-banner"
    set backup-gateway "100.100.100.1" "host1.com" "host2"
    set ipv4-split-include OfficeLAN
end
```

IP address assignment

After you have enabled the basic configuration, you can configure IP address assignment for clients, as well as DNS and WINS server assignment. Usually you will want to assign IP addresses to clients.

The simplest method to assign IP addresses to clients is to assign addresses from a specific range, similar to a DHCP server.

If your clients are authenticated by a RADIUS server, you can obtain the user's IP address assignment from the Framed-IP-Address attribute. The user must be authenticated using XAuth.

IKE Mode Config can also use a remote DHCP server to assign the client IP addresses. Up to eight addresses can be selected for either IPv4 or IPv6. After the DHCP proxy has been configured, the `assign-ip-from` command is used to assign IP addresses via DHCP.

Assigning IP addresses from an address range - CLI

If your VPN uses IPv4 addresses,

```
config vpn ipsec phase1-interface
   edit vpn1
      set mode-cfg-ipversion 4
      set assign-ip enable
      set assign-ip-type ip
      set assign-ip-from range
      set ipv4-start-ip <range_start>
      set ipv4-end-ip <range_end>
      set ipv4-netmask <netmask>
   end
```

If your VPN uses IPv6 addresses,

```
config vpn ipsec phase1-interface
   edit vpn1
      set mode-cfg-ipversion 6
      set assign-ip enable
      set assign-ip-type ip
      set assign-ip-from range
      set ipv6-start-ip <range_start>
      set ipv6-end-ip <range_end>
   end
```

Assigning IP addresses from a RADIUS server - CLI

The users must be authenticated by a RADIUS server and assigned to the FortiGate user group `<grpname>`. Since the IP address will not be static, `type` is set to dynamic, and `mode-cfg` is enabled. This is IKE Configuration Method so that compatible clients can configure themselves with settings that the FortiGate unit provides.

```
config vpn ipsec phase1-interface
```

```
edit vpn1
   set type dynamic
      set mode-cfg enable
      set assign-ip enable
      set assign-ip-from usrgrp
      set xauthtype auto
      set authusrgrp <grpname>
end
```

Assigning IP address from DHCP - CLI

The DHCP proxy must first be enabled for IKE Mode Config to use DHCP to assign the VPN client IP address(es).

```
config system settings
   set dhcp-proxy enable
   set dhcp-server-ip [ipv4 address]
   set dhcp6-server-ip [ipv6-address]
```

(Up to eight server addresses can be configured)

```
end

config vpn ipsec phase1-interface
   edit vpn1
      set mode-cfg enable
      set assign-ip-from dhcp
   next
end
```

Certificate groups

IKE certificate groups consisting of up to four RSA certificates can be used in IKE Phase 1. Since CA and local certificates are global, the IKE daemon loads them once for all VDOMs and indexes them into trees based on subject and public key hash (for CA certificates), or certificate name (for local certicates). Certifcates are linked together based on the issuer, and certificate chains are built by traversing these links. This reduces the need to keep multiple copies of certificates that could exist in multiple chains.

IKE certificate groups can be configured through the CLI.

Configuring the IKE local ID - CLI

```
config vpn certificate local
edit <name>
   set ike-localid <string>
   set ike-localid-type {asnldn | fqdn}
end
```

Internet-browsing configuration

This section explains how to support secure web browsing performed by dialup VPN clients, and/or hosts behind a remote VPN peer. Remote users can access the private network behind the local FortiGate unit and browse the Internet securely. All traffic generated remotely is subject to the security policy that controls traffic on the private network behind the local FortiGate unit.

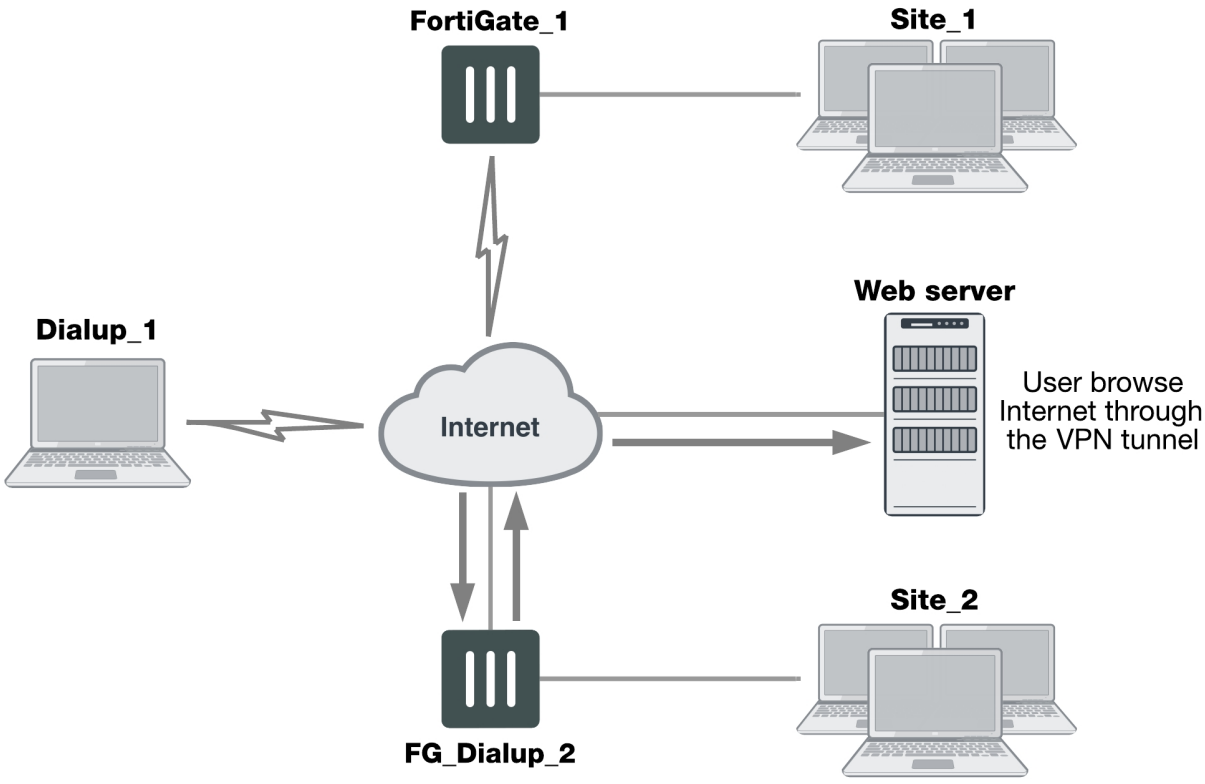
The following topics are included in this section:

Configuration overview

A VPN provides secure access to a private network behind the FortiGate unit. You can also enable VPN clients to access the Internet securely. The FortiGate unit inspects and processes all traffic between the VPN clients and hosts on the Internet according to the Internet browsing policy. This is accomplished even though the same FortiGate interface is used for both encrypted VPN client traffic and unencrypted Internet traffic.

In the figure below, FortiGate_1 enables secure Internet browsing for FortiClient Endpoint Security users such as Dialup_1 and users on the Site_2 network behind FortiGate_2, which could be a VPN peer or a dialup client.

Example Internet-browsing configuration



You can adapt any of the following configurations to provide secure Internet browsing:

- A gateway-to-gateway configuration (see Gateway-to-gateway configurations on page 1)
- A FortiClient dialup-client configuration (see FortiClient dialup-client configurations on page 1)
- A FortiGate dialup-client configuration (see FortiGate dialup-client configurations on page 1)

The procedures in this section assume that one of these configurations is in place, and that it is operating properly.

To create an internet-browsing configuration based on an existing gateway-to-gateway configuration, you must edit the gateway-to-gateway configuration as follows:

- On the FortiGate unit that will provide Internet access, create an Internet browsing security policy. See Configuration overview on page 2063, below.
- Configure the remote peer or client to route all traffic through the VPN tunnel. You can do this on a FortiGate unit or on a FortiClient Endpoint Security application. See Configuration overview on page 2063.

Creating an Internet browsing security policy

On the FortiGate unit that acts as a VPN server and will provide secure access to the Internet, you must create an Internet browsing security policy. This policy differs depending on whether your gateway-to-gateway configuration is policy-based or route-based.

Creating an Internet browsing policy - policy-based VPN

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information and then select **OK**:

Name	Enter an appropriate name for the policy.
Incoming Interface	The interface to which the VPN tunnel is bound.
Outgoing Interface	The interface to which the VPN tunnel is bound.
Source	The internal range address of the remote spoke site.
Destination Address	**all**
Action	Select **IPsec**. Under **VPN Tunnel**, select the tunnel that provides access to the private network behind the FortiGate unit. Select **Allow traffic to be initiated from the remote site**.
NAT	Enable **NAT**.

Creating an Internet browsing policy - route-based VPN

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information and then select **OK**:

Name	Enter an appropriate name for the policy.
Incoming Interface	The IPsec VPN interface.

Outgoing Interface	The interface that connects to the Internet. The virtual IPsec interface is configured on this physical interface.
Source	The internal range address of the remote spoke site.
Destination Address	**all**
Action	ACCEPT
NAT	Enable **NAT**.

The VPN clients must be configured to route all Internet traffic through the VPN tunnel.

Routing all remote traffic through the VPN tunnel

To make use of the Internet browsing configuration on the VPN server, the VPN peer or client must route all traffic through the VPN tunnel. Usually, only the traffic destined for the private network behind the FortiGate VPN server is sent through the tunnel.

The remote end of the VPN can be a FortiGate unit that acts as a peer in a gateway-to-gateway configuration, or a FortiClient application that protects an individual client PC.

- To configure a remote peer FortiGate unit for Internet browsing via VPN, see Configuring a FortiGate remote peer to support Internet browsing on page 2065.
- To configure a FortiClient Endpoint Security application for Internet browsing via VPN, see Configuring a FortiClient application to support Internet browsing on page 2066.

These procedures assume that your VPN connection to the protected private network is working and that you have configured the FortiGate VPN server for Internet browsing as described in Configuration overview on page 2063.

Configuring a FortiGate remote peer to support Internet browsing

The configuration changes to send all traffic through the VPN differ for policy-based and route-based VPNs.

Routing all traffic through a policy-based VPN

1. At the FortiGate dialup client, go to **Policy & Objects > IPv4 Policy**.
2. Select the IPsec security policy and then select **Edit**.
3. From the **Destination Address** list, select **all**.
4. Select **OK**.

Packets are routed through the VPN tunnel, not just those destined for the protected private network.

Routing all traffic through a route-based VPN

1. At the FortiGate dialup client, go to **Network > Static Routes**.
2. Select the default route (destination IP 0.0.0.0) and then select **Edit**. If there is no default route, select **Create New**. Enter the following information and select **OK**:

Destination IP/Mask	Set to **Subnet** and enter **0.0.0.0/0.0.0.0** in the field provided.

Device	Select the IPsec virtual interface.
Administrative Distance	Leave at default.

All packets are routed through the VPN tunnel, not just packets destined for the protected private network.

Configuring a FortiClient application to support Internet browsing

By default, the FortiClient application configures the PC so that traffic destined for the remote protected network passes through the VPN tunnel but all other traffic is sent to the default gateway. You need to modify the FortiClient settings so that it configures the PC to route all outbound traffic through the VPN.

Routing all traffic through VPN - FortiClient application

1. At the remote host, start FortiClient.
2. Go to **Remote Access**.
3. Select the definition that connects FortiClient to the FortiGate dialup server, select the **Settings** icon, and select **Edit the selected connection**.
4. In the **Edit VPN Connection** dialog box, select **Advanced Settings**.
5. In the **Remote Network** group, select **Add**.
6. In the **IP** and **Subnet Mask** fields, type `0.0.0.0/0.0.0.0` and select **OK**.

   The address is added to the **Remote Network** list. The first destination IP address in the list establishes a VPN tunnel. The second destination address (`0.0.0.0/0.0.0.0` in this case) forces all other traffic through the VPN tunnel.
7. Select **OK**.

Redundant VPN configurations

This section discusses the options for supporting redundant and partially redundant IPsec VPNs, using route-based approaches.

The following topics are included in this section:

Configuration overview

A FortiGate unit with two interfaces connected to the Internet can be configured to support redundant VPNs to the same remote peer. If the primary connection fails, the FortiGate unit can establish a VPN using the other connection.

Redundant tunnels do not support Tunnel Mode or manual keys. You must use Interface Mode.

A fully-redundant configuration requires redundant connections to the Internet on both peers. The figure below shows an example of this. This is useful to create a reliable connection between two FortiGate units with static IP addresses.

When only one peer has redundant connections, the configuration is partially-redundant. For an example of this, see Configuration overview on page 2067. This is useful to provide reliable service from a FortiGate unit with static IP addresses that accepts connections from dialup IPsec VPN clients.

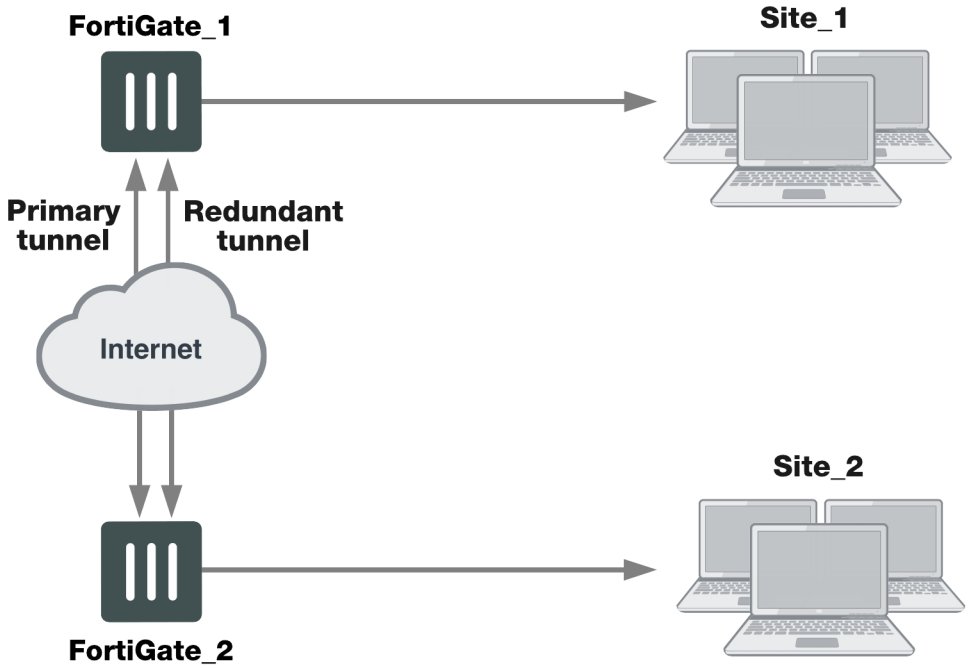
In a fully-redundant VPN configuration with two interfaces on each peer, four distinct paths are possible for VPN traffic from end to end. Each interface on a peer can communicate with both interfaces on the other peer. This ensures that a VPN will be available as long as each peer has one working connection to the Internet.

You configure a VPN and an entry in the routing table for each of the four paths. All of these VPNs are ready to carry data. You set different routing distances for each route and only the shortest distance route is used. If this route fails, the route with the next shortest distance is used.

The redundant configurations described in this chapter use route-based VPNs, otherwise known as virtual IPsec interfaces. This means that the FortiGate unit must operate in NAT mode. You must use auto-keying. A VPN that is created using manual keys cannot be included in a redundant-tunnel configuration.

The configuration described here assumes that your redundant VPNs are essentially equal in cost and capability. When the original VPN returns to service, traffic continues to use the replacement VPN until the replacement VPN fails. If your redundant VPN uses more expensive facilities, you want to use it only as a backup while the main VPN is down. For information on how to do this, see Configuration overview on page 2067.

Example redundant-tunnel configuration



A VPN that is created using manual keys cannot be included in a redundant-tunnel configuration.

General configuration steps

A redundant configuration at each VPN peer includes:

- One Phase 1 configuration (virtual IPsec interface) for each path between the two peers. In a fully-meshed redundant configuration, each network interface on one peer can communicate with each network interface on the remote peer. If both peers have two public interfaces, this means that each peer has four paths, for example.
- One Phase 2 definition for each Phase 1 configuration.
- One static route for each IPsec interface, with different distance values to prioritize the routes.
- Two Accept security policies per IPsec interface, one for each direction of traffic.
- Dead peer detection enabled in each Phase 1 definition.

The procedures in this section assume that two separate interfaces to the Internet are available on each VPN peer.

Configuring the VPN peers - route-based VPN

VPN peers are configured using Interface Mode for redundant tunnels.

Configure each VPN peer as follows:

1. Ensure that the interfaces used in the VPN have static IP addresses.
2. Create a Phase 1 configuration for each of the paths between the peers.
3. Enable dead peer detection so that one of the other paths is activated if this path fails.
4. Enter these settings in particular, and any other VPN settings as required:

Path 1

Remote Gateway	Select **Static IP Address**.
IP Address	Type the IP address of the primary interface of the remote peer.
Local Interface	Select the primary public interface of this peer.
Dead Peer Detection	Enable

Path 2

Remote Gateway	Select **Static IP Address**.
IP Address	Type the IP address of the secondary interface of the remote peer.
Local Interface	Select the primary public interface of this peer.
Dead Peer Detection	Enable

Path 3

Remote Gateway	Select **Static IP Address**.
IP Address	Type the IP address of the primary interface of the remote peer.
Local Interface	Select the secondary public interface of this peer.
Dead Peer Detection	Enable

Path 4

Remote Gateway	Select **Static IP Address**.
IP Address	Type the IP address of the secondary interface of the remote peer.
Local Interface	Select the secondary public interface of this peer.
Dead Peer Detection	Enable

For more information, see Phase 1 parameters on page 1967.

5. Create a Phase 2 definition for each path. See Phase 2 parameters on page 1985. Select the Phase 1 configuration (virtual IPsec interface) that you defined for this path. You can select the name from the Static IP Address part of the list.
6. Create a route for each path to the other peer. If there are two ports on each peer, there are four possible paths between the peer devices.

Destination IP/Mask	The IP address and netmask of the private network behind the remote peer.
Device	One of the virtual IPsec interfaces on the local peer.
Distance	For each path, enter a different value to prioritize the paths.

7. Define the security policy for the local primary interface. See Defining VPN security policies on page 1. You need to create two policies for each path to enable communication in both directions. Enter these settings in particular:

Incoming Interface	Select the local interface to the internal (private) network.
Source Address	All
Outgoing Interface	Select one of the virtual IPsec interfaces you created in Step 2.
Destination Address	All
Schedule	Always
Service	Any
Action	ACCEPT

8. Select **Create New**, leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**, and enter these settings:

Incoming Interface	Select one of the virtual IPsec interfaces you created in Step 2.
Source Address	All
Outgoing Interface	Select the local interface to the internal (private) network.
Destination Address	All
Schedule	Always
Service	Any
Action	ACCEPT

9. Place the policy in the policy list above any other policies having similar source and destination addresses.
10. Repeat this procedure at the remote FortiGate unit.

Creating a backup IPsec interface

You can configure a route-based VPN that acts as a backup facility to another VPN. It is used only while your main VPN is out of service. This is desirable when the redundant VPN uses a more expensive facility.

You can configure a backup IPsec interface only in the CLI. The backup feature works only on interfaces with static addresses that have dead peer detection enabled. The `monitor` option creates a backup VPN for the specified Phase 1 configuration.

In the following example, backup_vpn is a backup for main_vpn.

```
config vpn ipsec phase1-interface
   edit main_vpn
      set dpd on
      set interface port1
      set nattraversal enable
      set psksecret "hard-to-guess"
      set remote-gw 192.168.10.8
      set type static
   end
   edit backup_vpn
      set dpd on
      set interface port2
      set monitor main_vpn
      set nattraversal enable
      set psksecret "hard-to-guess"
      set remote-gw 192.168.10.8
      set type static
   end
```

Transparent mode VPNs

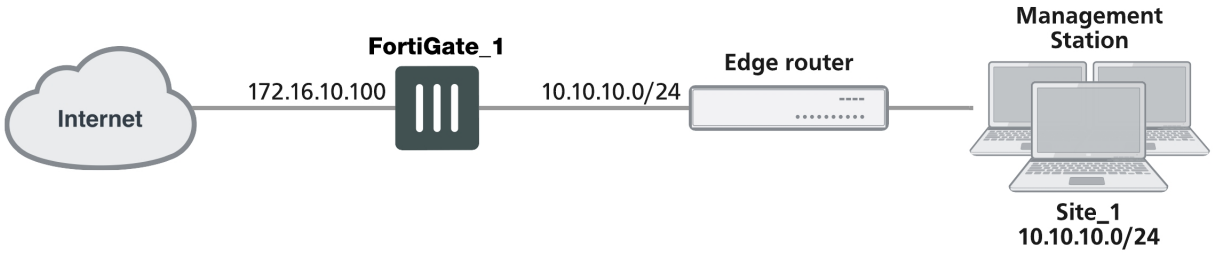
This section describes transparent VPN configurations, in which two FortiGate units create a VPN tunnel between two separate private networks transparently.

The following topics are included in this section:

Configuration overview

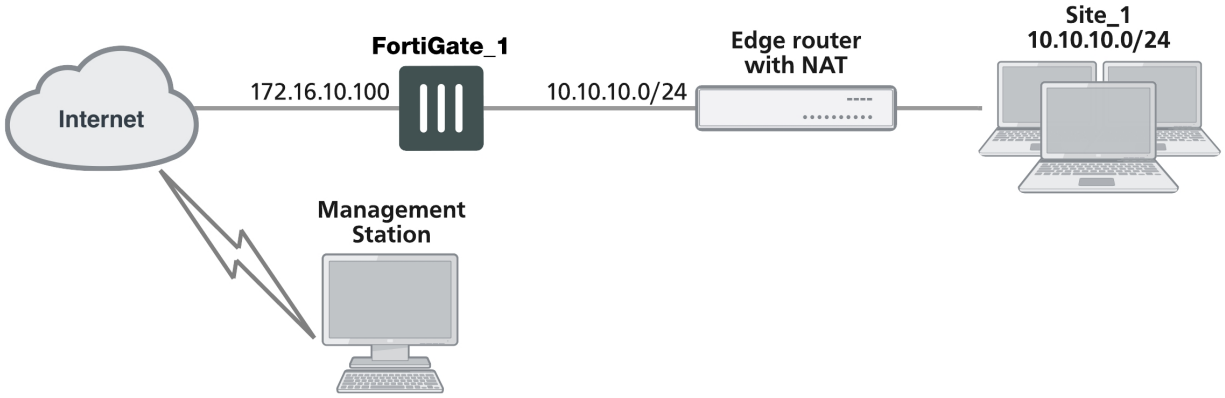
In transparent mode, all interfaces of the FortiGate unit except the management interface (which by default is assigned IP address 10.10.10.1/255.255.255.0) are invisible at the network layer. Typically, when a FortiGate unit runs in transparent mode, different network segments are connected to the FortiGate interfaces. The figure below shows the management station on the same subnet. The management station can connect to the FortiGate unit directly through the web-based manager.

Management station on internal network



An edge router typically provides a public connection to the Internet and one interface of the FortiGate unit is connected to the router. If the FortiGate unit is managed from an external address (see the figure below), the router must translate (NAT) a routable address to direct management traffic to the FortiGate management interface.

Management station on external network



In a transparent VPN configuration, two FortiGate units create a VPN tunnel between two separate private networks transparently. All traffic between the two networks is encrypted and protected by FortiGate security policies.

Both FortiGate units may be running in transparent mode, or one could be running in transparent mode and the other running in NAT mode. If the remote peer is running in NAT mode, it must have a static public IP address.

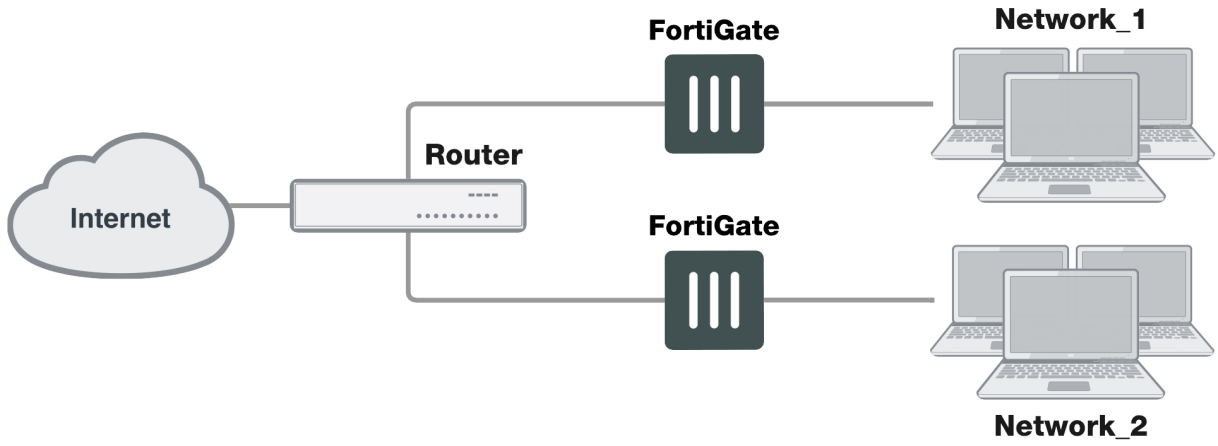
VPNs between two FortiGate units running in transparent mode do not support inbound/outbound NAT (supported through CLI commands) within the tunnel. In addition, a FortiGate unit running in transparent mode cannot be used in a hub-and-spoke configuration.

Encrypted packets from the remote VPN peer are addressed to the management interface of the local FortiGate unit. If the local FortiGate unit can reach the VPN peer locally, a static route to the VPN peer must be added to the routing table on the local FortiGate unit. If the VPN peer connects through the Internet, encrypted packets from the local FortiGate unit must be routed to the edge router instead. For information about how to add a static route to the FortiGate routing table, see the Advanced Routing Guide.

In the example configuration shown above, Network Address Translation (NAT) is enabled on the router. When an encrypted packet from the remote VPN peer arrives at the router through the Internet, the router performs inbound NAT and forwards the packet to the FortiGate unit. Refer to the software supplier's documentation to configure the router.

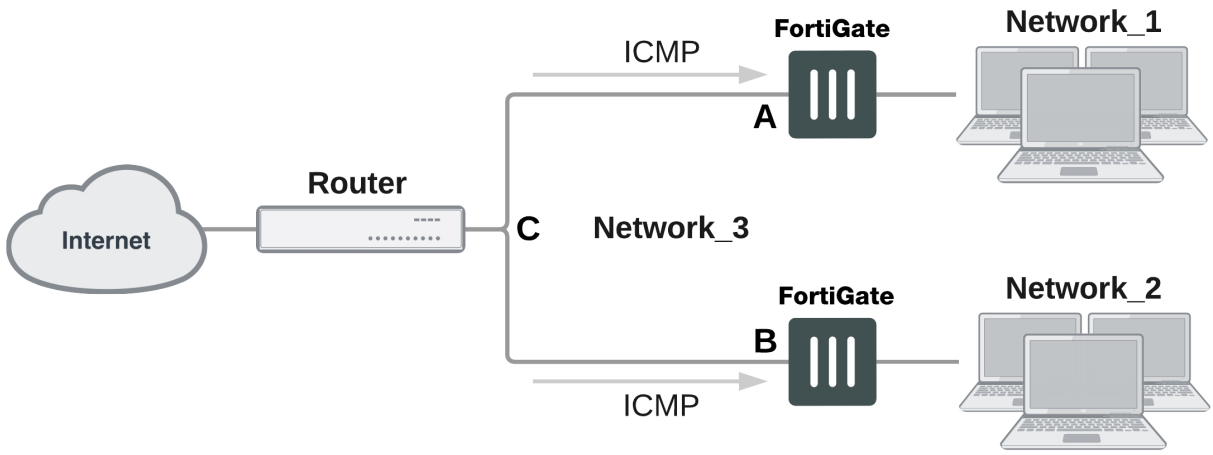
If you want to configure a VPN between two FortiGate units running in transparent mode, each unit must have an independent connection to a router that acts as a gateway to the Internet, and both units must be on separate networks that have a different address space. When the two networks linked by the VPN tunnel have different address spaces (see the figure below), at least one router must separate the two FortiGate units, unless the packets can be redirected using ICMP (as shown in the following figure).

Link between two FortiGate units in transparent mode



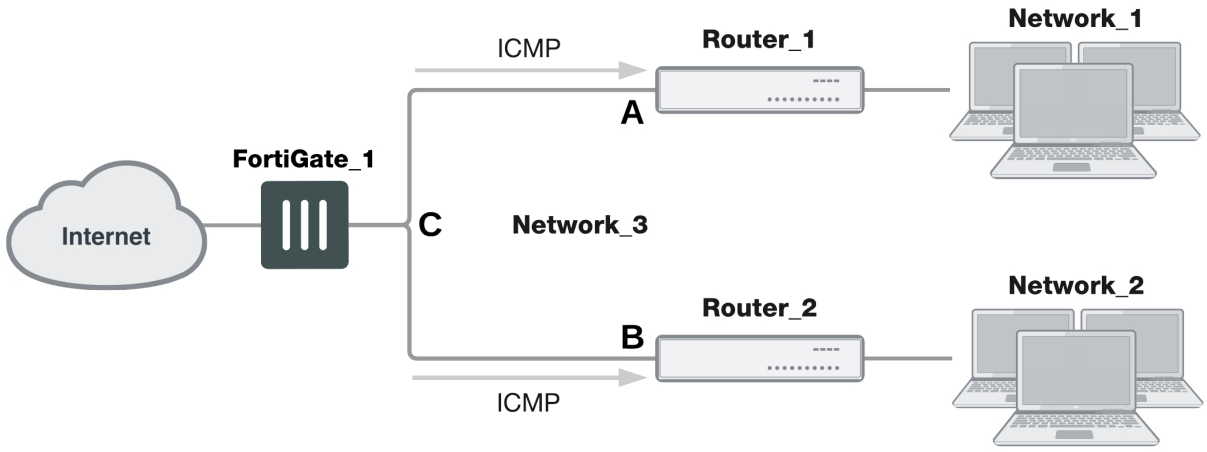
In the figure below, interface C behind the router is the default gateway for both FortiGate units. Packets that cannot be delivered on Network_1 are routed to interface C by default. Similarly, packets that cannot be delivered on Network_2 are routed to interface C. In this case, the router must be configured to redirect packets destined for Network_1 to interface A and redirect packets destined for Network_2 to interface B.

ICMP redirecting packets to two FortiGate units in transparent mode



If there are additional routers behind the FortiGate unit (see the figure below) and the destination IP address of an inbound packet is on a network behind one of those routers, the FortiGate routing table must include routes to those networks. For example, in the following figure, the FortiGate unit must be configured with static routes to interfaces A and B in order to forward packets to Network_1 and Network_2 respectively.

Destinations on remote networks behind internal routers



Transparent VPN infrastructure requirements

- The local FortiGate unit must be operating in transparent mode.
- The management IP address of the local FortiGate unit specifies the local VPN gateway. The management IP address is considered a static IP address for the local VPN peer.
- If the local FortiGate unit is managed through the Internet, or if the VPN peer connects through the Internet, the edge router must be configured to perform inbound NAT and forward management traffic and/or encrypted packets to the FortiGate unit.
- If the remote peer is operating in NAT mode, it must have a static public IP address.

A FortiGate unit operating in transparent mode requires the following basic configuration to operate as a node on the IP network:

- The unit must have sufficient routing information to reach the management station.
- For any traffic to reach external destinations, a default static route to an edge router that forwards packets to the Internet must be present in the FortiGate routing table.
- When all of the destinations are located on the external network, the FortiGate unit may route packets using a single default static route. If the network topology is more complex, one or more static routes in addition to the default static route may be required in the FortiGate routing table.

Only policy-based VPN configurations are possible in transparent mode.

Before you begin

An IPsec VPN definition links a gateway with a tunnel and an IPsec policy. If your network topology includes more than one virtual domain, you must choose components that were created in the same virtual domain. Therefore, before you define a transparent VPN configuration, choose an appropriate virtual domain in which to create the required interfaces, security policies, and VPN components. For more information, see the Virtual Domains guide.

Configuring the VPN peers

1. The local VPN peer need to operate in transparent mode.
   To determine if your FortiGate unit is in transparent mode, go to the **Dashboard > System Information** widget. Select **[change]**. Select transparent for the **Operation Mode**. Two new fields will appear to enter the **Management IP/Netmask**, and the **Default Gateway**.
   In transparent mode, the FortiGate unit is invisible to the network. All of its interfaces are on the same subnet and share the same IP address. You only have to configure a management IP address so that you can make configuration changes.

   The remote VPN peer may operate in NAT mode or transparent mode.
2. At the local FortiGate unit, define the Phase 1 parameters needed to establish a secure connection with the remote peer. See Phase 1 parameters on page 1967. Select **Advanced** and enter these settings in particular:

Remote Gateway	Select **Static IP Address**.
IP Address	Type the IP address of the public interface to the remote peer. If the remote peer is a FortiGate unit running in transparent mode, type the IP address of the remote management interface.
Advanced	Select **Nat-traversal**, and type a value into the **Keepalive Frequency** field. These settings protect the headers of encrypted packets from being altered by external NAT devices and ensure that NAT address mappings do not change while the VPN tunnel is open. For more information, see Phase 1 parameters on page 1967 and Phase 1 parameters on page 1967.

3. Define the Phase 2 parameters needed to create a VPN tunnel with the remote peer. See Phase 2 parameters on page 1985. Select the set of Phase 1 parameters that you defined for the remote peer. The name of the remote peer can be selected from the **Static IP Address** list.
4. Define the source and destination addresses of the IP packets that are to be transported through the VPN tunnel. See Defining VPN security policies on page 1. Enter these settings in particular:

- For the originating address (source address), enter the IP address and netmask of the private network behind the local peer network. for the management interface, for example, `10.10.10.0/24`. This address needs to be a range to allow traffic from your network through the tunnel. Optionally select `any` for this address.
- For the remote address (destination address), enter the IP address and netmask of the private network behind the remote peer (for example, `192.168.10.0/24`). If the remote peer is a FortiGate unit running in transparent mode, enter the IP address of the remote management interface instead.

5. Define an IPsec security policy to permit communications between the source and destination addresses. See Defining VPN security policies on page 1. Enter these settings in particular:

Incoming Interface	Select the local interface to the internal (private) network.
Source Address	Select the source address that you defined in Step 4.
Outgoing Interface	Select the interface to the edge router. When you configure the IPsec security policy on a remote peer that operates in NAT mode, you select the public interface to the external (public) network instead.
Destination Address	Select the destination address that you defined in Step 4.
VPN Tunnel	Select **Use Existing** and select the name of the Phase 2 tunnel configuration that you created in Step 3 from the drop-down list. Select **Allow traffic to be initiated from the remote site** to enable traffic from the remote network to initiate the tunnel.

6. Place the policy in the policy list above any other policies having similar source and destination addresses.
7. Define another IPsec security policy to permit communications between the source and destination addresses in the opposite direction. This security policy and the previous one form a bi-directional policy pair. See Defining VPN security policies on page 1. Enter these settings in particular:

Incoming Interface	Select the interface to the edge router. When you configure the IPsec security policy on a remote peer that operates in NAT mode, you select the public interface to the external (public) network instead.
Source Address	Select the destination address that you defined in Step 4..
Outgoing Interface	Select the local interface to the internal (private) network.
Destination Address	Select the source address that you defined in Step 4.
VPN Tunnel	Select **Use Existing** and select the name of the Phase 2 tunnel configuration that you created in Step 3 from the drop-down list. Select **Allow traffic to be initiated from the remote site** to enable traffic from the remote network to initiate the tunnel.

8. Repeat this procedure at the remote FortiGate unit to create bidirectional security policies. Use the local interface and address information local to the remote FortiGate unit.

For more information on transparent mode, see the System Administration Guide.

IPv6 IPsec VPNs

This chapter describes how to configure your FortiGate unit's IPv6 IPsec VPN functionality.

By default IPv6 configurations to not appear on the Web-based Manager. You need to enable the feature first.

To enable IPv6

1. Go to **System > Feature Select**.
2. Enable **IPv6**.
3. Select **Apply**.

The following topics are included in this section:

IPv6 IPsec support

FortiOS supports route-based IPv6 IPsec, but not policy-based. This section describes how IPv6 IPsec support differs from IPv4 IPsec support. FortiOS 4.0 MR3 is IPv6 Ready Logo Program Phase 2 certified.

Where both the gateways and the protected networks use IPv6 addresses, sometimes called IPv6 over IPv6, you can create either an auto-keyed or manually-keyed VPN. You can combine IPv6 and IPv4 addressing in an auto-keyed VPN in the following ways:

IPv4 over IPv6	The VPN gateways have IPv6 addresses. The protected networks have IPv4 addresses. The Phase 2 configurations at either end use IPv4 selectors.
IPv6 over IPv4	The VPN gateways have IPv4 addresses. The protected networks use IPv6 addresses. The Phase 2 configurations at either end use IPv6 selectors.

Compared with IPv4 IPsec VPN functionality, there are some limitations:

- Except for IPv6 over IPv4, remote gateways with Dynamic DNS are not supported.
- Selectors cannot be firewall address names. Only IP address, address range and subnet are supported.
- Redundant IPv6 tunnels are not supported.

Certificates

On a VPN with IPv6 Phase 1 configuration, you can authenticate using VPN certificates in which the common name (cn) is an IPv6 address. The `cn-type` keyword of the `user peer` command has an option, `ipv6`, to support this.

Configuration examples

This section consists of the following configuration examples:

- Site-to-site IPv6 over IPv6 VPN example
- Site-to-site IPv6 over IPv4 VPN example
- Site-to-site IPv4 over IPv6 VPN example

Site-to-site IPv6 over IPv6 VPN example

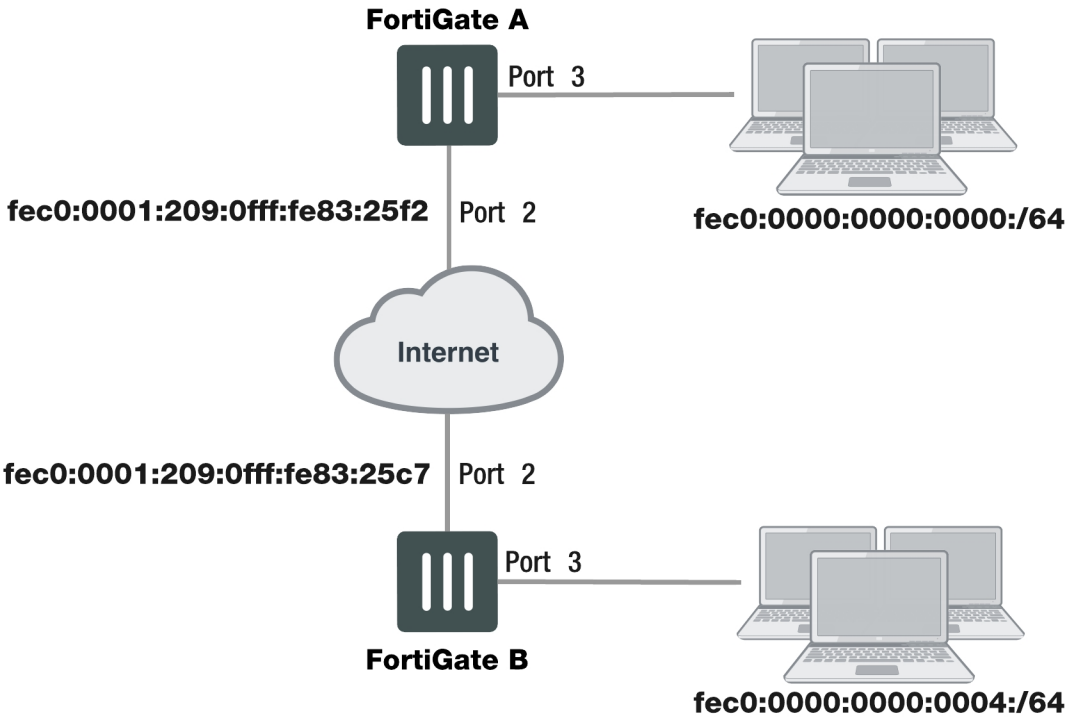
In this example, computers on IPv6-addressed private networks communicate securely over public IPv6 infrastructure.

By default IPv6 configurations to not appear on the Web-based Manager. You need to enable the feature first.

To enable IPv6

1. Go to **System > Feature Select**.
2. Enable **IPv6**.
3. Select **Apply**.

Example IPv6-over-IPv6 VPN topology



Configure FortiGate A interfaces

Port 2 connects to the public network and port 3 connects to the local network.

```
config system interface
```

```
    edit port2
      config ipv6
        set ip6-address fec0::0001:209:0fff:fe83:25f2/64
      end
    next
    edit port3
      config ipv6
        set ip6-address fec0::0000:209:0fff:fe83:25f3/64
      end
    next
end
```

Configure FortiGate A IPsec settings

The Phase 1 configuration creates a virtual IPsec interface on port 2 and sets the remote gateway to the public IP address FortiGate B. This configuration is the same as for an IPv4 route-based VPN, except that `ip-version` is set to `6` and the `remote-gw6` keyword is used to specify an IPv6 remote gateway address.

```
config vpn ipsec phase1-interface
  edit toB
    set ip-version 6
    set interface port2
    set remote-gw6 fec0:0000:0000:0003:209:0fff:fe83:25c7
    set dpd [disable | on-idle | on-demand]
    set psksecret maryhadalittlelamb
    set proposal 3des-md5 3des-sha1
  end
```

By default, Phase 2 selectors are set to accept all subnet addresses for source and destination. The default setting for `src-addr-type` and `dst-addr-type` is `subnet`. The IPv6 equivalent is `subnet6`. The default subnet addresses are 0.0.0.0/0 for IPv4, `::/0` for IPv6.

```
config vpn ipsec phase2-interface
  edit toB2
    set phase1name toB
    set proposal 3des-md5 3des-sha1
    set pfs enable
    set replay enable
    set src-addr-type subnet6
    set dst-addr-type subnet6
  end
```

Configure FortiGate A security policies

Security policies are required to allow traffic between port3 and the IPsec interface toB in each direction. The address `all6` must be defined using the `firewall address6` command as `::/0`.

```
config firewall policy6
  edit 1
    set srcintf port3
    set dstintf toB
    set srcaddr all6
    set dstaddr all6
    set action accept
    set service ANY
    set schedule always
  next
```

```
   edit 2
      set srcintf toB
      set dstintf port3
      set srcaddr all6
      set dstaddr all6
      set action accept
      set service ANY
      set schedule always
   end
```

Configure FortiGate A routing

This simple example requires just two static routes. Traffic to the protected network behind FortiGate B is routed via the virtual IPsec interface toB. A default route sends all IPv6 traffic out on port2.

```
config router static6
   edit 1
      set device port2
      set dst 0::/0
   next
   edit 2
      set device toB
      set dst fec0:0000:0000:0004::/64
   end
```

Configure FortiGate B

The configuration of FortiGate B is very similar to that of FortiGate A. A virtual IPsec interface toA is configured on port2 and its remote gateway is the public IP address of FortiGate A. Security policies enable traffic to pass between the private network and the IPsec interface. Routing ensures traffic for the private network behind FortiGate A goes through the VPN and that all IPv6 packets are routed to the public network.

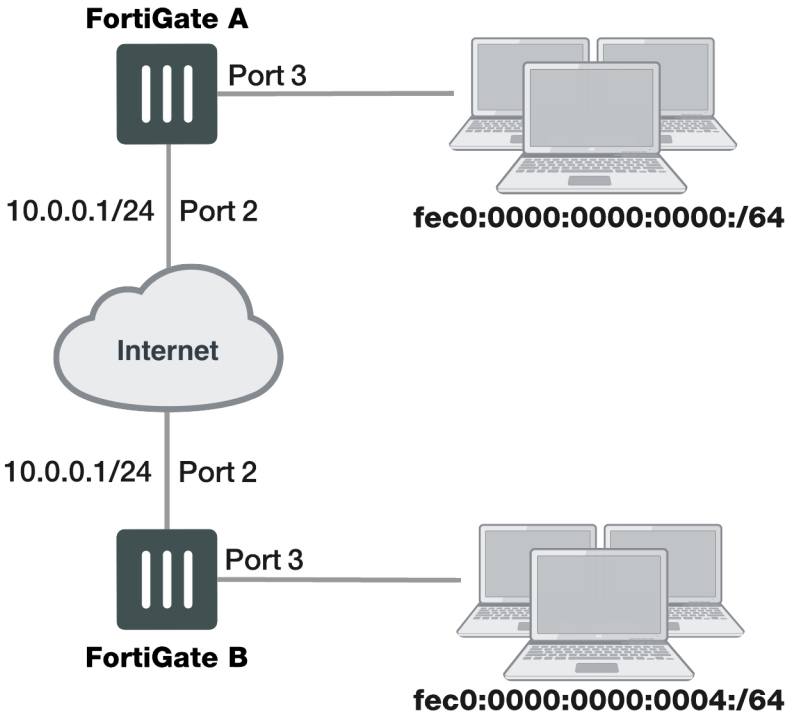
```
config system interface
   edit port2
      config ipv6
         set ip6-address fec0::0003:209:0fff:fe83:25c7/64
      end
   next
   edit port3
      config ipv6
         set ip6-address fec0::0004:209:0fff:fe83:2569/64
      end
   end
config vpn ipsec phase1-interface
   edit toA
      set ip-version 6
      set interface port2
      set remote-gw6 fec0:0000:0000:0001:209:0fff:fe83:25f2
      set dpd [disable | on-idle | on-demand]
      set psksecret maryhadalittlelamb
      set proposal 3des-md5 3des-sha1
   end
config vpn ipsec phase2-interface
   edit toA2
      set phase1name toA
      set proposal 3des-md5 3des-sha1
      set pfs enable
```

```
      set replay enable
      set src-addr-type subnet6
      set dst-addr-type subnet6
   end
config firewall policy6
   edit 1
      set srcintf port3
      set dstintf toA
      set srcaddr all6
      set dstaddr all6
      set action accept
      set service ANY
      set schedule always
   next
   edit 2
      set srcintf toA
      set dstintf port3
      set srcaddr all6
      set dstaddr all6
      set action accept
      set service ANY
      set schedule always
   end
config router static6
   edit 1
      set device port2
      set dst 0::/0
   next
   edit 2
      set device toA
      set dst fec0:0000:0000:0000::/64
end
```

Site-to-site IPv6 over IPv4 VPN example

In this example, IPv6-addressed private networks communicate securely over IPv4 public infrastructure.

Example IPv6-over-IPv4 VPN topology



Configure FortiGate A interfaces

Port 2 connects to the IPv4 public network and port 3 connects to the IPv6 LAN.

```
config system interface
   edit port2
      set 10.0.0.1/24
      next
      edit port3
      config ipv6
         set ip6-address fec0::0001:209:0fff:fe83:25f3/64
      end
```

Configure FortiGate A IPsec settings

The Phase 1 configuration uses IPv4 addressing.

```
config vpn ipsec phase1-interface
   edit toB
      set interface port2
      set remote-gw 10.0.1.1
      set dpd [disable | on-idle | on-demand]
      set psksecret maryhadalittlelamb
      set proposal 3des-md5 3des-sha1
   end
```

The Phase 2 configuration uses IPv6 selectors. By default, Phase 2 selectors are set to accept all subnet addresses for source and destination. The default setting for `src-addr-type` and `dst-addr-type` is `subnet`. The IPv6 equivalent is `subnet6`. The default subnet addresses are 0.0.0.0/0 for IPv4, `::/0` for IPv6.

```
config vpn ipsec phase2-interface
   edit toB2
      set phase1name toB
      set proposal 3des-md5 3des-sha1
      set pfs enable
      set replay enable
      set src-addr-type subnet6
      set dst-addr-type subnet6
   end
```

Configure FortiGate A security policies

IPv6 security policies are required to allow traffic between port3 and the IPsec interface toB in each direction. Define the address `all6` using the `firewall address6` command as `::/0`.

```
config firewall policy6
   edit 1
      set srcintf port3
      set dstintf toB
      set srcaddr all6
      set dstaddr all6
      set action accept
      set service ANY
      set schedule always
   next
   edit 2
      set srcintf toB
      set dstintf port3
      set srcaddr all6
      set dstaddr all6
      set action accept
      set service ANY
      set schedule always
   end
```

Configure FortiGate A routing

This simple example requires just two static routes. Traffic to the protected network behind FortiGate B is routed via the virtual IPsec interface toB using an IPv6 static route. A default route sends all IPv4 traffic, including the IPv4 IPsec packets, out on port2.

```
config router static6
      edit 1
         set device toB
         set dst fec0:0000:0000:0004::/64
      end
   config router static
      edit 1
         set device port2
         set dst 0.0.0.0/0
         set gateway 10.0.0.254
      end
```

Configure FortiGate B

The configuration of FortiGate B is very similar to that of FortiGate A. A virtual IPsec interface toA is configured on port2 and its remote gateway is the IPv4 public IP address of FortiGate A. The IPsec Phase 2 configuration has IPv6 selectors.

IPv6 security policies enable traffic to pass between the private network and the IPsec interface. An IPv6 static route ensures traffic for the private network behind FortiGate A goes through the VPN and an IPv4 static route ensures that all IPv4 packets are routed to the public network.

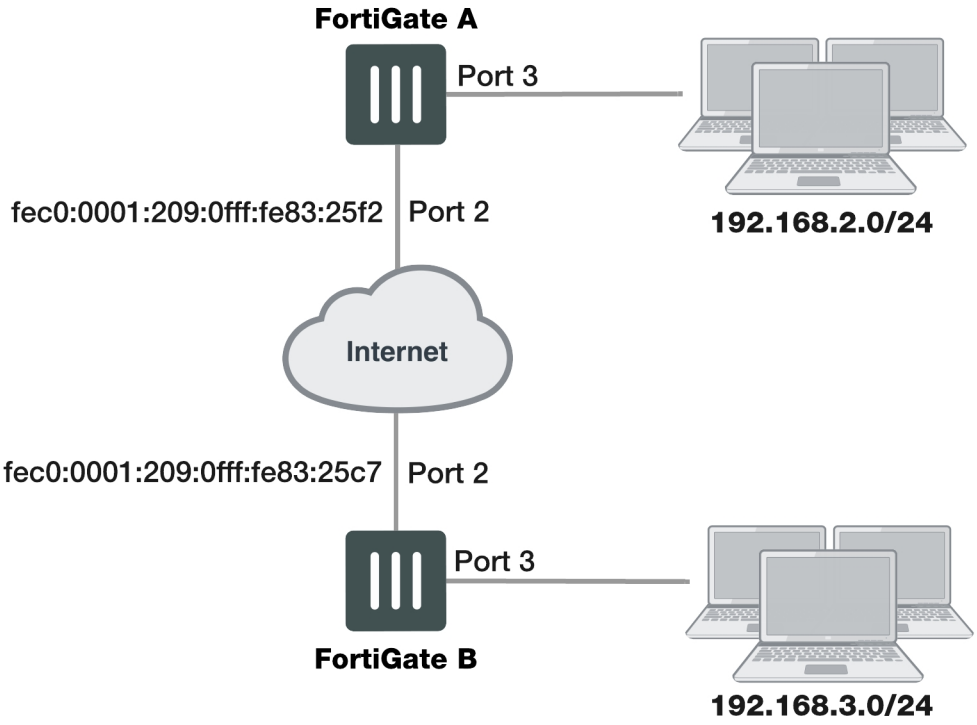
```
config system interface
   edit port2
      set 10.0.1.1/24
   next
   edit port3
      config ipv6
         set ip6-address fec0::0004:209:0fff:fe83:2569/64
      end
config vpn ipsec phase1-interface
   edit toA
      set interface port2
      set remote-gw 10.0.0.1
      set dpd [disable | on-idle | on-demand]
      set psksecret maryhadalittlelamb
      set proposal 3des-md5 3des-sha1
   end
config vpn ipsec phase2-interface
   edit toA2
      set phase1name toA
      set proposal 3des-md5 3des-sha1
      set pfs enable
      set replay enable
      set src-addr-type subnet6
      set dst-addr-type subnet6
   end
config firewall policy6
   edit 1
      set srcintf port3
      set dstintf toA
      set srcaddr all6
      set dstaddr all6
      set action accept
      set service ANY
      set schedule always
   next
   edit 2
      set srcintf toA
      set dstintf port3
      set srcaddr all6
      set dstaddr all6
      set action accept
      set service ANY
      set schedule always
   end
config router static6
   edit 1
      set device toA
```

```
      set dst fec0:0000:0000:0000::/64
   end
config router static
   edit 1
      set device port2
      set gateway 10.0.1.254
   end
```

Site-to-site IPv4 over IPv6 VPN example

In this example, two private networks with IPv4 addressing communicate securely over IPv6 infrastructure.

Example IPv4-over-IPv6 VPN topology



Configure FortiGate A interfaces

Port 2 connects to the IPv6 public network and port 3 connects to the IPv4 LAN.

```
config system interface
   edit port2
      config ipv6
         set ip6-address fec0::0001:209:0fff:fe83:25f2/64
      end
   next
   edit port3
      set 192.168.2.1/24
   end
```

Configure FortiGate A IPsec settings

The Phase 1 configuration is the same as in the IPv6 over IPv6 example.

```
config vpn ipsec phase1-interface
   edit toB
      set ip-version 6
      set interface port2
      set remote-gw6 fec0:0000:0000:0003:209:0fff:fe83:25c7
      set dpd [disable | on-idle | on-demand]
      set psksecret maryhadalittlelamb
      set proposal 3des-md5 3des-sha1
   end
```

The Phase 2 configuration is the same as you would use for an IPv4 VPN. By default, Phase 2 selectors are set to accept all subnet addresses for source and destination.

```
config vpn ipsec phase2-interface
   edit toB2
      set phase1name toB
      set proposal 3des-md5 3des-sha1
      set pfs enable
      set replay enable
   end
```

Configure FortiGate A security policies

Security policies are required to allow traffic between port3 and the IPsec interface toB in each direction. These are IPv4 security policies.

```
config firewall policy
   edit 1
      set srcintf port3
      set dstintf toB
      set srcaddr all
      set dstaddr all
      set action accept
      set service ANY
      set schedule always
   next
   edit 2
      set srcintf toB
      set dstintf port3
      set srcaddr all
      set dstaddr all
      set action accept
      set service ANY
      set schedule always
   end
```

Configure FortiGate A routing

This simple example requires just two static routes. Traffic to the protected network behind FortiGate B is routed via the virtual IPsec interface toB using an IPv4 static route. A default route sends all IPv6 traffic, including the IPv6 IPsec packets, out on port2.

```
config router static6
   edit 1
      set device port2
      set dst 0::/0
   next
   edit 2
```

```
      set device toB
      set dst 192.168.3.0/24
   end
```

Configure FortiGate B

The configuration of FortiGate B is very similar to that of FortiGate A. A virtual IPsec interface toA is configured on port2 and its remote gateway is the public IP address of FortiGate A. The IPsec Phase 2 configuration has IPv4 selectors.

IPv4 security policies enable traffic to pass between the private network and the IPsec interface. An IPv4 static route ensures traffic for the private network behind FortiGate A goes through the VPN and an IPv6 static route ensures that all IPv6 packets are routed to the public network.

```
config system interface
   edit port2
      config ipv6
         set ip6-address fec0::0003:fe83:25c7/64
      end
   next
   edit port3
      set 192.168.3.1/24
   end
config vpn ipsec phase1-interface
   edit toA
      set ip-version 6
      set interface port2
      set remote-gw6 fec0:0000:0000:0001:209:0fff:fe83:25f2
      set dpd [disable | on-idle | on-demand]
      set psksecret maryhadalittlelamb
      set proposal 3des-md5 3des-sha1
   end
config vpn ipsec phase2-interface
   edit toA2
      set phase1name toA
      set proposal 3des-md5 3des-sha1
      set pfs enable
      set replay enable
   end
config firewall policy
   edit 1
      set srcintf port3
      set dstintf toA
      set srcaddr all
      set dstaddr all
      set action accept
      set service ANY
      set schedule always
   next
   edit 2
      set srcintf toA
      set dstintf port3
      set srcaddr all
      set dstaddr all
      set action accept
      set service ANY
      set schedule always
```

```
    end
config router static6
    edit 1
        set device port2
        set dst 0::/0
    next
    edit 2
        set device toA
        set dst 192.168.2.0/24
    end
```

L2TP and IPsec (Microsoft VPN)

This section describes how to set up a VPN that is compatible with the Microsoft Windows native VPN, which is Layer 2 Tunneling Protocol (L2TP) with IPsec encryption.

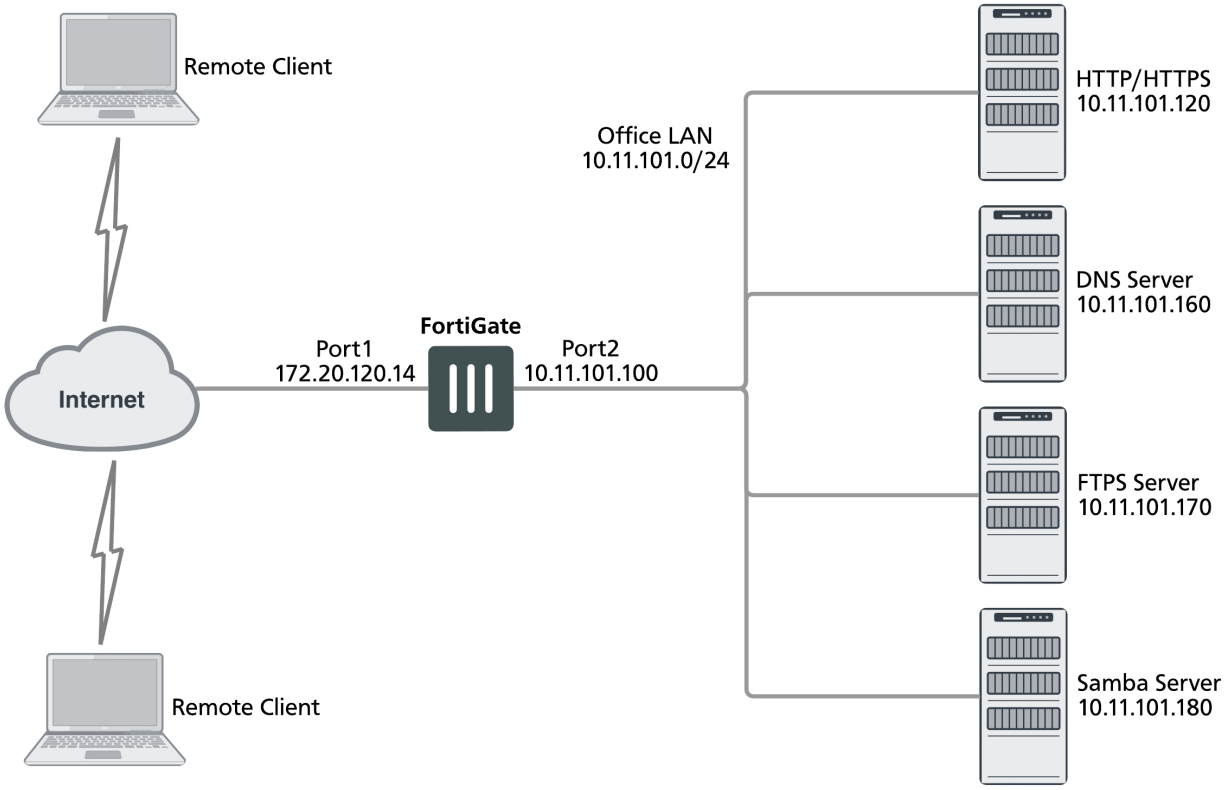
The following topics are included in this section:

For troubleshooting information, refer to Troubleshooting L2TP and IPsec.

Overview

The topology of a VPN for Microsoft Windows dialup clients is very similar to the topology for FortiClient Endpoint Security clients.

Example FortiGate VPN configuration with Microsoft clients



For users, the difference is that instead of installing and using the FortiClient application, they configure a network connection using the software built into the Microsoft Windows operating system. Starting in FortiOS 4.0 MR2, you can configure a FortiGate unit to work with unmodified Microsoft VPN client software.

Layer 2 Tunneling Protocol (L2TP)

L2TP is a tunneling protocol published in 1999 that is used with VPNs, as the name suggests. Microsoft Windows operating system has a built-in L2TP client starting since Windows 2000. Mac OS X 10.3 system and higher also

have a built-in client.

L2TP provides no encryption and used UDP port 1701. IPsec is used to secure L2TP packets. The initiator of the L2TP tunnel is called the L2TP Access Concentrator (LAC).

L2TP and IPsec is supported for native Windows XP, Windows Vista and Mac OSX native VPN clients. However, in Mac OSX (OSX 10.6.3, including patch releases) the L2TP feature does not work properly on the Mac OS side.

Assumptions

The following assumptions have been made for this example:

- L2TP protocol traffic is allowed through network firewalls (TCP and UDP port 1701)
- User has Microsoft Windows 2000 or higher — a Windows version that supports L2TP

Configuration overview

The following section consists of configuring the FortiGate unit and configuring the Windows PC.

Configuring the FortiGate unit

To configure the FortiGate unit, you must:

- Configure LT2P users and firewall user group.
- Configure the L2TP VPN, including the IP address range it assigns to clients.
- Configure an IPsec VPN with encryption and authentication settings that match the Microsoft VPN client.
- Configure security policies.

Configuring LT2P users and firewall user group

Remote users must be authenticated before they can request services and/or access network resources through the VPN. The authentication process can use a password defined on the FortiGate unit or an established external authentication mechanism such as RADIUS or LDAP.

Creating user accounts

You need to create user accounts and then add these users to a firewall user group to be used for L2TP authentication. The Microsoft VPN client can automatically send the user's Window network logon credentials. You might want to use these for their L2TP user name and password.

Creating a user account - web-based manager

1. Go to **User & Device > User Definition**and select **Create New**.
2. Enter the **User Name**.
3. Do one of the following:
   - Select **Password** and enter the user's assigned password.
   - Select **Match user on LDAP server**, **Match user on RADIUS server**, or **Match user onTACACS+ server** and select the authentication server from the list. The authentication server must be already configured on the FortiGate unit.
4. Select **OK**.

Creating a user account - CLI

To create a user account called `user1` with the password `123_user`, enter:

```
config user local
   edit user1
      set type password
      set passwd "123_user"
      set status enable
   end
```

Creating a user group

When clients connect using the L2TP-over-IPsec VPN, the FortiGate unit checks their credentials against the user group you specify for L2TP authentication. You need to create a firewall user group to use for this purpose.

Creating a user group - web-based manager

1. Go to **User & Device > User Groups**, select **Create New**, and enter the following:

Name	Type or edit the user group name (for example, `L2TP_group`).
Type	Select **Firewall**.
Available Users/Groups	The list of Local users, RADIUS servers, LDAP servers, TACACS+ servers, or PKI users that can be added to the user group. To add a member to this list, select the name and then select the right arrow button.
Members	The list of Local users, RADIUS servers, LDAP servers, TACACS+ servers, or PKI users that belong to the user group. To remove a member, select the name and then select the left arrow button.

2. Select **OK**.

Creating a user group - CLI

To create the user group L2TP_group and add members User_1, User_2, and User_3, enter:

```
config user group
   edit L2TP_group
      set group-type firewall
      set member User_1 User_2 User_3
   end
```

Configuring L2TP

You can only configure L2TP settings in the CLI. As well as enabling L2TP, you set the range of IP address values that are assigned to L2TP clients and specify the user group that can access the VPN. For example, to allow access to users in the L2TP_group and assign them addresses in the range 192.168.0.50 to 192.168.0.59, enter:

```
config vpn l2tp
   set sip 192.168.0.50
   set eip 192.168.0.59
   set status enable
   set usrgrp "L2TP_group"
end
```

One of the security policies for the L2TP over IPsec VPN uses the client address range, so you need also need to create a firewall address for that range. For example,

```
config firewall address
   edit L2TPclients
      set type iprange
      set start-ip 192.168.0.50
      set end-ip 192.168.0.59
end
```

Alternatively, you could define this range in the web-based manager.

Configuring IPsec

The Microsoft VPN client uses IPsec for encryption. The configuration needed on the FortiGate unit is the same as for any other IPsec VPN with the following exceptions.

- Transport mode is used instead of tunnel mode.
- The encryption and authentication proposals must be compatible with the Microsoft client.

Whether Transport mode is *required* depends on the configuration of the peer device (typically an old Windows device, since newer versions of Windows don't require IPsec and L2TP—they can run IPsec natively).

When configuring L2TP, do not name the VPN "L2TP" as that will result in a conflict.

L2TP over IPsec is supported on the FortiGate unit for both policy-based and route-based configurations, but the following example is policy-based.

Configuring Phase 1 - web-based manager

1. Go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).

Name	Enter a name for this VPN, dialup_p1 for example.
Remote Gateway	**Dialup User**
Local Interface	Select the network interface that connects to the Internet. For example, port1.
Mode	**Main (ID protection)**
Authentication Method	**Preshared Key**
Pre-shared Key	Enter the preshared key. This key must also be entered in the Microsoft VPN client.
Advanced	Select **Advanced** to enter the following information.

Phase 1 Proposal	Enter the following Encryption/Authentication pairs: AES256-MD5, 3DES-SHA1, AES192-SHA1
Diffie-Hellman Group	2
NAT Traversal	Enable
Dead Peer Detection	Enable

Configuring Phase 1 - CLI

To create a Phase 1 configuration called dialup_p1 on a FortiGate unit that has port1 connected to the Internet, you would enter:

```
config vpn ipsec phase1
   edit dialup_p1
      set type dynamic
      set interface port1
      set mode main
      set psksecret ********
      set proposal aes256-md5 3des-sha1 aes192-sha1
      set dhgrp 2
      set nattraversal enable
      set dpd [disable | on-idle | on-demand]
end
```

It is worth noting here that the command `config vpn ipsec phase1` is used rather than `config vpn ipsec phase1-interface` because this configuration is policy-based and not route-based.

Configuring Phase 2 - web-based manager

1. Open the **Phase 2 Selectors** panel.
2. Enter the following information and then select **OK**.

Phase 2 Proposal	Enter the following Encryption/Authentication pairs: AES256-MD5, 3DES-SHA1, AES192-SHA1
Enable replay detection	Enable
Enable perfect forward secrecy (PFS)	Disable
Keylife	3600 seconds

3. Make this a transport-mode VPN. You must use the CLI to do this. If your Phase 2 name is dialup_p2, you would enter:

```
config vpn ipsec phase2
   edit dialup_p2
      set encapsulation transport-mode
   end
```

Configuring Phase 2 - CLI

To configure a Phase 2 to work with your phase_1 configuration, you would enter:

```
config vpn ipsec phase2
   edit dialup_p2
      set phase1name dialup_p1
      set proposal aes256-md5 3des-sha1 aes192-sha1
      set replay enable
      set pfs disable
      set keylifeseconds 3600
      set encapsulation transport-mode
   end
```

Once again, note here that the command `config vpn ipsec phase2` is used rather than `config vpn ipsec phase2-interface` because this configuration is policy-based and not route-based.

Configuring security policies

The security policies required for L2TP over IPsec VPN are:

- An IPsec policy, as you would create for any policy-based IPsec VPN
- A regular ACCEPT policy to allow traffic from the L2TP clients to access the protected network

Configuring the IPsec security policy - web-based manager

1. Go to **System > Feature Select** and enable **Policy-based IPsec VPN**.
2. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
3. Set the **Action** to **IPsec** and enter the following information:

Incoming Interface	Select the interface that connects to the private network behind this FortiGate unit.
Source Address	All
Outgoing Interface	Select the FortiGate unit's public interface.
Destination Address	All
VPN Tunnel	Select **Use Existing** and select the name of the Phase 1 configuration that you created. For example, dialup_p1. See Configuring IPsec on page 2092.
Allow traffic to be initiated from the remote site	enable

4. Select **OK**.

Configuring the IPsec security policy - CLI

If your VPN tunnel (Phase 1) is called dialup_p1, your protected network is on port2, and your public interface is port1, you would enter:

```
config firewall policy
   edit 0
      set srcintf port2
      set dstintf port1
      set srcaddr all
      set dstaddr all
      set action ipsec
      set schedule always
      set service all
      set inbound enable
      set vpntunnel dialup_p1
   end
```

Configuring the ACCEPT security policy - web-based manager

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
3. Enter the following information and select **OK**:

Incoming Interface	Select the FortiGate unit's public interface.
Source Address	Select the firewall address that you defined for the L2TP clients.
Outgoing Interface	Select the interface that connects to the private network behind this FortiGate unit.
Destination Address	All
Action	ACCEPT

Configuring the ACCEPT security policy - CLI

If your public interface is port1, your protected network is on port2, and L2TPclients is the address range that L2TP clients use, you would enter:

```
config firewall policy
   edit 1
      set srcintf port1
      set dstintf port2
      set srcaddr L2TPclients
      set dstaddr all
      set action accept
      set schedule always
      set service all
   end
```

Configuring the Windows PC

Configuration of the Windows PC for a VPN connection to the FortiGate unit consists of the following:

1. In Network Connections, configure a Virtual Private Network connection to the FortiGate unit.
2. Ensure that the IPSEC service is running.
3. Ensure that IPsec has not been disabled for the VPN client. It may have been disabled to make the Microsoft VPN compatible with an earlier version of FortiOS.

The instructions in this section are based on Windows XP. Other versions of Windows may vary slightly.

Configuring the network connection

1. Open **Network Connections**.
   This is available through the Control Panel.
2. Double-click **New Connection Wizard** and **Select Next**.
3. Select **Connect to the network at my workplace**.
4. Select **Next**.
5. Select **Virtual Private Network connection** and select **Next**.
6. In the **Company Name** field, enter a name for the connection and select **Next**.
7. Select **Do not dial the initial connection** and then select **Next**.
8. Enter the public IP address or FQDN of the FortiGate unit and select **Next**.
9. Optionally, select **Add a shortcut to this connection to my desktop**.
10. Select **Finish**.
    The **Connect** dialog opens on the desktop.
11. Select **Properties** and then select the **Security** tab.
12. Select **IPsec Settings**.
13. Select **Use pre-shared key for authentication**, enter the preshared key that you configured for your VPN, and select **OK**.
14. Select **OK**.

Checking that the IPsec service is running

1. Open **Administrative Tools** through the Control Panel.
2. Double-click **Services**.
3. Look for IPSEC Services. Confirm that the **Startup Type** is **Automatic** and **Status** is set to **Started**. If needed, double-click **IPsec Services** to change these settings.

Checking that IPsec has not been disabled

1. Select **Start > Run**.
2. Enter regedit and select **OK**.
3. Find the Registry key HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\RasMan\Parameters
4. If there is a ProhibitIPsec value, it must be set to 0.

GRE over IPsec (Cisco VPN)

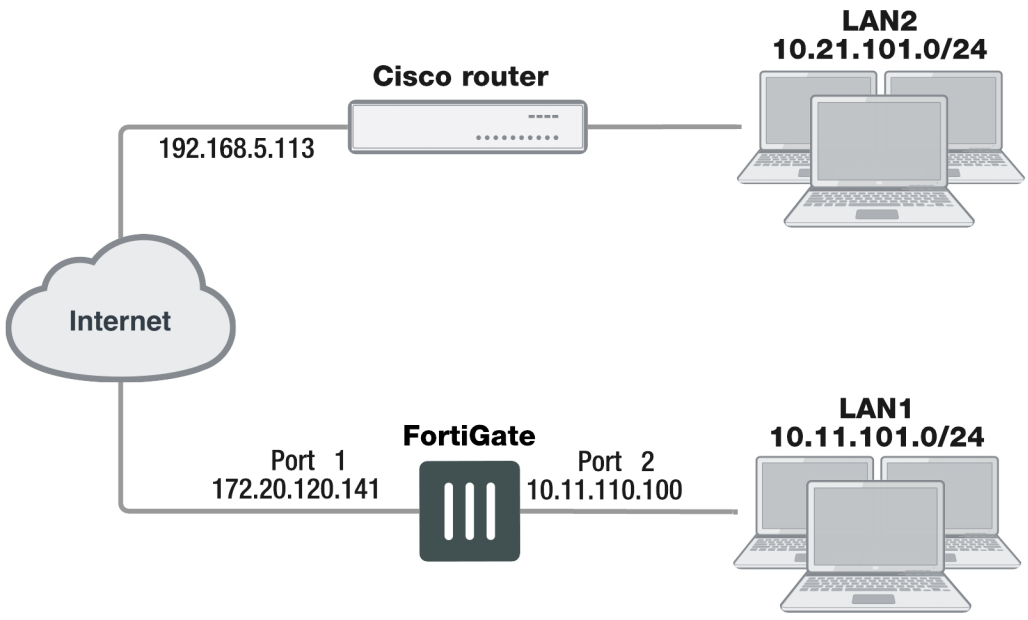
This section describes how to configure a FortiGate VPN that is compatible with Cisco-style VPNs that use GRE in an IPsec tunnel.

The following topics are included in this section:

Cisco products that include VPN support often use Generic Routing Encapsulation (GRE) protocol tunnel over IPsec encryption. This chapter describes how to configure a FortiGate unit to work with this type of Cisco VPN.

Cisco VPNs can use either transport mode or tunnel mode IPsec. Before FortiOS 4.0 MR2, the FortiGate unit was compatible only with tunnel mode IPsec.

Example FortiGate to Cisco GRE-over-IPsec VPN



In this example, users on LAN1 are provided access to LAN2.

Configuration overview

The following section consists of configuring the FortiGate unit and configuring the Cisco router.

Configuring the FortiGate unit

There are several steps to the GRE-over-IPsec configuration:

- Enable overlapping subnets. This is needed because the IPsec and GRE tunnels will use the same addresses.
- Configure a route-based IPsec VPN on the external interface.
- Configure a GRE tunnel on the virtual IPsec interface. Set its local gateway and remote gateway addresses to match the local and remote gateways of the IPsec tunnel.
- Configure security policies to allow traffic to pass in both directions between the GRE virtual interface and the IPsec virtual interface.
- Configure security policies to allow traffic to pass in both directions between the protected network interface and the GRE virtual interface.
- Configure a static route to direct traffic destined for the network behind the Cisco router into the GRE-over-IPsec tunnel.

Enabling overlapping subnets

By default, each FortiGate unit network interface must be on a separate network. The configuration described in this chapter assigns an IPsec tunnel end point and the external interface to the same network. Enable subnet overlap as follows:

```
config system settings
   set allow-subnet-overlap enable
end
```

Configuring the IPsec VPN

A route-based VPN is required. It must use encryption and authentication algorithms compatible with the Cisco equipment to which it connects. In this chapter, preshared key authentication is shown.

Configuring the IPsec VPN - web-based manager

1. Define the Phase 1 configuration needed to establish a secure connection with the remote Cisco device. Enter these settings in particular:

Name	Enter a name to identify the VPN tunnel, tocisco for example. This is the name of the virtual IPsec interface. It appears in Phase 2 configurations, security policies and the VPN monitor.
Remote Gateway	Select **Static IP Address**.
IP Address	Enter the IP address of the Cisco device public interface. For example, 192.168.5.113.
Local Interface	Select the FortiGate unit's public interface. For example, 172.20.120.141.
Mode	Select **Main (ID Protection)**.

Authentication Method	**Preshared Key**
Pre-shared Key	Enter the preshared key. It must match the preshared key on the Cisco device.
Advanced	Select the Advanced button to see the following settings.
Phase 1 Proposal	**3DES-MD5** At least one proposal must match the settings on the Cisco unit.

For more information about these settings, see Phase 1 parameters on page 1967.

2. Define the Phase 2 parameters needed to create a VPN tunnel with the remote peer. For compatibility with the Cisco router, Quick Mode Selectors must be entered, which includes specifying protocol 47, the GRE protocol. Enter these settings in particular:

Phase 2 Proposal	**3DES-MD5** At least one proposal must match the settings on the Cisco unit.
Quick Mode Selector	
Source Address	Enter the GRE local tunnel end IP address. For example 172.20.120.141.
Source Port	0
Destination Address	Enter the GRE remote tunnel end IP address. For example 192.168.5.113.
Destination Port	0
Protocol	47

For more information about these settings, see Phase 2 parameters on page 1985.

3. If the Cisco device is configured to use transport mode IPsec, you need to use transport mode on the FortiGate VPN. You can configure this only in the CLI. In your Phase 2 configuration, set `encapsulation` to `transport-mode` as follows:

```
config vpn phase2-interface
   edit to_cisco_p2
      set encapsulation transport-mode
   end
```

Configuring the IPsec VPN - CLI

```
config vpn ipsec phase1-interface
   edit tocisco
      set interface port1
      set proposal 3des-sha1 aes128-sha1
      set remote-gw 192.168.5.113
      set psksecret xxxxxxxxxxxxxxx
```

```
   end
config vpn ipsec phase2-interface
   edit tocisco_p2
      set phase1name "tocisco"
      set proposal 3des-md5
      set encapsulation tunnel-mode // if tunnel mode
      set encapsulation transport-mode // if transport mode
      set protocol 47
      set src-addr-type ip
      set dst-start-ip 192.168.5.113
      set src-start-ip 172.20.120.141
   end
```

Adding IPsec tunnel end addresses

The Cisco configuration requires an address for its end of the IPsec tunnel. The addresses are set to match the GRE gateway addresses. Use the CLI to set the addresses, like this:

```
config system interface
   edit tocisco
      set ip 172.20.120.141 255.255.255.255
      set remote-ip 192.168.5.113
   end
```

Configuring the GRE tunnel

The GRE tunnel runs between the virtual IPsec public interface on the FortiGate unit and the Cisco router. You must use the CLI to configure a GRE tunnel. In the example, you would enter:

```
config system gre-tunnel
   edit gre1
      set interface tocisco
      set local-gw 172.20.120.141
      set remote-gw 192.168.5.113
end
```

`interface` is the virtual IPsec interface, `local-gw` is the FortiGate unit public IP address, and `remote-gw` is the remote Cisco device public IP address

Adding GRE tunnel end addresses

You will also need to add tunnel end addresses. The Cisco router configuration requires an address for its end of the GRE tunnel. Using the CLI, enter tunnel end addresses that are not used elsewhere on the FortiGate unit, like this:

```
config system interface
   edit gre1
      set ip 10.0.1.1 255.255.255.255
      set remote-ip 10.0.1.2
   end
```

Configuring security policies

Two sets of security policies are required:

- Policies to allow traffic to pass in both directions between the GRE virtual interface and the IPsec virtual interface.
- Policies to allow traffic to pass in both directions between the protected network interface and the GRE virtual interface.

Configuring security policies - web-based manager

1. Define an ACCEPT firewall security policy to permit communications between the protected network and the GRE tunnel:

Incoming Interface	Select the interface that connects to the private network behind this FortiGate unit.
Source Address	**All**
Outgoing Interface	Select the GRE tunnel virtual interface you configured.
Destination Address	**All**
Action	**ACCEPT**
Enable NAT	Disable

2. To permit the remote client to initiate communication, you need to define a firewall address security policy for communication in that direction:

Incoming Interface	Select the GRE tunnel virtual interface you configured.
Source Address	**All**
Outgoing Interface	Select the interface that connects to the private network behind this FortiGate unit.
Destination Address	**All**
Action	**ACCEPT**
Enable NAT	Disable

3. Define a pair of ACCEPT firewall address security policies to permit traffic to flow between the GRE virtual interface and the IPsec virtual interface:

Incoming Interface	Select the GRE virtual interface. See Configuring the GRE tunnel on page 2100.
Source Address	**All**
Outgoing Interface	Select the virtual IPsec interface you created. See Configuring the IPsec VPN on page 2098.
Destination Address	**All**
Action	**ACCEPT**
Enable NAT	Disable

Incoming Interface	Select the virtual IPsec interface you created. See Configuring the IPsec VPN on page 2098.
Source Address	**All**
Outgoing Interface	Select the GRE virtual interface.See Configuring the GRE tunnel on page 2100.
Destination Address	**All**
Action	**ACCEPT**
Enable NAT	Disable

Configuring security policies - CLI

```
config firewall policy
   edit 1 // LAN to GRE tunnel
      set srcintf port2
      set dstintf gre1
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
      set service ANY
   next
   edit 2 // GRE tunnel to LAN
      set srcintf gre1
      set dstintf port2
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
      set service ANY
   next
   edit 3 // GRE tunnel to IPsec interface
      set srcintf "gre1"
      set dstintf "tocisco"
      set srcaddr "all"
      set dstaddr "all"
      set action accept
      set schedule "always"
      set service "ANY"
   next
   edit 4 // IPsec interface to GRE tunnel
      set srcintf "tocisco"
      set dstintf "gre1"
      set srcaddr "all"
      set dstaddr "all"
      set action accept
      set schedule "always"
      set service "ANY"
   end
```

Configuring routing

Traffic destined for the network behind the Cisco router must be routed to the GRE tunnel. To do this, create a static route

1. Go to **Network > Static Routes** and select **Create New**.
2. Enter the following information and select **OK**.

Destination IP/Mask	Enter the IP address and netmask for the network behind the Cisco router. For example 10.21.101.0 255.255.255.0.
Device	Select the GRE virtual interface.
Distance (Advanced)	Leave setting at default value.

In the CLI, using the example values, you would enter

```
config router static
   edit 0
      set device gre1
      set dst 10.21.101.0 255.255.255.0
   end
```

Configuring the Cisco router

Using Cisco IOS, you would configure the Cisco router as follows, using the addresses from the example:

```
config ter
crypto ipsec transform-set myset esp-3des esp-md5-hmac
no mode
exit
no ip access-list extended tunnel
ip access-list extended tunnel
permit gre host 192.168.5.113 host 172.20.120.141
exit
interface Tunnel1
ip address 10.0.1.2 255.255.255.0
tunnel source 192.168.5.113
tunnel destination 172.20.120.141
!
ip route 10.11.101.0 255.255.255.0 Tunnel1
end
clea crypto sa
clea crypto isakmp
```

For transport mode, change `no mode` to `mode transport`.

This is only the portion of the Cisco router configuration that applies to the GRE-over-IPsec tunnel. For more information, refer to the Cisco documentation.

Protecting OSPF with IPsec

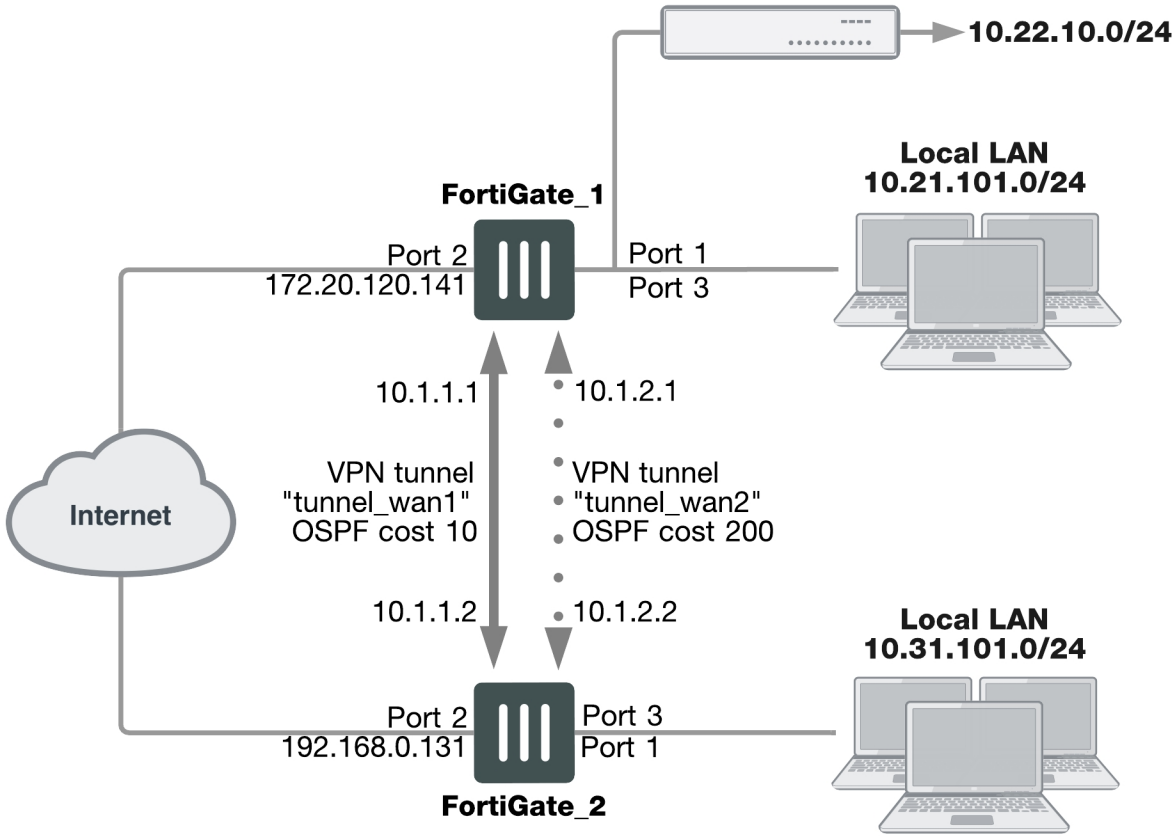
For enhanced security, OSPF dynamic routing can be carried over IPsec VPN links.

The following topics are included in this section:

Configuration overview

This chapter shows an example of OSPF routing conducted over an IPsec tunnel between two FortiGate units. The network shown below is a single OSPF area. FortiGate_1 is an Area border router that advertises a static route to 10.22.10.0/24 in OSPF. FortiGate_2 advertises its local LAN as an OSPF internal route.

OSPF over an IPsec VPN tunnel



The section Configuration overview describes the configuration with only one IPsec VPN tunnel, tunnel_wan1. Then, the section Configuration overview describes how you can add a second tunnel to provide a redundant backup path. This is shown above as VPN tunnel “tunnel_wan2”.

Only the parts of the configuration concerned with creating the IPsec tunnel and integrating it into the OSPF network are described. It is assumed that security policies are already in place to allow traffic to flow between the interfaces on each FortiGate unit.

OSPF over IPsec configuration

There are several steps to the OSPF-over-IPsec configuration:

- Configure a route-based IPsec VPN on an external interface. It will connect to a corresponding interface on the other FortiGate unit. Define the two tunnel-end addresses.
- Configure a static route to the other FortiGate unit.
- Configure the tunnel network as part of the OSPF network and define the virtual IPsec interface as an OSPF interface.

This section describes the configuration with only one VPN, tunnel_wan1. The other VPN is added in the section Configuration overview on page 2104.

Configuring the IPsec VPN

A route-based VPN is required. In this chapter, preshared key authentication is shown. Certificate authentication is also possible. Both FortiGate units need this configuration.

Configuring Phase 1

1. Define the Phase 1 configuration needed to establish a secure connection with the other FortiGate unit. For more information, see Phase 1 parameters on page 1967.

   Enter these settings in particular:

Name	Enter a name to identify the VPN tunnel, tunnel_wan1 for example. This becomes the name of the virtual IPsec interface.
Remote Gateway	Select **Static IP Address**.
IP Address	Enter the IP address of the other FortiGate unit's public (Port 2) interface.
Local Interface	Select this FortiGate unit's public (Port 2) interface.
Mode	Select **Main (ID Protection)**.
Authentication Method	**Preshared Key**
Pre-shared Key	Enter the preshared key. It must match the preshared key on the other FortiGate unit.
Advanced	Select **Advanced**.

Assigning the tunnel end IP addresses

1. Go to **Network > Interfaces**, select the virtual IPsec interface that you just created on Port 2 and select **Edit**.
2. In the **IP** and **Remote IP** fields, enter the following tunnel end addresses:

	FortiGate_1	FortiGate_2
IP	10.1.1.1	10.1.1.2
Remote_IP	10.1.1.2	10.1.1.1

These addresses are from a network that is not used for anything else.

Configuring Phase 2

1. Enter a name to identify this Phase 2 configuration, twan1_p2, for example.
2. Select the name of the Phase 1 configuration that you defined in Step "Configuration overview" on page 2104, tunnel_wan1 for example.

Configuring static routing

You need to define the route for traffic leaving the external interface.

1. Go to **Network > Static Routes**, select **Create New**.
2. Enter the following information.

Destination IP/Mask	Leave as 0.0.0.0 0.0.0.0.
Device	Select the external interface.
Gateway	Enter the IP address of the next hop router.

Configuring OSPF

This section does not attempt to explain OSPF router configuration. It focusses on the integration of the IPsec tunnel into the OSPF network. This is accomplished by assigning the tunnel as an OSPF interface, creating an OSPF route to the other FortiGate unit.

This configuration uses loopback interfaces to ease OSPF troubleshooting. The OSPF router ID is set to the loopback interface address.The loopback interface ensures the router is always up. Even though technically the router ID doesn't have to match a valid IP address on the FortiGate unit, having an IP that matches the router ID makes troubleshooting a lot easier.

The two FortiGate units have slightly different configurations. FortiGate_1 is an AS border router that advertises its static default route. FortiGate_2 advertises its local LAN as an OSPF internal route.

Setting the router ID for each FortiGate unit to the lowest possible value is useful if you want the FortiGate units to be the designated router (DR) for their respective ASes. This is the router that broadcasts the updates for the AS.

Leaving the IP address on the OSPF interface at 0.0.0.0 indicates that all potential routes will be advertised, and it will not be limited to any specific subnet. For example if this IP address was 10.1.0.0, then only routes that match that subnet will be advertised through this interface in OSPF.

FortiGate_1 OSPF configuration

When configuring FortiGate_1 for OSPF, the loopback interface is created, and then you configure OSPF area networks and interfaces.

With the exception of creating the loopback interface, OSPF for this example can all be configured in either the web-based manager or CLI.

Creating the loopback interface

A loopback interface can be configured in the CLI only. For example, if the interface will have an IP address of 10.0.0.1, you would enter:

```
config system interface
```

```
edit lback1
   set vdom root
      set ip 10.0.0.1 255.255.255.255
      set type loopback
end
```

The loopback addresses and corresponding router IDs on the two FortiGate units must be different. For example, set the FortiGate 1 loopback to 10.0.0.1 and the FortiGate 2 loopback to 10.0.0.2.

Configuring OSPF area, networks, and interfaces - web-based manager

1. On FortiGate_1, go to **Network > OSPF**.
2. Enter the following information to define the router, area, and interface information.

Router ID	Enter `10.0.0.1`. Select **Apply** before entering the remaining information.
Advanced Options	
Redistribute	Select the **Connected** and **Static** check boxes. Use their default metric values.
Areas	Select **Create New**, enter the **Area** and **Type** and then select **OK**.
Area	0.0.0.0
Type	Regular
Interfaces	Enter a name for the OSPF interface, ospf_wan1 for example.
Name	
Interface	Select the virtual IPsec interface, tunnel_wan1.
IP	0.0.0.0

3. For **Networks**, select **Create New**.
4. Enter the **IP/Netmask** of `10.1.1.0/255.255.255.0` and an **Area** of `0.0.0.0`.
5. For **Networks**, select **Create New**.
6. Enter the **IP/Netmask** of `10.0.0.1/255.255.255.0` and an **Area** of `0.0.0.0`.
7. Select **Apply**.

Configuring OSPF area and interfaces - CLI

Your loopback interface is 10.0.0.1, your tunnel ends are on the 10.1.1.0/24 network, and your virtual IPsec interface is named `tunnel_wan1`. Enter the following CLI commands:

```
config router ospf
   set router-id 10.0.0.1
   config area
      edit 0.0.0.0
   end
   config network
      edit 4
```

```
            set prefix 10.1.1.0 255.255.255.0
         next
         edit 2
            set prefix 10.0.0.1 255.255.255.255
         end
      config ospf-interface
         edit ospf_wan1
            set cost 10
            set interface tunnel_wan1
            set network-type point-to-point
         end
      config redistribute connected
         set status enable
      end
      config redistribute static
         set status enable
      end
   end
```

FortiGate_2 OSPF configuration

When configuring FortiGate_2 for OSPF, the loopback interface is created, and then you configure OSPF area networks and interfaces.

Configuring FortiGate_2 differs from FortiGate_1 in that three interfaces are defined instead of two. The third interface is the local LAN that will be advertised into OSPF.

With the exception of creating the loopback interface, OSPF for this example can all be configured in either the web-based manager or CLI.

Creating the loopback interface

A loopback interface can be configured in the CLI only. For example, if the interface will have an IP address of 10.0.0.2, you would enter:

```
config system interface
   edit lback1
      set vdom root
      set ip 10.0.0.2 255.255.255.255
      set type loopback
   end
```

The loopback addresses on the two FortiGate units must be different. For example, set the FortiGate 1 loopback to 10.0.0.1 and the FortiGate 2 loopback to 10.0.0.2.

Configuring OSPF area and interfaces - web-based manager

1. On FortiGate_2, go to **Network > OSPF**.
2. Complete the following.

Router ID	10.0.0.2
Areas	Select **Create New**, enter the **Area** and **Type** and then select **OK**.
Area	`0.0.0.0`

Type	Regular
Interfaces	
Name	Enter a name for the OSPF interface, ospf_wan1 for example.
Interface	Select the virtual IPsec interface, tunnel_wan1.
IP	0.0.0.0

3. For **Networks**, select **Create New**.
4. Enter the following information for the loopback interface:

IP/Netmask	10.0.0.2/255.255.255.255
Area	0.0.0.0

5. For **Networks**, select **Create New**.
6. Enter the following information for the tunnel interface:

IP/Netmask	10.1.1.0/255.255.255.255
Area	0.0.0.0

7. For **Networks**, select **Create New**.
8. Enter the following information for the local LAN interface:

IP/Netmask	10.31.101.0/255.255.255.255
Area	0.0.0.0

9. Select **Apply**.

Configuring OSPF area and interfaces - CLI

If for example, your loopback interface is 10.0.0.2, your tunnel ends are on the 10.1.1.0/24 network, your local LAN is 10.31.101.0/24, and your virtual IPsec interface is named tunnel_wan1, you would enter:

```
config router ospf
   set router-id 10.0.0.2
   config area
      edit 0.0.0.0
   end
   config network
      edit 1
         set prefix 10.1.1.0 255.255.255.0
      next
      edit 2
         set prefix 10.31.101.0 255.255.255.0
      next
      edit 2
         set prefix 10.0.0.2 255.255.255.255
      end
```

```
      config ospf-interface
         edit ospf_wan1
            set interface tunnel_wan1
            set network-type point-to-point
         end
   end
```

Creating a redundant configuration

You can improve the reliability of the OSPF over IPsec configuration described in the previous section by adding a second IPsec tunnel to use if the default one goes down. Redundancy in this case is not controlled by the IPsec VPN configuration but by the OSPF routing protocol.

To do this you:

- Create a second route-based IPsec tunnel on a different interface and define tunnel end addresses for it.
- Add the tunnel network as part of the OSPF network and define the virtual IPsec interface as an additional OSPF interface.
- Set the OSPF cost for the added OSPF interface to be significantly higher than the cost of the default route.

Adding the second IPsec tunnel

The configuration is the same as in Configuring the IPsec VPN on page 2105, but the interface and addresses will be different. Ideally, the network interface you use is connected to a different Internet service provider for added redundancy.

When adding the second tunnel to the OSPF network, choose another unused subnet for the tunnel ends, 10.1.2.1 and 10.1.2.2 for example.

Adding the OSPF interface

OSPF uses the metric called cost when determining the best route, with lower costs being preferred. Up to now in this example, only the default cost of 10 has been used. Cost can be set only in the CLI.

The new IPsec tunnel will have its OSPF cost set higher than that of the default tunnel to ensure that it is only used if the first tunnel goes down. The new tunnel could be set to a cost of 200 compared to the default cost is 10. Such a large difference in cost will ensure this new tunnel will only be used as a last resort.

If the new tunnel is called tunnel_wan2, you would enter the following on both FortiGate units:

```
config router ospf
   config ospf-interface
      edit ospf_wan2
         set cost 200
         set interface tunnel_wan2
         set network-type point-to-point
      end
   end
```

Redundant OSPF routing over IPsec

This example sets up redundant secure communication between two remote networks using an Open Shortest Path First (OSPF) VPN connection. In this example, the HQ FortiGate unit will be called FortiGate 1 and the Branch FortiGate unit will be called FortiGate 2.

The steps include:

1. Creating redundant IPsec tunnels on FortiGate 1.
2. Configuring IP addresses and OSPF on FortiGate 1.
3. Configuring firewall addresses on FortiGate 1.
4. Configuring security policies on FortiGate 1.
5. Creating redundant IPsec tunnels for FortiGate 2.
6. Configuring IP addresses and OSPF on FortiGate 2.
7. Configuring firewall addresses on FortiGate 2.
8. Configuring security policies on FortiGate 2.

Creating redundant IPsec tunnels on FortiGate 1

1. Go to **VPN > IPsec Tunnels**.
2. Select **Create New**, name the primary tunnel and select **Custom VPN Tunnel (No Template)**.
3. Set the following:

Remote Gateway	Static IP Address
IP Address	FortiGate 2's wan1 IP
Local Interface	wan1 (the primary Internet-facing interface)
Pre-shared Key	Enter

4. Go to **VPN > IPsec Tunnels**.
5. Select **Create New**, name the secondary tunnel and select **Custom VPN Tunnel (No Template)**.
6. Set the following:

Remote Gateway	Static IP Address
IP Address	FortiGate 2's wan2 IP
Local Interface	wan2 (the secondary Internet-facing interface)
Pre-shared Key	Enter

Configuring IP addresses and OSPF on FortiGate 1

1. Go to **Network > Interfaces**.
2. Select the arrow for **wan1** to expand the list.

3. Edit the primary tunnel interface and create IP addresses.

IP	10.1.1.1
Remote IP	10.1.1.2

4. Select the arrow for **wan2** to expand the list.
5. Edit the secondary tunnel interface and create IP addresses.

IP	10.2.1.1
Remote IP	10.2.1.2

6. Go to **Network > OSPF** and enter the **Router ID** for FortiGate 1.
7. Select **Create New** in the **Area** section.
8. Add the backbone area of **0.0.0.0**.
9. Select **Create New** in the **Networks** section.
10. Create the networks and select **Area 0.0.0.0** for each one.
11. Select **Create New** in the **Interfaces** section.
12. Create primary and secondary tunnel interfaces.
13. Set a **Cost** of **10** for the primary interface and **100** for the secondary interface.

Configuring firewall addresses on FortiGate 1

1. Go to **Policy & Objects > Addresses**.
2. Create/Edit the subnets behind FortiGate 1 and FortiGate 2.
3. Create/Edit the primary and secondary interfaces of FortiGate 2.

Configuring security policies on FortiGate 1

1. Go to **Policy & Objects > IPv4 Policy**.
2. Create the four security policies required for both FortiGate 1's primary and secondary interfaces to connect to FortiGate 2's primary and secondary interfaces.

Creating redundant IPsec tunnels on FortiGate 2

1. Go to **VPN > IPsec Tunnels**.
2. Select **Create New**, name the primary tunnel and select **Custom VPN Tunnel (No Template)**.
3. Set the following:

Remote Gateway	Static IP Address
IP Address	FortiGate 1's wan1 IP
Local Interface	wan1 (the primary Internet-facing interface)
Pre-shared Key	Enter

4. Go to **VPN > IPsec Tunnels**.
5. Select **Create New**, name the secondary tunnel and select **Custom VPN Tunnel (No Template)**.
6. Set the following:

Remote Gateway	Static IP Address
IP Address	FortiGate 1's wan1 IP
Local Interface	wan2 (the secondary Internet-facing interface)
Pre-shared Key	Enter

Configuring IP addresses and OSPF on FortiGate 1

1. Go to **Network > Interfaces**.
2. Select the arrow for **wan1** to expand the list.
3. Edit the primary tunnel interface and create IP addresses.

IP	10.1.1.2
Remote IP	10.1.1.1

4. Select the arrow for **wan2** to expand the list.
5. Edit the secondary tunnel interface and create IP addresses.

IP	10.2.1.2
Remote IP	10.2.1.1

6. Go to **Network > OSPF** and enter the **Router ID** for FortiGate 2.
7. Select **Create New** in the **Area** section.
8. Add the backbone area of **0.0.0.0**.
9. Select **Create New** in the **Networks** section.
10. Create the networks and select **Area 0.0.0.0** for each one.
11. Select **Create New** in the **Interfaces** section.
12. Create primary and secondary tunnel interfaces.
13. Set a **Cost** of **10** for the primary interface and **100** for the secondary interface.

Configuring firewall addresses on FortiGate 2

1. Go to **Policy & Objects > Addresses**.
2. Create/Edit the subnets behind FortiGate 1 and FortiGate 2.
3. Create/Edit the primary and secondary interfaces of FortiGate 2.

Configuring security policies on FortiGate 2

1. Go to **Policy & Objects > IPv4 Policy**.
2. Create the four security policies required for both FortiGate 2's primary and secondary interfaces to connect to FortiGate 1's primary and secondary interfaces.

Results

1. Go to **Monitor > IPsec Monitor** to verify the statuses of both the primary and secondary IPsec VPN tunnels on FortiGate 1 and FortiGate 2.
2. Go to **Monitor > Routing Monitor**. Monitor to verify the routing table on FortiGate 1 and FortiGate 2. Type **OSPF** for the **Type** and select **Apply Filter** to verify the OSPF route.
3. Verify that traffic flows via the primary tunnel:
   - From a PC1 set to IP:10.20.1.100 behind FortiGate 1, run a tracert to a PC2 set to IP address 10.21.1.00 behind FortiGate 2 and vise versa.
   - From PC1, you should see that the traffic goes through 10.1.1.2 which is the primary tunnel interface IP set on FortiGate 2.
   - From PC2, you should see the traffic goes through 10.1.1.1 which is the primary tunnel interface IP set on FortiGate 1.
4. The VPN network between the two OSPF networks uses the primary VPN connection. Disconnect the wan1 interface and confirm that the secondary tunnel will be used automatically to maintain a secure connection.
5. Verify the IPsec VPN tunnel statuses on FortiGate 1 and FortiGate 2. Both FortiGates should show that primary tunnel is DOWN and secondary tunnel is UP.
6. Go to **Monitor > IPsec Monitor** to verify the status.
7. Verify the routing table on FortiGate 1 and FortiGate 2.
   The secondary OSPF route (with cost = 100) appears on both FortiGate units.
8. Go to **Monitor > Routing Monitor**. Type **OSPF** for the **Type** and select **Apply Filter** to verify OSPF route.
9. Verify that traffic flows via the secondary tunnel:
   - From a PC1 set to IP:10.20.1.100 behind FortiGate 1, run a tracert to a PC2 set to IP:10.21.1.100 behind FortiGate 2 and vice versa.
   - From PC1, you should see that the traffic goes through 10.2.1.2 which is the secondary tunnel interface IP set on FortiGate 2.
   - From PC2, you should see the traffic goes through 10.2.1.1 which is the secondary tunnel interface IP set on FortiGate 1.

OSPF over dynamic IPsec

The following example shows how to create a dynamic IPsec VPN tunnel that allows OSPF.

Configuring IPsec on FortiGate 1

1. Go to **Dashboard** and enter the **CLI Console** widget
2. Create phase 1:

```
config vpn ipsec phase1-interface
   edit "dial-up"
      set type dynamic
      set interface "wan1"
      set mode-cfg enable
      set proposal 3des-sha1
      set add-route disable
      set ipv4-start-ip 10.10.101.0
      set ipv4-end-ip 10.10.101.255
      set psksecret
   next
end
```

3. Create phase 2:

```
config vpn ipsec phase2-interface
   edit "dial-up-p2"
      set phase1name "dial-up"
      set proposal 3des-sha1 aes128-sha1
   next
end
```

Configuring OSPF on FortiGate 1

1. Go to **Dashboard** and enter the **CLI Console** widget.
2. Create OSPF route.

```
config router ospf
   set router-id 172.20.120.22
      config area
         edit 0.0.0.0
         next
      end
      config network
         edit 1
            set prefix 10.10.101.0 255.255.255.0
         next
      end
      config redistribute "connected"
         set status enable
      end
      config redistribute "static"
         set status enable
      end
end
```

Adding policies on FortiGate 1

1. Go to **Policy & Objects > IPv4 Policy** and create a policy allowing OSPF traffic from **dial-up** to **port5**.
2. Go to **Policy & Objects > IPv4 Policy** and create a policy allowing OSPF traffic from **port5** to **dial-up** interfaces.

Configuring IPsec on FortiGate 2

1. Go to **Dashboard** and enter the **CLI Console** widget
2. Create phase 1:

```
config vpn ipsec phase1-interface
   edit "dial-up-client"
      set interface "wan1"
      set mode-cfg enable
      set proposal 3des-sha1
      set add-route disable
      set remote-gw 172.20.120.22
      set psksecret
   next
end
```

3. Create phase 2:

```
config vpn ipsec phase2-interface
   edit "dial-up-client"
      set phase1name "dial-up-client"
      set proposal 3des-sha1 aes128-sha1
      set auto-negotiate enable
   next
end
```

Configuring OSPF on FortiGate 2

1. Go to **Dashboard** and enter the **CLI Console** widget.
2. Create OSPF route.

```
config router ospf
   set router-id 172.20.120.15
      config area
         edit 0.0.0.0
         next
      end
      config network
         edit 1
            set prefix 10.10.101.0 255.255.255.0
         next
      end
      config redistribute "connected"
         set status enable
      end
      config redistribute "static"
         set status enable
      end
end
```

Adding policies on FortiGate 2

1. Go to **Policy & Objects > IPv4 Policy** and create a policy allowing OSPF traffic from **dial-up-client** to **port5**.
2. Go to **Policy & Objects > IPv4 Policy** and create a policy allowing OSPF traffic from **port5** to **dial-up-client** interfaces.

Verifying the tunnel is up

Go to **Monitor > IPsec Monitor** to verify that the tunnel is **Up**.

Results

1. From FortiGate 1, go to **Monitor > Routing Monitor** and verify that routes from FortiGate 2 were successfully advertised to FortiGate 1 via OSPF.
2. From FortiGate 1, go to **Dashboard**. Enter the CLI Console widget and type this command to verify OSPF neighbors:

```
get router info ospf neighbor

OSPF process 0:
Neighbor      ID Pri State Dead  Time     Address Interface
172.20.120.25 1  Full  /     -   00:00:34 10.10.101.1  dial-up_0
```

3. From FortiGate 2, go to **Monitor > Routing Monitor** and verify that routes from FortiGate 1 were successfully advertised to FortiGate 2 via OSPF.
4. From FortiGate 2, go to **Dashboard**. Enter the CLI Console widget and type this command to verify OSPF neighbors:

```
get router info ospf neighbor

OSPF process 0:
Neighbor      ID Pri State Dead  Time     Address     Interface
172.20.120.22 1  Full  /     -   00:00:30 10.10.101.2  dial-up_client
```

BGP over dynamic IPsec

The following example shows how to create a dynamic IPsec VPN tunnel that allows BGP.

Configuring IPsec on FortiGate 1

1. Go to **Policy & Objects > Addresses** and select create new **Address**.

Name	Remote_loop_int
Type	Subnet
Subnet/IP Range	10.10.10.10
Interface	any

2. Create an **Address Group**.

Group Name	VPN_DST
Show in Address List	enable
Members	Remote_loop_int all

3. Go to **Dashboard** and enter the CLI Console widget.
4. Create phase 1:

```
config vpn ipsec phase1-interface
   edit Dialup
      set type dynamic
      set interface wan1
      set mode aggressive
      set peertype one
      set mode-cfg enable
      set proposal 3des-sha1 aes128-sha1
      set peerid dial
      set assign-ip disable
      set psksecret
   next
end
```

5. Create phase 2:

```
config vpn ipsec phase2-interface
   edit dial_p2
      set phase1name Dialup
      set proposal 3des-sha1 aes128-sha1
      set src-addr-type name
      set dst-addr-type name
      set src-name all
      set dst-name VPN_DST
   next
```

```
end
```

Configuring BGP on FortiGate 1

1. Go to **Network > Interfaces** and create a Loopback interface.
2. Set **IP/Network Mask** to **20.20.20.20/255.255.255.255**.
3. Go to **Dashboard** and enter the CLI Console widget.
4. Create a BGP route.

```
config router bgp
   set as 100
   set router-id 1.1.1.1
      config neighbor
         edit 10.10.10.10
            set ebgp-enforce-multihop enable
            set remote-as 200
            set update-source loop
         next
      end
      config redistribute connected
         set status enable
      end
end
```

Adding policies on FortiGate 1

1. Go to **Policy & Objects > IPv4 Policy** and create a policy allowing BGP traffic from **Dialup** to **loop** interfaces.
2. Go to **Policy & Objects > IPv4 Policy** and create a policy allowing BGP traffic from **loop** to **Dialup** interfaces.

Configuring IPsec on FortiGate 2

1. Go to **Dashboard** and enter the CLI Console widget.
2. Create phase 1:

```
config vpn ipsec phase1-interface
   edit Dialup
      set interface wan1
      set mode aggressive
      set mode-cfg enable
      set proposal 3des-sha1 aes128-sha1
      set localid dial
      set remote-gw 172.20.120.22
      set assign-ip disable
      set psksecret
   next
end
```

3. Create phase 2:

```
config vpn ipsec phase2-interface
   edit dial_p2
      set phase1name Dialup
      set proposal 3des-sha1 aes128-sha1
      set keepalive enable
   next
end
```

Configuring BGP on FortiGate 2

1. Go to **Network > Interfaces** and create a Loopback interface.
2. Set **IP/Network Mask** to **10.10.10.10/255.255.255.255**.
3. Go to **Dashboard** and enter the **CLI Console** widget.
4. Create a BGP route.

```
config router bgp
   set as 200
   set router-id 1.1.1.2
      config neighbor
         edit 20.20.20.20
            set ebgp-enforce-multihop enable
            set remote-as 100
            set update-source loop
         next
      end
      config redistribute connected
         set status enable
      end
end
```

Adding policies on FortiGate 2

1. Go to **Policy & Objects > IPv4 Policy** and create a policy allowing BGP traffic from **Dialup** to **loop** interfaces.
2. Go to **Policy & Objects > IPv4 Policy** and create a policy allowing BGP traffic from **loop** to **Dialup** interfaces.

Adding a static route on FortiGate 2

Go to **Network > Static Routes** and add a route to the remote Loopback interface via Dialup interface.

Destination IP/Mask	20.20.20.20/255.255.255.255
Device	Dialup
Administrative Distance	10

Verifying the tunnel is up

Go to **Monitor > IPsec Monitor** to verify that the tunnel is **Up**.

Results

1. From FortiGate 1, go to **Monitor > Routing Monitor** and verify that routes from FortiGate 2 were successfully advertised to FortiGate 1 via BGP.
2. From FortiGate 1, go to **Dashboard**.
3. Enter the **CLI Console** widget and type this command to verify BGP neighbors:

```
get router info bgp summary
```

4. From FortiGate 2, go to **Monitor > Routing Monitor** and verify that routes from FortiGate 1 were successfully advertised to FortiGate 2 via BGP.
5. From FortiGate 2, go to **Dashboard**.
6. Enter the **CLI Console** widget and type this command to verify BGP neighbors:

```
get router info bgp summary
```

IPsec Auto-Discovery VPN (ADVPN)

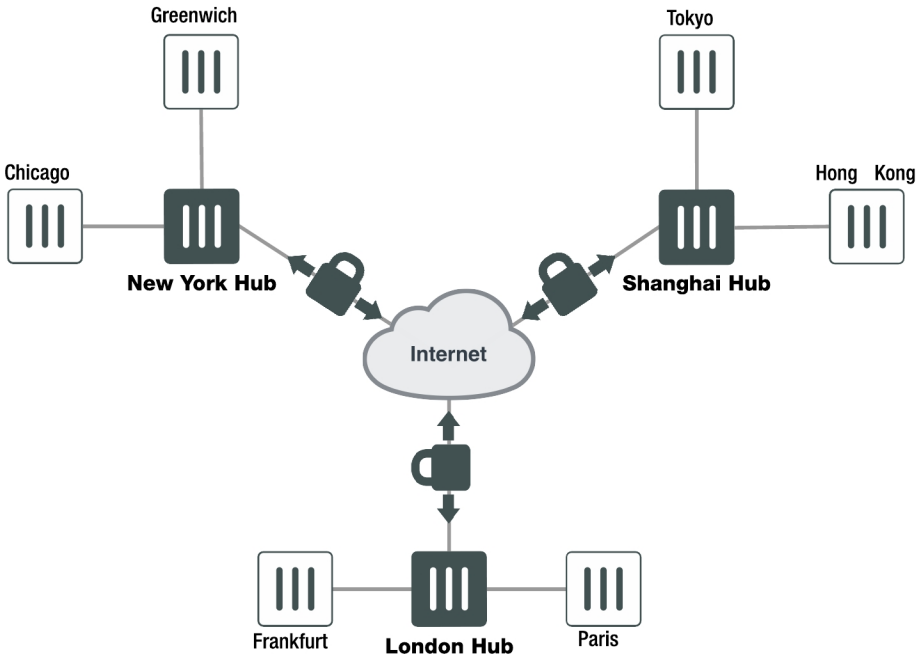
Consider a company that wants to provide direct secure (IPsec) connections between all of its offices in New York, Chicago, Greenwich, London, Paris, Frankfurt, Tokyo, Shanghai, and Hong Kong.

A straightforward solution is to create a full mesh of connections such that every site has eight IPsec configurations, one for each of the other sites. If there were ninety sites, that could still be done but now the configuration is becoming tedious, since every time a new site is added, N-1 other sites have to have their configuration updated.

An efficient and secure alternative is IPsec Auto-Discovery VPN (ADVPN), which allows a minimum amount of configuration per site but still allows direct IPsec connections to be made between every site. RFC 7018 essentially describes this problem, along with some requirements for candidate solutions.

The ADVPN solution involves partitioning the sites into spokes and hubs such that a spoke has to have enough IPsec configuration to enable it to connect to at least one hub. A hub does not have specific configuration for each spoke, so the amount of configuration does not grow with the number of spokes that are connected to that hub. A hub to hub connection would typically involve both hubs having configuration for each other.

So, one possible partition for the original nine sites would be that Chicago and Greenwich would be spokes for the New York hub, Paris and Frankfurt would be spokes for the London hub, and Tokyo and Hong Kong would be spokes for the Shanghai hub:



Once a spoke has established a connection to its hub then initially IPsec traffic to another site transits via one or more hubs. For example, traffic from Chicago to Hong Kong would transit via the New York and Shanghai hubs. This transit traffic then triggers an attempt to create a more direct connection.

In FortiOS:

- Direct connections are only created between the two endpoints that want to exchange traffic (e.g. Chicago and Hong Kong); we do not create intermediate connections (say Chicago to Shanghai, or New York to Hong Kong) as a side-effect.
- Learning the peer subnets is done via a dynamic routing protocol running over the IPsec connections.
- Negotiation of the direct connections is done via IKE.
- Both PSK and certificate authentication is supported.

Example ADVPN configuration

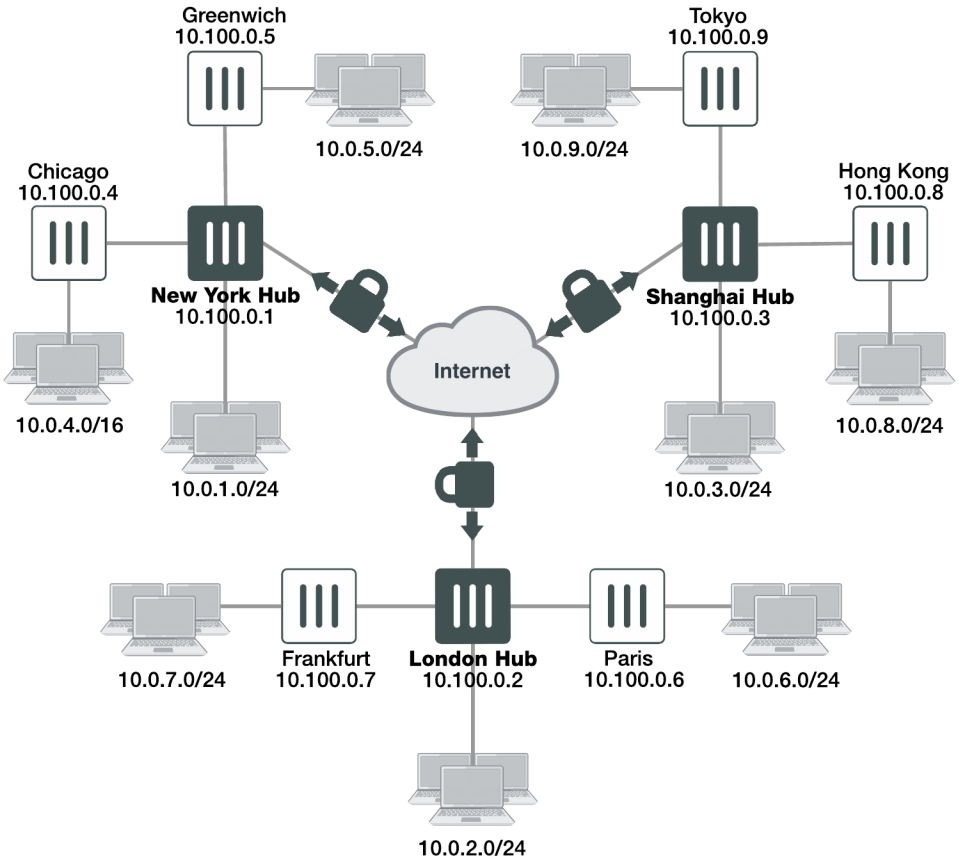
Since dynamic routing with IPsec under FortiOS requires that an interface have an IP address, then for every site a unique IP address from some unused range is allocated. For example we'll assume that 10.100.0.0/16 is unused and so assign the IP addresses:

- Chicago 10.100.0.4
- Greenwich 10.100.0.5
- New York 10.100.0.1
- London 10.100.0.2
- Shanghai 10.100.0.3
- Paris 10.100.0.6
- Frankfurt 10.100.0.7
- Hong Kong 10.100.0.8
- Tokyo 10.100.0.9

We'll assume that each site has one or more subnets that it protects that it wants to make available to the peers. For the purposes of exposition we'll assume there is only one subnet per site and they are allocated as:

- Chicago 10.0.4.0/16
- Greenwich 10.0.5.0/24
- New York 10.0.1.0/24
- London 10.0.2.0/24
- Shanghai 10.0.3.0/24
- Paris 10.0.6.0/24
- Frankfurt 10.0.7.0/24
- Hong Kong 10.0.8.0/24
- Tokyo 10.0.9.0/24

Our example network topology now looks like this:



The configuraton in Chicago would be as follows:

```
config vpn ipsec phase1-interface
   edit "New York"
      set type static
      set interface wan1
      set remote-gw <New-York-IP-address>
      set psk <New-York-PSK>
      set auto-discovery-receiver enable
   next
end
```

The attribute `auto-discovery-receiver` indicates that this IPsec tunnel wishes to participate in an auto-discovery VPN. The IPsec interface would then have its IP assigned according to the Chicago address:

```
config system interface
   edit "New York"
      set ip 10.100.0.4/32
      set remote-ip 10.100.0.1
   next
end
```

RIP (for simplicity, you could use OSPF or BGP) is then configured to run on the IPsec interface and on the Chicago subnet (you could use redistribute connected, but we'll allow for the fact that there may be other subnets learned from another router on the 10.0.4.0/24 subnet):

```
config router rip
```

```
    edit 1
      set prefix 10.100.0.0/16
    next
    edit 2
      set prefix 10.0.4.0/24
    next
end
```

Other than the firewall policy and a minimal phase 2 configuration, this concludes the configuration for Chicago.

Each spoke would have a similar configuration.

The New York hub would have a dynamic phase 1 for its spoke connections, and two static phase 1s for its connections to the other hubs:

```
config vpn ipsec phase1-interface
    edit "Spokes"
      set type dynamic
      set interface wan1
      set psk <New-York-PSK>
      set auto-discovery-sender enable
      set auto-discovery-psk enable
      set add-route disable
    next
    edit "London"
      set type static
      set interface wan1
      set psk <New-York-London-PSK>
      set auto-discovery-forwarder enable
    next
    edit "Shanghai"
      set type static
      set interface wan1
      set psk <New-York-Shanghai-PSK>
      set auto-discovery-forwarder enable
    next
end
```

The 'Spokes' connection has `set auto-discovery-sender enable` to indicate that when IPsec traffic transits the hub it should optionally generate a message to the initiator of the traffic to indicate that it could perhaps establish a more direct connection. The `set add-route disable` ensures that IKE does not automatically add a route back over the spoke and instead leaves routing to a separately configured routing protocol.

The two inter-hub connections have `set auto-discovery-forwarder enable` to indicate that these connections can participate in the auto-discovery process. The interface IP addresses are assigned:

```
config system interface
    edit "Spokes"
      set ip 10.100.0.1/32
      set remote-ip 10.100.0.254
    next
    edit "London"
      set ip 10.100.0.1/32
      set remote-ip 10.100.0.2
    next
    edit "London"
      set ip 10.100.0.1/32
```

```
      set remote-ip 10.100.0.3
   next
end
```

Following this, RIP is enabled on the relevant interfaces:

```
config router rip
   edit 1
      set prefix 10.100.0.0/16
   next
   edit 2
      set prefix 10.0.1.0/24
   next
end
```

A similar configuration would be used on the other two hubs.

Traffic flow and tunnel connection

With the configuration in place at all spokes and hubs, assuming all the spokes are connected to a hub, then Chicago would learn (via RIP) that the route to the Hong Kong subnet 10.0.8.0/24 is via its "New York" interface. If a device on the Chicago protected subnet (say 10.0.4.45) attempted to send traffic to the Hong Kong proected subnet (say 10.0.8.13) then it should flow over the New York interface to New York, which should then transmit it over the Shanghai tunnel to Shanghai, which should then send it over the dynamically negotiated Hong Kong tunnel to Hong Kong.

At the point when the traffic transits New York it should notice that the Chicago Spoke tunnel and the Shanghai tunnel have auto-discovery enabled, causing the New York hub to send a message via IKE to Chicago informing it that it may want to try and negotiate a direct connection for traffic from 10.0.4.45 to 10.0.8.13.

On receipt of this message, IKE on Chicago creates the (FortiOS-specific) IKE INFORMATIONAL SHORTCUT-QUERY message which contains the Chicago public IP address, the source IP of the traffic (10.0.4.45), the desired destination IP (10.0.8.13), and the PSK that should be used to secure any direct tunnel (if certificates are confgured, it is assumed that they all share the same CA and so no additional authentication information is required). This message is sent via IKE to New York since routing indicates that New York is the best route to 10.0.8.13.

On receipt of the IKE INFORMATIONAL query, New York checks its routing table to see who owns 10.0.8.13. It finds that 10.0.8.13 should be routed via Shanghai, and since Shanghai is marked as an auto-discovery-forwarder then the query is forwarded.

Shanghai repeats the process, finds that 10.0.8.13 should be routed via its Hong Kong Spoke and so sends it to Hong Kong. Hong Kong checks 10.0.8.13, finds that it owns the subnet, so it remembers the Chicago public IP address (and PSK) and creates an IKE INFORMATIONAL reply message containing its external IP address. To work out where to send the IKE message, the FortiGate does a routing lookup for the original source IP (10.0.4.45), determines that the message should be routed via its Shanghai tunnel and so sends the reply back to Shanghai. The reply then makes its way back to Chicago following the reverse of the path that it used to arrive at Hong Kong.

When the reply makes it back to the Chicago initator then it now knows the IP address of the Hong Kong device. Chicago now creates a new dynamic tunnel with the remote gateway as the Hong Kong public IP address and initiates an IKE negotiation (the dynamic tunnel nameis auto-generated from the tunnel over which it performed the query; in this case it would be called 'New York_0').

This negotiation should succeed since Hong Kong is set up to expect an attempted negotiation from the Chicago public IP address. Once the negotiation succeeds, RIP will start to run on the newly created tunnels at Chicago and Hong Kong. This will update the routing on Chicago (and Hong Kong) so that the prefered route to 10.0.8.0 (10.0.4.0) is via the newly created tunnel rather than via the connection to New York (Shanghai).

Notes about ADVPN in FortiOS

- Auto-discovery is only supported by IKEv1.
- All Spokes must have an IP address that is routable from any other spoke; devices behind NAT are not currently supported.
- The feature requires the use of a dynamic routing protocol. There is no support for IKE handling routing.
- RIP is not a very scalable routing protocol. When there are more than a few spokes it would be advisable to use route summarization to avoid huge RIP updates. Better yet, use BGP instead of RIP.
- It is assumed that spokes will not be used to transit other spoke traffic, for example: traffic from Chicago to Tokyo would not transit an existing Chicago to Hong Kong tunnel even though that has a shorter hop count than a route via New York and Shanghai.
- There is no facility to allow you to filter which traffic that transits the hub should trigger the message sent to the initiator suggesting it create a direct connection. Currently any and all traffic will trigger it.

Logging and monitoring

This section provides some general logging and monitoring procedures for VPNs.

The following topics are included in this section:

Monitoring VPN connections

You can use the monitor to view activity on IPsec VPN tunnels and to start or stop those tunnels. The display provides a list of addresses, proxy IDs, and timeout information for all active tunnels.

Monitoring connections to remote peers

The list of tunnels provides information about VPN connections to remote peers that have static IP addresses or domain names. You can use this list to view status and IP addressing information for each tunnel configuration. You can also start and stop individual tunnels from the list.

To view the list of static-IP and dynamic-DNS tunnels go to **Monitor > IPsec Monitor**.

Monitoring dialup IPsec connections

The list of dialup tunnels provides information about the status of tunnels that have been established for dialup clients. The list displays the IP addresses of dialup clients and the names of all active tunnels. The number of tunnels shown in the list can change as dialup clients connect and disconnect.

To view the list of dialup tunnels go to **Monitor > IPsec Monitor**.

If you take down an active tunnel while a dialup client such as FortiClient is still connected, FortiClient will continue to show the tunnel connected and idle. The dialup client must disconnect before another tunnel can be initiated.

The list of dialup tunnels displays the following statistics:

- The Name column displays the name of the tunnel.
- The meaning of the value in the Remote gateway column changes, depending on the configuration of the network at the far end:
  - When a FortiClient dialup client establishes a tunnel, the Remote gateway column displays either the public IP address and UDP port of the remote host device (on which the FortiClient Endpoint Security application is installed), or if a NAT device exists in front of the remote host, the Remote gateway column displays the public IP address and UDP port of the remote host.
  - When a FortiGate dialup client establishes a tunnel, the Remote gateway column displays the public IP address and UDP port of the FortiGate dialup client.
- The Username column displays the peer ID, certificate name, or XAuth user name of the dialup client (if a peer ID, certificate name, or XAuth user name was assigned to the dialup client for authentication purposes).
- The Timeout column displays the time before the next key exchange. The time is calculated by subtracting the time elapsed since the last key exchange from the keylife.
- The Proxy ID Source column displays the IP addresses of the hosts, servers, or private networks behind the FortiGate unit. A network range may be displayed if the source address in the security encryption policy was expressed as a range of IP addresses.

- The meaning of the value in the Proxy ID Destination column changes, depending on the configuration of the network at the far end:
  - When a FortiClient dialup client establishes a tunnel:
  - If VIP addresses are not used and the remote host connects to the Internet directly, the Proxy ID Destination field displays the public IP address of the Network Interface Card (NIC) in the remote host.
  - If VIP addresses are not used and the remote host is behind a NAT device, the Proxy ID Destination field displays the private IP address of the NIC in the remote host.
  - If VIP addresses were configured (manually or through FortiGate DHCP relay), the Proxy ID Destination field displays either the VIP address belonging to a FortiClient dialup client, or a subnet address from which VIP addresses were assigned.
- When a FortiGate dialup client establishes a tunnel, the Proxy ID Destination field displays the IP address of the remote private network.

VPN event logs

You can configure the FortiGate unit to log VPN events. For IPsec VPNs, Phase 1 and Phase 2 authentication and encryption events are logged. For information about how to interpret log messages, see the FortiGate Log Message Reference.

Logging VPN events

1. Go to **Log & Report > Log Settings**.
2. Verify that the **VPN activity event** option is selected.
3. Select **Apply**.

Viewing event logs

1. Go to **Log & Report > VPN Events**.
2. Select the **Log location**.

Sending tunnel statistics to FortiAnalyzer

By default, logged events include tunnel-up and tunnel-down status events. Other events, by default, will appear in the FortiAnalyzer report as "No Data Available". More accurate results require logs with `action=tunnel-stats`, which is used in generating reports on the FortiAnalyzer (rather than the tunnel-up and tunnel-down event logs). The FortiGate does not, by default, send `tunnel-stats` information.

To allow VPN `tunnel-stats` to be sent to FortiAnalyzer, configure the FortiGate unit as follows using the CLI:

```
config system settings
   set vpn-stats-log ipsec ssl
   set vpn-stats-period 300
end
```

Troubleshooting

This section contains tips to help you with some common challenges of IPsec VPNs.

A VPN connection has multiple stages that can be confirmed to ensure the connection is working properly. It is easiest to see if the final stage is successful first since if it is successful the other stages will be working properly. Otherwise, you will need to work back through the stages to see where the problem is located.

When a VPN connection is properly established, traffic will flow from one end to the other as if both ends were physically in the same place. If you can determine the connection is working properly then any problems are likely problems with your applications.

On some FortiGate units, such as the FortiGate 94D, you cannot ping over the IPsec tunnel without first setting a source-IP. In this scenario, you must assign an IP address to the virtual IPSEC VPN interface. Anything sourced from the FortiGate going over the VPN will use this IP address.

If the egress/outgoing interface (determined by kernel route) has an IP address, then use the IP address of the egress/outgoing interface. Otherwise, use the IP address of the first interface from the interface list (that has an IP address).

The first diagnostic command worth running, in any IPsec VPN troubleshooting situation, is the following:

```
diagnose vpn tunnel list
```

This command is very useful for gathering statistical data such as the number of packets encrypted versus decrypted, the number of bytes sent versus received, the SPI identifier, etc. This kind of information in the resulting output can make all the difference in determining the issue with the VPN.

Another appropriate diagnostic command worth trying is:

```
diagnose debug flow
```

This command will inform you of any lack of firewall policy, lack of forwarding route, and of policy ordering issues.

The following is a list of such potential issues. Bear in mind that the troubleshooting suggestions below are not exhaustive, and may not reflect your network topology.

The options to configure policy-based IPsec VPN are unavailable.

Go to **System > Feature Select**. Select **Show More** and turn on **Policy-based IPsec VPN**.

The VPN connection attempt fails.

If your VPN fails to connect, check the following:

- Ensure that the **pre-shared keys** match exactly (see The pre-shared key does not match (PSK mismatch error). below).
- Ensure that both ends use the same P1 and P2 proposal settings (seeThe SA proposals do not match (SA proposal mismatch). below).
- Ensure that you have allowed inbound and outbound traffic for all necessary network services, especially if services such as DNS or DHCP are having problems.
- Check that a static route has been configured properly to allow routing of VPN traffic.

- Ensure that your FortiGate unit is in NAT/Route mode, rather than Transparent.
- Check your NAT settings, enabling NAT traversal in the Phase 1 configuration while disabling NAT in the security policy. You might need to pin the PAT/NAT session table, or use some of kind of NAT-T keepalive to avoid the expiration of your PAT/NAT translation.
- Ensure that both ends of the VPN tunnel are using Main mode, unless multiple dial-up tunnels are being used.
- If you have multiple dial-up IPsec VPNs, ensure that the peer ID is configured properly on the FortiGate and that clients have specified the correct local ID. Furthermore, in circumstances where multiple remote dialup VPN tunnels exist, each tunnel must have a peer ID set.
- If you are using FortiClient, ensure that your version is compatible with the FortiGate firmware by reading the FortiOS Release Notes.
- If you are using Perfect Forward Secrecy (PFS), ensure that it is used on both peers. You can use the `diagnose vpn tunnel list` command to troubleshoot this.
- Ensure that the **Quick Mode selectors** are correctly configured. If part of the setup currently uses firewall addresses or address groups, try changing it to either specify the IP addresses or use an expanded address range. This is especially useful if the remote endpoint is not a FortiGate device.
- If XAUTH is enabled, ensure that the settings are the same for both ends, and that the FortiGate unit is set to **Enable as Server**.
- Check IPsec VPN Maximum Transmission Unit (MTU) size. A 1500 byte MTU is going to exceed the overhead of the ESP-header, including the additional ip_header,etc. You can use the `diagnose vpn tunnel list` command to troubleshoot this.
- If your FortiGate unit is behind a NAT device, such as a router, configure port forwarding for UDP ports 500 and 4500.
- Remove any Phase 1 or Phase 2 configurations that are not in use. If a duplicate instance of the VPN tunnel appears on the IPsec Monitor, reboot your FortiGate unit to try and clear the entry.

If you are still unable to connect to the VPN tunnel, run the following diagnostic command in the CLI:

```
diagnose debug application ike -1
diagnose debug enable
```

The resulting output may indicate where the problem is occurring. When you are finished, disable the diagnostics by using the following command:

```
diagnose debug reset
diagnose debug disable
```

The VPN tunnel goes down frequently.

If your VPN tunnel goes down often, check the Phase 2 settings and either increase the **Keylife** value or enable **Autokey Keep Alive**.

The pre-shared key does not match (PSK mismatch error).

It is possible to identify a PSK mismatch using the following combination of CLI commands:

```
diag vpn ike log filter name <phase1-name>
diag debug app ike -1
diag debug enable
```

This will provide you with clues as to any PSK or other proposal issues. If it is a PSK mismatch, you should see something similar to the following output:

```
ike 0:TRX:322: PSK auth failed: probable pre-shared key mismatch
ike Negotiate SA Error:
```

The SA proposals do not match (SA proposal mismatch).

The most common problem with IPsec VPN tunnels is a mismatch between the proposals offered between each party. Without a match and proposal agreement, Phase 1 can never establish. Use the following command to show the proposals presented by both parties.

```
diag debug app ike -1
diag debug enable
```

The resulting output should include something similar to the following, where blue represents the remote VPN device, and green represents the local FortiGate.

```
responder received SA_INIT msg
incoming proposal:
proposal id = 1:
   protocol = IKEv2:
      encapsulation = IKEv2/none
         type=ENCR, val=AES_CBC (key_len = 256)
         type=INTEGR, val=AUTH_HMAC_SHA_96
         type=PRF, val=PRF_HMAC_SHA
         type=DH_GROUP, val=1536.
proposal id = 2:
   protocol = IKEv2:
      encapsulation = IKEv2/none
         type=ENCR, val=3DES_CBC
         type=INTEGR, val=AUTH_HMAC_SHA_2_256_128
         type=PRF, val=PRF_HMAC_SHA2_256
         type=DH_GROUP, val=1536.
proposal id = 1:
   protocol = IKEv2:
      encapsulation = IKEv2/none
         type=ENCR, val=AES_CBC (key_len = 128)
         type=INTEGR, val=AUTH_HMAC_SHA_96
         type=PRF, val=PRF_HMAC_SHA
         type=DH_GROUP, val=1536.
```

Pre-existing IPsec VPN tunnels need to be cleared.

Should you need to clear an IKE gateway, use the following commands:

```
diagnose vpn ike restart
diagnose vpn ike gateway clear
```

LAN interface connection

To confirm whether a VPN connection over LAN interfaces has been configured correctly, issue a ping or traceroute command on the network behind the FortiGate unit to test the connection to a computer on the remote network. If the connection is properly configured, a VPN tunnel will be established automatically when the first data packet destined for the remote network is intercepted by the FortiGate unit.

If the ping or traceroute fail, it indicates a connection problem between the two ends of the tunnel. This may or may not indicate problems with the VPN tunnel. You can confirm this by going to **Monitor > IPsec Monitor**

where you will be able to see your connection. A green arrow means the tunnel is up and currently processing traffic. A red arrow means the tunnel is not processing traffic, and this VPN connection has a problem.

If the connection has problems, see Troubleshooting VPN connections on page 2133.

Dialup connection

A dialup VPN connection has additional steps. To confirm that a VPN between a local network and a dialup client has been configured correctly, at the dialup client, issue a ping command to test the connection to the local network. The VPN tunnel initializes when the dialup client attempts to connect.

If the ping or traceroute fail, it indicates a connection problem between the two ends of the tunnel. This may or may not indicate problems with the VPN tunnel, or dialup client. As with the LAN connection, confirm the VPN tunnel is established by checking **Monitor > IPsec Monitor**.

Troubleshooting VPN connections

If you have determined that your VPN connection is not working properly through Troubleshooting on page 2130, the next step is to verify that you have a phase2 connection.

If traffic is not passing through the FortiGate unit as you expect, ensure the traffic does not contain IPcomp packets (IP protocol 108, RFC 3173). FortiGate units do not allow IPcomp packets, they compress packet payload, preventing it from being scanned.

Testing Phase 1 and 2 connections is a bit more difficult than testing the working VPN. This is because they require diagnose CLI commands. These commands are typically used by Fortinet customer support to discover more information about your FortiGate unit and its current configuration.

Before you begin troubleshooting, you must:

- Configure FortiGate units on both ends for interface VPN
- Record the information in your VPN Phase 1 and Phase 2 configurations - for our example here the remote IP address is 10.11.101.10 and the names of the phases are Phase 1 and Phase 2
- Install a telnet or SSH client such as putty that allows logging of output
- Ensure that the admin interface supports your chosen connection protocol so you can connect to your FortiGate unit admin interface.

For this example, default values were used unless stated otherwise.

Obtaining diagnose information for the VPN connection - CLI

1. Log into the CLI as admin with the output being logged to a file.
2. Stop any diagnose debug sessions that are currently running with the CLI command
   ```
   diagnose debug disable
   ```
3. Clear any existing log-filters by running
   ```
   diagnose vpn ike log-filter clear
   ```
4. Set the log-filter to the IP address of the remote computer (10.11.101.10). This filters out all VPN connections except ones to the IP address we are concerned with. The command is
   ```
   diagnose vpn ike log-filter dst-addr4 10.11.101.10.
   ```
5. Set up the commands to output the VPN handshaking. The commands are:
   ```
   diagnose debug app ike 255
   ```

```
diagnose debug enable
```

6. Have the remote FortiGate initiate the VPN connection in the web-based manager by going to **VPN > IPsec Tunnels** and selecting **Bring up**.

   This makes the remote FortiGate the initiator and the local FortiGate becomes the responder. Establishing the connection in this manner means the local FortiGate will have its configuration information as well as the information the remote computer sends. Having both sets of information locally makes it easier to troubleshoot your VPN connection.
7. Watch the screen for output, and after roughly 15 seconds enter the following CLI command to stop the output.
   ```
   diagnose debug disable
   ```
8. If needed, save the log file of this output to a file on your local computer. Saving the output to a file can make it easier to search for a particular phrase, and is useful for comparisons.

Troubleshooting a Phase 1 VPN connection

Using the output from Obtaining diagnose information for the VPN connection - CLI on page 2133, search for the word `proposal` in the output. It may occur once indicating a successful connection, or it will occur two or more times for an unsuccessful connection — there will be one proposal listed for each end of the tunnel and each possible combination in their settings. For example if 10.11.101.10 selected both Diffie-Hellman Groups 1 and 5, that would be at least 2 proposals set.

A successful negotiation proposal will look similar to

```
IPsec SA connect 26 10.12.101.10->10.11.101.10:500
config found
created connection: 0x2f55860 26 10.12.101.10->10.11.101.10:500
IPsec SA connect 26 10.12.101.10->10.11.101.10:500 negotiating
no suitable ISAKMP SA, queuing quick-mode request and initiating ISAKMP SA negotiation
initiator: main mode is sending 1st message...
cookie 3db6afe559e3df0f/0000000000000000
out [encryption]
sent IKE msg (ident-i1send): 10.12.101.10:500->10.11.101.10:500, len=264,
    id=3db6afe559e3df0f/0000000000000000
diaike 0: comes 10.12.101.1:500->10.11.101.1:500,ifindex=26....
```

Note the phrase "`initiator: main mode is sending 1st message...`" which shows you the handshake between the ends of the tunnel is in progress. Initiator shows the remote unit is sending the first message.

Troubleshooting invalid ESP packets using Wireshark

The following section provides information to help debug an encryption key mismatch. The ESP packet invalid error is due to an encryption key mismatch after a VPN tunnel has been established. When an IPsec VPN tunnel is up, but traffic is not able to pass through the tunnel, Wireshark (or an equivalent program) can be used to determine whether there is an encryption mismatch. A mismatch could occur for many reasons, one of the most common is the instability of an ISP link (ADSL, Cable), or it could effectively be any device in the physical connection.

The following information is required to troubleshoot the problem.

- Take a packet sniffer trace on both FortiGates.
- Run the `diag vpn tunnel list` command a few times on both FortiGates when generating traffic that will pass through the tunnel.

In the following example, the error message was seen on the recipient FortiGate:

```
date=2010-12-28 time=18:19:35 devname=Kosad_VPN device_id=FG300B3910600118 log_
id=0101037132 type=event subtype=ipsec pri=critical vd="root" msg="IPsec ESP" action="error" rem_
ip=180.87.33.2 loc_ip=121.133.8.18 rem_port=32528 loc_port=4500 out_intf="port2"
cookies="88d40f65d555ccaf/05464e20e4afc835" user="N/A" group="N/A" xauth_user="N/A" xauth_
group="N/A" vpn_tunnel="fortinet_0" status=esp_error error_num=Invalid ESP packet detected (HMAC
validation failed). spi=c32b09f7 seq=00000012
```

This is the output of the command `diag vpn tunnel list` on the FortiGate:

```
inet ver=1 serial=2 192.168.1.205:4500->121.133.8.18:4500 lgwy=dyn tun=intf mode=auto bound_if=4

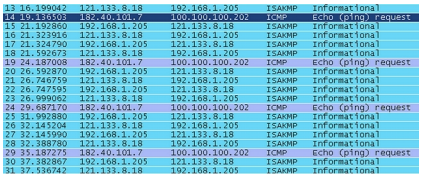
53	62.688010	192.168.1.205	121.133.8.18	ESP	ESP (SPI=0xc32b09f7)
54	64.542991	192.168.1.205	121.133.8.18	ISAKMP	Informational
55	64.797878	121.133.8.18	192.168.1.205	ISAKMP	Informational
56	64.798749	192.168.1.205	121.133.8.18	ISAKMP	Informational
57	64.957283	121.133.8.18	192.168.1.205	ISAKMP	Informational

How to verify if the original packet has been encrypted correctly

To verify, it is necessary to decrypt the ESP packet using Wireshark. Open the packet capture that is taken from initiator FortiGate using Wireshark. Go to **Edit > Preferences**, expand **Protocol** and look for **ESP**. Select "**Attempt to detect/decode encrypted ESP payloads**", and fill in the information for the encryption algorithm and the keys. This information can be obtained from the output of the command `diag vpn tunnel list`.

If the packet was encrypted correctly using the correct key, then the decryption will be successful and it will be possible to see the original package as shown below:



13	16.199042	121.133.8.18	192.168.1.205	ISAKMP	Informational
14	19.183593	192.168.1.205	100.100.100.202	ICMP	Echo (ping) request
15	21.192860	192.168.1.205	121.133.8.18	ISAKMP	Informational
16	21.323916	121.133.8.18	192.168.1.205	ISAKMP	Informational
17	21.324790	192.168.1.205	121.133.8.18	ISAKMP	Informational
18	21.592673	121.133.8.18	192.168.1.205	ISAKMP	Informational
19	24.187008	182.40.101.7	100.100.100.202	ICMP	Echo (ping) request
20	26.592870	192.168.1.205	121.133.8.18	ISAKMP	Informational
21	26.746759	121.133.8.18	192.168.1.205	ISAKMP	Informational
22	26.747595	192.168.1.205	121.133.8.18	ISAKMP	Informational
23	26.999062	121.133.8.18	192.168.1.205	ISAKMP	Informational
24	29.687170	182.40.101.7	100.100.100.202	ICMP	Echo (ping) request
25	31.992880	192.168.1.205	121.133.8.18	ISAKMP	Informational
26	32.145204	121.133.8.18	192.168.1.205	ISAKMP	Informational
27	32.145990	192.168.1.205	121.133.8.18	ISAKMP	Informational
28	32.388780	121.133.8.18	192.168.1.205	ISAKMP	Informational
29	35.187275	182.40.101.7	100.100.100.202	ICMP	Echo (ping) request
30	37.382867	192.168.1.205	121.133.8.18	ISAKMP	Informational
31	37.536742	121.133.8.18	192.168.1.205	ISAKMP	Informational

Repeat the decryption process for the packet capture from the recipient firewall. If the decryption failed using the same key, the packet may be corrupted and the interface should then be checked for CRC or packet errors

VPN troubleshooting tips

More in-depth VPN troubleshooting can be found in the Troubleshooting guide.

Attempting hardware offloading beyond SHA1

If you are trying to off-load VPN processing to a network processing unit (NPU), remember that only SHA1 authentication is supported. For high levels of authentication such as SHA256, SHA384, and SHA512 hardware offloading is not an option — all VPN processing must be done in software.

Enable/disable IPsec ASIC-offloading

Much like NPU-offload in IKE phase1 configuration, you can enable or disable the usage of ASIC hardware for IPsec Diffie-Hellman key exchange and IPsec ESP traffic. By default hardware offloading is used. For debugging purposes, sometimes it is best for all the traffic to be processed by software.

```
config sys global
   set ipsec-asic-offload [enable | disable]
end
```

Check Phase 1 proposal settings

Ensure that both sides have at least one Phase 1 proposal in common. Otherwise they will not connect. If there are many proposals in the list, this will slow down the negotiating of Phase 1. If its too slow, the connection may timeout before completing. If this happens, try removing some of the unused proposals.

NPU offloading is supported when the local gateway is a loopback interface.

Check your routing

If routing is not properly configured with an entry for the remote end of the VPN tunnel, traffic will not flow properly. You may need static routes on both ends of the tunnel. If routing is the problem, the proposal will likely setup properly but no traffic will flow.

Try enabling XAuth

If one end of an attempted VPN tunnel is using XAuth and the other end is not, the connection attempt will fail. The log messages for the attempted connection will not mention XAuth is the reason, but when connections are failing it is a good idea to ensure both ends have the same XAuth settings. If you do not know the other end's settings enable or disable XAuth on your end to see if that is the problem.

General troubleshooting tips

Most connection failures are due to a configuration mismatch between the FortiGate unit and the remote peer. In general, begin troubleshooting an IPsec VPN connection failure as follows:

1. Ping the remote network or client to verify whether the connection is up. See General troubleshooting tips on page 2136.
2. Traceroute the remote network or client. If DNS is working, you can use domain names. Otherwise use IP addresses.

3. Check the routing behind the dialup client. Routing problems may be affecting DHCP. If this appears to be the case, configure a DHCP relay service to enable DHCP requests to be relayed to a DHCP server on or behind the FortiGate server.
4. Verify the configuration of the FortiGate unit and the remote peer. Check the following IPsec parameters:
   - The mode setting for ID protection (main or aggressive) on both VPN peers must be identical.
   - The authentication method (preshared keys or certificates) used by the client must be supported on the FortiGate unit and configured properly.
   - If preshared keys are being used for authentication purposes, both VPN peers must have identical preshared keys.
   - The remote client must have at least one set of Phase 1 encryption, authentication, and Diffie-Hellman settings that match corresponding settings on the FortiGate unit.
   - Both VPN peers must have the same NAT traversal setting (enabled or disabled).
   - The remote client must have at least one set of Phase 2 encryption and authentication algorithm settings that match the corresponding settings on the FortiGate unit.
   - If you are using manual keys to establish a tunnel, the **Remote SPI** setting on the FortiGate unit must be identical to the **Local SPI** setting on the remote peer, and vise versa.
5. To correct the problem, see the following table.

VPN troubleshooting tips

Configuration problem	Correction
Mode settings do not match.	Select complementary mode settings. See Phase 1 parameters on page 1967.
Peer ID or certificate name of the remote peer or dialup client is not recognized by FortiGate VPN server.	Check Phase 1 configuration. Depending on the Remote Gateway and Authentication Method settings, you have a choice of options to authenticate FortiGate dialup clients or VPN peers by ID or certificate name (see Phase 1 parameters on page 1967). If you are configuring authentication parameters for FortiClient dialup clients, refer to the Authenticating FortiClient Dialup Clients Technical Note.
Preshared keys do not match.	Reenter the preshared key. See Phase 1 parameters on page 1967.
Phase 1 or Phase 2 key exchange proposals are mismatched.	Make sure that both VPN peers have at least one set of proposals in common for each phase. See Phase 1 parameters on page 1967 and Phase 2 parameters on page 1985.
NAT traversal settings are mismatched.	Select or clear both options as required. See Phase 1 parameters on page 1967 and Phase 1 parameters on page 1967.

A word about NAT devices

When a device with NAT capabilities is located between two VPN peers or a VPN peer and a dialup client, that device must be NAT traversal (NAT-T) compatible for encrypted traffic to pass through the NAT device. For more information, see Phase 1 parameters on page 1967.

Troubleshooting L2TP and IPsec

This section describes some checks and tools you can use to resolve issues with L2TP-over-IPsec VPNs.

This section includes:

- Quick checks
- Mac OS X and L2TP
- Setting up logging
- Using the FortiGate unit debug commands

Quick checks

The table below is a list of common L2TP over IPsec VPN problems and the possible solutions.

Problem	What to check
IPsec tunnel does not come up.	Check the logs to determine whether the failure is in Phase 1 or Phase 2. Check the settings, including encapsulation setting, which must be transport-mode. Check the user password. Confirm that the user is a member of the user group assigned to L2TP. On the Windows PC, check that the IPsec service is running and has not been disabled. See Troubleshooting L2TP and IPsec on page 2138.
Tunnel connects, but there is no communication.	Did you create an ACCEPT security policy from the public network to the protected network for the L2TP clients? See Troubleshooting L2TP and IPsec on page 2138.

Mac OS X and L2TP

FortiOS allows L2TP connections with empty AVP host names and therefore Mac OS X L2TP connections can connect to the FortiGate.

Prior to FortiOS 4.0 MR3, FortiOS refused L2TP connections with empty AVP host names in compliance with RFC 2661 and RFC 3931.

Setting up logging

L2TP logging must be enabled to record L2TP events. Alert email can be configured to report L2TP errors.

Configuring FortiGate logging for L2TP over IPsec

1. Go to **Log & Report > Log Settings**.
2. Select **Event Log**.
3. Select the **VPN activity event** check box.
4. Select **Apply**.

Viewing FortiGate logs

1. Go to **Log & Report > VPN Events**.
2. Select the **Log location** if required.
3. After each attempt to start the L2TP over IPsec VPN, select **Refresh** to view logged events.

Using the FortiGate unit debug commands

Viewing debug output for IKE and L2TP

1. Start an SSH or Telnet session to your FortiGate unit.
2. Enter the following CLI commands

```
diagnose debug application ike -1
diagnose debug application l2tp -1
diagnose debug enable
```

3. Attempt to use the VPN and note the debug output in the SSH or Telnet session.
4. Enter the following command to reset debug settings to default:

```
diagnose debug reset
```

Using the packet sniffer

1. Start an SSH or Telnet session to your FortiGate unit.
2. Enter the following CLI command

```
diagnose sniffer packet any icmp 4
```

3. Attempt to use the VPN and note the debug output.
4. Enter `Ctrl-C` to end sniffer operation.

Typical L2TP over IPsec session startup log entries - raw format

```

Troubleshooting GRE over IPsec

This section describes some checks and tools you can use to resolve issues with the GRE-over-IPsec VPN.

Quick checks

Here is a list of common problems and what to verify.

Problem	What to check
No communication with remote network.	Use the `execute ping` command to ping the Cisco device public interface. Use the FortiGate VPN Monitor page to see whether the IPsec tunnel is up or can be brought up.

Problem	What to check
IPsec tunnel does not come up.	Check the logs to determine whether the failure is in Phase 1 or Phase 2. Check that the encryption and authentication settings match those on the Cisco device. Check the encapsulation setting: tunnel-mode or transport-mode. Both devices must use the same mode.
Tunnel connects, but there is no communication.	Check the security policies. See Troubleshooting GRE over IPsec on page 2140. Check routing. See Troubleshooting GRE over IPsec on page 2140.

Setting up logging

Configuring FortiGate logging for IPsec

1. Go to **Log & Report > Log Settings**.
2. Select the **Event Logging**.
3. Select **VPN activity event**.
4. Select **Apply**.

Viewing FortiGate logs

1. Go to **Log & Report > VPN Events**.
2. Select the log storage type.
3. Select **Refresh** to view any logged events.

GRE tunnel keepalives

In the event that each GRE tunnel endpoint has keepalive enabled, firewall policies allowing GRE are required in both directions. The policy should be configured as follows (where the IP addresses and interface names are for example purposes only):

```
config firewall policy
   edit < id >
      set srcintf "gre"
      set dstintf "port1"
      set srcaddr "1.1.1.1"
      set dstaddr "2.2.2.2"
      set action accept
      set schedule "always"
      set service "GRE"
   next
end
```

Cisco compatible keep-alive support for GRE

The FortiGate can send a GRE keepalive response to a Cisco device to detect a GRE tunnel. If it fails, it will remove any routes over the GRE interface.

Configuring keepalive query - CLI:

```
config system gre-tunnel
   edit <id>
      set keepalive-interval <value: 0-32767>
      set keepalive-failtimes <value: 1-255>
   next
end
```

GRE tunnel with multicast traffic

If you want multicast traffic to traverse the GRE tunnel, you need to configure a multicast policy as well as enable multicast forwarding.

- To configure a multicast policy, use the `config firewall multicast-policy` command.
- To enable multicast forwarding, use the following commands:

```
config system settings
   set multicast-forward enable
end
```

Using diagnostic commands

There are some diagnostic commands that can provide useful information. When using diagnostic commands, it is best practice that you connect to the CLI using a terminal program, such as puTTY, that allows you to save output to a file. This will allow you to review the data later on at your own speed without worry about missed data as the diag output scrolls by.

Using the packet sniffer - CLI:

1. Enter the following CLI command:
   ```
   diag sniff packet any icmp 4
   ```
2. Ping an address on the network behind the FortiGate unit from the network behind the Cisco router.

   The output will show packets coming in from the GRE interface going out of the interface that connects to the protected network (LAN) and vice versa. For example:
   ```
   114.124303 gre1 in 10.0.1.2 -> 10.11.101.10: icmp: echo request
   114.124367 port2 out 10.0.1.2 -> 10.11.101.10: icmp: echo request
   114.124466 port2 in 10.11.101.10 -> 10.0.1.2: icmp: echo reply
   114.124476 gre1 out 10.11.101.10 -> 10.0.1.2: icmp: echo reply
   ```
3. Enter `CTRL-C` to stop the sniffer.

Viewing debug output for IKE - CLI:

1. Enter the following CLI commands
   ```
   diagnose debug application ike -1
   diagnose debug enable
   ```
2. Attempt to use the VPN or set up the VPN tunnel and note the debug output.
3. Enter CTRL-C to stop the debug output.
4. Enter the following command to reset debug settings to default:
   ```
   diagnose debug reset
   ```

Chapter 18 - IPv6

The origins of Internet Protocol Version 6 (IPv6) date back to December 1998 with the publication of RFC 2460, which describes IPv6 as the successor to IPv4, the standard communications protocol still in use by the majority of users today. This transition away from IPv4 was a direct response to the foreseeable exhaustion of 32-bit IPv4 addresses, which are virtually all but assigned—all 4.3 billion.

IPv4 uses 32-bit addresses, which means that there is a theoretical address limit of 2 to the power of 32. The IPv6 address scheme is based on a 128-bit address, resulting in a theoretical address limit of 2 to the power of 128.

Possible addresses:

IPv4 = Roughly 4.3 billion

IPv6 = Over 340 undecillion (340 followed by 36 digits)

Assuming a world population of approximately 8 billion people, IPv6 would allow for each individual to have approximately 42,535,295,865,117,200,000,
000,000,000 devices with an IP address. That's 42 quintillion devices, so it's unlikely that we will ever need to worry about the availability of IPv6 addresses.

Aside from the difference of possible addresses, there is also the different formatting of the addresses. A computer would view an IPv4 address as a 32-bit string of binary digits made up of 1s and 0s, broken up into 4 octets of 8 digits separated by a period:

```
10101100.00010000.11111110.00000001
```

To make the number more user-friendly, we translate the address into decimal, again 4 octets separated by a period:

```
172.16.254.1
```

A computer would view an IPv6 address as a 128-bit string of binary digits made up of 1s and 0s, broken up into 8 octets of 16 digits separated by a colon:

```
0010000000000001:0000110110111:0000000000000000:0000000000010:0000000000000000:0000000000000000:0000000000000000:0000000000100000
```

To make this number a little more user-friendly, we translate it into hexadecimal, again 8 octets separated by a colon, for example:

```
2001:0db8:0000:0002:0000:0000:0000:0020
```

We can further simplify the above address. Because any four-digit group of zeros within an IPv6 address may be reduced to a single zero or altogether omitted, the above address can be reduced to:

```
2001:0db8:0000:0002:0:0:0:20
```

or

```
2001:db8:0:2::20
```

IPv6 packet structure

Each IPv6 packet consists of a mandatory fixed header and optional extension headers, and carries a payload, which is typically either a datagram and/or Transport Layer information. The payload could also contain data for the Internet Layer or Link Layer. Unlike IPv4, IPv6 packets aren't fragmented by routers, requiring hosts to implement Maximum Transmission Unit (MTU) Path Discovery for MTUs larger than the smallest MTU (which is 1280 octets).

Jumbograms and jumbo payloads

In IPv6, packets which exceed the MTU of the underlying network are labelled jumbograms, which consist of a jumbo payload. A jumbogram typically exceeds the IP MTU size limit of 65,535 octets, and provides the jumbo payload option, which can allow up to nearly 4GiB of payload data, as defined in RFC 2675. When the MTU is determined to be too large, the receiving host sends a 'Packet too Big' ICMPv6 type 2 message to the sender.

Fragmentation and reassembly

As noted, packets that are too large for the MTU require hosts to perform MTU Path Discovery to determine the maximum size of packets to send. Packets that are too large require a 'Fragment' extension header, to divide the payload into segments that are 8 octets in length (except for the last fragment, which is smaller). Packets are reassembled according to the extension header and the fragment offset.

Benefits of IPv6

Some of the benefits of IPv6 include:

- More efficient routing
- Reduced management requirement
- Stateless auto-reconfiguration of hosts
- Improved methods to change Internet Service Providers
- Better mobility support
- Multi-homing
- Security
- Scoped address: link-local, site-local, and global address space

What's new for IPv6 in FortiOS 5.4

New features in 5.4.0

DHCPv6 server is configurable in delegated mode (295007)

Downstream IPv6 interfaces can receive address assignments on delegated subnets from a DHCP server that serves an upstream interface.

DHCPv6-PD configuration

Enable DHCPv6 Prefix Delegation on upstream interface (port10):

```
config system interface
   edit "port10"
     config ipv6
       set dhcp6-prefix-delegation enable
     end
end
```

Assign delegated prefix on downstream interface (port1). Optionally, specific delegated prefixes can be specified:

```
config system interface
   edit "port1"
     config ipv6
       set ip6-mode delegated
       set ip6-upstream-interface "port10"
       set ip6-subnet ::1:0:0:0:1/64
       set ip6-send-adv enable
       config ipv6-delegated-prefix-list
         edit 1
           set upstream-interface "port10"
           set autonomous-flag enable
           set onlink-flag enable
           set subnet 0:0:0:100::/64
         end
     end
   end
```

DHCPv6 Server configuration

Configuring a server that uses delegated prefix and DNS from upstream:

```
config system dhcp6 server
   edit 1
     set dns-service delegated
     set interface "wan2"
     set upstream-interface "wan1"
     set ip-mode delegated
     set subnet 0:0:0:102::/64
   end
```

FortiGate can connect to FortiAnalyzer using IPv6 addresses (245620)

When configuring your FortiGate to send logs to a FortiAnalyzer you can specify an IPv4 or an IPv6 address.

IPv6 neighbor discovery limits changes(248076)

You can use the following command to configure the maximum number of IPv6 neighbors that can be discovered by the IPv6 Neighbor Discovery Protocol (NDP) and added to the IPv6 neighbor database.

```
config system global
   set ndp-max-entry <integer>
end
```

The number of entries can be in the range 65,536 to 2,147,483,647. The default value of 0 means 65,536 entries.

Support IPv6 blackhole routing (220101)

Similar to IPv4 blackhole routing, IPv6 blackhole routing is now supported. Use the following command to enable IPv6 blackhole routing:

```
config router static6
   edit 1
      set blackhole enable/disable
   next
end
```

TFTP session helper for IPv6 (263127)

TFTP is supported over nat66 and nat46.

FTP, PPTP and RTSP session helper enhancements for IPv6 (244986)

The FTP, PPTP and RTSP session helpers support NAT-64 customer-side translator (CLAT) sessions.

Central Management ratings and update servers can use IPv6 addresses (297144)

You can configure servers for Central Management using either IPv4 or IPv6 addresses. The `addr-type` field sets the address type. The address is entered in the `server-address` or `server-address6` field as appropriate.

```
config system central-management
   set type fortimanager
   set fmg "2000:172:16:200::207"
   set vdom "vdom1"
   config server-list
      edit 1
         set server-type rating update
         set addr-type ipv6
         set server-address6 2000:172:16:200::207
      end
   end
```

Allow asymmetric routing for ICMP (258734)

Where network topology requires asymmetric routing for ICMP traffic, you can configure the FortiGate to permit the asymmetric ICMP traffic. This is done in the CLI. There are separate fields for IPv4 and IPv6 versions of ICMP.

```
config system settings
   set asymroute-icmp enable
   set asymroute-icmp6 enable
end
```

IPv6 Features

In order to configure IPv6 features using the web-based manager, IPv6 must be enabled using Feature Select. Go to **System > Config > Features**, enable IPv6, and click **Apply**.

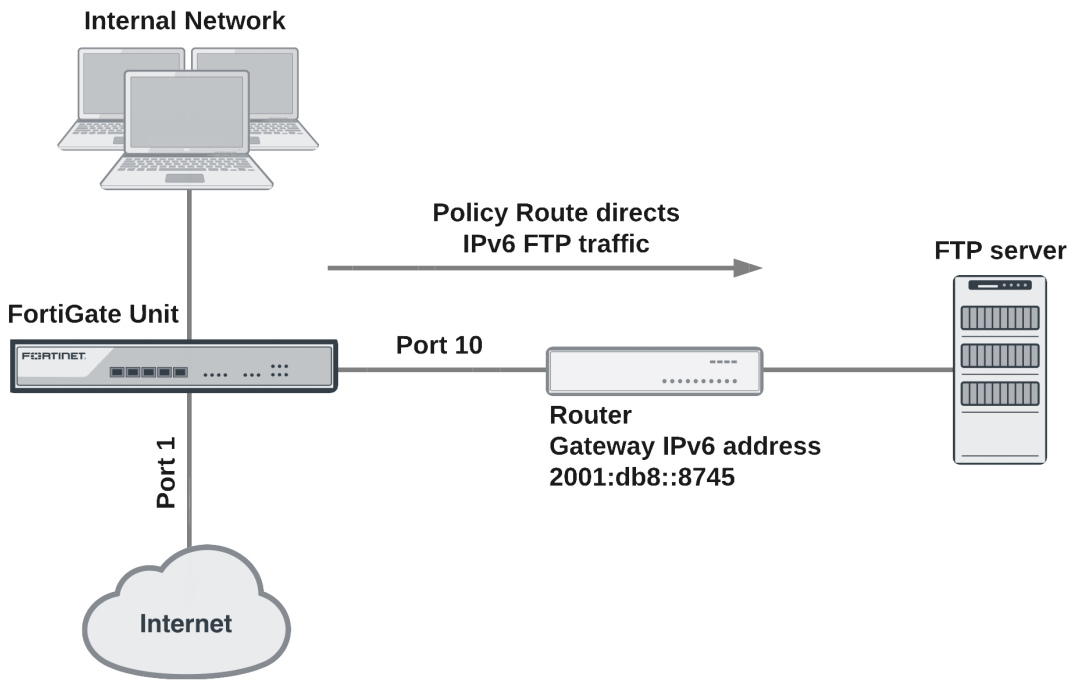
The following IPv6 features are available from the FortiOS web manager:

IPv6 policies

IPv6 security policies are created both for an IPv6 network and a transitional network. A transitional network is a network that is transitioning over to IPv6 but must still have access to the Internet or must connect over an IPv4 network.

These policies allow for this specific type of traffic to travel between the IPv6 and IPv4 networks. The IPv6 options for creating these policies is hidden by default. You must enable this feature under **System > Config > Features**.

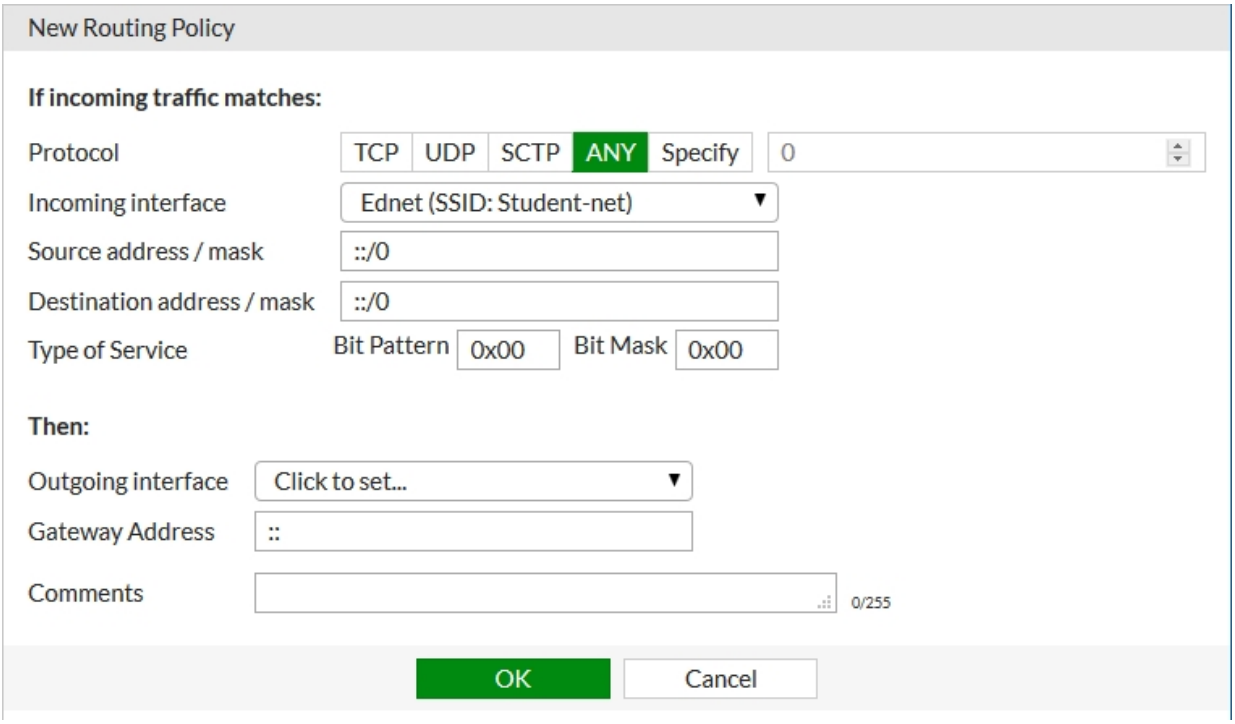
IPv6 policy route



IPv6 policy routing

IPv6 policy routing functions in the same was as IPv4 policy routing. To add an IPv6 policy route, go to **Network > Policy Routes** and select **Create New > IPv6 Policy Route**.

Adding an IPv6 Policy route



You can also use the following command to add IPv6 policy routes:

```
config router policy6
   edit 0
      set input-device <interface>
      set src <ipv6_ip>
      set dst <ipv6_ip>
      set protocol <0-255>
      set gateway <ipv6_ip>
      set output-device <interface>
      set tos <bit_pattern>
      set tos-mask <bit_mask>
   end
```

IPv6 security policies

IPv6 security policies support all the features supported by IPv4 security policies:

- Policy types and subtypes.
- NAT support including using the destination interface IP address, fixed port, and dynamic IP pools.
- All security features (antivirus, web filtering, application control, IPS, email filtering, DLP, VoIP, and ICAP).
- All traffic shaping options, including: shared traffic shaping, reverse shared traffic shaping, and per-IP traffic shaping.
- All user and device authentication options.

IPv6 explicit web proxy

You can use the explicit web proxy for IPv6 traffic. To do this you need to:

- Enable the IPv6 explicit web proxy from the CLI.
- Enable the explicit web proxy for one or more FortiGate interfaces. These interfaces also need IPv6 addresses.
- Add IPv6 web proxy security policies to allow the explicit web proxy to accept IPv6 traffic.

Use the following steps to set up a FortiGate unit to accept IPv6 traffic for the explicit web proxy at the Internal interface and forward IPv6 explicit proxy traffic out the wan1 interface to the Internet.

1. Enter the following CLI command to enable the IPv6 explicit web proxy:

```
config web-proxy explicit
   set status enable
   set ipv6-status enable
end
```

2. Go to **Network > Interfaces** and edit the **internal** interface, select **Enable Explicit Web Proxy** and select **OK**.
3. Go to **Policy & Objects > Explicit Proxy Policy** and select **Create New** to add an IPv6 explicit web proxy security policy with the following settings shown.

   This IPv6 explicit web proxy policy allows traffic from all IPv6 IP addresses to connect through the explicit web proxy and through the wan1 interface to any IPv6 addresses that are accessible from the wan1 interface.

If you have enabled both the IPv4 and the IPv6 explicit web proxy, you can combine IPv4 and IPv6 addresses in a single explicit web proxy policy to allow both IPv4 and IPv6 traffic through the proxy.

Example IPv6 Explicit Web Proxy security policy

Restricting the IP address of the explicit IPv6 web proxy

You can use the following command to restrict access to the IPv6 explicit web proxy using only one IPv6 address. The IPv6 address that you specify must be the IPv6 address of an interface that the explicit HTTP proxy is enabled on. You might want to use this option if the explicit web proxy is enabled on an interface with multiple IPv6 addresses.

For example, to require users to connect to the IPv6 address 2001:db8:0:2::30 to connect to the explicit IPv6 HTTP proxy, use the following command:

```
config web-proxy explicit
   set incoming-ipv6 2001:db8:0:2::30
```

```
end
```

Restricting the outgoing source IP address of the IPv6 explicit web proxy

You can use the following command to restrict the source address of outgoing web proxy packets to a single IPv6 address. The IP address that you specify must be the IPv6 address of an interface that the explicit HTTP proxy is enabled on. You might want to use this option if the explicit HTTP proxy is enabled on an interface with multiple IPv6 addresses.

For example, to restrict the outgoing packet source address to 2001:db8:0:2::50:

```
config http-proxy explicit
   set outgoing-ip6 2001:db8:0:2::50
end
```

VIP64

VIP64 policies can be used to configure static NAT virtual IPv6 address for IPv4 addresses. VIP64 can be configured from the CLI using the following commands:

```
config firewall vip64
   edit <zname_str>
      set arp-reply {enable | disable}
      set color <color_int>
      set comment <comment_str>
      set extip <address_ipv6>[-address_ipv6]
      set extport <port_int>
      set id <id_num_str>
      set mappedip [<start_ipv4>-<end_ipv4>]
      set mappedport <port_int>
      set portforward {enable | disable}
      set src-filter <addr_str>
   end
```

VIP64 CLI Variables and Defaults

Variable	Description	Default
`<zname_str>`	Enter the name of this virtual IP address.	No default.
`arp-reply {enable | disable}`	Select to respond to ARP requests for this virtual IP address.	enable
`color <color_int>`	Enter the number of the color to use for the group icon in the web-based manager.	0
`comment <comment_str>`	Enter comments relevant to the configured virtual IP.	No default.

Variable	Description	Default
`extip <address_ipv6>[-address_ipv6]`	Enter the IP address or address range on the external interface that you want to map to an address or address range on the destination network. If `mappedip` is an IP address range, the FortiGate unit uses `extip` as the first IP address in the external IP address range, and calculates the last IP address required to create an equal number of external and mapped IP addresses for one-to-one mapping. To configure a dynamic virtual IP that accepts connections destined for any IP address, set `extip` to ::.	::
`extport <port_int>`	Enter the external port number that you want to map to a port number on the destination network. This option only appears if `portforward` is enabled. If `portforward` is enabled and you want to configure a static NAT virtual IP that maps a range of external port numbers to a range of destination port numbers, set `extport` to the first port number in the range. Then set `mappedport` to the start and end of the destination port range. The FortiGate unit automatically calculates the end of the `extport` port number range.	0
`id <id_num_str>`	Enter a unique identification number for the configured virtual IP. Not checked for uniqueness. Range 0 - 65535.	No default.

Variable	Description	Default
mappedip [<start_ipv4>-<end_ipv4>]	Enter the IP address or IP address range on the destination network to which the external IP address is mapped. If mappedip is an IP address range, the FortiGate unit uses extip as the first IP address in the external IP address range, and calculates the last IP address required to create an equal number of external and mapped IP addresses for one-to-one mapping. If mappedip is an IP address range, the FortiGate unit uses extip as a single IP address to create a one-to-many mapping.	0.0.0.0
mappedport <port_int>	Enter the port number on the destination network to which the external port number is mapped. You can also enter a port number range to forward packets to multiple ports on the destination network. For a static NAT virtual IP, if you add a map to port range the FortiGate unit calculates the external port number range.	0
portforward {enable | disable}	Select to enable port forwarding. You must also specify the port forwarding mappings by configuring extport and mappedport.	disable
src-filter <addr_str>	Enter a source address filter. Each address must be in the form of an IPv4 subnet (x:x:x:x:x:x:x:x/n). Separate addresses with spaces.	null

VIP46 policies can be used to configure static NAT virtual IPv4 address for IPv6 addresses. VIP46 can be configured from the CLI using the following commands (see the table below for variable details):

```
config firewall vip46
   edit <name_str>
      set arp-reply {enable | disable}
      set color <color_int>
      set comment <comment_str>
      set extip <address_ipv4>[-address_ipv4]
      set extport <port_int>
```

```
    set id <id_num_str>
    set mappedip [<start_ipv6>-<end_ipv6>]
    set mappedport <port_int>
    set portforward {enable | disable}
    set src-filter <add_str>
end
```

VIP46 CLI Variables and Defaults

Variable	Description	Default
`<name_str>`	Enter the name of this virtual IP address.	No default.
`arp-reply {enable | disable}`	Select to respond to ARP requests for this virtual IP address.	enable
`color <color_int>`	Enter the number of the color to use for the group icon in the web-based manager.	0
`comment <comment_str>`	Enter comments relevant to the configured virtual IP.	No default.
`extip <address_ipv4>[-address_ipv4]`	Enter the IP address or address range on the external interface that you want to map to an address or address range on the destination network. If `mappedip` is an IP address range, the FortiGate unit uses `extip` as the first IP address in the external IP address range, and calculates the last IP address required to create an equal number of external and mapped IP addresses for one-to-one mapping. To configure a dynamic virtual IP that accepts connections destined for any IP address, set `extip` to 0.0.0.0.	0.0.0.0

Variable	Description	Default
extport <port_int>	Enter the external port number that you want to map to a port number on the destination network. This option only appears if portforward is enabled. If portforward is enabled and you want to configure a static NAT virtual IP that maps a range of external port numbers to a range of destination port numbers, set extport to the first port number in the range. Then set mappedport to the start and end of the destination port range. The FortiGate unit automatically calculates the end of the extport port number range.	0
id <id_num_str>	Enter a unique identification number for the configured virtual IP. Not checked for uniqueness. Range 0 - 65535.	No default.
mappedip [<start_ipv6>-<end_ipv6>]	Enter the IP address or IP address range on the destination network to which the external IP address is mapped. If mappedip is an IP address range, the FortiGate unit uses extip as the first IP address in the external IP address range, and calculates the last IP address required to create an equal number of external and mapped IP addresses for one-to-one mapping. If mappedip is an IP address range, the FortiGate unit uses extip as a single IP address to create a one-to-many mapping.	::

Variable	Description	Default
`mappedport <port_int>`	Enter the port number on the destination network to which the external port number is mapped. You can also enter a port number range to forward packets to multiple ports on the destination network. For a static NAT virtual IP, if you add a map to port range the FortiGate unit calculates the external port number range.	0
`portforward {enable | disable}`	Select to enable port forwarding. You must also specify the port forwarding mappings by configuring `extport` and `mappedport`.	disable
`src-filter <addr_str>`	Enter a source address filter. Each address must be in the form of an IPv4 subnet (x.x.x.x/n). Separate addresses with spaces.	null

IPv6 Network Address Translation

NAT66, NAT64, and DNS64 are now supported for IPv6. These options provide IPv6 NAT and DNS capabilities withIPv6-IPv4 tunnelling or dual stack configurations. The commands are available only in the CLI.

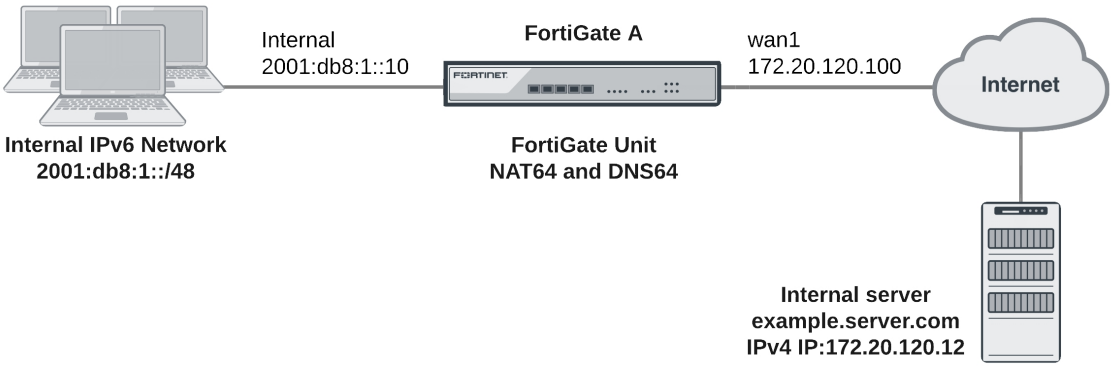
Fortinet supports all features described in RFC 6146. However, for DNS64 there is no support for handling Domain Name System Security Extensions (DNSSEC). DNSSEC is for securing types of information that are provided by the DNS as used on an IP network or networks. You can find more information about DNS64 in RFC 6147.

NAT64 and DNS64 (DNS proxy)

NAT64 is used to translate IPv6 addresses to IPv4 addresses so that a client on an IPv6 network can communicate transparently with a server on an IPv4 network.

NAT64 is usually implemented in combination with the DNS proxy called DNS64. DNS64 synthesizes AAAA records from A records and is used to synthesize IPv6 addresses for hosts that only have IPv4 addresses. ‘DNS proxy’ and ‘DNS64’ are interchangeable terms.

Example NAT64 configuration



With a NAT64 and DNS64 configuration in place on a FortiGate unit, clients on an IPv6 network can transparently connect to addresses on an IPv4 network. NAT64 and DNS64 perform the IPv4 to IPv6 transition, allowing clients that have already switched to IPv6 addresses to continue communicating with servers that still use IPv4 addresses.

To enable NAT64 and DNS64, use the following CLI commands:

Enable NAT64

```
config system nat64
   set status enable
end
```

Enable the DNS proxy on the IPv6 interface

```
config system dns-server
   edit internal
   end
```

In your DHCP6 configuration, configure the IPv6 interface IP address as the DNS6 server IP address. The FortiGate will proxy DNS requests to the system DNS server.

```
config system dhcp6 server
   edit 1
      set interface internal
      config ip-range
         edit 1
            set start-ip 2001:db8:1::11
            set end-ip 2001:db8:1::20
         end
      set dns-server1 2001:db8:1::10
   end
```

NAT64 policies

You can configure security policies for NAT64 using the web-based manager. For these options to appear, the feature must be enabled using **System > Feature Select**. You can then configure the policies under **Policy & Objects > NAT64 Policy**.

NAT64 policies and can also be configured from the CLI using the following command:

```
config firewall policy64
```

In the following section, you will configure a NAT64 policy that allows connections from an internal IPv6 network to an external IPv4 network.

Configuring NAT64 to allow a host on the IPv6 network to connect to the Internet server

In this example, the Internal IPv6 network address is 2001:db8:1::/48 and the external IPv4 network address is 172.20.120.0/24. NAT64 is configured to allow a user on the internal network to connect to the server at IPv4 address 172.20.120.12. In this configuration, sessions exiting the wan1 interface must have their source address changed to an IPv4 address in the range 172.20.120.200 to 172.20.120.210.

Enter the following command to enable NAT64:

```
config system nat64
   set status enable
end
```

Enabling NAT64 with the `config system nat64` command means that all IPv6 traffic received by the current VDOM can be subject to NAT64 if the source and destination address matches an NAT64 security policy.

By default, the setting `always-synthesize-aaaa-record` is enabled. If you disable this setting, the DNS proxy (DNS64) will attempt to find an AAAA records for queries to domain names and therefore resolve the host names to IPv6 addresses. If the DNS proxy cannot find an AAAA record, it synthesizes one by adding the NAT64 prefix to the A record.

By using the `nat64-prefix` option of the `config system nat64` command to change the default nat64 prefix from the well-known prefix of 64:ff9b::/96 and setting `always-synthesize-aaaa-record` to `enable` (default), the DNS proxy does not check for AAAA records but rather synthesizes AAAA records.

As an alternative to the above entry, there is the optional configuration that would allow the resolution of CNAME queries.

```
config system nat64
   set status enable
   set nat64-prefix 64:ff9b::/96
   set always-synthesize-aaaa-record enable
end
```

Enter the following command to add an IPv6 firewall address for the internal network:

```
config firewall address6
   edit internal-net6
      set ip6 2001:db8:1::/48
   end
```

Enter the following command to add an IPv4 firewall address for the external network:

```
config firewall address
   edit external-net4
      set subnet 172.20.120.0/24
      set associated-interface wan1
   end
```

Enter the following command to add an IP pool containing the IPv4 address that the should become the source address of the packets exiting the wan1 interface:

```
config firewall ippool
```

```
edit exit-pool4
   set startip 172.20.120.200
   set endip 172.20.120.210
end
```

Enter the following command to add a NAT64 policy that allows connections from the internal IPv6 network to the external IPv4 network:

```
config firewall policy64
   edit 0
      set srcintf internal
      set srcaddr internal-net6
      set dstintf wan1
      set dstaddr external-net4
      set action accept
      set schedule always
      set service ANY
      set logtraffic enable
      set ippool enable
      set poolname exit-pool4
   end
```

The `srcaddr` can be any IPv6 firewall address and the `dstaddr` can be any IPv4 firewall address.

Other NAT64 policy options include `fixedport`, which can be used to prevent NAT64 from changing the destination port. You can also configure traffic shaping for NAT64 policies.

How a host on the internal IPv6 network communicates with example.server.com that only has IPv4 address on the Internet

1. The host on the internal network does a DNS lookup for example.server.com by sending a DNS query for an AAAA record for example.server.com.
2. The DNS query is intercepted by the FortiGate DNS proxy.
3. The DNS proxy attempts to resolve the query with a DNS server on the Internet and discovers that there are no AAAA records for example.server.com.
4. The previous step is skipped if `always-synthesize-aaaa-record` is enabled.
5. The DNS proxy performs an A-record query for example.server.com and gets back an RRSet containing a single A record with the IPv4 address 172.20.120.12.
6. The DNS proxy then synthesizes an AAAA record. The IPv6 address in the AAAA record begins with the configured NAT64 prefix in the upper 96 bits and the received IPv4 address in the lower 32 bits. By default, the resulting IPv6 address is 64:ff9b::172.20.120.12.
7. The host on the internal network receives the synthetic AAAA record and sends a packet to the destination address 64:ff9b::172.20.120.12.
8. The packet is routed to the FortiGate internal interface where it is accepted by the NAT64 security policy.
9. The FortiGate unit translates the destination address of the packets from IPv6 address 64:ff9b::172.20.120.12 to IPv4 address 172.20.120.12 and translates the source address of the packets to 172.20.120.200 (or another address in the IP pool range) and forwards the packets out the wan1 interface to the Internet.

NAT66

NAT66 is used for translating an IPv6 source or destination address to a different IPv6 source or destination address. NAT66 is not as common or as important as IPv4 NAT, as many IPv6 addresses do not need NAT66 as

much as IPv4 NAT. However, NAT66 can be useful for a number of reasons. For example, you may have changed the IP addresses of some devices on your network but want traffic to still appear to be coming from their old addresses. You can use NAT66 to translate the source addresses of packets from the devices to their old source addresses.

In FortiOS, NAT66 options can be added to an IPv6 security policy from the CLI. Configuring NAT66 is very similar to configuring NAT in an IPv4 security policy. For example, use the following command to add an IPv6 security policy that translates the source address of IPv6 packets to the address of the destination interface (similar to IPv4 source NAT:

```
config firewall policy6
   edit 0
      set srcintf internal
      set dstintf wan1
      set srcaddr internal_net
      set dstaddr all
      set action accept
      set schedule always
      set service ANY
      set nat enable
   end
```

Its also can be useful to translate one IPv6 source address to another address that is not the same as the address of the exiting interface. You can do this using IP pools. For example, enter the following command to add an IPv6 IP pool containing one IPv6 IP address:

```
config firewall ippool6
   edit example_6_pool
      set startip 2001:db8::
      set endip 2001:db8::
   end
```

Enter the following command to add an IPv6 firewall address that contains a single IPv6 IP address.

```
config firewall address6
   edit device_address
      set ip6 2001:db8::132/128
   end
```

Enter the following command to add an IPv6 security policy that accepts packets from a device with IP address 2001:db8::132 and translates the source address to 2001:db8::.

```
config firewall policy6
   edit 0
      set srcintf internal
      set dstintf wan1
      set srcaddr device_address
      set dstaddr all
      set action accept
      set schedule always
      set service ANY
      set nat enable
      set ippool enable
      set poolname example_6_pool
   end
```

NAT66 destination address translation

NAT66 can also be used to translate destination addresses. This is done in an IPv6 policy by using IPv6 virtual IPs. For example, enter the following command to add an IPv6 virtual IP that maps the destination address 2001:db8::dd to 2001:db8::ee.

```
config firewall vip6
   edit example-vip6
      set extip 2001:db8::dd
      set mappedip 2001:db8::ee
   end
```

Enter the following command to add an IPv6 security policy that accepts packets with a destination address 2001:db8::dd and translates that destination address to 2001:db8::ee.

```
config firewall policy6
   edit 0
      set srcintf internal
      set dstintf wan1
      set srcaddr all
      set dstaddr example-vip6
      set action accept
      set schedule always
      set service ANY
   end
```

NAT64 and NAT66 session failover

The FortiGate Clustering Protocol (FGCP) supports IPv6, NAT64, and NAT66 session failover. If session pickup is enabled, these sessions are synchronized between cluster members and, after an HA failover, the sessions will resume with only minimal interruption.

NAT46

NAT46 is used to translate IPv4 addresses to IPv6 addresses so that a client on an IPv4 network can communicate transparently with a server on an IPv6 network.

To enable NAT46, use the following CLI command:

```
config firewall vip46
```

NAT46 policies

Security policies for NAT46 can be configured from the web-based manager. For these options to appear in the web-based manager, this feature must be enabled using **System > Feature Select**. You can then configure the policies under **Policy & Objects > NAT46 Policy**.

NAT46 policies and can also be configured from the CLI using the following command:

```
config firewall policy46
```

ICMPv6

Internet Control Message Protocol version 6 (ICMPv6) is the new implementation of the Internet Control Message Protocol (ICMP) that is part of Internet Protocol version 6 (IPv6). The ICMPv6 protocol is defined in RFC 4443.

ICMPv6 is a multipurpose protocol. It performs such things as:

- error reporting in packet processing
- diagnostic functions
- Neighbor Discovery process
- IPv6 multicast membership reporting

It is also designed as a framework to use extensions for use with future implementations and changes.

Examples of extensions that have already been written for ICMPv6:

- Neighbor Discovery Protocol (NDP) - a node discovery protocol in IPv6 which replaces and enhances functions of ARP.
- Secure Neighbor Discovery Protocol (SEND) - an extension of NDP with extra security.
- Multicast Router Discovery (MRD) - allows discovery of multicast routers.
- ICMPv6 messages use IPv6 packets for transportation and can include IPv6 extension headers. ICMPv6 includes some of the functionality that in IPv4 was distributed among protocols such as ICMPv4, ARP (Address Resolution Protocol), and IGMP (Internet Group Membership Protocol version 3).
- ICMPv6 has simplified the communication process by eliminating obsolete messages.

ICMPv6 messages are subdivided into two classes: error messages and information messages.

Error Messages are divided into four categories:

- Destination Unreachable
- Time Exceeded
- Packet Too Big
- Parameter Problems
- Information messages are divided into three groups:
- Diagnostic messages
- Neighbor Discovery messages
- Messages for the management of multicast groups.

ICMPv6 Types and Codes

ICMPv6 has a number of messages that are identified by the “Type” field. Some of these types have assigned “Code” fields as well. The table below shows the different types of ICMP Types with their associated codes if there are any.

Type codes 0 − 127 are error messages and type codes 128 − 255 are for information messages.

ICMPv6 Types and Codes

Type #	Type Name	Code
0	Reserved	0 - no route to destination 1 - communication with destination administratively prohibited 2 - beyond scope of source address 3 - address unreachable 4 - port unreachable 5 - source address failed ingress/egress policy 6 - reject route to destination 7 - Error in Source Routing Header
1	Destination Unreachable	
2	Packet Too Big	
3	Time Exceeded	0 - hop limit exceeded in transit 1 - fragment reassembly time exceeded
4	Parameter Problem	0 - erroneous header field encountered 1 - unrecognized Next Header type encountered 2 - unrecognized IPv6 option encountered
100	Private Experimentation	
101	Private Experimentation	
102 - 126	Unassigned	
127	Reserved for expansion if ICMPv6 error messages	
128	Echo Request	
129	Echo Replay	
130	Multicast Listener Query	

Type #	Type Name	Code
131	Multicast Listener Report	
132	Multicast Listener Done	
133	Router Solicitation	
134	Router Advertisement	
135	Neighbor Solicitation	
136	Neighbor Advertisement	
137	Redirect Message	
138	Router Renumbering	0 - Router Renumbering Command 1 - Router Renumbering Result 255 - Sequence Number Reset
139	ICMP Node Information Query	0 - The Data field contains an IPv6 address which is the Subject of this Query. 1 - The Data field contains a name which is the Subject of this Query, or is empty, as in the case of a NOOP. 2 - The Data field contains an IPv4 address which is the Subject of this Query.
140	ICMP Node Information Response	0 - A successful reply. The Reply Data field may or may not be empty. 1 - The Responder refuses to supply the answer. The Reply Data field will be empty. 2 - The Qtype of the Query is unknown to the Responder. The Reply Data field will be empty.
141	Inverse Neighbor Discovery Solicitation Message	
142	Inverse Neighbor Discovery Advertisement Message	
143	Version 2 Multicast Listener Report	
144	Home Agent Address Discovery Request Message	

Type #	Type Name	Code
145	Home Agent Address Discovery Reply Message	
146	Mobile Prefix Solicitation	
147	Mobile Prefix Advertisement	
148	Certification Path Solicitation Message	
149	Certification Path Advertisement Message	
150	ICMP messages utilized by experimental mobility protocols such as Seamoby	
151	Multicast Router Advertisement	
152	Multicast Router Solicitation	
153	Multicast Router Termination	
154	FMIPv6 Messages	
155	RPL Control Message	
156	ILNPv6 Locator Update Message	
157	Duplicate Address Request	
158	Duplicate Address Confirmation	
159 – 199	Unassigned	
200	Private experimentation	
201	Private experimentation	
255	Reserved for expansion of ICMPv6 informational messages	

IPv6 in dynamic routing

Unless otherwise stated, routing protocols apply to IPv4 addressing. This is the standard address format used. However, IPv6 is becoming more popular and new versions of the dynamic routing protocols have been introduced.

As with most advanced routing features on your FortiGate unit, IPv6 settings for dynamic routing protocols must be enabled before they will be visible in the GUI. To enable IPv6 configuration in the GUI, enable it in **System > Feature Select**. Alternatively, you can directly configure IPv6 for RIP, BGP, or OSPF protocols using CLI commands.

Dual stack routing

Dual stack routing implements dual IP layers in hosts and routers, supporting both IPv6 and IPv4. A dual stack architecture supports both IPv4 and IPv6 traffic and routes the appropriate traffic as required to any device on the network. Administrators can update network components and applications to IPv6 on their own schedule, and even maintain some IPv4 support indefinitely if that is necessary. Devices that are on this type of network, and connect to the Internet, can query Internet DNS servers for both IPv4 and IPv6 addresses. If the Internet site supports IPv6, the device can easily connect using the IPv6 address. If the Internet site does not support IPv6, then the device can connect using the IPv4 addresses.

In FortiOS, dual stack architecture it is not comprised merely of basic addressing functions that operate in both versions of IP. The other features of the appliance, such as UTM and routing, can also use both IP stacks.

If an organization with a mixed network uses an Internet service provider that does not support IPv6, they can use an IPv6 tunnel broker to connect to IPv6 addresses that are on the Internet. FortiOS supports IPv6 tunnelling over IPv4 networks to tunnel brokers. The tunnel broker extracts the IPv6 packets from the tunnel and routes them to their destinations.

IPv6 tunnelling

IPv6 Tunnelling is the act of tunnelling IPv6 packets from an IPv6 network through an IPv4 network to another IPv6 network. Unlike NAT, once the packet reaches its final destination, the true originating address of the sender will still be readable. The IPv6 packets are encapsulated within packets with IPv4 headers, which carry their IPv6 payload through the IPv4 network.

The key to IPv6 tunnelling is the ability of the two devices to be dual stack compatible in order to work with both IPv4 and IPv6 at the same time. In the process, the entry node of the tunnel portion of the path will create an encapsulating IPv4 header and transmit the encapsulated packet. The exit node at the end of the tunnel receives the encapsulated packet, removes the IPv4 header, updates the IPv6 header, and processes the packet.

There are two types of tunnels in IPv6:

Automatic tunnels: Automatic tunnels are configured by using IPv4 address information embedded in an IPv6 address – the IPv6 address of the destination host includes information about which IPv4 address the packet should be tunnelled to.

Configured tunnels: Configured tunnels must be configured manually. These tunnels are used when using IPv6 addresses that do not have any embedded IPv4 information. The IPv6 and IPv4 addresses of the endpoints of the tunnel must be specified.

Tunnel configuration

There are a few ways in which the tunnelling can be performed depending on which segment of the path between the endpoints of the session the encapsulation takes place.

Host to Host: Dual Stack capable hosts that are interconnected by an IPv4 infrastructure can tunnel IPv6 packets between themselves. In this case, the tunnel spans the entire path taken by the IPv6 packets.

Network Device to Host: Dual Stack capable network devices can tunnel IPv6 packets to their final destination IPv6 or IPv4 host. This tunnel spans only the last segment of the path taken by the IPv6 packets.

The node that does the encapsulation needs to maintain soft state information about each tunnel in order to process the IPv6 packets.

Use the following command to tunnel IPv6 traffic over an IPv4 network. The IPv6 interface is configured under `config system interface`. The command to do the reverse is `config system ipv6-tunnel`. These commands are not available in Transparent mode.

```
config system sit-tunnel
   edit <tunnel name>
      set destination <tunnel _address>
      set interface <name>
      set ip6 <address_ipv6>
      set source <address_ipv4>
   end
```

Variable	Description	Default
`edit <tunnel_name>`	Enter a name for the IPv6 tunnel.	No default.
`destination <tunnel_ address>`	The destination IPv4 address for this tunnel.	0.0.0.0
`interface <name>`	The interface used to send and receive traffic for this tunnel.	No default.
`ip6 <address_ipv6>`	The IPv6 address for this tunnel.	No default.
`source <address_ipv4>`	The source IPv4 address for this tunnel.	0.0.0.0

Tunnelling IPv6 through IPsec VPN

A variation on tunnelling IPv6 through IPv4 is to use an IPsec VPN tunnel between two FortiGate devices. FortiOS supports IPv6 over IPsec. In this sort of scenario, two networks using IPv6 behind FortiGate units are separated by the Internet, which uses IPv4. An IPsec VPN tunnel is created between the FortiGate units and a tunnel is created over the IPv4-based Internet, but the traffic in the tunnel is IPv6. This has the additional advantage of securing the traffic.

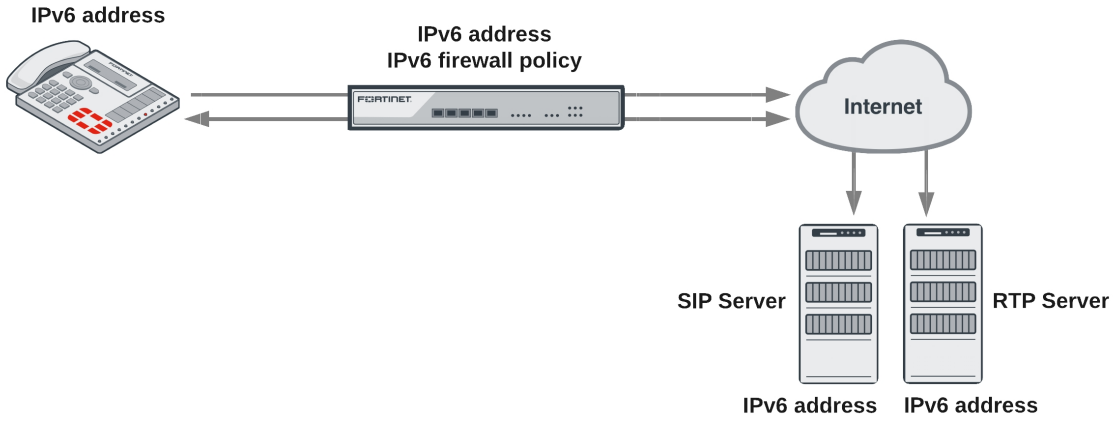
For configuration information, see IPv6 IPsec VPN on page 2175.

SIP over IPv6

FortiOS supports Sessions Initiate Protocol (SIP) over IPv6. The SIP application-level gateway (ALG) can process SIP messages that use IPv6 addresses in the headers, bodies, and in the transport stack. The SIP ALG cannot modify the IPv6 addresses in the SIP headers so FortiGate units cannot perform SIP or RTP NAT over IPv6 and also cannot translate between IPv6 and IPv4 addresses.

In the scenario shown below, a SIP phone connects to the Internet through a FortiGate unit operating. The phone and the SIP and RTP servers all have IPv6 addresses.

The FortiGate unit has IPv6 security policies that accept SIP sessions. The SIP ALG understands IPv6 addresses and can forward IPv6 sessions to their destinations. Using SIP application control features the SIP ALG can also apply rate limiting and other settings to SIP sessions.



To enable SIP support for IPv6 add an IPv6 security policy that accepts SIP packets and includes a VoIP profile.

New Fortinet FortiGate IPv6 MIB fields

The following IPv6 MIB fields have been added to the Fortinet FortiGate MIB. These MIB entries can be used to display IPv6 session and policy statistics.

- IPv6 Session Counters:

```
fgSysSes6Count
fgSysSes6Rate1
fgSysSes6Rate10
fgSysSes6Rate30
fgSysSes6Rate60
```

- IPv6 Policy Statistics:

```
fgFwPol6StatsTable
fgFwPol6StatsEntry
FgFwPol6StatsEntry
fgFwPol6ID
fgFwPol6PktCount
fgFwPol6ByteCount
```

- IPv6 Session Statistics:

```
fgIp6SessStatsTable
fgIp6SessStatsEntry
FgIp6SessStatsEntry
fgIp6SessNumber
```

The fgSysSesCount and fgSysSesRateX MIBs report statistics for IPv4 plus IPv6 sessions combined. This behavior was not changed.

New OIDs

The following OIDs have been added:

```
FORTINET-FORTIGATE-MIB:fortinet.fnFortiGateMib.fgSystem.fgSystemInfo
.fgSysSes6Count   1.3.6.1.4.1.12356.101.4.1.15
.fgSysSesRate1    1.3.6.1.4.1.12356.101.4.1.16
.fgSysSesRate10   1.3.6.1.4.1.12356.101.4.1.17
.fgSysSesRate30   1.3.6.1.4.1.12356.101.4.1.18
.fgSysSesRate60   1.3.6.1.4.1.12356.101.4.1.19

FORTINET-FORTIGATE-MIB:fortinet.fnFortiGateMib.fgFirewall.fgFwPolicies.fgFwPolTables
.fgFwPol6StatsTable.fgFwPol6StatsEntry.fgFwPol6ID   1.3.6.1.4.1.12356.101.5.1.2.2.1.1
.fgFwPol6StatsTable.fgFwPol6StatsEntry.fgFwPol6PktCount   1.3.6.1.4.1.12356.101.5.1.2.2.1.
    2
.fgFwPol6StatsTable.fgFwPol6StatsEntry.fgFwPol6ByteCount   1.3.6.1.4.1.12356.101.5.1.2.2.1
    .3

FORTINET-FORTIGATE-MIB:fortinet.fnFortiGateMib.fgInetProto.fgInetProtoTables
.fgIp6SessStatsTable.fgIp6SessStatsEntry.fgIp6SessNumber 1.3.6.1.4.1.12356.101.11.2.3.1.1
```

EXAMPLE SNMP get/walk output

```
// Session6 stats excerpt from sysinfo:
snmpwalk -v2c -cpublic 192.168.1.111 1.3.6.1.4.1.12356.101.4
FORTINET-FORTIGATE-MIB::fgSysSes6Count.0 = Gauge32: 203
FORTINET-FORTIGATE-MIB::fgSysSes6Rate1.0 = Gauge32: 10 Sessions Per Second
FORTINET-FORTIGATE-MIB::fgSysSes6Rate10.0 = Gauge32: 2 Sessions Per Second
FORTINET-FORTIGATE-MIB::fgSysSes6Rate30.0 = Gauge32: 1 Sessions Per Second
FORTINET-FORTIGATE-MIB::fgSysSes6Rate60.0 = Gauge32: 0 Sessions Per Second

// FwPolicy6 table:

// IP6SessNumber:
snmpwalk -v2c -cpublic 192.168.1.111 1.3.6.1.4.1.12356.101.11.2.3.1
FORTINET-FORTIGATE-MIB::fgIp6SessNumber.1 = Counter32: 89
```

IPv6 Per-IP traffic shaper

You can add any Per-IP traffic shaper to an IPv6 security policy using the following command:

```
config firewall policy6
   edit 0
      set per-ip-shaper "new-perip-shaper"
   end
```

DHCPv6

You can use DHCP with IPv6 using the CLI. To configure DHCP, ensure IPv6 is enabled by going to **System > Feature Select** and enabling **IPv6**.

Use the CLI command

```
config system dhcp6
```

For more information on the configuration options, see the FortiGate CLI Reference.

DHCP delegated mode

Downstream IPv6 interfaces can receive address assignments on delegated subnets from a DHCP server that serves an upstream interface.

DHCPv6-PD configuration

Enable DHCPv6 Prefix Delegation on upstream interface (port10):

```
config system interface
   edit "port10"
     config ipv6
       set dhcp6-prefix-delegation enable
     end
   end
```

Assign delegated prefix on downstream interface (port1). Optionally, specific delegated prefixes can be specified:

```
config system interface
  edit "port1"
    config ipv6
      set ip6-mode delegated
      set ip6-upstream-interface "port10"
      set ip6-subnet ::1:0:0:0:1/64
      set ip6-send-adv enable
      config ipv6-delegated-prefix-list
        edit 1
          set upstream-interface "port10"
          set autonomous-flag enable
          set onlink-flag enable
          set subnet 0:0:0:100::/64
        end
      end
    end
```

DHCPv6 Server configuration

Configuring a server that uses delegated prefix and DNS from upstream:

```
config system dhcp6 server
   edit 1
     set dns-service delegated
```

```
    set interface "wan2"
    set upstream-interface "wan1"
    set ip-mode delegated
    set subnet 0:0:0:102::/64
  end
```

DHCPv6 relay

You can use the following command to configure a FortiGate interface to relay DHCPv6 queries and responses from one network to a network with a DHCPv6 server and back. The command enables DHCPv6 relay and includes adding the IPv6 address of the DHCP server that the FortiGate unit relays DHCPv6 requests to:

```
config system interface
  edit internal
    config ipv6
      set dhcp6-relay-service enable
      set dhcp6-relay-type regular
      set dhcp6-relay-ip 2001:db8:0:2::30
    end
```

IPv6 forwarding

Policies, IPS, Application Control, flow-based antivirus, web filtering, and DLP

FortiOS fully supports flow-based inspection of IPv6 traffic. This includes full support for IPS, application control, virus scanning, and web filtering.
To add flow-based inspection to IPv6 traffic go to **Policy & Objects > IPv6 Policy** and select **Create New** to add an IPv6 Security Policy. Configure the policy to accept the traffic to be scanned. Under **Security Profiles**, select the profiles to apply to the traffic.

Obtaining IPv6 addresses from an IPv6 DHCP server

From the CLI, you can configure any FortiGate interface to get an IPv6 address from an IPv6 DHCP server. For example, to configure the wan2 interface to get an IPv6 address from an IPv6 DHCP server enter the following command:

```
config system interface
  edit wan2
    config ipv6
      set ip6-mode dhcp
    end
```

IPv6 Configuration

This section contains configuration information for IPv6 on FortiOS. Attempts are made to include scenarios in each section to better assist with the configuration and to orient the information toward a particular task.

You will find information on the following:

By default IPv6 configurations do not appear in the web-based manager. You need to enable the feature first.

To enable IPv6:

1. Go to **System > Features**.
2. Select **IPv6** and click **Apply**.

IPv6 address groups

To create IPv6 address groups from existing IPv6 addresses - web-based manager

Your company has 3 internal servers with IPv6 addresses that it would like to group together for the purposes of a number of policies.

1. Go to **Policy & Objects > Addresses** and select **Create New > Address Group.**
2. Select **IPv6 Group**, and fill out the fields with the following information:

Group Name	Web_Server_Cluster
Members	Web_Server-1
	Web_Server-2
	Web_Server-3

3. Select **OK.**

To create IPv6 address groups from existing IPv6 addresses - CLI

```
config firewall addrgrp6
   edit Web_Server_Cluster
      set member Web_Server-1 Web_Server-2 Web_Server-3
   end
```

To verify that the addresses were added correctly

1. Go to **Policy & Objects > Addresses**. Check that the addresses have been added to the address list and that they are correct.
2. From the CLI, enter the following commands:

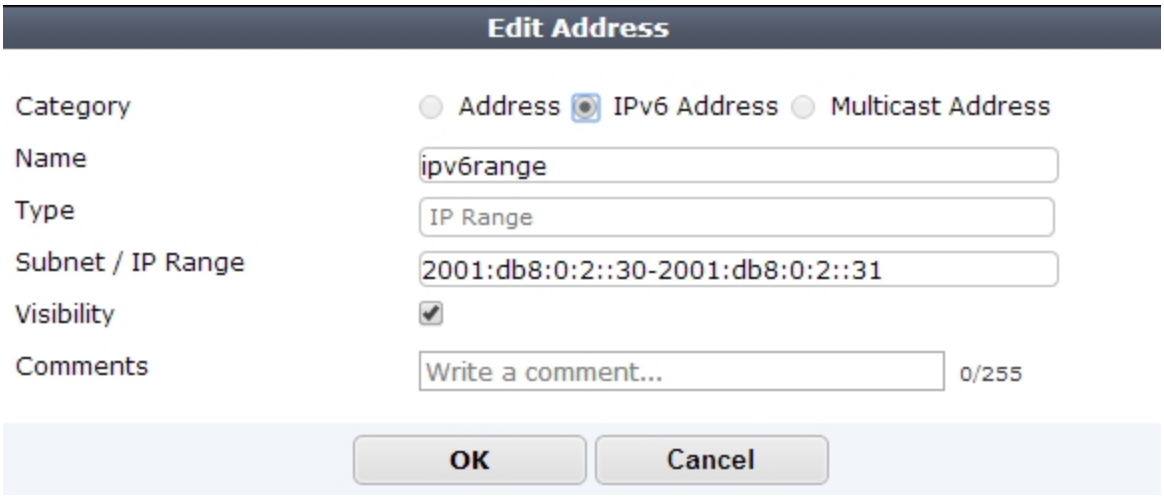
```
config firewall addgrp6
   edit <the name of the address that you wish to verify>
      Show full-configuration
```

IPv6 address ranges

You can configure IPv6 address ranges in both the GUI and the CLI.

To configure IPv6 address ranges - web-based manager:

1. Go to **Policy & Objects > Addresses**.
2. Set the **Type** to **IP Range** and enter the IPv6 addresses as shown:



To configure IPv6 address ranges - CLI:

```
config firewall address6
   edit ipv6range
      set type iprange
      set start-ip 2001:db8:0:2::30
      set end-ip 2001:db8:0:2::31
   end
```

IPv6 firewall addresses

Scenario: Mail Server

You need to create an IPv6 address for the Mail Server on Port1 of your internal network. This server is on the network off of port1.

- The IP address is 2001:db8:0:2::20/128
- There should be a tag for this address being for a server.

Configuring the Example using the GUI

1. Go to **Policy & Objects > Objects > Addresses** and select **Create New > Address.**
2. Select **IPv6 Address** and fill out the fields with the following information

Name	Mail_Server
Type	Subnet
IPv6 Address	2001:db8:0:2::20/128

3. Select **OK.**

Configuring the Example using the CLI

Enter the following CLI command:

```
config firewall address6
   edit Mail_Server
      set type ipprefix
      set subnet 2001:db8:0:2::20/128
   end
```

Scenario: First Floor Network

You need to create an IPv6 address for the subnet of the internal network off of Port1. These computers connect to port1. The network uses the IPv6 addresses: fdde:5a7d:f40b:2e9d:xxxx:xxxx:xxxx:xxxx

There should be a reference to this being the network for the 1st floor of the building.

1. Go to **Policy & Objects > Objects > Addresses**
2. Select **Create New > Address.**Select **IPv6 Address** and fill out the fields with the following information:

Name	Internal_Subnet_1
Type	Subnet / IP Range
IPv6 Address	2001:db8:0:2::/64
Comments	Network for 1st Floor

3. Select **OK.**
4. Enter the following CLI command:

```
config firewall address6
   edit Internal_Subnet_1
      set comment "Network for 1st Floor"
      set type ipprefix
      set subnet 2001:db8:0:2::/64
   end
```

Scenario: Accounting Team

You need to create an IPv6 address for the Accounting Team that's on the 1st Floor. These users are off of various ports of the FortiGate, but they have all been assigned addresses between 2001:db8:0:2::2000 and 2001:db8:0:2::a000

Configuring the Example using the GUI

1. Go to **Policy & Objects > Objects > Addresses** and select **Create New > Address.**
2. Select **IPv6 Address** and fill out the fields with the following information

Name	Accounting_Team
Type	IP Range
Subnet / IP Range	2001:db8:0:2::2000-2001:db8:0:2::a000

3. Select **OK.**

Configuring the Example using the CLI

Enter the following CLI command:

```
config firewall address6
   edit Accounting_Team
      set type iprange
      set visibility enable
      set start-ip 2001:db8:0:2::2000
      set end-ip 2001:db8:0:2::a000
      end
```

To verify that the addresses were added correctly:

1. Go to **Policy & Objects > Objects > Addresses.** Check that the addresses have been added to the address list and that they are correct.
2. Enter the following CLI command:

```
config firewall address6
   edit <the name of the address that you wish to verify>
      Show full-configuration
```

ICMPv6

The IT Manager is doing some diagnostics and would like to temporarily block the successful replies of ICMP Node information Responses between 2 IPv6 networks.

The ICMP type for ICMP Node informations responses is 140. The codes for a successful response is 0.

To configure ICMPv6 - web-based manager:

1. Go to **Policy & Objects > Services** and select **Create New > Service**.
2. Fill out the fields with the following information

Name	diagnostic-test1
Service Type	Firewall
Show in Service List	Enabled

Category	Uncategorized
Protocol Type	ICMP6
Type	140

3. Select **OK.**
4. Enter the following CLI command:

```
config firewall service custom
   edit diagnostic-test1
      set protocol ICMP6
      set icmptype 140
      set icmpcode 0
      set visibility enable
   end
```

To verify that the category was added correctly:

1. Go to **Policy & Objects > Services**. Check that the services have been added to the services list and that they are correct.
2. Enter the following CLI command:

```
config firewall service custom
   edit <the name of the service that you wish to verify>
      show full-configuration
```

IPv6 IPsec VPN

This chapter describes how to configure your FortiGate unit's IPv6 IPsec VPN functionality.

By default IPv6 configurations do not appear in the web-based manager. You need to enable the feature first.

To enable IPv6:

1. Go to **System > Features**.
2. Select **IPv6** and click **Apply**.

The topics in this section include:

- Overview of IPv6 IPsec support
- Configuring IPv6 IPsec VPNs
- Site-to-site IPv6 over IPv6 VPN example
- Site-to-site IPv4 over IPv6 VPN example
- Site-to-site IPv6 over IPv4 VPN example

Overview of IPv6 IPsec support

FortiOS supports route-based IPv6 IPsec, but not policy-based. This section describes how IPv6 IPsec support differs from IPv4 IPsec support.

Where both the gateways and the protected networks use IPv6 addresses, sometimes called IPv6 over IPv6, you can create either an auto-keyed or manually-keyed VPN. You can also combine IPv6 and IPv4 addressing in an auto-keyed VPN in the following ways:

IPv4 over IPv6	The VPN gateways have IPv6 addresses. The protected networks have IPv4 addresses. The phase 2 configurations at either end use IPv4 selectors.
IPv6 over IPv4	The VPN gateways have IPv4 addresses. The protected networks use IPv6 addresses. The phase 2 configurations at either end use IPv6 selectors.

Compared with IPv4 IPsec VPN functionality, there are some limitations:

- Except for IPv6 over IPv4, remote gateways with Dynamic DNS are not supported.
- Selectors cannot be firewall address names. Only IP address, address range and subnet are supported.
- Redundant IPv6 tunnels are not supported.

Certificates

On a VPN with IPv6 phase 1 configuration, you can authenticate using VPN certificates in which the common name (cn) is an IPv6 address. The `cn-type` keyword of the `user peer` command has an option, `ipv6`, to support this.

Configuring IPv6 IPsec VPNs

Configuration of an IPv6 IPsec VPN follows the same sequence as for an IPv4 route-based VPN: phase 1 settings, phase 2 settings, security policies, and routing.

Phase 1 configuration

In the web-based manager, you define the Phase 1 as IPv6 in the Advanced settings. Enable the IPv6 Version check box. You can then enter an IPv6 address for the remote gateway.

In the CLI, you define an IPsec phase 1 configuration as IPv6 by setting `ip-version` to `6`. Its default value is `4`. Then, the `local-gw` and `remote-gw` keywords are hidden and the corresponding `local-gw6` and `remote-gw6` keywords are available. The values for `local-gw6` and `remote-gw6` must be IPv6 addresses. For example:

```
config vpn ipsec phase1-interface
   edit tunnel6
      set ip-version 6
      set remote-gw6 0:123:4567::1234
      set interface port3
      set proposal 3des-md5
   end
```

Phase 2 configuration

To create an IPv6 IPsec phase 2 configuration in the web-based manager, you need to define IPv6 selectors in the Advanced settings. Change the default “0.0.0.0/0” address for Source address and Destination address to the

IPv6 value "::/0". If needed, enter specific IPv6 addresses, address ranges or subnet addresses in these fields.

In the CLI, set `src-addr-type` and `dst-addr-type` to `ip6`, `range6` or `subnet6` to specify IPv6 selectors. By default, zero selectors are entered, "::/0" for the `subnet6` address type, for example. The simplest IPv6 phase 2 configuration looks like this:

```
config vpn ipsec phase2-interface
   edit tunnel6_p2
      set phase1name tunnel6
      set proposal 3des-md5
      set src-addr-type subnet6
      set dst-addr-type subnet6
   end
```

Security policies

To complete the VPN configuration, you need a security policy in each direction to permit traffic between the protected network's port and the IPsec interface. You need IPv6 policies unless the VPN is IPv4 over IPv6.

Routing

Appropriate routing is needed for both the IPsec packets and the encapsulated traffic within them. You need a route, which could be the default route, to the remote VPN gateway via the appropriate interface. You also need a route to the remote protected network via the IPsec interface.

To create a static route - web-based manager:

1. Go to **Network > Static Routes**.
2. Select the drop-down arrow on the **Create New** button and select **IPv6 Route**.
3. Enter the information and select **OK**.

To create a static route - CLI:

1. In the CLI, use the `router static6` command. For example, where the remote network is `fec0:0000:0000:0004::/64` and the IPsec interface is `toB`:

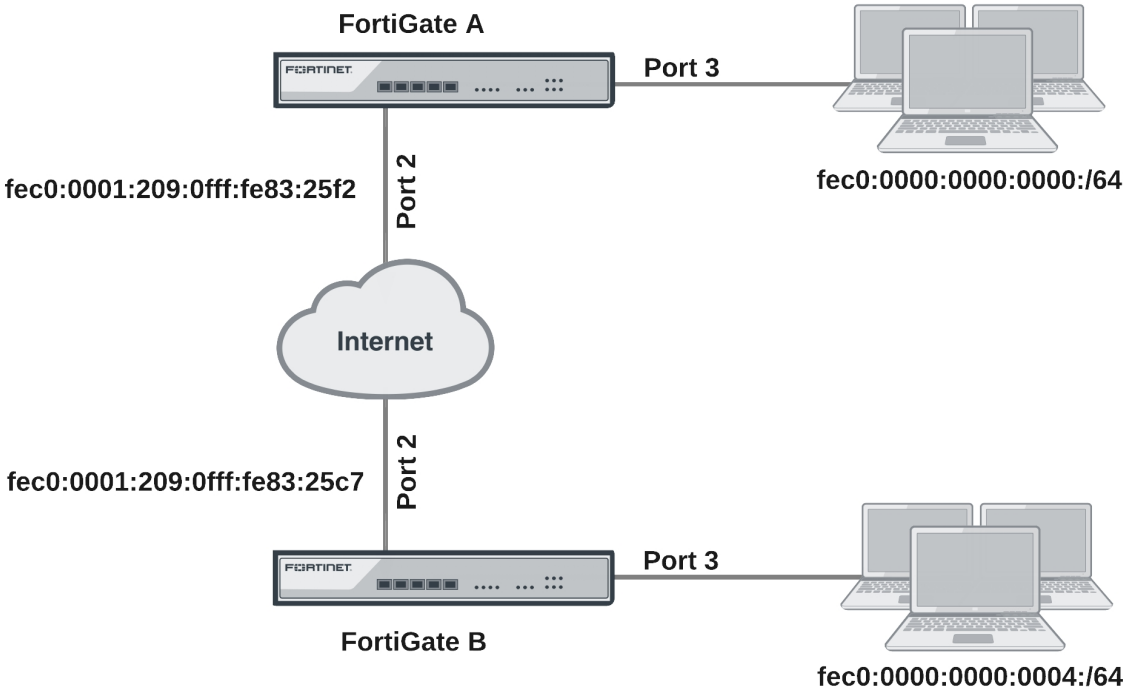
```
config router static6
   edit 1
      set device port2
      set dst 0::/0
   next
   edit 2
      set device toB
      set dst fec0:0000:0000:0004::/64
   next
end
```

If the VPN is IPV4 over IPv6, the route to the remote protected network is an IPv4 route. If the VPN is IPv6 over IPv4, the route to the remote VPN gateway is an IPv4 route.

Site-to-site IPv6 over IPv6 VPN example

In this example, computers on IPv6-addressed private networks communicate securely over public IPv6 infrastructure.

Example IPv6-over-IPv6 VPN topology



Configure FortiGate A interfaces

Port 2 connects to the public network and port 3 connects to the local network.

```
config system interface
   edit port2
      config ipv6
         set ip6-address fec0::0001:209:0fff:fe83:25f2/64
      end
   next
   edit port3
      config ipv6
         set ip6-address fec0::0000:209:0fff:fe83:25f3/64
      end
   next
end
```

Configure FortiGate A IPsec settings

The phase 1 configuration creates a virtual IPsec interface on port 2 and sets the remote gateway to the public IP address FortiGate B. This configuration is the same as for an IPv4 route-based VPN, except that `ip-version` is set to `6` and the `remote-gw6` keyword is used to specify an IPv6 remote gateway address.

```
config vpn ipsec phase1-interface
   edit toB
      set ip-version 6
      set interface port2
```

```
      set remote-gw6 fec0:0000:0000:0003:209:0fff:fe83:25c7
      set dpd enable
      set psksecret maryhadalittlelamb
      set proposal 3des-md5 3des-sha1
   end
```

By default, phase 2 selectors are set to accept all subnet addresses for source and destination. The default setting for `src-addr-type` and `dst-addr-type` is `subnet`. The IPv6 equivalent is `subnet`. The default subnet addresses are 0.0.0.0/0 for IPv4, `::/0` for IPv6.

```
config vpn ipsec phase2-interface
   edit toB2
      set phase1name toB
      set proposal 3des-md5 3des-sha1
      set pfs enable
      set replay enable
      set src-addr-type subnet6
      set dst-addr-type subnet6
   end
```

Configure FortiGate A security policies

Security policies are required to allow traffic between port3 and the IPsec interface toB in each direction. The address `all6` must be defined using the `firewall address6` command as `::/0`.

```
config firewall policy6
   edit 1
      set srcintf port3
      set dstintf toB
      set srcaddr all6
      set dstaddr all6
      set action accept
      set service ANY
      set schedule always
   next
   edit 2
      set srcintf toB
      set dstintf port3
      set srcaddr all6
      set dstaddr all6
      set action accept
      set service ANY
      set schedule always
   end
```

Configure FortiGate A routing

This simple example requires just two static routes. Traffic to the protected network behind FortiGate B is routed via the virtual IPsec interface toB. A default route sends all IPv6 traffic out on port2.

```
config router static6
   edit 1
      set device port2
      set dst 0::/0
   next
   edit 2
      set device toB
      set dst fec0:0000:0000:0004::/64
   end
```

Configure FortiGate B

The configuration of FortiGate B is very similar to that of FortiGate A. A virtual IPsec interface toA is configured on port2 and its remote gateway is the public IP address of FortiGate A. Security policies enable traffic to pass between the private network and the IPsec interface. Routing ensures traffic for the private network behind FortiGate A goes through the VPN and that all IPv6 packets are routed to the public network.

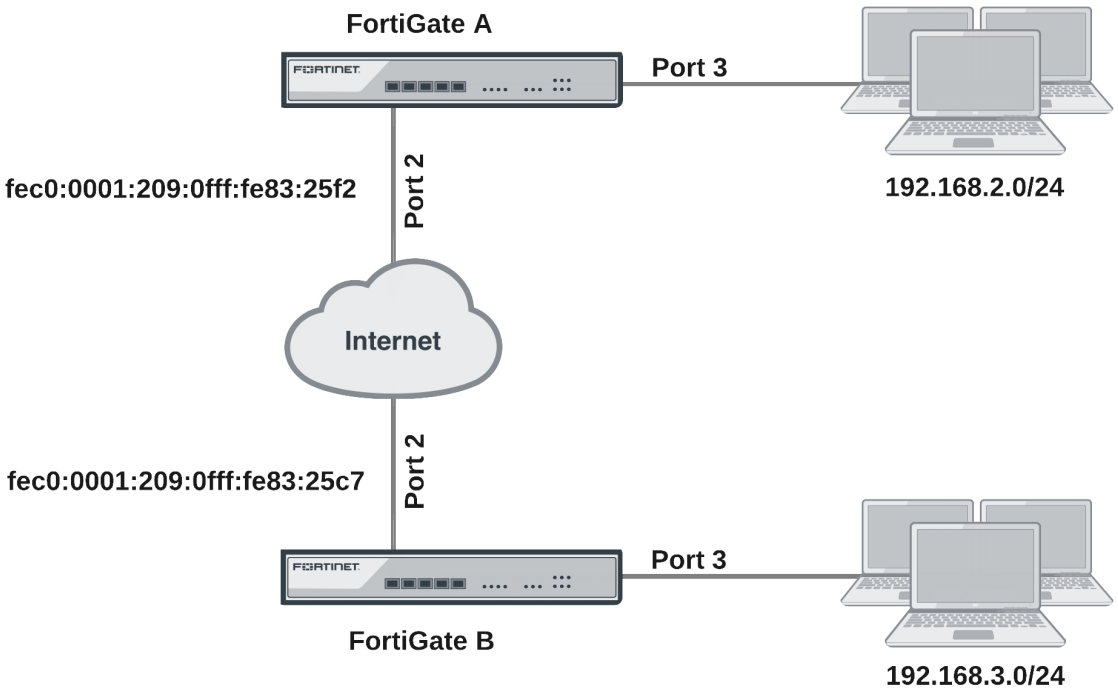
```
config system interface
   edit port2
      config ipv6
         set ip6-address fec0::0003:209:0fff:fe83:25c7/64
      end
   next
   edit port3
      config ipv6
         set ip6-address fec0::0004:209:0fff:fe83:2569/64
      end
   end
config vpn ipsec phase1-interface
   edit toA
      set ip-version 6
      set interface port2
      set remote-gw6 fec0:0000:0000:0001:209:0fff:fe83:25f2
      set dpd enable
      set psksecret maryhadalittlelamb
      set proposal 3des-md5 3des-sha1
   end
config vpn ipsec phase2-interface
   edit toA2
      set phase1name toA
      set proposal 3des-md5 3des-sha1
      set pfs enable
      set replay enable
      set src-addr-type subnet6
      set dst-addr-type subnet6
   end
config firewall policy6
   edit 1
      set srcintf port3
      set dstintf toA
      set srcaddr all6
      set dstaddr all6
      set action accept
      set service ANY
      set schedule always
   next
   edit 2
      set srcintf toA
      set dstintf port3
      set srcaddr all6
      set dstaddr all6
      set action accept
      set service ANY
      set schedule always
   end
config router static6
   edit 1
```

```
      set device port2
      set dst 0::/0
   next
   edit 2
      set device toA
      set dst fec0:0000:0000:0000::/64
end
```

Site-to-site IPv4 over IPv6 VPN example

In this example, two private networks with IPv4 addressing communicate securely over IPv6 infrastructure.

Example IPv4-over-IPv6 VPN topology



Configure FortiGate A interfaces

Port 2 connects to the IPv6 public network and port 3 connects to the IPv4 LAN.

```
config system interface
   edit port2
      config ipv6
         set ip6-address fec0::0001:209:0fff:fe83:25f2/64
      end
   next
   edit port3
      set 192.168.2.1/24
   end
```

Configure FortiGate A IPsec settings

The phase 1 configuration is the same as in the IPv6 over IPv6 example.

```
config vpn ipsec phase1-interface
   edit toB
      set ip-version 6
      set interface port2
      set remote-gw6 fec0:0000:0000:0003:209:0fff:fe83:25c7
      set dpd enable
      set psksecret maryhadalittlelamb
      set proposal 3des-md5 3des-sha1
   end
```

The phase 2 configuration is the same as you would use for an IPv4 VPN. By default, phase 2 selectors are set to accept all subnet addresses for source and destination.

```
config vpn ipsec phase2-interface
   edit toB2
      set phase1name toB
      set proposal 3des-md5 3des-sha1
      set pfs enable
      set replay enable
   end
```

Configure FortiGate A security policies

Security policies are required to allow traffic between port3 and the IPsec interface toB in each direction. These are IPv4 security policies.

```
config firewall policy
   edit 1
      set srcintf port3
      set dstintf toB
      set srcaddr all
      set dstaddr all
      set action accept
      set service ANY
      set schedule always
   next
   edit 2
      set srcintf toB
      set dstintf port3
      set srcaddr all
      set dstaddr all
      set action accept
      set service ANY
      set schedule always
   end
```

Configure FortiGate A routing

This simple example requires just two static routes. Traffic to the protected network behind FortiGate B is routed via the virtual IPsec interface toB using an IPv4 static route. A default route sends all IPv6 traffic, including the IPv6 IPsec packets, out on port2.

```
config router static6
   edit 1
      set device port2
```

```
      set dst 0::/0
   next
   edit 2
      set device toB
      set dst 192.168.3.0/24
   end
```

Configure FortiGate B

The configuration of FortiGate B is very similar to that of FortiGate A. A virtual IPsec interface toA is configured on port2 and its remote gateway is the public IP address of FortiGate A. The IPsec phase 2 configuration has IPv4 selectors.

IPv4 security policies enable traffic to pass between the private network and the IPsec interface. An IPv4 static route ensures traffic for the private network behind FortiGate A goes through the VPN and an IPv6 static route ensures that all IPv6 packets are routed to the public network.

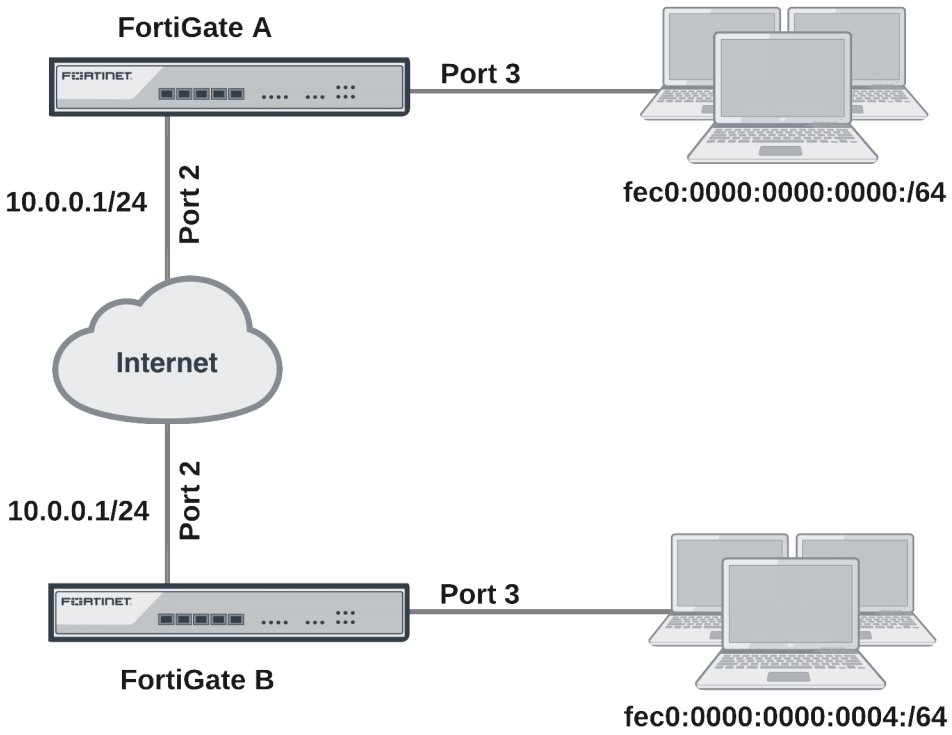
```
config system interface
   edit port2
      config ipv6
         set ip6-address fec0::0003:fe83:25c7/64
      end
   next
   edit port3
      set 192.168.3.1/24
   end
config vpn ipsec phase1-interface
   edit toA
      set ip-version 6
      set interface port2
      set remote-gw6 fec0:0000:0000:0001:209:0fff:fe83:25f2
      set dpd enable
      set psksecret maryhadalittlelamb
      set proposal 3des-md5 3des-sha1
   end
config vpn ipsec phase2-interface
   edit toA2
      set phase1name toA
      set proposal 3des-md5 3des-sha1
      set pfs enable
      set replay enable
   end
config firewall policy
   edit 1
      set srcintf port3
      set dstintf toA
      set srcaddr all
      set dstaddr all
      set action accept
      set service ANY
      set schedule always
   next
   edit 2
      set srcintf toA
      set dstintf port3
      set srcaddr all
      set dstaddr all
```

```
      set action accept
      set service ANY
      set schedule always
   end
config router static6
   edit 1
      set device port2
      set dst 0::/0
   next
   edit 2
      set device toA
      set dst 192.168.2.0/24
   end
```

Site-to-site IPv6 over IPv4 VPN example

In this example, IPv6-addressed private networks communicate securely over IPv4 public infrastructure.

Example IPv6-over-IPv4 VPN topology



Configure FortiGate A interfaces

Port 2 connects to the IPv4 public network and port 3 connects to the IPv6 LAN.

```
config system interface
   edit port2
      set 10.0.0.1/24
```

```
      next
      edit port3
      config ipv6
         set ip6-address fec0::0001:209:0fff:fe83:25f3/64
      end
```

Configure FortiGate A IPsec settings

The phase 1 configuration uses IPv4 addressing.

```
config vpn ipsec phase1-interface
   edit toB
      set interface port2
      set remote-gw 10.0.1.1
      set dpd enable
      set psksecret maryhadalittlelamb
      set proposal 3des-md5 3des-sha1
   end
```

The phase 2 configuration uses IPv6 selectors. By default, phase 2 selectors are set to accept all subnet addresses for source and destination. The default setting for `src-addr-type` and `dst-addr-type` is `subnet`. The IPv6 equivalent is `subnet6`. The default subnet addresses are 0.0.0.0/0 for IPv4, `::/0` for IPv6.

```
config vpn ipsec phase2-interface
   edit toB2
      set phase1name toB
      set proposal 3des-md5 3des-sha1
      set pfs enable
      set replay enable
      set src-addr-type subnet6
      set dst-addr-type subnet6
   end
```

Configure FortiGate A security policies

IPv6 security policies are required to allow traffic between port3 and the IPsec interface toB in each direction. Define the address `all6` using the `firewall address6` command as `::/0`.

```
config firewall policy6
   edit 1
      set srcintf port3
      set dstintf toB
      set srcaddr all6
      set dstaddr all6
      set action accept
      set service ANY
      set schedule always
   next
   edit 2
      set srcintf toB
      set dstintf port3
      set srcaddr all6
      set dstaddr all6
      set action accept
      set service ANY
      set schedule always
   end
```

Configure FortiGate A routing

This simple example requires just two static routes. Traffic to the protected network behind FortiGate B is routed via the virtual IPsec interface toB using an IPv6 static route. A default route sends all IPv4 traffic, including the IPv4 IPsec packets, out on port2.

```
config router static6
   edit 1
      set device toB
      set dst fec0:0000:0000:0004::/64
   end
config router static
   edit 1
      set device port2
      set dst 0.0.0.0/0
      set gateway 10.0.0.254
   end
```

Configure FortiGate B

The configuration of FortiGate B is very similar to that of FortiGate A. A virtual IPsec interface toA is configured on port2 and its remote gateway is the IPv4 public IP address of FortiGate A. The IPsec phase 2 configuration has IPv6 selectors.

IPv6 security policies enable traffic to pass between the private network and the IPsec interface. An IPv6 static route ensures traffic for the private network behind FortiGate A goes through the VPN and an IPv4 static route ensures that all IPv4 packets are routed to the public network.

```
config system interface
   edit port2
      set 10.0.1.1/24
   next
   edit port3
      config ipv6
         set ip6-address fec0::0004:209:0fff:fe83:2569/64
      end
config vpn ipsec phase1-interface
   edit toA
      set interface port2
      set remote-gw 10.0.0.1
      set dpd enable
      set psksecret maryhadalittlelamb
      set proposal 3des-md5 3des-sha1
   end
config vpn ipsec phase2-interface
   edit toA2
      set phase1name toA
      set proposal 3des-md5 3des-sha1
      set pfs enable
      set replay enable
      set src-addr-type subnet6
      set dst-addr-type subnet6
   end
config firewall policy6
   edit 1
      set srcintf port3
      set dstintf toA
      set srcaddr all6
      set dstaddr all6
      set action accept
      set service ANY
      set schedule always
   next
   edit 2
      set srcintf toA
      set dstintf port3
      set srcaddr all6
      set dstaddr all6
      set action accept
      set service ANY
      set schedule always
   end
config router static6
   edit 1
      set device toA
```

```
      set dst fec0:0000:0000:0000::/64
   end
config router static
   edit 1
      set device port2
      set gateway 10.0.1.254
   end
```

TCP MSS values

TCP MSS values, which control the maximum amount of data that can be sent in a single packet, can be set for IPv6 policies (for both the sender and the receiver). You can configure TCP MSS values in IPv6 using the following CLI commands:

```
config firewall policy6
   edit <index_int>
      set tcp-mss-sender <value>
      set tcp-mss-receiver <value>
   end
```

BGP and IPv6

FortiGate units support IPv6 over BGP using the same `config router bgp` command as IPv4, but different subcommands.

The main CLI keywords have IPv6 equivalents that are identified by the “6” on the end of the keyword, such as with `config network6` or `set allowas-in6`.

IPv6 BGP commands include:

```
config router bgp
   set activate6 {enable | disable}
   set allowas-in6 <max_num_AS_integer>
   set allowas-in-enable6 {enable | disable}
   set as-override6 {enable | disable}
   set attribute-unchanged6 [as-path] [med] [next-hop]
   set capability-default-originate6 {enable | disable}
   set capability-graceful-restart6 {enable | disable}
   set default-originate-route-map6 <routemap_str>
   set distribute-list-in6 <access-list-name_str>
   set distribute-list-out6 <access-list-name_str>
   set filter-list-in6 <aspath-list-name_str>
   set filter-list-out6 <aspath-list-name_str>
   set maximum-prefix6 <prefix_integer>
   set maximum-prefix-threshold6 <percentage_integer>
   set maximum-prefix-warning-only6 {enable | disable}
   set next-hop-self6 {enable | disable}
   set prefix-list-in6 <prefix-list-name_str>
   set prefix-list-out6 <prefix-list-name_str>
   set remove-private-as6 {enable | disable}
   set route-map-in6 <routemap-name_str>
   set route-map-out6 <routemap-name_str>
   set route-reflector-client6 {enable | disable}
   set route-server-client6 {enable | disable}
   set send-community6 {both | disable | extended | standard}
   set soft-reconfiguration6 {enable | disable}
   set unsuppress-map6 <route-map-name_str>
```

```
    config network6
    config redistribute6
end
```

RIPng — RIP and IPv6

RIP next generation, or RIPng, is the version of RIP that supports IPv6.

This is an example of a typical small network configuration using RIPng routing.

Your internal R&D network is working on a project for a large international telecom company that uses IPv6. For this reason, you have to run IPv6 on your internal network and you have decided to use only IPv6 addresses.

Your network has two FortiGate units running the RIPng dynamic routing protocol. Both FortiGate units are connected to the ISP router and the internal network. This configuration provides some redundancy for the R&D internal network enabling it to reach the internet at all times.

This section includes the following topics:

- Network layout and assumptions
- Configuring the FortiGate units system information
- Configuring RIPng on FortiGate units
- Configuring other network devices
- Testing the configuration
- Debugging IPv6 on RIPng

Network layout and assumptions

Basic network layout

Your internal R&D network is working on a project for a large international telecom company that uses IPv6. For this reason, you have to run IPv6 on your internal network and you have decided to use only IPv6 addresses.

Your network has two FortiGate units running the RIPng dynamic routing protocol. Both FortiGate units are connected to the ISP router and the internal network. This configuration provides some redundancy for the R&D internal network enabling it to reach the internet at all times.

All internal computers use RIP routing, so no static routing is required. And all internal computers use IPv6 addresses.

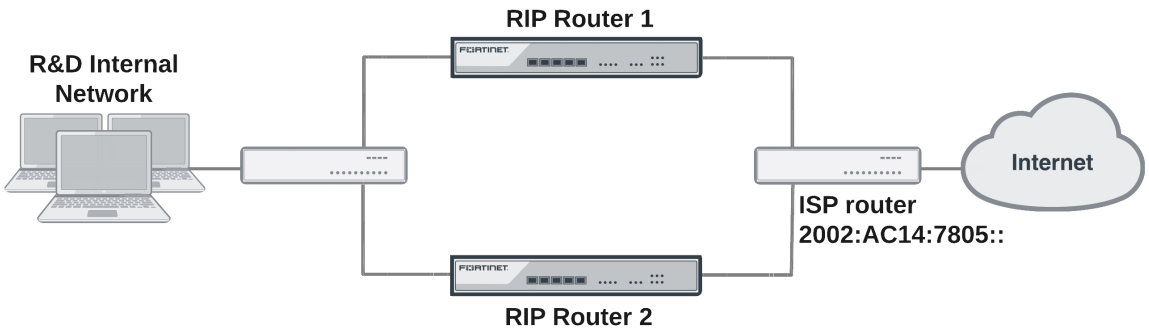
Where possible in this example, the default values will be used or the most general settings. This is intended to provide an easier configuration that will require less troubleshooting.

In this example the routers, networks, interfaces used, and IP addresses are as follows:

Rip example network topology

Network	Router	Interface & Alias	IPv6 address
R&D	Router1	port1 (internal)	2002:A0B:6565:0:0:0:0:0
		port2 (ISP)	2002:AC14:7865:0:0:0:0:0
	Router2	port1 (internal)	2002:A0B:6566:0:0:0:0:0
		port2 (ISP)	2002:AC14:7866:0:0:0:0:0

Network topology for the IPv6 RIPng example



Assumptions

The following assumptions have been made concerning this example:

- All FortiGate units have 5.0+ firmware, and are running factory default settings.
- All CLI and web-based manager navigation assumes the unit is running in NAT/Route operating mode, with VDOMs disabled.
- All FortiGate units have interfaces labelled port1 and port2 as required.
- All firewalls have been configured for each FortiGate unit to allow the required traffic to flow across interfaces.
- All network devices are support IPv6 and are running RIPng.

Configuring the FortiGate units system information

Each FortiGate unit needs IPv6 enabled, a new hostname, and interfaces configured.

To configure system information on Router1 - web-based manager:

1. Go to **Dashboard**.
2. For **Host name**, select **Change**.
3. Enter “Router1”.
4. Go to **System > Feature Select**.
5. Enable **IPv6** and click **Apply**.

6. Go to **Network > Interfaces**.
7. Edit port1 (internal) interface.
8. Set the following information, and select **OK**.

Alias	internal
IP/Netmask	2002:A0B:6565::/0
Administrative Access	HTTPS SSH PING
Description	Internal RnD network
Administrative Status	Up

9. Edit port2 (ISP) interface.
10. Set the following information, and select **OK**.

Alias	ISP
IP/Netmask	2002:AC14:7865::/0
Administrative Access	HTTPS SSH PING
Description	ISP and internet
Administrative Status	Up

To configure system information on Router1 - CLI:

```
config system global
   set hostname Router1
   set gui-ipv6 enable
end
config system interface
   edit port1
      set alias internal
      set allowaccess https ping ssh
      set description "Internal RnD network"
      config ipv6
         set ip6-address 2002:a0b:6565::/0
      end
   next
   edit port2
      set alias ISP
      set allowaccess https ping ssh
      set description "ISP and internet"
      config ipv6
         set ip6-address 2002:AC14:7865::
      end
   end
```

To configure system information on Router2 - web-based manager:

1. Go to **Dashboard**.
2. For **Host name**, select **Change**.
3. Enter “Router2”.
4. Go to **System > Feature Select**.
5. Enable **IPv6** and click **Apply**.
6. Go to **Network > Interfaces**.
7. Edit port1 (internal) interface.
8. Set the following information, and select **OK**.

Alias	internal
IP/Netmask	2002:A0B:6566::/0
Administrative Access	HTTPS SSH PING
Description	Internal RnD network
Administrative Status	Up

9. Edit port2 (ISP) interface.
10. Set the following information, and select **OK**.

Alias	ISP
IP/Netmask	2002:AC14:7866::/0
Administrative Access	HTTPS SSH PING
Description	ISP and internet
Administrative Status	Up

To configure system information on Router2 - CLI:

```
config system global
   set hostname Router2
   set gui-ipv6 enable
end
config system interface
   edit port1
      set alias internal
      set allowaccess https ping ssh
      set description "Internal RnD network"
      config ipv6
         set ip6-address 2002:a0b:6566::/0
      end
   next
   edit port2
      set alias ISP
      set allowaccess https ping ssh
      set description "ISP and internet"
```

```
      config ipv6
        set ip6-address 2002:AC14:7866::
      end
    end
```

Configuring RIPng on FortiGate units

Now that the interfaces are configured, you can configure RIPng on the FortiGate units.

There are only two networks and two interfaces to include — the internal network, and the ISP network. There is no redistribution, and no authentication. In RIPng there is no specific command to include a subnet in the RIP broadcasts. There is also no information required for the interfaces beyond including their name.

As this is a CLI only configuration, configure the ISP router and the other FortiGate unit as neighbors. This was not part of the previous example as this feature is not offered in the web-based manager. Declaring neighbors in the configuration like this will reduce the discovery traffic when the routers start up.

Since RIPng is not supported in the web-based manager, this section will only be entered in the CLI.

To configure RIPng on Router1 - CLI:

```
config router ripng
   config interface
      edit port1
      next
      edit port2
      end
   config neighbor
      edit 1
         set interface port1
         set ipv6 2002:a0b:6566::/0
      next
      edit 2
         set interface port2
         set ipv6 2002:AC14:7805::/0
      end
```

To configure RIPng on Router2 - CLI:

```
config router ripng
   config interface
      edit port1
      next
      edit port2
      end
   config neighbor
      edit 1
         set interface port1
         set ipv6 2002:a0b:6565::/0
      next
      edit 2
         set interface port2
         set ipv6 2002:AC14:7805::/0
      end
```

Configuring other network devices

The other devices on the internal network all support IPv6, and are running RIPng where applicable. They only need to know the internal interface network addresses of the FortiGate units.

The ISP routers need to know the FortiGate unit information such as IPv6 addresses.

Testing the configuration

In addition to normal testing of your network configuration, you must also test the IPv6 part of this example.

For troubleshooting problems with your network, see the FortiOS Handbook Troubleshooting chapter.

Testing the IPv6 RIPng information

There are some commands to use when checking that your RIPng information is correct on your network. These are useful to check on your RIPng FortiGate units on your network. Comparing the output between devices will help you understand your network better, and also track down any problems.

```
diagnose ipv6 address list
```

View the local scope IPv6 addresses used as next-hops by RIPng on the FortiGate unit.

```
diagnose ipv6 route list
```

View ipv6 addresses that are installed in the routing table.

```
get router info6 routing-table
```

View the routing table. This information is almost the same as the previous command (diagnose ipv6 route list) however it is presented in an easier to read format.

```
get router info6 rip interface external
```

View brief output on the RIP information for the interface listed. The information includes if the interface is up or down, what routing protocol is being used, and whether passive interface or split horizon are enabled.

```
get router info6 neighbor-cache list
```

View the IPv6/MAC address mapping. This also displays the interface index and name associated with the address.

Debugging IPv6 on RIPng

The debug commands are very useful to see what is happening on the network at the packet level. There are a few changes to debugging the packet flow when debugging IPv6.

The following CLI commands specify both IPv6 and RIP, so only RIPng packets will be reported. The output from these commands will show you the RIPng traffic on your FortiGate unit including RECV, SEND, and UPDATE actions.

The addresses are in IPv6 format.

```
diagnose debug enable
diagnose ipv6 router rip level info
diagnose ipv6 router rip all enable
```

These three commands will:

Turn on debugging in general

Set the debug level to information, a verbose reporting level

Turn on all RIP router settings

Part of the information displayed from the debugging is the metric (hop count). If the metric is 16, then that destination is unreachable since the maximum hop count is 15.

In general, you should see an update announcement, followed by the routing table being sent out, and a received reply in response.

IPv6 RSSO support

RADIUS Single Sign-On (RSSO) is supported in IPv6, but can only be configured in the CLI:

```
config firewall policy6
   edit <id>
      set rsso enable
      set fall-through-unathenticated enable
   end
```

IPv6 IPS

IPv6 IPS signature scan can be enabled by interface policy. The user can create an normal IPS sensor and assign it to the IPv6 interface policy.

```
config firewall interface-policy6
   edit 1
      set interface "port1"
      set srcaddr6 "all"
      set dstaddr6 "all"
      set service6 "ANY"
      set ips-sensor-status enable
      set ips-sensor "all_default"
   next
end
```

Blocking IPv6 packets by extension headers

FortiOS can now block IPv6 packets based on the extension headers, using the CLI syntax:

```
config firewall ipv6-eh-filter.
```

The following commands are now available:

- `set hop-opt {disable | enable}`: Block packets with Hop-by-Hop Options header.
- `set dest-opt {disable | enable}`: Block packets with Destination Options header.
- `set hdopt-type <integer>`: Block specific Hop-by-Hop and/or Destination Option types (maximum 7 types, each between 0 and 255).
- `set routing {disable | enable}`: Block packets with Routing header.
- `set routing-type <integar>`: Block specific Routing header types (maximum 7 types, each between 0 and 255).
- `set fragment {disable | enable}`: Block packets with Fragment header.
- `set auth {disable | enable}`: Block packets with Authentication header.
- `set no-next {disable | enable}`: Block packets with No Next header.

IPv6 Denial of Service policies

Denial of Service (DoS) policies can now be configured by going to **Policy & Objects > IPv6 DoS Policy**. For more information, refer to the “Interface Policies” section of the FortiOS Handbook Firewall chapter.

Configure hosts in an SNMP v1/2c community to send queries or receive traps

When you add a host to an SNMP v1/2c community you can now decide whether the FortiGate unit will accept queries from the host or whether the FortiGate unit will send traps to the host. You can also configure the host for both traps and queries. You can add up to 16 IPv4 hosts and up to 16 IPv6 hosts.

Use the following command to add two hosts to an SNMP community:

```
config system snmp community
   config hosts
      edit 1
         set ip 172.20.120.1
         set host-type query
      end
   config hosts6
      edit 1
         set ip 2001:db8:0:2::30
         set host-type trap
      end
```

IPv6 PIM sparse mode multicast routing

FortiOS supports PIM sparse mode multicast routing for IPv6 multicast (multicast6) traffic and is compliant with RFC 4601. You can use the following command to configure IPv6 PIM sparse multicast routing.

```
config router multicast6
   set multicast-routing {enable | disable}
      config interface
         edit <interface-name>
            set hello-interval <1-65535 seconds>
            set hello-holdtime <1-65535 seconds>
      end
      config pim-sm-global
      config rp-address
         edit <index>
            set ipv6-address <ipv6-address>
      end
```

The following diagnose commands for IPv6 PIM sparse mode are also available:

```
diagnose ipv6 multicast status
diagnose ipv6 multicast vif
diagnose ipv6 multicast mroute
```

Chapter 19 - Logging and Reporting

This FortiOS Handbook chapter contains the following sections:

Logging and reporting overview provides general information about logging. We recommend that you begin with this chapter as it contains information for both beginners and advanced users as well. It contains an explanation of log messages, files, and devices, and an overview of the Reporting functions.

Logging and reporting for small networks provides an overview of setting up a small network for logging, with a look at a possible setup with a backup solution and a customized report.

Logging and reporting for large networks provides an overview of setting up a larger, enterprise-level network, with configuration of multiple FortiGate units, multiple FortiAnalyzer units as a backup solution, and a sample procedure for creating a more intensive and broad report to suit the larger network.

Advanced logging provides a series of separate tutorials for possible tasks and procedures an advanced user may want to undertake with their FortiGate-powered network. It contains explanations of advanced backup, logging, and report solutions.

Troubleshooting and logging provides a short overview of how log messages can be used to identify and solve problems within the network, how to identify and solve logging database issues, and how to solve connection issues between FortiGate and FortiAnalyzer units.

Logging and reporting overview

Logging and reporting in FortiOS can help you in determining what is happening on your network, as well as informing you of certain network activity, such as detection ofa virus or IPsec VPN tunnel errors. Logging and reporting go hand in hand, and can become a valuable tool for information as well as helping to show others the activity that is happening on the network.

This section explains logging and reporting features that are available in FortiOS, and how they can be used to help you manage or troubleshoot issues. This includes how the FortiGate unit records logs, what a log message is, and what the log database is.

What is logging?

Logging records the traffic passing through the FortiGate unit to your network and what action the FortiGate unit took during its scanning process of the traffic. This recorded information is called a log message.

After a log message is recorded, it is stored within a log file which is then stored on a log device. A log device is a central storage location for log messages. The FortiGate unit supports several log devices, such as FortiAnalyzer units, the FortiCloud service, and Syslog servers. A FortiGate unit's system memory and local disk can also be configured to store logs, and because of this, are also considered log devices.

You must subscribe to FortiCloud before you will be able to configure the FortiGate unit to send logs to a FortiCloud server.

When the recorded activity needs to be read in a more human way, the FortiGate unit can generate a Report. A report gathers all the log information that is needed for the report, and presents it in a graphical format, with customizable design and automatically generated charts. Reports can be used to present a graphical representation of what is going on in the network. Reports can also be generated on a FortiAnalyzer unit; if you want to generate reports on a FortiAnalyzer, see the FortiAnalyzer Setup and Administration Guide to help you create and generate those reports.

How the FortiGate unit records log messages

The FortiGate unit records log messages in a specific order, storing them on a log device. The order of how the FortiGate unit records log messages is as follows:

1. Incoming traffic is scanned.
2. During the scanning process, the FortiGate unit performs necessary actions, and simultaneously records the actions and results.
3. Log messages are sent to the log device.

Example: How the FortiGate unit records a DLP event

1. The FortiGate unit receives incoming traffic and scans for any matches associated within its firewall policies containing a DLP sensor.
2. A match is found; the DLP sensor, dlp_sensor, had a rule within it called All-HTTP with the action Exempt applied to the rule. The sensor also has Enable Logging selected, which indicates to the FortiGate unit that the activity should be recorded and placed in the DLP log file.

3. The FortiGate unit exempts the match, and places the recorded activity (the log message) within the DLP log file.
4. According to the log settings that were configured, logs are stored on the FortiGate unit's local hard drive. The FortiGate unit places the DLP log file on the local hard drive.

FortiOS features available for logging

Logs record FortiGate activity, providing detailed information about what is happening on your network. This recorded activity is found in log files, which are stored on a log device. However, logging FortiGate activity requires configuring certain settings so that the FortiGate unit can record the activity. These settings are often referred to as log settings, and are found in most security profiles, but also in **Log & Report > Log Settings**.

Log settings provide the information that the FortiGate unit needs so that it knows what activities to record. This topic explains what activity each log file records, as well as additional information about the log file, which will help you determine what FortiGate activity the FortiGate unit should record.

Traffic

Traffic logs record the traffic that is flowing through your FortiGate unit. Since traffic needs firewall policies to properly flow through the unit, this type of logging is also referred to as firewall policy logging. Firewall policies control all traffic that attempts to pass through the FortiGate unit, between FortiGate interfaces, zones and VLAN sub-interfaces.

Logging traffic works in the following way:

- firewall policy has logging enabled on it (Log Allowed Traffic)
- packet comes into an inbound interface
- a possible log packet is sent regarding a match in the firewall policy, such as a URL filter
- traffic log packet is sent, per firewall policy
- packet passes and is sent out an interface

Traffic log messages are stored in the traffic log file. Traffic logs can be stored any log device, even system memory.

All security profile-related logs are now tracked within the Traffic logs, as of FortiOS 5.0, so all forward traffic can be searched in one place, such as if you are looking to see all activity from a particular address, security feature or traffic. Security profile logs are still tracked separately in the **Security Log** section, which only appears when logs exist.

If you have enabled and configured WAN Optimization, you can enable logging of this activity in the CLI using the `config wanopt setting` command. These logs contain information about WAN Optimization activity and are found in the traffic log file. When configuring logging of this activity, you must also enable logging within the security policy itself, so that the activity is properly recorded.

Sniffer

The Sniffer log records all traffic that passes through a particular interface that has been configured to act as a One-Armed Sniffer, so it can be examined separately from the rest of the Traffic logs.

Other Traffic

The traffic log also records interface traffic logging, which is referred to as Other Traffic. Other Traffic is enabled only in the CLI. When enabled, the FortiGate unit records traffic activity on interfaces as well as firewall policies.

Logging Other Traffic puts a significant system load on the FortiGate unit and should be used only when necessary.

Logging other traffic works in the following way:

- firewall policy has logging enabled on it (Log Allowed Traffic) and other-traffic
- packet comes into an interface
- interface log packet is sent to the traffic log that is enabled on that particular interface
- possible log packet is sent regarding a match in the firewall policy, such as URL filter
- interface log packet is sent to the traffic log if enabled on that particular interface
- packet passes and is sent out an interface
- interface log packet is sent to traffic (if enabled) on that particular interface

Event

The event log records administration management as well as FortiGate system activity, such as when a configuration has changed, admin login, or high availability (HA) events occur. Event logs are an important log file to record because they record FortiGate system activity, which provides valuable information about how your FortiGate unit is performing.

Event logs help you in the following ways:

- keeping track of configuration setting changes
- IPsec negotiation, SSL VPN and tunnel activity
- quarantine events, such as banned users
- system performance
- HA events and alerts
- firewall authentication events
- wireless events on models with WiFi capabilities
- activities concerning modem and internet protocols L2TP, PPP and PPPoE
- VIP activities
- AMC disk's bypass mode
- VoIP activities that include SIP and SCCP protocols.

As of 5.4, every 'execute' CLI command now generates an 'audit' event log, allowing you to track configuration changes. You can enable/disable this feature in the CLI:

```
config system global
   set cli-audit-log [enable|disable]
end
```

The FortiGate unit records event logs only when events are enabled.

Traffic Shaping

Traffic shaping, per-IP traffic shaping and reverse direction traffic shaping settings can be applied to a firewall policy, appearing within the traffic log messages.

By enabling this feature, you can see what traffic shaping, per-IP traffic shaping and reverse direction traffic shaping settings are being used.

Data Leak Prevention

Data Leak Prevention logs, or DLP logs, provide valuable information about the sensitive data trying to get through to your network as well as any unwanted data trying to get into your network. The DLP rules within a DLP sensor can log the following traffic types:

- email (SMTP, POP3 or IMAP; if SSL content SMTPS, POP3S, and IMAPS)
- HTTP
- HTTPS
- FTP
- NNTP
- IM

A DLP sensor must have log settings enabled for each DLP rule and compound rule, as well as applied to a firewall policy so that the FortiGate unit records this type of activity. A DLP sensor can also contain archiving options, which these logs are then archived to the log device.

NAC Quarantine

Within the DLP sensor, there is an option for enabling NAC Quarantine. The NAC Quarantine option allows the FortiGate unit to record details of DLP operation that involve the ban and quarantine actions, and sends these to the event log file. The NAC Quarantine option must also be enabled within the Event Log settings. When enabling NAC quarantine within a DLP Sensor, you must enable this in the CLI because it is a CLI-only command.

Media Access Control (MAC) Address

MAC address logs provide information about MAC addresses that the FortiGate unit sees on the network as well as those removed from the network. These log messages are stored in the event log (as subtype network; you can view these log messages in **Log & Report > System Events**) and are, by default, disabled in the CLI. You can enable logging MAC addresses using the following command syntax:

```
config log setting
   set neighbor-event enable
end
```

When enabled, a new log message is recorded every time a MAC address entry is added to the ARP table, and also when a MAC address is removed as well. A MAC address log message is also recorded when MAC addresses are connected to the local switch, or from a FortiAP or FortiSwitch unit.

Application control

Application control logs provide detailed information about the traffic that internet applications such as Skype are generating. The application control feature controls the flow of traffic from a specific application, and the FortiGate unit examines this traffic for signatures that the application generates.

The log messages that are recorded provide information such as the type of application being used (such as P2P software), and what type of action the FortiGate unit took. These log messages can also help you to determine the top ten applications that are being used on your network. This feature is called application control monitoring and you can view the information from a widget on the Executive Summary page.

The application control list that is used must have logging enabled within the list, as well as logging enabled within each application entry. Each application entry can also have packet logging enabled. Packet logging for application control records the packet when an application type is identified, similar to IPS packet logging.

Logging of application control activity can only be recorded when an application control list is applied to a firewall policy, regardless of whether or not logging is enabled within the application control list.

Antivirus

Antivirus logs are recorded when, during the antivirus scanning process, the FortiGate unit finds a match within the antivirus profile, which includes the presence of a virus or grayware signature. Antivirus logs provide a way to understand what viruses are trying to get in, as well as additional information about the virus itself, without having to go to the FortiGuard Center and do a search for the detected virus. The link is provided within the log message itself.

These logs provide valuable information such as:

- the name of the detected virus
- the name of the oversized file or infected file
- the action the FortiGate unit took, for example, a file was blocked
- URL link to the FortiGuard Center which gives detailed information about the virus itself

The antivirus profile must have log settings enabled within it so that the FortiGate unit can record this activity, as well as having the antivirus profile applied to a firewall policy.

Web Filter

Web filter logs record HTTP traffic activity. These log messages provide valuable and detailed information about this particular traffic activity on your network. Web filtering activity is important to log because it can inform you about:

- what types of web sites employees are accessing
- users attempting to access banned web sites and how often this occurs
- network congestion due to employees accessing the Internet at the same time
- web-based threats resulting from users visiting non-business-related web sites

Web Filter logs are an effective tool to help you determine if you need to update your web filtering settings within a web filter profile due to unforeseen threats or network congestion. These logs also inform you about web filtering quotas that have been configured for filtering HTTP traffic.

You must configure logging settings within the web filter profile and apply the filter to a firewall policy so that the FortiGate unit can record the activity.

IPS (attack)

IPS logs, also referred to as attack logs, record attacks that occurred against your network. Attack logs contain detailed information about whether the FortiGate unit protected the network using anomaly-based defense settings or signature-based defense settings, as well as what the attack was.

The IPS or attack log file is especially useful because the log messages that are recorded contain a link to the FortiGuard Center, where you can find more information about the attack. This is similar to antivirus logs, where a link to the FortiGuard Center is provided as well that informs you of the virus that was detected by the FortiGate unit.

An IPS sensor with log settings enabled must be applied to a firewall policy so that the FortiGate unit can record the activity.

Packet logs

When you enable packet logging within an IPS signature override or filter, the FortiGate unit examines network packets, and if a match is found, saves them to the attack log. Packet logging is designed to be used as a diagnostic tool that can focus on a narrow scope of diagnostics, rather than a log that informs you of what is occurring on your network.

You should use caution when enabling packet logging, especially within IPS filters. Filter configuration that contains thousands of signatures could potentially cause a flood of saved packets, which would take up a lot of storage space on the log device. It would also take a great deal of time to sort through all the log messages, as well as consume considerable system resources to process.

You can archive packets, but you must enable this option on the Log Settings page. If your log configuration includes multiple FortiAnalyzer units, packet logs are only sent to the primary (first) FortiAnalyzer unit. Sending packet logs to the other FortiAnalyzer units is not supported.

Email filter

Email filter logs, also referred to as spam filter logs, record information regarding the content within email messages. For example, within an email filter profile, a match is found that finds the email message to be considered spam.

Email filter logs are recorded when the FortiGate unit finds a match within the email filter profile and logging settings are enabled within the profile.

If you are using a Banned Words List for email filtering, note that the filter pattern number is only recorded when the source email address contains a banned word.

Archives (DLP)

Recording DLP logs for network use is called DLP archiving. The DLP engine examines email, FTP, IM, NNTP, and web traffic. Archived logs are usually saved for historical use and can be accessed at any time. IPS packet logs can also be archived, within the Log Settings page.

You can start with the two default DLP sensors that have been configured specifically for archiving log data, Content_Archive and Content_Summary. They are available in **Security Profiles > Data Leak Prevention**. Content_Archive provides full content archiving, while Content_Summary provides summary archiving. For more information about how to configure DLP sensors, see the Security Features chapter of the FortiOS Handbook.

You must enable the archiving to record log archives. Logs are not archived unless enabled, regardless of whether or not the DLP sensor for archiving is applied to the firewall policy.

Network scan

Network scan logs are recorded when a scheduled scan of the network occurs. These log messages provide detailed information about the network's vulnerabilities regarding software, as well as the discovery of any further vulnerabilities.

A scheduled scan must be configured and logging enabled within the Event Log settings, for the FortiGate unit to record these log messages.

Log messages

Log messages are recorded by the FortiGate unit, giving you detailed information about the network activity. Each log message has a unique number that helps identify it, as well as containing fields; these fields, often called log fields, organize the information so that it can be easily extracted for reports.

These log fields are organized in such a way that they form two groups: the first group, made up of the log fields that come first, is called the log header. The log header contains general information, such as the unique log identification and date and time that indicates when the activity was recorded. The log body is the second group, and contains all the other information about the activity. There are no two log message bodies that are alike, however, there may be fields common to most log bodies, such as the `srcintf` or `identidix` log fields.

The log header also contains information about the log priority level which is indicated in the `level` field. The priority level indicates the immediacy and the possible repercussions of the logged action. For example, if the field contains 'alert', you need to take immediate action with regards to what occurred. There are six log priority levels.

The log severity level is the level at and above which the FortiGate unit records logs. The log severity level is defined by you when configuring the logging location. The FortiGate unit will log all messages at and above the priority level you select. For example, if you select Error, the unit will log only Error, Critical, Alert, and Emergency level messages.

Log priority levels

Levels	Description
0 - Emergency	The system has become unstable.
1 - Alert	Immediate action is required.
2 - Critical	Functionality is affected.
3 - Error	An error condition exists and functionality could be affected.
4 - Warning	Functionality could be affected.
5 - Notification	Information about normal events.
6 - Information	General information about system operations.

The Debug priority level, not shown above, is rarely used. It is the lowest log priority level and usually contains some firmware status information that is useful when the FortiGate unit is not functioning properly.

Example log header fields

Log header	
date=(2010-08-03)	The year, month and day of when the event occurred in yyyy-mm-dd format.

Log header	
time=(12:55:06)	The hour, minute and second of when the event occurred in the format hh:mm:ss.
log_id=(2457752353)	A five or ten-digit unique identification number. The number represents that log message and is unique to that log message. This ten-digit number helps to identify the log message.
type=(dlp)	The section of system where the event occurred.
subtype=(dlp)	The subtype category of the log message.
level=(notice)	The priority level of the event. See the table above.
vd=(root)	The name of the virtual domain where the action/event occurred in. If no virtual domains exist, this field always contains root.

Example log body fields

Log body	
policyid=(1)	The ID number of the firewall policy that applies to the session or packet. Any policy that is automatically added by the FortiGate will have an index number of zero.
identidx=(0)	The identity-based policy identification number. This field displays zero if the firewall policy does not use an identity-based policy; otherwise, it displays the number of the identity-based policy entry that the traffic matched. This number is not globally unique, it is only locally unique within a given firewall policy.
sessionid=(311)	The serial number of the firewall session of which the event happened.
srcip=(10.10.10.1)	The source IP address.
srcport=(1190)	The source port number.
srcintf=(internal)	The source interface name.
dstip=(192.168.1.122)	The destination IP address.
dstport=(80)	The destination port number.
dstintf=(wan1)	The destination interface name.
service=(https)	The IP network service that applies to the session or packet. The services displayed correspond to the services configured in the firewall policy.
status=(detected)	The action the FortiGate unit took.

Log body	
hostname=(example.com)	The home page of the web site.
url=(/image/trees_pine_ forest/)	The URL address of the web page that the user was viewing.
msg=(data leak detected (Data Leak Prevention Rule matched)	Explains the FortiGate activity that was recorded. In this example, the data leak that was detected matched the rule, All-HTTP, in the DLP sensor.
rulename=(All-HTTP)	The name of the DLP rule within the DLP sensor.
action=(log-only)	The action that was specified within the rule. In some rules within sensors, you can specify content archiving. If no action type is specified, this field display log-only.
severity=(1)	The level of severity for that specific rule.

Logs from other devices, such as the FortiAnalyzer unit and Syslog server, contain a slightly different log header. For example, when viewing FortiGate log messages on the FortiAnalyzer unit, the log header contains the following log fields when viewed in the Raw format:

```
itime=1302788921 date=20110401 time=09:04:23 devname=FG50BH3G09601792 device_
    id=FG50BH3G09601792 log_id=0100022901 type=event subtype=system level=notice vd=root
```

The log body contains the rest of the information of the log message, and this information is unique to the log message itself.

For detailed information on all log messages, see the *FortiGate Log Message Reference*.

Explanation of a debug log message

Debug log messages are only generated if the log severity level is set to Debug. The Debug severity level is the lowest log severity level and is rarely used. This severity level usually contains some firmware status information that is useful when the FortiGate unit is not functioning properly. Debug log messages are generated by all types of FortiGate features.

The following is an example of a debug log message:

```
date=2010-01-25 time=17:25:54 logid=9300000000 type=webfilter subtype=urlfilter
    level=debug msg="found in cache"
```

Example of a Debug log message

Debug log	
date=(2010-01-25)	The year, month and day of when the event occurred in the format yyyy-mm-dd.
time=(17:25:54)	The hour, minute and second of when the event occurred in the format hh:mm:ss.

Debug log	
logid=(93000000000)	A ten-digit unique identification number. The number represents that log message and is unique to that log message. This ten-digit number helps to identify the log message.
type=(webfilter)	The section of system where the event occurred. There are eleven log types in FortiOS 4.0.
subtype=(urlfilter)	The subtype of the log message. This represents a policy applied to the FortiGate feature in the firewall policy.
level=(debug)	The priority level of the event. There are six priority levels to specify.
msg=("found in cache")	Explains the activity or event that the FortiGate unit recorded.

Viewing log messages and archives

Depending on the log device, you may be able to view logs within the web-based manager or CLI on the FortiGate unit. If you have configured a FortiAnalyzer unit, local hard disk, or system memory, you can view log messages from within the web-based manager or CLI. If you have configured either a Syslog or WebTrends server, you will not be able to view log messages from the web-based manager or CLI. There is also no support for viewing log messages stored on a FortiCloud server, from the FortiGate unit's web-based manager or CLI.

You do not have to view log messages from only the web-based manager. You can view log messages from the CLI as well, using the `execute log display` command. This command allows you to see specific log messages that you already configured within the `execute log filter` command. The `execute log filter` command configures what log messages you will see, how many log messages you can view at one time (a maximum of 1000 lines of log messages), and the type of log messages you can view. For more information about viewing log messages in the CLI, see "Viewing logs from the CLI".

There are two log viewing options in FortiOS: Format and Raw. The Raw format displays logs as they appear within the log file. You can view log messages in the Raw format using the CLI or a text editor, such as Notepad. Format is in a more human-readable format, and you can easily filter information when viewing log messages this way. The Format view is what you see when viewing logs in the web-based manager.

When you download the log messages from within the log message page (for example, **Log & Report > Forward Traffic**), you are downloading log messages in the Raw format.

Viewing log messages in detail

From any log page, you can view detailed information about the log message in the log viewer table, located (by default) at the bottom of the page. Each page contains this log viewer table. The Log Viewer Table can contain the Archive tab, which allows you to see the archived version of the log message. The Archive tab only displays the archived log's details if archiving is enabled and logs are being archived by the FortiGate unit, but archived logs will also be recorded when using a FortiAnalyzer unit or the FortiCloud service.

When you are viewing traffic log messages, some of the categories (such as 'Application Name') have entries that can be selected to open a dialog box containing FortiGuard information about the entry. From within the dialog box, you can select the Reference link and go directly to the corresponding FortiGuard page, which contains additional information.

Viewing logs in Raw format allows you to view all log fields at once, as well as have a log file available regardless of whether you are archiving logs or not. You download the log file by selecting **Download Log**. The log file is named in the following format: <log_type><log_location><log_date/time>.<log_number>.log. For example, SystemEventLog-disk-2012-09-19T12_13_46.933949.log, which is an event log. The time period is the day and month of when the log was downloaded, not the time period of the log messages within the file itself.

Quarantine

Within the Log & Report menu, you can view detailed information about each quarantined file. The information can either be sorted or filtered, depending on what you want to view.

You must enable quarantine settings within an antivirus profile and the destination must be configured in the CLI using the `config antivirus quarantine` command. The destination can be either a FortiAnalyzer unit or local disk.

Sort the files by file name, date, service, status, duplicate count (DC), or time to live (TTL). Filter the list to view only quarantined files with a specific status or from a specific service.

The file quarantine list displays the following information about each quarantined file.

Quarantine page

Lists all files that are considered quarantined by the unit. On this page you can filter information so that only specific files are displayed on the page.

GUI Item	Description
Source	Either **FortiAnalyzer** or **Local Disk**, depending where you configure to quarantined files to be stored.
Sort by	Sort the list. Choose from: **Status**, **Service**, **File Name**, **Date**, **TTL**, or **Duplicate Count**. Select **Apply** to complete the sort.
Filter	Filter the list. Choose either **Status** (infected, blocked, or heuristics) or **Service** (IMAP, POP3, SMTP, FTP, HTTP, MM1, MM3, MM4, MM7, IM, or NNTP). Select **Apply** to complete the filtering. Heuristics mode is configurable through the CLI only. If your unit supports SSL content scanning and inspection Service can also be IMAPS, POP3S, SMTPS, or HTTPS. For more information, see the Security Features chapter of the FortiOS Handbook.
Apply	Select to apply the sorting and filtering selections to the list of quarantined files.
Delete	Select to delete the selected files.
Page Controls	Use the controls to page through the list.

GUI Item	Description
Remove All Entries	Removes all quarantined files from the local hard disk. This icon only appears when the files are quarantined to the hard disk.
File Name	The file name of the quarantined file. When a file is quarantined, all spaces are removed from the file name, and a 32-bit checksum is performed on the file. The checksum appears in the replacement message but not in the quarantined file. The file is stored on the FortiGate hard disk with the following naming convention: <32bit_CRC>.<processed_filename> For example, a file named Over Size.exe is stored as 3fc155d2.oversize.exe.
Date	The date and time the file was quarantined, in the format dd/mm/yyyy hh:mm. This value indicates the time that the first file was quarantined if duplicates are quarantined.
Service	The service from which the file was quarantined (HTTP, FTP, IMAP, POP3, SMTP, MM1, MM3, MM4, MM7, IM, NNTP, IMAPS, POP3S, SMTPS, or HTTPS).
Status	The reason the file was quarantined: **infected**, **heuristics**, or **blocked**.
Status Description	Specific information related to the status, for example, “File is infected with “W32/Klez.h”” or “File was stopped by file block pattern.”
DC	Duplicate count. A count of how many duplicates of the same file were quarantined. A rapidly increasing number can indicate a virus outbreak.
TTL	Time to live in the format hh:mm. When the TTL elapses, the FortiGate unit labels the file as EXP under the TTL heading. In the case of duplicate files, each duplicate found refreshes the TTL. The TTL information is not available if the files are quarantined on a FortiAnalyzer unit.
Upload status	**Y** indicates the file has been uploaded to Fortinet for analysis, **N** indicates the file has not been uploaded. This option is available only if the FortiGate unit has a local hard disk.
Download	Select to download the corresponding file in its original format. This option is available only if the FortiGate unit has a local hard disk.
Submit	Select to upload a suspicious file to Fortinet for analysis. This option is available only if the FortiGate unit has a local hard disk.

Customizing the display of log messages on the web-based manager

Customizing log messages on the web-based manager allows you to remove or add columns from the page and filter the information that appears. For example, you can view only log messages that appeared on December 4, between the hours of 8:00 and 8:30 am.

1. Select the submenu in **Log & Report** in which you want to customize the display of log messages, such as **Log & Report > Forward Traffic**.
2. Right click on the title bar at the top of any column, and uncheck a column title such as **Date/Time** to remove it from the interface. Check other columns to add them to the interface. When you are finished, click outside the menu and the page will refresh with the new column settings in place.
3. Choose a column you'd like to filter, and select the funnel icon next to the title of the column. For example, select the funnel in the Src (Source) column. In the text field, enter the source IP address 1.1.1.1 and then select the check box beside **NOT**.
   This filters out the all log messages that have the 1.1.1.1 source IP address in the source IP log field, such as the ones generated when running log tests in the CLI.
4. Select **OK** to save the customize settings, and then view the log messages on the page.
   Log messages that originate from the 1.1.1.1 source address will no longer appear in the list.

How to download log messages and view them from on a computer

After recording some activity, you can download log messages to view them from a computer. This is can be very useful when in a remote location, or if you want to view log messages at your convenience, or to view packet logs or traffic logs.

1. In Log & Report, select the submenu that you want to download log messages from.
   For example, **Log & Report > Forward Traffic**.
2. Select the **Download Log** option and save the log file to your computer.
   The log file will be downloaded like any other file. Log file names contain their log type and date in the name, so it is recommended to create a folder in which to archive your log messages, as they can be sorted easily.
3. Open a text editor such as Notepad, open the log file, and then scroll to view all the log messages.
   You can easily search or scroll through the logs to see the information that is available.

Log files and types

As the log messages are being recorded, log messages are also being put into different log files. The log file contains the log messages that belong to that log type, for example, traffic log messages are put in the traffic log file.

When downloading the log file from within **Log & Report**, the file name indicates the log type and the device on which it is stored, as well as the date, time, and a unique id for that log.

This name is in the format <logtype> - <logdevice> - <date> T <time> . <id>.log.

For example, AntiVirusLog-disk-2012-09-13T11_07_57.922495.log.

Below, each of the different log files are explained. Traffic and Event logs come in multiple types, but all contain the base type such as 'Event' in the filename.

Log Types based on network traffic

Log Type	Description
Traffic	The traffic logs records all traffic to and through the FortiGate interface. Different categories monitor different kinds of traffic, whether it be forward, local, or sniffer.
Event	The event logs record management and activity events within the device in particular areas: System, Router, VPN, User, Endpoint, HA, WAN Opt./Cache, and WiFi. For example, when an administrator logs in or logs out of the web-based manager, it is logged both in System and in User events.
Antivirus	The antivirus log records virus incidents in Web, FTP, and email traffic.
Web Filter	The web filter log records HTTP FortiGate log rating errors including web content blocking actions that the FortiGate unit performs.
Application Control	The application log records application usage, monitoring or blocking as configured in the security profiles.
Intrusion	The intrusion log records attacks that are detected and prevented by the FortiGate unit.
Email Filter	The email filter log records blocking of email address patterns and content in SMTP, IMAP, and POP3 traffic.
Vulnerability Scan	The Vulnerability Scan (Netscan) log records vulnerabilities found during the scanning of the network.
Data Leak Prevention	The Data Leak Prevention log records log data that is considered sensitive and that should not be made public. This log also records data that a company does not want entering their network.
VoIP	The VoIP log records VoIP traffic and messages. It only appears if VoIP is enabled on the Administrator Settings page.

Log database and datasets

The log database, also known as the SQL log database, is used to store logs on FortiGate units that have a built-in hard disk. The log database uses Structured Query Lanaguage (SQL), specifically it uses SQLite which is an embedded Relational Database Management System (RDBMS).

If you have disabled SQL logging and have factory defaults on the FortiGate unit, and then you upgrade the firmware, the upgrade will automatically disable SQL logging. When this occurs, you must re-enable SQL logging manually.

The FortiGate unit creates a database table for each log type, when log data is recorded. If the FortiGate unit is not recording log data, it does not create log tables for that device.

The command syntax, `get report database schema`, allows you to view all the tables, column names and types that are available to use when creating SQL statements for datasets.

If you want to view the size of the database, as well as the log database table entries, use the `get log sql status` command. This command displays the amount of free space that is available as well as the first and last log database entry time and date.

The output of the `get log sql status` command contains information similar to the following:

```
Database size: 294912
Free size in database: 0
Database Page Size: 8192
Entry number:
Event: 49
Traffic: 370
Attack: 2
AntiVirus: 4
WebFilter: 254
AntiSpam: 2
Netscan: 18
Total: 699
First entry time: 2012-09-10 11:41:02
Last entry time: 2012-09-13 02:59:59
```

The log database is not only used to store logs, but also used to extract the information for reports. Reports are built from datasets, which are SQL statements that tell the FortiGate unit how to extract the information from the database. You can create your own datasets; however, SQL knowledge is required. Default datasets are available for reports.

Notifications about network activity

Alert email messages provide notification about activities or events logged. These email messages also provide notification about log severities that are recorded, such as a critical or emergency.

You can send alert email messages to up to three email addresses. Alert messages are also logged and can be viewed from the Event Log menu, in the System Event log file.

You can use the alert email feature to monitor logs for log messages, and to send email notification about a specific activity or event logged. For example, if you require notification about administrators logging in and out, you can configure an alert email that is sent whenever an administrator logs in and out. You can also base alert email messages on the severity levels of the logs.

Before configuring alert email, you must configure at least one DNS server if you are configuring with an Fully Qualified Domain Server (FQDN). The FortiGate unit uses the SMTP server name to connect to the mail server, and must look up this name on your DNS server. You can also specify an IP address.

The default minimum log severity level is Alert. If the FortiGate unit collects more than one log message before an interval is reached, the FortiGate unit combines the messages and sends out one alert email.

How to configure email notifications

The following explains how to configure an alert email notification for IPsec tunnel errors, firewall authentication failure, configuration changes and FortiGuard license expiry.

1. In **System > Advanced**, under **Email Service**, configure the SMTP server.
   The SMTP server settings allow the FortiGate unit to know exactly where the email will be sent from, as well as

who to send it to. The SMTP server must be a server that does not support SSL/TLS connections; if the SMTP server does, the alert email configuration will not work. The FortiGate unit does not currently support SSL/TLS connections for SMTP servers.

2. In **Log & Report > Alert E-mail**, enter the source email in the Email From field, and up to three target addresses in the Email To fields.
3. Below the email entry, you can configure the email responses. By default, the **Send alert email for the following** is enabled. Select the check boxes beside **IPsec tunnel errors**, **Configuration changes** and **Firewall authentication failure**.
   These alerts will be sent to the email address specified when the trigger occurs. For example, a user attempts to connect to the branch office of the company but cannot; the FortiGate unit detects an IPsec tunnel error, records the event, and then sends the notice to the email address specified in the SMTP server settings.
4. Select **FortiGuard license expiry time:** and then enter 10 so that the email notification will be sent ten days prior to the FortiGuard license expiration.
   You can choose up to 100 days prior to when the license will expire. The default time is 15 days. By using this alert email notification, you can easily know when to send an re-registration request long before the expiry.

Log devices

The FortiGate unit supports a variety of log devices, including the FortiCloud service and FortiAnalyzer units. This provides greater flexibility not only when choosing a log device, but also when your logging requirements need updating.

When you have developed a plan that meets your logging needs and requirements, you need to select the log device that is appropriate for that plan. A log device must be able to store all the logs you need, and if you require archiving those logs, you must consider what log devices support this option.

During this process of deciding what log device meets your needs and requirements, you must also figure out how to provide a backup solution in the event the log device that the FortiGate unit is sending logs to has become unavailable. A backup solution should be an important part of your log setup because it helps you to maintain all logs and prevents lost logs, or logs that are not sent to the log device. For example, a daily backup of log files to the FortiAnalyzer unit occurs at 5 pm.

Log devices provide a central location for storing logs recorded by the FortiGate unit. The following are log devices that the FortiGate unit supports:

- FortiGate system memory
- Hard disk or AMC
- SQL database (for FortiGate units that have a hard disk)
- FortiAnalyzer unit
- FortiCloud service
- Syslog server

These log devices, except for the FortiGate system memory and local hard disk, can also be used as a backup solution. For example, you can configure logging to the FortiGate unit's local disk, but also configure logging to a FortiCloud server and archive logs to both the FortiCloud server and a FortiAnalyzer unit.

If you are formatting a disk that contains more than just logs, all information on the disk will be lost.

FortiGate unit's system memory and hard disk

The FortiGate unit's system memory and hard disk can store all log types, including log archives and traffic logs. Traffic logs and log archives are larger files, and need a lot of room when being logged by the FortiGate unit.

When the system memory is full, the FortiGate unit overwrites the oldest messages, and all log messages stored in memory are cleared when the FortiGate unit restarts. By default, logging to memory is enabled. This means that most of the time you will only need to modify the default settings to your network logging requirements. Real-time logging occurs whenever memory logging is enabled, and is enabled by default. Real-time logging means that the activity is being recorded as it happens.

All FortiGate units 100D and larger are capable of disk logging, but it is disabled by default, as it is not recommended. For flash memory-based units, constant rewrites to flash drives can reduce the lifetime and efficiency of the memory. For hard-disk units, it can affect performance under heavy strain. Therefore, disk logging must be manually enabled in the CLI under `config log disk setting` to appear in the interface at all.

Models without a hard disk are not recommended for disk logging. For all units, disk logging must be enabled in the CLI. For some low-end and older models, disk logging is unavailable. Check a product's Feature Matrix for more information. In either case, Fortinet recommends using either a FortiAnalyzer unit or the FortiCloud service.

Local disk or memory logging is not required for you to configure logging to a FortiAnalyzer unit.

If you are registered with the FortiCloud service, your unit will log both locally and to the service by default. In order to configure the rate and time of uploads to the service, you must register a contract account for the FortiCloud service, which will also grant you additional space.

FortiAnalyzer unit

The FortiAnalyzer unit can log all FortiGate features, which includes log archives. You can also configure the FortiGate unit to upload logs to the FortiAnalyzer unit at a scheduled time.

Encryption of the logs is supported by default and logs are sent using IPsec or SSL VPN. When the FortiAnalyzer and FortiGate units have SSL encryption, both must choose a setting for the enc-algorithm command (CLI) for encryption to take place. By default, this is enabled and the default setting is a SSL communication with high and medium encryption algorithms. The setting that you choose must be the same for both.

FortiGate units can support logging to multiple FortiAnalyzer units. This logging solution is a backup redundancy solution, since logs are sent to all three units and whenever one of the FortiAnalyzer units fails, the others still carry on storing logs.

If you are using evaluation software FortiGate and FortiAnalyzer-VM images, you will only be able to use low-level encryption.

The FortiGate unit can also connect to a FortiAnalyzer unit using Automatic Discovery. Automatic Discovery is a method of establishing a connection to a FortiAnalyzer unit by using the FortiGate unit to find a FortiAnalyzer unit on the network. The Fortinet Discovery Protocol (FDP) is used to located the FortiAnalyzer unit. Both the FortiGate and FortiAnalyzer units must be on the same subnet to use FDP, and they must also be able to connect using UDP.

When you enable automatic discovery in the CLI, the FortiGate unit uses HELLO packets to locate any FortiAnalyzer units that are available on the network within the same subnet. When the FortiGate unit discovers a

FortiAnalyzer unit, the FortiGate unit automatically enables logging to the FortiAnalyzer unit and begins sending log data.

Syslog server

The Syslog server is a remote computer running syslog software. Syslog is a standard for forwarding log messages in an IP network, and can be used when considering a log backup solution for your network logging requirements.

FortiGate units support the reliable syslog feature, which is based on RFC 3195. Reliable syslog logging uses TCP, which ensures that connections are set up, including that packets are transmitted.

There are several profiles available for reliable syslog, but only the RAW profile is currently supported on the FortiGate units. The RAW profile is designed to provide a high-performance, low-impact footprint using essentially the same format as the existing UDP-based syslog service. The reliable syslog feature is available on FortiGate units running FortiOS 4.0 MR1 and higher.

When enabling the reliable syslog (available only in the CLI), TCP is used. The feature is disabled by default, and when enabled, the FortiGate unit automatically changes the port number to TCP 601. This is based on RFC 3195. The default port for syslog is port 514.

If you are using the local hard disk on a device for WAN Optimization, it will not prevent you from logging to remote FortiAnalyzer devices or Syslog servers. Some models have two hard disks, allowing both local logging and Wan Opt.

If you have Virtual Domains configured, each VDOM may only be assigned one FortiAnalyzer device and one Syslog server, by overriding the global configuration. The root VDOM is not limited in this way.

How to choose a log device for your network topology

When planning the log requirements, you must also consider your network's topology and whether archiving is required, such as if there is a legal requirement to keep a historical record of network activity. The following explains what steps to take when choosing a log device for your specific network topology.

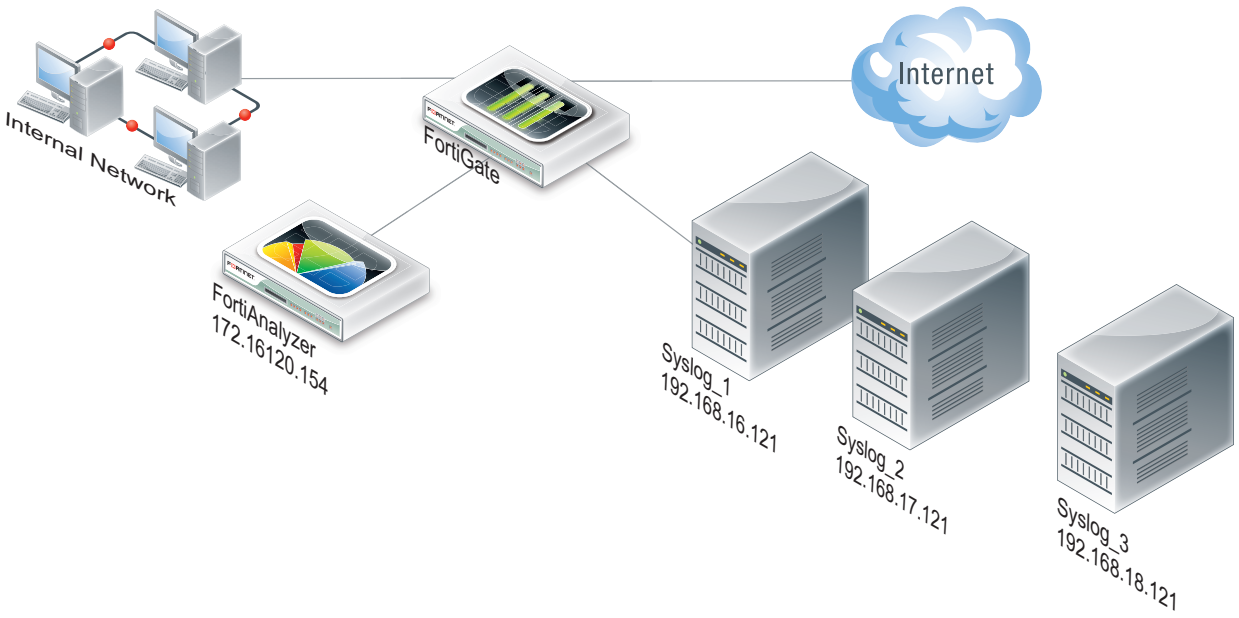
1. **What is the scope of your network topology?**
   If it is a SOHO/SMB network, then logging to the FortiGate unit's local hard disk or the default FortiCloud service would be efficient. If the network topology is a large enterprise, you will need FortiAnalyzer units, a FortiCloud contract, Syslog servers, or any combination.
2. **Is archiving required?**
   If the network activity that is being logged needs to be archived, then, depending on your network topology, you would choose a FortiAnalyzer unit. FortiAnalyzer units store archives in the same way that FortiGate units do, but are able to store large amounts of logs and archives.
3. **When troubleshooting, you may want to log a larger amount of traffic; how much storage space will you need?**
   Logs can be configured to roll, which is similar to zipping a file; this will lower the space requirements needed to contain them. You can also download logs from the FortiGate unit and save them on a server or on a computer to view and access later, to prevent them from piling up and being overwritten. If you're regularly logging large amounts of traffic, you should consider a FortiAnalyzer or FortiCloud account .

4. **Should I invest in a log device that can grow as my network grows?**
   All networks grow, so investing in a device that can grow with your network and that can be expanded is a good investment. For example, if you currently have a SOHO/SMB topology, but see growth already starting, a FortiAnalyzer unit would be best. A FortiAnalyzer unit provides ample storage space, and you can add two more FortiAnalyzer units to access additional storage and create a redundancy log backup solution.

How to create a backup solution for logging

The following helps to explain how to create a log backup solution for a small network topology. This example has one FortiAnalyzer unit and a subscription to the FortiCloud Service.

Example of an integrated FortiAnalyzer unit and Syslog servers in a network



1. Log in to the CLI and modify what features will be logged to the FortiAnalyzer unit as well as the settings to the default log device, the FortiGate unit's hard drive.
   By default, the FortiGate unit logs to either the system memory or hard drive, whichever is available on the FortiGate unit. Low-end FortiGate units may have logging disabled by default.
2. In the CLI, use the `config log fortianalyzer setting` command to configure logging to the FortiAnalyzer unit.
   You can only configure log settings for the FortiAnalyzer unit in the CLI. Configuring to upload logs to a FortiAnalyzer unit can be configured in both the CLI and web-based manager.
3. In the CLI, configure the settings for the Syslog server; also enable reliable syslog as well.
   Reliable syslog verifies that logs are sent to the syslog server. When you enable this setting, the default port becomes port 601.

Reports

Reports provide a way to analyze log data without manually going through a large amount of logs to get to the information you need. This section explains how to configure a FortiOS report and how to modify the existing default FortiOS Security Features report. The FortiOS default Security Features report is a report that gathers security feature activity information and compiles it into a report. This section also explains how to view these reports.

Reports provide a clear, concise overview of what is happening on your network based on log data, without manually going through large amounts of logs. Reports can be configured on a FortiGate unit or a FortiAnalyzer

unit. However, in this document only FortiOS reports are explained. FortiOS reports are the reports that are generated on the FortiGate unit. FortiAnalyzer reports are configured on a FortiAnalyzer unit and for information about those reports, see the FortiAnalyzer Administration Guide.

Disk logging must be enabled for local reporting to be enabled. Local Reporting can then be enabled in **System > Feature Select** in order to view and edit reports. Not all devices are capable of disk logging; check the Feature Matrix to see if your unit has a hard disk.

What are FortiOS reports?

FortiOS reports are configured from logs stored on the FortiGate unit's hard drive. These reports, generated by the FortiGate unit itself, provide a central location for both configuring and generating reports. A default FortiOS report, called the FortiGate Security Feature Daily Activity Report, is available for you to modify to your requirements. The default report provides a way to quickly and easily set up your own report from within the web-based manager. The default FortiOS report is a report that compiles security feature activity from various security-related logs, such as virus and attack logs.

What you can do with the default FortiOS report

On the **Local Reports** page, you can set the frequency and timing of auto-generated reports.

You can select **Run Now**on the **Local Reports** page to immediately create a report with the current layout and design. More complex reports may take longer to generate. After generating a report, you can view it by selecting it from the list below **Run Now**.

Historical reports will be marked as 'Scheduled' if created automatically, or 'On Demand' if created by selecting **Run Now**.

Best Practices: Log management

When the FortiGate unit records FortiGate activity, valuable information is collected that provides insight into how to better protect network traffic against attacks, including misuse and abuse. There is a lot to consider before enabling logging on a FortiGate unit, such as what FortiGate activities to enable and which log device is best suited for your network's logging needs. A plan can help you in deciding the FortiGate activities to log, a log device, as well as a backup solution in the event the log device fails.

This plan should provide you with an outline, similar to the following:

- what FortiGate activities you want and/or need logged (for example, security features)
- the logging device best suited for your network structure
- if you want or require archiving of log files
- ensuring logs are not lost in the event a failure occurs.

After the plan is implemented, you need to manage the logs and be prepared to expand on your log setup when the current logging requirements are outgrown. Good log management practices help you with these tasks.

Log management practices help you to improve and manage logging requirements. Logging is an ever-expanding tool that can seem to be a daunting task to manage. The following management practices will help you when issues arise, or your logging setup needs to be expanded.

1. Revisit your plan on a yearly basis to verify that your logging needs are being met by your current log setup. For example, your company or organization may require archival logging, but not at the beginning of your network's lifespan. Archival logs are stored on a FortiGate unit's local hard drive, a FortiAnalyzer unit, or a FortiCloud server, in increasing order of size.

2. Configure an alert message that will notify you of activities that are important to be aware about. For example: if a branch office does not have a FortiGate administrator, you will need to know at all times that the IPsec VPN tunnel is still up and running. An alert email notification message can be configured to send only if IPsec tunnel errors occur.
3. If your organization or company uses peer-to-peer programs such as Skype or other instant messaging software, use the Applications FortiView dashboard, or the Executive Summary's report widget (Top 10 Application Bandwidth Usage Per Hour Summary) to help you monitor the usage of these types of instant messaging software. These widgets can help you in determining how these applications are being used, including if there is any misuse and abuse. Their information is taken from application log messages; however, application log messages should be viewed as well since they contain the most detailed information.
4. Ensure that your backup solution is up-to-date. If you have recently expanded your log setup, you should also review your backup solution. The backup solution provides a way to ensure that all logs are not lost in the event that the log device fails or issues arise with the log device itself.

Logging and reporting for small networks

This section explains how to configure the FortiGate unit for logging and reporting in a small office or SOHO/SMB network. To properly configure this type of network, you will be modifying the default log settings, as well as the default FortiOS report.

The following procedures are examples and can be used to help you when configuring your own network's log topology. Since some of these settings must be modified or enabled or disabled in the CLI, it is recommended to review the FortiGate CLI Reference for any additional information about the commands used herein, as well as any that you would need to use in your own network's log topology.

Modifying default log device settings

The default log device settings must be modified so that system performance is not compromised. The FortiGate unit, by default, has all logging of FortiGate features enabled, except for traffic logging. The default logging location will be either the FortiGate unit's system memory or hard disk, depending on the model. Units with a flash disk are not recommended for disk logging.

Modifying the FortiGate unit's system memory default settings

When the FortiGate unit's default log device is its system memory, the following is modified for a small network topology. The following is an example of how to modify these default settings.

To modify the default system memory settings

1. Log in to the CLI.
2. Enter the following command syntax to modify the logging settings:

```
config log memory setting
   set ips-archive disable
   set status enable
end
```

3. The following example command syntax modifies which FortiGate features that are enabled for logging:

```
config log memory filter
   set forward-traffic enable
   set local-traffic enable
   set sniffer-traffic enable
   set anomaly enable
   set voip disable
   set multicast-traffic enable
   set dns enable
end
```

Modifying the FortiGate unit's hard disk default settings

When the FortiGate unit's default log device is its hard disk, you need to modify those settings to your network's logging needs so that you can effectively log what you want logged. The following is an example of how to modify these default settings.

To modify the default hard disk settings

1. Log in to the CLI.
2. Enter the following command syntax to modify the logging settings:

```
config log disk setting
   set ips-archive disable
   set status enable
   set max-log-file-size 1000
   set storage FLASH
   set log-quota 100
   set report-quota 100
end
```

3. In the CLI, enter the following to disable certain event log messages that you do not want logged:

```
config log disk filter
   set sniffer-traffic disable
   set local-traffic enable
end
```

Testing sending logs to the log device

After modifying both the settings and the FortiGate features for logging, you can test that the modified settings are working properly. This test is done in the CLI.

To test sending logs to the log device

1. In the CLI, enter the following command syntax:

```
diag log test
```

When you enter the command, the following appears:

```
generating a system event message with level - warning
generating an infected virus message with level - warning
generating a blocked virus message with level - warning
generating a URL block message with level - warning
generating a DLP message with level - warning
generating an IPS log message
generating an anomaly log message
generating an application control IM message with level - information
generating an IPv6 application control IM message with level - information
generating deep application control logs with level - information
generating an antispam message with level - notification
generating an allowed traffic message with level - notice
generating a multicast traffic message with level - notice
generating a ipv6 traffic message with level - notice
generating a wanopt traffic log message with level - notification
generating a HA event message with level - warning
generating netscan log messages with level - notice
generating a VOIP event message with level - information
generating a DNS event message with level - information
generating authentication event messages
generating a Forticlient message with level - information
generating a NAC QUARANTINE message with level - notification
generating a URL block message with level - warning
```

2. In the web-based interface, go to **Log & Report > System Events**, and view the logs to see some of the recently generated test log messages.
   You will be able to tell the test log messages from real log messages because they do not have “real” information; for example, the test log messages for the vulnerability scan contain the destination IP address of 1.1.1.1 or 2.2.2.2.

Configuring the backup solution

A backup solution provides a way to ensure logs are not lost. The following backup solution explains logging to a FortiCloud server and uploading logs to a FortiAnalyzer unit. With this backup solution, there can be three simultaneous storage locations for logs, the first being the FortiGate unit itself, the FortiAnalyzer unit and then the FortiCloud server.

Configuring logging to a FortiCloud server

The FortiCloud server can be used as a redundant backup, or your primary logging solution. The following assumes that this service has already been registered, and a subscription has been purchased for expanded space. The following is an example of how to these settings are configured for a network’s log configuration. You need to have access to both the CLI and the web-based manager when configuring uploading of logs. The upload time and interval settings can be configured in the web-based interface.

To configure logging to the FortiCloud server

1. Go to **Dashboard** and click **Login** next to **FortiCloud** in the **License Information** widget.
2. Enter your username and password, and click **OK**. (Or register, if you have not yet done so.)
3. Logs will automatically be uploaded to FortiCloud as long as your FortiGate is linked to your FortiCloud account.
4. To configure the upload time and interval, go to **Log & Report > Log Settings**.
5. Under the Logging and Archiving header, you can select your desired upload time.

With FortiCloud you can easily store and access FortiGate logs that can give you valuable insight into the health and security of your network.

Configuring uploading logs to the FortiAnalyzer unit

The logs will be uploaded to the FortiAnalyzer unit at a scheduled time. The following is an example of how to upload logs to a FortiAnalyzer unit.

To upload logs to a FortiAnalyzer unit

1. Go to **Log & Report > Log Settings**.
2. In the **Logging and Archiving** section, select the check box beside **Send Logs to FortiAnalyzer/FortiManager.**
3. Select **FortiAnalyzer (Daily at 00:00)**.
4. Enter the FortiAnalyzer unit’s IP address in the **IP Address** field.
5. To configure the daily upload time, open the CLI.
6. Enter the following to configure when the upload occurs, and the time when the unit uploads the logs:

```
config log fortianalyzer setting
   set upload-interval {daily | weekly | monthly}
   set upload-time <hh:mm>
end
```

7. To change the upload time, in the web-based manager, select **Change** beside the upload time period, and then make the changes in the Upload Schedule window. Select **OK**.

Testing uploading logs to a FortiAnalyzer unit

You should test that the FortiGate unit can upload logs to the FortiAnalyzer unit, so that the settings are configured properly.

To test the FortiAnalyzer upload settings

1. Go to **Log & Report > Log Settings.**
2. In the **Logging and Archiving** section, under **Send Logs to FortiAnalyzer/FortiManager**, change the time to the current time by selecting **Change**.
   For example, the current time is 11:10 am, so **Change** now has the time 11:10.
3. Select **OK**.

The logs will be immediately sent to the FortiAnalyzer unit, and will be available to view from within the FortiAnalyzer's interface.

Logging and reporting for large networks

This section explains how to configure the FortiGate unit for logging and reporting in a larger network, such as an enterprise network. To set up this type of network, you are modifying the default log settings, and you are also modifying the default report.

The following procedures are examples and can be used to help you when configuring your own network's log topology.

Since some of these settings must be modified or enabled or disabled in the CLI, it is recommended to review the FortiGate CLI Reference for any additional information about the commands used herein, as well as any that you would need to use in your own newtork's log topology.

Modifying default log device settings

The default log device settings must be modified so that system performance is not compromised. The FortiGate unit, by default, has all logging of FortiGate features enabled and well as logging to either the FortiGate unit's system memory or hard disk, depending on the model.

Modifying multiple FortiGate units' system memory default settings

When the FortiGate unit's default log device is its system memory, you can modify it to fit your log network topology. In this topic, the following is an example of how you can modify these default settings.

To modify the default system memory settings

1. Log in to the CLI.
2. Enter the following command syntax to modify the logging settings:

```
config log memory setting
   set ips-archive disable
   set status enable
end
```

3. Enter the following command syntax to modify the FortiGate features that are enabled for logging:

```
config log memory filter
   set forward-traffic enable
   set local-traffic enable
   set sniffer-traffic enable
   set anomaly enable
   set voip disable
   set multicast-traffic enable
   set dns enable
end
```

4. Repeat steps 2 and 3 for the other FortiGate units.
5. Test the modified settings using the procedure below.

Modifying multiple FortiGate units' hard disk default log settings

You will have to modify each FortiGate unit's hard disk default log settings. The following is an example of how to modify these default settings.

To modify the default hard disk settings

1. Log in to the CLI.
2. Enter the following command syntax to modify the logging settings:

```
config log disk setting
   set ips-archive disable
   set status enable
   set max-log-file-size 1000
   set storage Internal
   set log-quota 100
   set report-quota 100
end
```

3. In the CLI, enter the following to disable certain event log messages that you do not want logged:

```
config log disk filter
   set sniffer-traffic disable
   set local-traffic enable
end
```

4. Repeat the steps 2 to 4 for the other FortiGate units.
5. Test the modified settings using the procedure below.

Testing the modified log settings

After modifying both the settings and the FortiGate features for logging, you can test that the modified settings are working properly. This test is done in the CLI.

To test sending logs to the log device

1. In the CLI, enter the following command syntax:

```
diag log test
```

When you enter the command, the following appears:

```
generating a system event message with level - warning
generating an infected virus message with level - warning
generating a blocked virus message with level - warning
generating a URL block message with level - warning
generating a DLP message with level - warning
generating an IPS log message
generating an anomaly log message
generating an application control IM message with level - information
generating an IPv6 application control IM message with level - information
generating deep application control logs with level - information
generating an antispam message with level - notification
generating an allowed traffic message with level - notice
generating a multicast traffic message with level - notice
generating a ipv6 traffic message with level - notice
generating a wanopt traffic log message with level - notification
generating a HA event message with level - warning
```

```
generating netscan log messages with level - notice
generating a VOIP event message with level - information
generating a DNS event message with level - information
generating authentication event messages
generating a Forticlient message with level - information
generating a NAC QUARANTINE message with level - notification
generating a URL block message with level - warning
```

2. In the web-based interface, go to **Log & Report > System Events**, and view the logs to see some of the recently generated test log messages.
   You will be able to tell the test log messages from real log messages because they do not have “real” information; for example, the test log messages for the vulnerability scan contain the destination IP address of 1.1.1.1 or 2.2.2.2.

Configuring the backup solution

Even though you are logging to multiple FortiAnalyzer units, this is more of a redundancy solution rather than a complete backup solution in this example.

The multiple FortiAnalyzer units act similar to a HA cluster, since if one FortiAnalyzer unit fails, the others continue storing the logs they receive. In a backup solution, the logs are backed up to another secure location if something happens to the log device.

A good alternate or redundant option is the FortiCloud service, which can provide secure online logging and management for multiple devices.

Configuring logging to multiple FortiAnalyzer units

The following example shows how to configure logging to multiple FortiAnalyzer units. Configuring multiple FortiAnalyzer units is quick and easy; however, you can only configure up to three FortiAnalyzer units per FortiGate unit.

To configure multiple FortiAnalyzer units

1. In the CLI, enter the following command syntax to configure the first FortiAnalyzer unit:

```
config log fortianalyzer setting
   set status enable
   set server 172.20.120.22
   set max-buffer-size 1000
   set buffer-max-send 2000
   set address-mode static
   set conn-timeout 100
   set monitor-keepalive-period 120
   set monitor-failure-retry-period 2000
end
```

2. Disable the features that you do not want logged, using the following example command syntax. You can view the CLI Reference to see what commands are available.

```
config log fortianalyzer filter
   set forward-traffic (enable | disable)
   ...
end
```

3. Enter the following commands for the second FortiAnalyzer unit:

```
    config log fortianalyzer2 setting
       set status enable
       set server 172.20.120.23
       set max-buffer-size 1000
       set buffer-max-send 2000
       set address-mode static
       set conn-timeout 100
       set monitor-keepalive-period 120
       set monitor-failure-retry-period 2000
end
```

4. Disable the features that you do not want logged, using the following example command syntax.

```
config log fortianalyzer filter
   set event (enable | disable)
   ...
end
```

5. Enter the following commands for the last FortiAnalyzer unit:

```
    config log fortianalyzer3 setting
       set status enable
       set server 172.20.120.23
       set max-buffer-size 1000
       set buffer-max-send 2000
       set address-mode static
       set conn-timeout 100
       set monitor-keepalive-period 120
       set monitor-failure-retry-period 2000
end
```

6. Disable the features that you do not want logged, using the following example command syntax.

```
config log fortianalyzer filter
   set voip (enable | disable)
   ...
end
```

7. Test the configuration by using the procedure, "Testing the modified log settings".
8. On the other FortiGate units, configure steps 1 through 6, ensuring that logs are being sent to the FortiAnalyzer units.

Configuring logging to the FortiCloud server

The FortiCloud server can be used as a redundant backup, or your primary logging solution. The following assumes that this service has already been registered, and a subscription has been purchased for expanded space. The following is an example of how to these settings are configured for a network's log configuration. You need to have access to both the CLI and the web-based manager when configuring uploading of logs. The upload time and interval settings can be configured in the web-based interface.

To configure logging to the FortiCloud server

1. Go to **Dashboard** and click **Login** next to **FortiCloud** in the License Information widget.
2. Enter your username and password, and click **OK**. (Or register, if you have not yet done so.)
3. Logs will automatically be uploaded to FortiCloud as long as your FortiGate is linked to your FortiCloud account.
4. To configure the upload time and interval, go to **Log & Report > Log Settings**.

5. Under the Logging and Archiving header, you can select your desired upload time.
6. With FortiCloud you can easily store and access FortiGate logs that can give you valuable insight into the health and security of your network.

Advanced logging

This section explains how to configure other log features within your existing log configuration. You may want to include other log features after initially configuring the log topology because the network has either outgrown the initial configuration, or you want to add additional features that will help your network's logging requirements.

The following topics are included in this section:

- Configuring logging to multiple Syslog servers
- Using Automatic Discovery to connect to a FortiAnalyzer unit
- Activating a FortiCloud account for logging purposes
- Viewing log storage space
- Customizing and filtering log messages
- Viewing logs from the CLI
- Configuring NAC quarantine logging
- Logging local-in policies
- Tracking specific search phrases in reports
- Advanced logging

Configuring logging to multiple Syslog servers

When configuring multiple Syslog servers (or one Syslog server), you can configure reliable delivery of log messages from the Syslog server. Configuring of reliable delivery is available only in the CLI.

If VDOMs are enabled, you can configure separate FortiAnalyzer unit or Syslog server for each VDOM.

To enable logging to multiple Syslog servers

1. Log in to the CLI.
2. Enter the following commands:

```
config log syslogd setting
   set csv {disable | enable}
   set facility <facility_name>
   set port <port_integer>
   set reliable {disable | enable}
   set server <ip_address>
   set status {disable | enable}
end
```

3. Enter the following commands to configure the second Syslog server:

```
config log syslogd2 setting
   set csv {disable | enable}
   set facility <facility_name>
   set port <port_integer>
   set reliable {disable | enable}
   set server <ip_address>
   set status {disable | enable}
end
```

4. Enter the following commands to configure the third Syslog server:

```
config log syslogd3 setting
   set csv {disable | enable}
   set facility <facility_name>
   set port <port_integer>
   set reliable {disable | enable}
   set server <ip_address>
   set status {disable | enable}
end
```

Most FortiGate features are, by default, enabled for logging. You can disable individual FortiGate features you do not want the Syslog server to record, as in this example:

```
config log syslogd filter
   set local-traffic {enable | disable}
   set severity {alert | critical | debug | emergency | error | information |
       notification | warning}
end
```

Using Automatic Discovery to connect to a FortiAnalyzer unit

Automatic Discovery can be used if the FortiAnalyzer unit is on the same network.

To connect using automatic discovery

1. Log in to the CLI.
2. Enter the following command syntax:

```
config log fortianalyzer setting
   set status enable
   set server <ip_address>
   set gui-display enable
   set address-mode auto-discovery
end
```

If your FortiGate unit is in Transparent mode, the interface using the automatic discovery feature will not carry traffic. For more information about how to enable the interface to also carry traffic when using the automatic discovery feature, see the Fortinet Knowledge Base article, Fortinet Discovery Protocol in Transparent mode.

The FortiGate unit searches within the same subnet for a response from any available FortiAnalyzer units.

Activating a FortiCloud account for logging purposes

When you subscribe to FortiCloud, you can configure to send logs to the FortiCloud server. The account activation can be done within the web-based manager, from the **License Information** widget located in **Dashboard**.

From this widget, you can easily create a new account, or log in to the existing account. From within the License Information widget, after the account is activated, you can go directly to the FortiCloud web portal, or log out of the service if you are already logged in.

To activate a FortiCloud account for logging purposes:

The following assumes that you are already at **Dashboard** and that you have located the License Information widget.

1. In the License Information widget, select **Activate** in the **FortiCloud** section.
   The Registration window appears. From this window, you create the login credentials that you will use to access the account.
2. Select **Create Account** and enter then information for the login credentials.
   After entering the login credentials, you are automatically logged in to your FortiCloud account.
3. Check that the account has been activated by viewing the account status from the License Information widget.

If you need more space, you can subscribe to the 200Gb FortiCloud service by selecting **Upgrade** in the **FortiCloud** section of the widget.

Viewing log storage space

The `diag sys logdisk usage` command allows you to view detailed information about how much space is currently being used for logs. This is useful when you see a high percentage, such as 92 percent for the disk's capacity. The FortiGate unit uses only 75 percent of the available disk capacity to avoid a high storage amount so when there is a high percentage, it refers to the percentage of the 75 percent that is available. For example, 92 percent of the 75 percent is available.

The following is an example of what you may see when you use `diag sys logdisk usage` command on a unit with no VDOMs configured:

```
diag sys logdisk usage
```

The following appears:

```
Total HD usage: 176MB/3011 MB
Total HD logging space: 22583MB
Total HD logging space for each vdom: 22583MB
HD logging space usage for vdom "root": 30MB/22583MB
```

Customizing and filtering log messages

When viewing log messages, you may want to customize and filter the information that you are seeing in the Log & Report menu (for example, Log & Report > Traffic Log > Forward Traffic). Filtering and customizing the display provides a way to view specific log information without scrolling through pages of log messages to find the information.

Customizing log messages is the process of removing or adding columns to the log display page, allowing you to view certain desired information. The most columns represent the fields from within a log message, for example, the user column represents the user field, as well as additional information. If you want to reset the customized columns on the page back to their defaults, you need to select **Reset All Columns** within the column title right-click menu.

Filtering information is similar to customizing, however, filtering allows you to enter specific information that indicates what should appear on the page. For example, including only log messages that appeared on February 24, between the hours of 8:00 and 8:30 am.

To customize and filter log messages

The following is an example that displays all traffic log messages that originate from the source IP address 172.20.120.24, as well as displaying only the columns:

- OS Name
- OS Version
- Policy ID
- Src (Source IP)

The following assumes that you are already on the page of the log messages you want to customize and filter. In this example, the log messages that we are customizing and filtering are in **Log & Report > Forward Traffic**.

1. On the Forward Traffic page, right click anywhere on a column title.
2. Right click on a column title, and mouse over **Column Settings** to open the list.
3. Select each checkmarked title to uncheck it and remove them all from the displayed columns.
4. Scroll down to the list of unchecked fields and select 'OS Name', 'OS Version', 'Policy ID', and 'Src' to add checkmarks next to them.
5. Click outside the menu, and wait for the page to refresh with the new settings in place.
6. Select the funnel icon next to the word Src in the title bar of the Src column.
7. Enter the IP you want displayed (in this example, 172.20.120.24) in the text box.
8. Click **Apply**, and wait for the page to reload.

Viewing logs from the CLI

You can easily view log messages from within the CLI. In this example, we are viewing DLP log messages.

1. Log in to the CLI and then enter the following to configure the display of the DLP log messages.

   ```
   execute log filter category 9
   execute log filter start-line 1
   execute log filter view-lines 20
   ```

   The customized display of log messages in the CLI is similar to how you customize the display of log messages in the web-based manager. For example, `category 9` is the DLP log messages, and the `start-line` is the first line in the log database table for DLP log messages, and there will be 20 lines (`view-lines 20`) that will display.

2. Enter the following to view the log messages:

   ```
   execute log display
   ```

   The following appears below execute log display:

   ```
   600 logs found
   20 logs returned
   ```

   along with the 20 DLP log messages.

Configuring NAC quarantine logging

NAC quarantine log messages provide information about what was banned and quarantined by a Antivirus profile. The following explains how to configure NAC quarantine logging and enable it on a policy. This procedure assumes the Antivirus profile is already in place.

To configure NAC quarantine logging

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select the policy that you want to apply the Antivirus profile to, and then select **Edit**.
3. Within the Security Profiles section, enable **Antivirus** and then select the profile from the drop-down list.
4. Select **OK**.
5. Log in to the CLI.
6. Enter the following to enable NAC quarantine in the DLP sensor:

```
config antivirus profile
   edit <profile_name>
      config nac-quar log enable
   end
```

Logging local-in policies

Local-in security policies are policies the control the flow of internal traffic, and can be used to broaden or restrict an administrator's access privileges. These local-in policies can also be configured to log traffic and activity that the policies control.

You can enable logging of local-in policies in the CLI, with the following commands:

```
config system global
   set gui-local-in-policy enable
end
```

The Local-In Policy page will then be available in **Policy & Objects > Local In Policy**. You can configure what local-in traffic to log in the CLI, or in **Log & Report > Log Settings**, under **Local Traffic Logging**.

When deciding what local-in policy traffic you want logged, consider the following:

Special Traffic

Traffic activity	Traffic Direction	Description
FortiGuard update annoucements	IN	All push announcements of updates that are coming from the FortiGuard system. For example, IPS or AV updates.
FortiGuard update requests	OUT	All updates that are checking for antivirus or IPS as well as other FortiGuard service updates.
Firewall authentication	IN	The authentication made using either the web-based manager or CLI.
Central management (a FortiGate unit being managed by a FortiManager unit)	IN	The access that a FortiManager has managing the FortiGate unit.

Traffic activity	Traffic Direction	Description
DNS	IN	All DNS traffic.
DHCP/DHCP Relay	IN	All DHCP and/or DHCP Relay traffic.
HA (heart beat sync policy)	IN/OUT	For high-end platforms with a backplane heart beat port.
HA (Session sync policy)	IN/OUT	This will get information from the CMDB and updated by session sync daemon.
CAPWAP	IN	This activity is logged only when a HAVE_CAPWAP is defined.
Radius	IN	This is recorded only within FortiCarrier.
NETBIOS forward	IN	Any interface that NETBIOS forward is enabled on.
RIP	IN	
OSPF	IN	
VRRP	IN	
BFD	IN	
IGMP	IN	This is recorded only when PIM is enabled.
PIM	IN	This is recorded only when PIM is enabled.
BGP	IN	This is recorded only when config bgp and bgp neightbor is enabled in the CLI.
WCCP policy	IN	Any interface that WCCP is enabled; however, if in Cache mode, this is not recorded because it is not available.
WAN Opt/ Web Cache	IN	Any interface where WAN Opt is enabled.
WANOpt Tunnel	IN	This is recorded when HAVE_WANOPT is defined.
SSL-VPN	IN	Any interface from a zone where the action in the policy is SSL VPN.
IPSEC	IN	
L2TP	IN	
PPTP	IN	
VPD	IN	This is recorded only when FortiClient is enabled.

Traffic activity	Traffic Direction	Description
Web cache db test facility	IN	This is recorded only when WA_CS_REMOTE_TEST is defined.
GDBserver	IN	This is recorded only when debug is enabled.

Tracking specific search phrases in reports

It is possible to use the Web Filter to track specific search keywords and phrases and record the results for display in the report.

You should verify that the web filter profile you are using indicates what search phrases you want to track and monitor, so that the report includes this information.

1. **Log in to the CLI and enter show webfilter profile default.**
   This provides details about the webfilter profile being used by the security policy. In this example, the details (shown in the following in bold) indicate that safe search is enabled, but not specified or being logged.

```
show webfilter profile default
   config webfilter profile
      edit "default"
         set comment "default web filtering"
         set inspection-mode flow-based
         set options https-scan
         set post-action comfort
            config web
               set safe-search url
            end
            config ftgd-wf
               config filters
                  edit 1
                     set action block
                     set category 2
                  next
                  edit 2
                     set action block
                     set category 7
                  next
                  edit 3
                     set action block
                     set category 8
```

2. **Enter the following command syntax so that logging and the keyword for the safe search will be included in logging.**

```
config webfilter profile
   edit default
      config web
         set log-search enable
         set keyword-match "fortinet" "easter" "easter bunny"
      end
   end
```

3. **To test that the keyword search is working, go to a web browser and begin searching for the words that were included in the webfilter profile, such as easter.**
   You can tell that the test works by going to **Log & Report > Forward Traffic** and viewing the log messages.

Troubleshooting and logging

This section explains how to troubleshoot logging configuration issues, as well as connection issues, that you may have with your FortiGate unit and a log device. This section also contains information about how to use log messages when troubleshooting issues that are about other FortiGate features, such as VPN tunnel errors.

Using log messages to help in troubleshooting issues

Log messages can help when troubleshooting issues that occur, since they can provide details about what is occurring. The uses and methods for involving logging in troubleshooting vary depending on the problem. The following are examples of how log messages can assist when troubleshooting networking issues.

Using IPS packet logging in diagnostics

This type of logging should only be enabled when you need to know about specific diagnostic information, for example, when you suspect a signature is triggered by a false positive. These log messages can help troubleshoot individual problems with misidentified or missing packets and network intrusions involving malicious packets.

To configure IPS packet logging

1. Go to **Security Profiles > Intrusion Protection**.
2. Select the IPS sensor that you want to enable IPS packet logging on, and then select **Edit**.
3. In the filter options, enable **Packet Logging**.
4. Select **OK**.

If you want to configure the packet quota, number of packets that are recorded before alerts and after attacks, use the following procedure.

To configure additional settings for IPS packet logging

1. Log in to the CLI.
2. Enter the following to start configuring additional settings:

```
config ips settings
     set ips-packet-quota <integer>
     set packet-log-history <integer>
     set packet-log-post-attack <integer>
end
```

Using HA log messages to determine system status

When the FortiGate unit is in HA mode, you may see the following log message content within the event log:

```
type=event subtype=ha level=critical msg= "HA slave heartbeat interface internal lost
    neighbor information"
```

OR

```
type=event subtype=ha level=critical msg= "Virtual cluster 1 of group 0 detected new
    joined HA member"
```

OR

```
type=event subtype=ha level=critical msg= "HA master heartbeat interface internal get peer
    information"
```

The log messages occur within a given time, and indicate that the units within the cluster are not aware of each other anymore. These log messages provide the information you need to fix the problem.

Connection issues between FortiGate unit and logging devices

If external logging devices are not recording the log information properly or at all, the problem will likely be due to one of two situations: no data is being received because the log device cannot be reached, or no data is being sent because the FortiGate unit is no longer logging properly.

Unable to connect to a supported log device

After configuring logging to a supported log device, and testing the connection, you may find you cannot connect. To determine whether this is the problem:

1. Verify that the information you entered is correct; it could be a simple mistake within the IP address or you may have not selected **Apply** on the Log Settings page after changing them, which would prevent them from taking effect.
2. Use `execute ping` to see if you can ping to the log device.
3. If you are unable to ping to the log device, check to see if the log device itself working and that it is on the network and assigned an appropriate address.

FortiGate unit has stopped logging

If the FortiGate unit stopped logging to a device, test the connection between both the FortiGate unit and device using the execute ping command. The log device may have been turned off, is upgrading to a new firmware version, or just not working properly.

The FortiGate unit may also have a corrupted log database. When you log into the web-based manager and you see an SQL database error message, it is because the SQL database has become corrupted. View "SQL database errors" in the next section before taking any further actions, to avoid losing your current logs.

Log database issues

If attempting to troubleshoot issues with the SQL log database, use the following to help guide you to solving issues that occur.

SQL statement syntax errors

There may be errors or inconsistencies in the SQL used to maintain the database. Here are some example error messages and possible causes:

```
You have an error in your SQL syntax (remote/MySQL)
```

or

```
ERROR: syntax error at or near... (local/PostgreSQL)
```

- Verify that the SQL keywords are spelled correctly, and that the query is well-formed.
- Table and column names are demarked by grave accent (`) characters. Single (') and double (") quotation marks will cause an error.

```
No data is covered.
```

- The query is correctly formed, but no data has been logged for the log type. Verify that you have configured the FortiGate unit to save that log type. On the Log Settings page, make sure that the log type is checked.

Connection problems

If well-formed SQL queries do not produce results, and logging is turned on for the log type, there may be a database configuration problem with the remote database.

Ensure that:

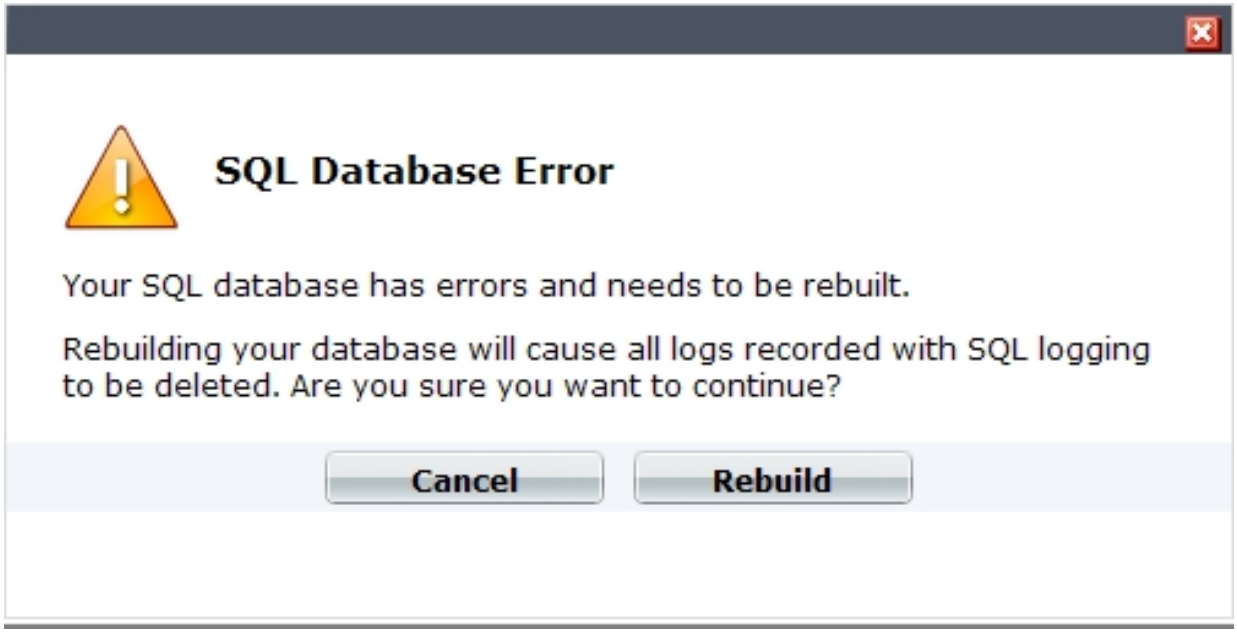
- MySQL is running and using the default port 3306.
- You have created an empty database and a user who has read/write permissions for the database.
- Here is an example of creating a new MySQL database named fazlogs, and adding a user for the database:

1. `#Mysql -u root -p`
2. `mysql>` Create database fazlogs;
3. `mysql>` Grant all privileges on fazlogs.* to 'fazlogger'@'*' identified by 'fazpassword';
4. `mysql>` Grant all privileges on fazlogs.* to 'fazlogger'@'localhost' identified by 'fazpassword';

SQL database errors

If the database seems inacessible, you may encounter the following error message after upgrading or downgrading the FortiGate unit's firmware image.

Example of an SQL database error message



The error message indicates that the SQL database is corrupted and cannot be updated with the SQL schemas any more. When you see this error message, you can do one of the following:

- select **Cancel** and back up all log files; then select **Rebuild** to blank and rebuild the database.
- select **Rebuild** immediately, which will blank the database and previous logs will be lost.

Until the database is rebuilt, no information will be logged by the FortiGate unit regardless of the log settings that are configured on the unit. When you select **Rebuild**, all logs are lost because the SQL database is erased and then rebuilt again. Logging resumes automatically according to your settings after the SQL database is rebuilt.

To view the status of the database, use the `diagnose debug sqldb-error status` command in the CLI. This command will inform you whether the database has errors present.

If you want to view the database's errors, use the `diagnose debug sqldb-error read` command in the CLI. This command indicates exactly what errors occurred, and what tables contain those errors.

Log files are backed up using the `execute backup {disk | memory } {alllogs | logs}` command in the CLI. You must use the text variable when backing up log files because the text variable allows you to view the log files outside the FortiGate unit. When you back up log files, you are really just copying the log files from the database to a specified location, such as a TFTP server.

Logging daemon (Miglogd)

The number of logging daemon child processes has been made available for editing. A higher number can affect performance, and a lower number can affect log processing time, although no logs will be dropped or lost if the number is decreased.

If you are suffering from performance issues, you can alter the number of logging daemon child processes, from 0 to 15, using the following syntax. The default is 8.

```
config system global
   set miglogd-children <integer>
end
```

Chapter 20 - Managing Devices

What's New in FortiOS 5.4
Managing “bring your own device”

This handbook chapter contains the following sections:

Managing “bring your own device” describes device monitoring, devices, device groups, and device policies. The administrator can monitor all types of devices and control their access to network resources.

What's New in FortiOS 5.4

802.1x Mac Authentication Bypass (197218)

Some FortiGate models contain a hardware switch. On the hardware switch interface, 802.1X authentication is available. You might want to bypass 802.1X authentication for devices such as printers that cannot authenticate, identifying them by their MAC addresses.

In the CLI, enable MAC authentication bypass on the interface:

```
config system interface
   edit "lan"
      set ip 10.0.0.200 255.255.255.0
      set security-mode 802.1X
      set security-mac-auth-bypass enable
      set security-groups "Radius-group"
   end
```

The devices that bypass authentication have entries in the RADIUS database with their MAC address in the User-Name and User-Password attributes instead of user credentials.

Vulnerability Scan status change(293156)

The FortiGate will no longer function as a vulnerability scanner, even in CLI mode. Vulnerability scans / assessments will handled by the FortiClient software.

FortiFone devices are now identified by FortiOS (289921)

FortiFone devices are now identified by FortiOS as **Fortinet FON**.

Support for MAC Authentication Bypass (MAB) (197218)

MAC Authentication Bypass allows devices without 802.1X capability (printers and IP phones for example) to bypass authentication and be allowed network access based on their MAC address. This feature requires RADIUS-based 802.1X authentication in which the RADIUS server contains a database of authorized MAC addresses.

MAC Authentication Bypass is configurable only in the CLI and only on interfaces configured for 802.1X authentication. For example:

```
config system interface
   edit "lan"
      set ip 10.0.0.200 255.255.255.0
      set vlanforward enable
      set security-mode 802.1X
      set security-mac-auth-bypass enable
      set security-groups "Radius-group"
   end
end
```

MAC Authentication Bypass is also available on WiFi SSIDs, regardless of authentication type. It is configurable only in the CLI. You need to enable the `radius-mac-auth` feature and specify the RADIUS server that will be used. For example:

```
config wireless-controller vap
   edit "office-ssid"
      set security wpa2-only-enterprise
      set auth usergroup
      set usergroup "staff"
      set radius-mac-auth enable
      set radius-mac-auth-server "ourRadius"
   end
end
```

Active device identification (279278)

Hosts whose device type cannot be determined passively are actively scanned using the same techniques as the vulnerability scan. This active scanning is enabled by default on models that support vulnerability scanning. You can turn off Active Scanning on any interface. In the GUI, go to the interface's page in **Network > Interfaces**.

CLI Syntax:

```
config system interface
   edit port1
      set device-identification enable
      set device-identification-active-scan disable
   end
```

Device Page Improvements (Detected and custom devices) (280271)

Devices are now in two lists on the **User & Device** menu. Detected devices are listed in the **Device List** where you can list them alphabetically, by type, or by interface. On the **Custom Devices and Groups** page you can

- create custom device groups
- predefine a device, assigning its device type and adding it to custom device groups

Device offline timeout is adjustable (269104)

A device is considered offline if it has not sent any packets during the timeout period. Prior to FortiOS 5.4, the timeout value was fixed at 90 seconds. Now the timeout can be set to any value from 30 to 31 536 000 seconds (365 days). The default value is 300 seconds (5 minutes). The timer is in the CLI:

```
config system global
   set device-idle-timeout 300
end
```

Improved detection of FortiOS-VM devices (272929)

A FortiGate-VM device is an instance of FortiOS running on a virtual machine (VM). The host computer does not have the Fortinet MAC addresses usually used to detect FortiGate units. Device detection now has two additional ways to detect FortiGate-VMs:

- the FortiGate vendor ID in FortiOS IKE messages
- the FortiGate device ID in FortiGuard web filter and spamfilter requests

Custom avatars for custom devices (299795)

You can upload an avatar for a custom device. The avatar is then displayed in the GUI wherever the device is listed, such as FortiView, log viewer, or policy configuration. To upload an avatar image,click Upload Image on

the New Device or Edit Device page of **User & Device > Custom Devices & Groups**. The image can be in any format your browser supports and will be automatically sized to 36 x 36 pixels for use in the FortiGate GUI.

Managing “bring your own device”

FortiOS can control network access for different types of personal mobile devices that your employees bring onto your premises. You can:

- identify and monitor the types of devices connecting to your networks, wireless or wired
- use MAC address based access control to allow or deny individual devices
- create security policies that specify device types
- enforce endpoint control on devices that can run FortiClient Endpoint Control software

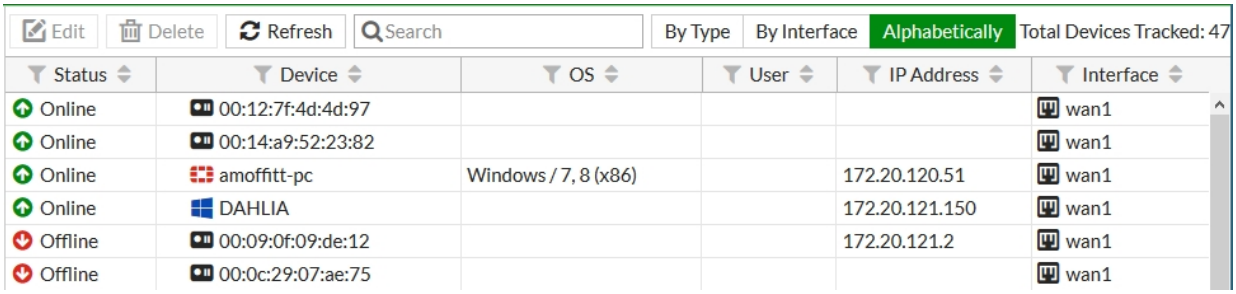
This chapter contains the following sections:

Device monitoring

The FortiGate unit can monitor your networks and gather information about the devices operating on those networks. Collected information includes:

- MAC address
- IP address
- operating system
- hostname
- user name
- how long ago the device was detected and on which FortiGate interface

You can go to **User & Device > Device List** to view this information. Mouse-over the **Device** column for more details.



Depending on the information available, the Device column lists the Alias or the MAC address of the device. For ease in identifying devices, Fortinet recommends that you assign each device an Alias.

Device monitoring is enabled separately on each interface. Device detection is intended for devices directly connected to your LAN ports. If enabled on a WAN port, device detection may be unable to determine the operating system on some devices. Hosts whose device type cannot be determined passively can be found by enabling active scanning on the interface.

You can also manually add devices. This enables you to ensure that a device with multiple interfaces is displayed as a single device.

To configure device monitoring

1. Go to **Network > Interfaces**.
2. Edit the interface that you want to monitor devices on.
3. In **Networked Devices**, turn on **Device Detection** and optionally turn on **Active Scanning**.
4. Select **OK**.
5. Repeat steps 2 through 4 for each interface that will monitor devices.

To assign an alias to a detected device or change device information

1. Go to **User & Device > Device List** and edit the device entry.
2. Enter an **Alias** such as the user’s name to identify the device.
3. Change other information as needed.
4. Select **OK**.

To add a device manually

1. Go to **User & Device > Custom Devices & Groups**.
2. Select **Create New > Device**.
3. Enter the following information:
   - Alias (required)
   - MAC address
   - Additional MACs (other interfaces of this device)
   - Device Type
   - Optionally, add the device to **Custom Groups**.
   - Optionally, enter **Comments**.
3. Select **OK**.

Device Groups

You can specify multiple device types in a security policy. As an alternative, you can add multiple device types to a custom device group and include the group in the policy. This enables you to create a different policy for devices that you know than for devices in general.

To create a custom device group and add devices to it

1. Go to **User & Device > Custom Devices & Groups**.
   The list of device groups is displayed.
2. Select **Create New > Device Group**.
3. Enter a **Name** for the new device group.
4. Click in the **Members** field and click a device type to add. Repeat to add other devices.
5. Select **OK**.

Controlling access with a MAC Address Access Control List

A MAC Address Access Control List (ACL) allows or blocks access on a network interface that includes a DHCP server. If the interface does not use DHCP, or if you want to limit network access to a larger group such as

employee devices, it is better to create a device group and specify that group in your security policies.

A MAC Address ACL functions as either

- a list of devices to block, allowing all other devices

or

- a list of devices to allow, blocking all other devices

Allowed devices are assigned an IP address. The Assign IP action assigns the device an IP address from the DHCP range. In a list of allowed devices, you can also use the Reserve IP action to always provide a specific IP address to the device.

The **Unknown MAC Address** entry applies to "other" unknown, unlisted devices. Its action must be opposite to that of the other entries. In an allow list, it must block. In a block list, it must allow.

To create a MAC Address ACL to allow only specific devices

1. Go to the SSID or network interface configuration.
2. In the **DHCP Server** section, expand **Advanced**.
   DHCP Server must be enabled.
3. In **MAC Reservation + Access Control**, select **Create New** and enter an allowed device’s **MAC Address**.
4. In the **IP or Action** column, select one of:
   - Assign IP — device is assigned an IP address from the DHCP server address range.
   - Reserve IP — device is assigned the IP address that you specify.
5. Repeat Steps "Controlling access with a MAC Address Access Control List" on page 2246 and "Controlling access with a MAC Address Access Control List" on page 2246 for each additional MAC address entry.
6. Set the **Unknown MAC Address** entry **IP or Action** to **Block**.
   Devices not in the list will be blocked.
7. Select **OK**.

To create a MAC Address ACL to block specific devices

1. Go to the SSID or network interface configuration.
2. In the **DHCP Server** section, expand **Advanced**.
   DHCP Server must be enabled.
3. In **MAC Reservation + Access Control,** select **Create New** and enter the **MAC Address** of a device that must be blocked.
4. In the **IP or Action** column, select **Block**.
5. Repeat Steps "Controlling access with a MAC Address Access Control List" on page 2246 and "Controlling access with a MAC Address Access Control List" on page 2246 for each device that must be blocked.
6. Set the **Unknown MAC Address** entry **IP or Action** to **Assign IP**.
   Devices not in the list will be assigned IP addresses.
7. Select **OK**.

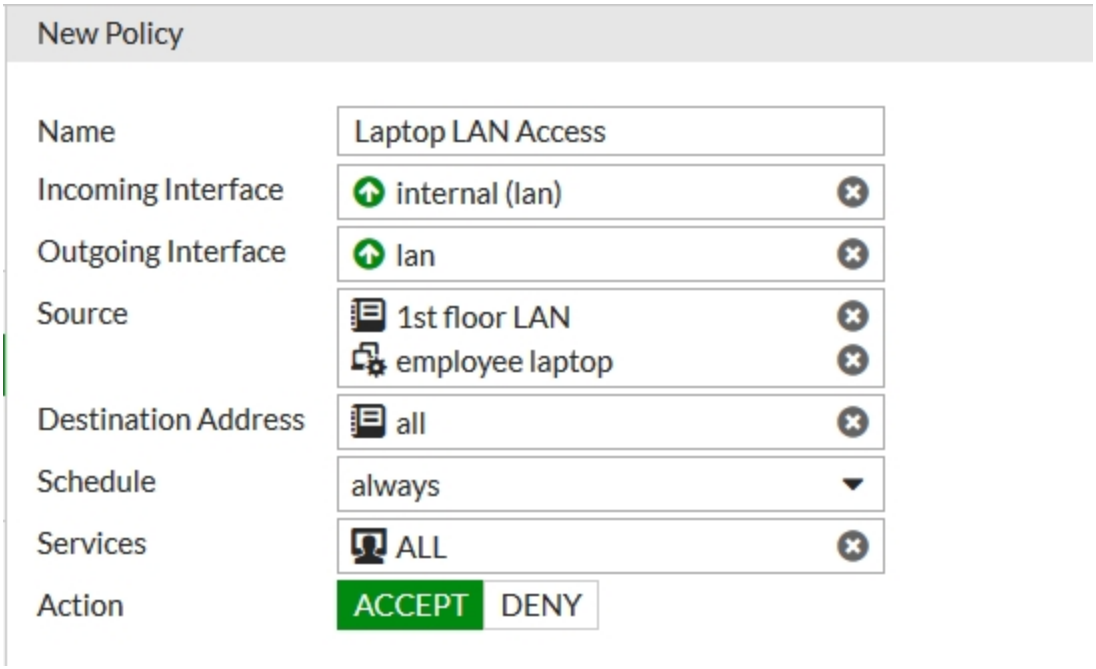
Security policies for devices

Security policies enable you to implement policies according to device type. For example:

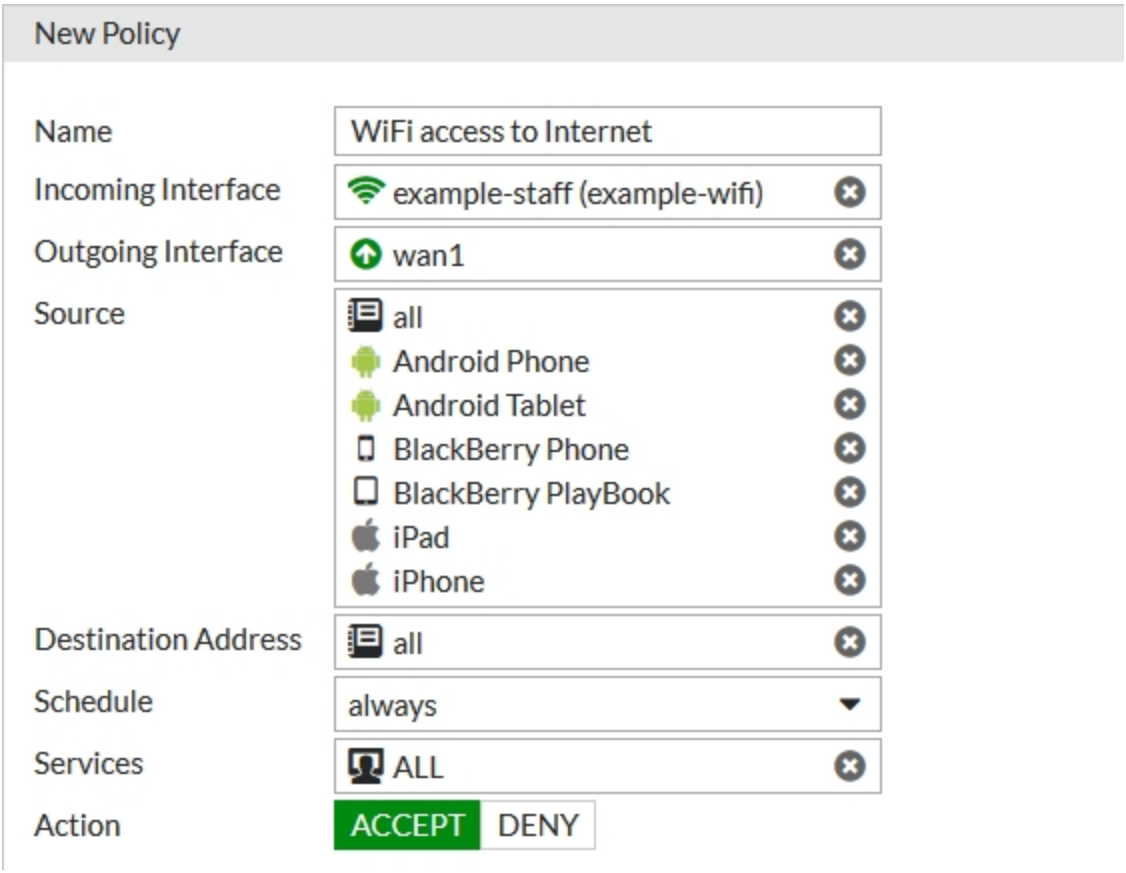
- Gaming consoles cannot connect to the company network or the Internet.
- Personal tablet and phone devices can connect to the Internet but not to company servers.
- Company-issued laptop computers can connect to the Internet and company servers. Web filtering and antivirus are applied.
- Employee laptop computers can connect to the Internet, but web filtering is applied. They can also connect to company networks, but only if FortiClient Endpoint Security is installed to protect against viruses.

The following images show these policies implemented for WiFi to the company network and to the Internet.

Device policies for company laptop access to the company network



Device policies for WiFi access to the Internet



The next section explains device policy creation in detail.

Creating device policies

Device-based security policies are similar to policies based on user identity:

- The policy enables traffic to flow from one network interface to another.
- NAT can be enabled.
- UTM protection can be applied.

To create a device policy

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Choose **Incoming Interface**, **Outgoing Interface** and **Source** as you would for any security policy.
3. In **Source**, select an address and the device types that can use this policy.
   You can select multiple devices or device groups.
4. Turn on **NAT** if appropriate.
5. Configure **Security Profiles** as you would for any security policy.
6. Select **OK**.

Adding endpoint protection

Optionally, you can require that users’ devices connecting to a particular network interface have FortiClient Endpoint Security software installed. Devices without an up-to-date installation of FortiClient software are restricted to a captive portal from which the user can download a FortiClient installer. For information about creating FortiClient profiles, see "Endpoint Protection".

To add endpoint protection to a security policy

1. Go to **Network > Interfaces** and edit the interface.
2. In **Admission Control** turn on **Allow FortiClient Connections** and **FortiClient Enforcement**.
3. Optionally, select sources (addresses and device types) to exempt from FortiClient enforcement.
4. Optionally, select destination addresses and services to exempt from FortiClient enforcement.
5. Select **OK**.

FortiOS pushes a FortiClient profile out to the FortiClient software, configuring network protection such as antivirus, application control, and web category filtering. To create these profiles, go to **Security Profiles > FortiClient Profiles**.

Chapter 21 - Managing a FortiSwitch with a FortiGate

Introduction

The maximum number of supported FortiSwitches depends on the FortiGate model:

FortiGate Model Range	Number of FortiSwitches Supported
Up to FortiGate-98 and FortiGate-VM01	8
FortiGate-100 to 280 and FortiGate-VM02	24
FortiGate-300 to 5*xx*	48
FortiGate-600 to 900 and FortiGate-VM04	64
FortiGate-1000 and up	128
FortiGate-3*xxx* and up, and FortiGate-VM08 and up	256

Supported Models

The following table shows the FortiSwitch models that support Fortilink mode when paired with the corresponding FortiGate models and the listed minimum software releases.

FortiGate Models	Earliest FortiOS	FortiSwitch Models
FGT-90D	5.2.2	FS-224D-POE
FGT-60D FGT-90D FGT-100D, FGT-140D (POE, T1) FGT-200D, FGT-240D, FGT-280D (POE) FGT-600C FGT-800C FGT-1000C	5.2.3	FSR-112D-POE FS-108D-POE FS-124D FS-124D-POE FS-224D-POE FS-224D-FPOE
	5.4.0	All FortiSwitch D-series models. FortiSwitchOS 3.3.x or 3.4.0 is recommended.

FortiGate Models	Earliest FortiOS	FortiSwitch Models
FGT-1200D FGT-1500D FGT-3700D FGT-3700DX	5.4.0	All FortiSwitch D-series models. FortiSwitchOS 3.3.x or 3.4.0 is recommended.
All FortiGate models that support FortiOS 5.4.1, with the following exceptions: FGR-30D, FGR-30D-A FGR-35D FG-52E FWF-60E FG-61E , FWF-61E FG-2000E FG-2500E	5.4.1	All FortiSwitch D-series models. FortiSwitchOS 3.4.2 or later is required in all managed switches.
FGT_60E FGT_61E FWF_60E FWF_61E FGT_100E FGT_101E	5.4.2	All FortiSwitch D-series models. FortiSwitch 3.4.2 or later is required in all managed switches.
FGT_80E, FGT_80E_POE FGT_81E, FGT_81E_POE FGT_100EF	5.4.3	All FortiSwitch D-series models. FortiSwitch 3.4.2 or later is required in all managed switches.

What's New

The following new Fortilink features are available

FortiOS 5.4.1 with FortiSwitchOS 3.4.2 (or later release)

- FortiLink support added for all of the FortiGate models
- Supports FortiSwitch stacking topologies
- Syslog Export from FortiSwitch to FortiGate
- Visibility in the FortiGate of devices connected to FortiSwitch ports
- FortiGate CLI support for FortiSwitch features (on non-FortiLink ports):
    - Spanning Tree
    - Link Aggregation Groups
    - Storm Control
    - Trusted/Untrusted Ports support (for DHCP snooping)
    - Port Statistics Display

Before You Begin

Before you configure the managed FortiSwitch unit, the following assumptions have been made in the writing of this manual:

- You have completed the initial configuration of the FortiSwitch unit, as outlined in the QuickStart Guide for your FortiSwitch, and you have administrative access to the FortiSwitch web-based manager and CLI.
- You have installed a FortiGate unit on your network and have administrative access to the FortiGate web-based manager and CLI.

How this Guide is Organized

This guide contains the following sections:

- Connecting FortiLink Ports - information about connecting FortiSwitch ports to FortiGate ports.
- FortiLink Configuration Using FortiGate GUI
- FortiLink Configuration Using FortiGate CLI
- Configuring Fortilink for FortiGate HA - how to configure Fortilink for FortiGate units in HA mode.
- Network Topologies for Managed FortiSwitch - describes configuration for various stacking topologies
- Optional Setup Tasks - describes other set up tasks.
- VLAN Configuration - configure VLANs from the FortiGate unit.
- FortiSwitch Port Features - configure Ports and POE from the FortiGate unit. Add STP and LAG?
- Additional Capabilities - describes additional FortiLink features in 5.4.1
- Troubleshooting - describes techniques for troubleshooting common problems.

Connecting FortiLink Ports

This section contains information about the FortiSwitch and FortiGate ports that you connect to establish a FortiLink connection.

For all FortiGate models, you can connect up to 16 FortiSwitches to one FortiGate unit.

In FortiSwitchOS 3.3.0 and later releases, you can use any of the switch ports for FortiLink. Some or all of the switch ports (depending on the model) support auto-discovery of the FortiLink ports.

You have a choice of connecting a single FortiLink port or multiple FortiLink ports as a logical interface (link-aggregation group, hardware switch or software switch).

Summary of the Steps

1. If required,enable the Switch Controller on FortiGate
2. Connect a cable between the FortiSwitch port(s) and the FortiGate port(s)

Enable the Switch Controller on FortiGate

Prior to connecting the FortiSwitch and FortiGate units, ensure that the Switch Controller feature is enabled on the FortiGate (depending on the FortiGate model and software release, this feature may be enabled by default).

Use the FortiGate web-based manager or CLI to enable the Switch Controller.

Using the FortiGate web-based manager

1. Go to **System > Feature Select**.
2. Turn on the **Switch Controller** feature.
3. Select **Apply**.

The menu option **WiFi & Switch Controller** now appears in the web-based manager.

Using the FortiGate CLI

Use the following command to enable the Switch Controller.

```
config system global
   set switch-controller enable
end
```

Connect the FortiSwitch and FortiGate

In FortiSwitchOS 3.3.0 and later releases, FortiSwitchOS provides additional flexibility for FortiLink:

- Use any switch port for FortiLink
- Provides auto-discovery of the FortiLink ports on the FortiSwitch
- Choice of a single FortiLink port or multiple FortiLink ports in a link-aggregation group (LAG)

Auto-discovery of the FortiSwitch Ports

In releases FortiSwitchOS 3.3.0 and beyond, the D-series FortiSwitch models support FortiLink auto-discovery, which is automatic detection of the port connected to the FortiGate.

You can use any of the switch ports for FortiLink. Use the following FortiSwitch CLI commands to configure a port for FortiLink auto-discovery:

```
config switch interface
   edit <port>
   set auto-discovery-fortilink enable
end
```

NOTE: Some FortiSwitch ports are enabled for auto-discovery by default. See table below.

NOTE: Complete this configuration step BEFORE connecting the switch to the FortiGate.

Each FortiSwitch model provides a set of ports that are enabled for FortiLink auto-discovery by default. If you connect the FortiLink using one of these ports, no switch configuration is required.

In general (in FortiSwitchOS 3.4.0 and later releases), the last four ports are the default auto-discovery FortiLink ports. You can also run the **show switch interface** CLI command on the FortiSwitch to see the ports that have auto-discovery enabled.

The table below lists the default auto-discovery ports for each switch model:

FortiSwitch Model	Default Auto-FortiLink ports
FS-108D	ports 9 and 10
FSR-112D	ports 9, 10, 11 and 12
FS-124D, FS-124D-POE	ports 23, 24, 25 and 26
FS-224D-POE	ports 21, 22, 23 and 24
FS-224D-FPOE	ports 25, 26, 27 and 28
FS-248D-POE	ports 49, 50, 51, and 52
FS-248D-FPOE	ports 49, 50, 51, and 52
FS-424D, FS-424D-POE, FS-424D-FPOE	ports 25 and 26
FS-448D, FS-448D-POE, FS-448D-FPOE	ports 49, 50, 51, and 52
FS-524D, FS-524D-FPOE	ports 25, 26, 27, 28, 29 and 30
FS-548D, FS-548D-FPOE	ports 49, 50, 51, 52, 53 and 54
FS-1024D, FS-1048D, FS-3032D	all ports

Choosing the FortiGate Ports

For all FortiGate models, you can connect up to 16 FortiSwitches to one FortiGate unit. The FortiGate manages all of the switches through one active FortiLink. The FortiLink may consist of one port or multiple ports (for a LAG).

As a general rule, FortiLink is supported on all ports that are listed as LAN ports or Switch ports.

FortiLink Configuration Using FortiGate GUI

This section describes the configuration steps to establish a FortiLink between a FortiSwitch and a FortiGate unit.

You can configure FortiLink using the FortiGate web-based manager (GUI) or the FortiGate CLI. We recommend using the FortiGate GUI, because the CLI steps are more complex (and therefore more prone to error).

If you use one of the auto-discovery FortiSwitch ports, you can establish the FortiLink connection (single port or LAG) with zero configuration steps on the FortiSwitch, and with a few simple configuration steps on the FortiGate.

Summary of the Steps

1. On the FortiGate, configure the FortLink port or create a logical FortLink interface.
2. Authorize the managed FortiSwitch.

Configure FortiLink as a Single Link

Configure the FortiLink port on the FortiGate using the following steps:

1. Go to **Network** > **Interfaces**
2. (Optional) If the FortiLink physical port is currently included in the internal interface, edit the internal interface and remove the desired port from the Physical Interface Members.
3. Edit the FortiLink port.
4. Enter the following fields in the **Edit Interface** form:
    a. **Addressing mode**: Set to **Dedicated to FortiSwitch**.
    b. **IP/Network Mask**: system automatically sets the IP address and network mask.
    c. (Optional) **Automatically authorize devices**: disable to manually authorize the FortiSwitch.
    d. Click **OK**.

Configure FortiLink as a Logical Interface

You can configure the FortiLink as a logical interface: link-aggregation group (LAG), hardware switch or software switch).

NOTE: LAG is supported on all FortiSwitch models and on FortiGate models FGT-100D and above. Hardware switch is supported on some FortiGate models.

Connect any of the FortiLink-capable ports on the FortiGate to the FortiSwitch. Make sure that you configure auto-discovery on the FortiSwitch ports (unless the port is a default auto-discovery port).

1. Go to **Network> Interfaces**
2. (Optional) If the FortiLink physical ports are currently included in the internal interface, edit the internal interface and remove the desired ports from the Physical Interface Members.
3. Click **Create New**
4. Enter the following fields in the **Add Interface** form:
    a. **Interface name**: enter a name for the interface (11 characters maximum).
    b. **Type**: select **802.3ad Aggregate**, **Hardware Switch**, or **Software Switch**.

c. **Physical Interface Members** : select the FortiGate ports for the logical interface.
d. **Addressing mode**: set to **Dedicated to FortiSwitch**.
e. **IP/Network Mask**: system automatically sets the IP address and network mask.
f. (Optional) **Automatically authorize devices**: disable to manually authorize the FortiSwitch.
g. Click **OK**.

FortiLink Split-Interface

You can create a FortiLink Split-Interface, which connects a FortiLink aggregate interface from one FortiGate to two FortiSwitches.

NOTE: The aggregate interface for this configuration must contain exactly two physical ports (one for each FortiSwitch).

You must enable the Split-Interface option on the FortiLink aggregate interface. From the FortiGate CLI, enter the following commands:

```
config system interface
   edit <name of the FortiLink interface>
      set fortilink-split-interface enable
end
```

Authorizing the FortiSwitch

If you configured the FortiLink interface to manually authorize the FortiSwitch as a managed switch, perform the following steps:

1. Go to **WiFi & Switch Controller** > **Managed FortiSwitch**.
2. (Optional)Click on the FortiSwitch faceplate and click **Authorize**. This step is required only if you disabled the automatic authorization field of the interface.

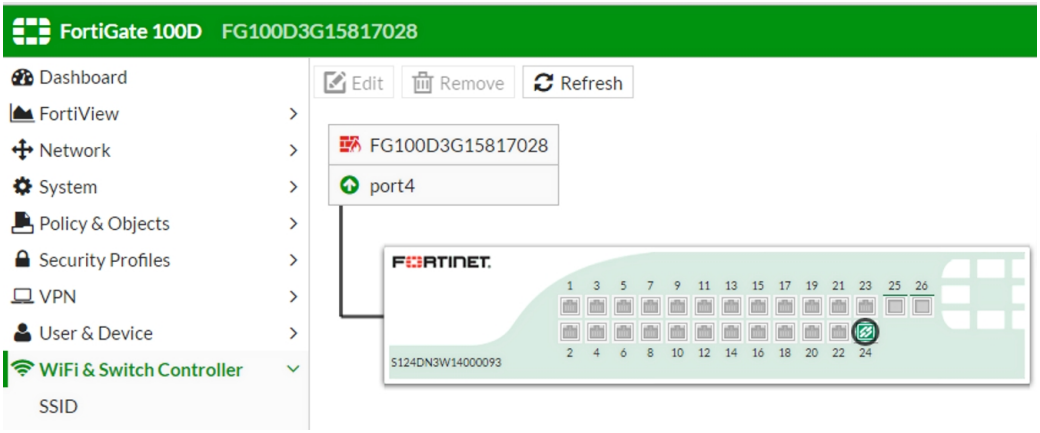
Managed FortiSwitch Display

The Managed FortiSwitch page displays the FortiGate name and its FortiLink interface, and the faceplate for the connected switch.

When the FortiLink is established successfully, the status is green (next to the FortiGate interface name and on the FortiSwitch faceplate) and the link between the ports is a solid line.

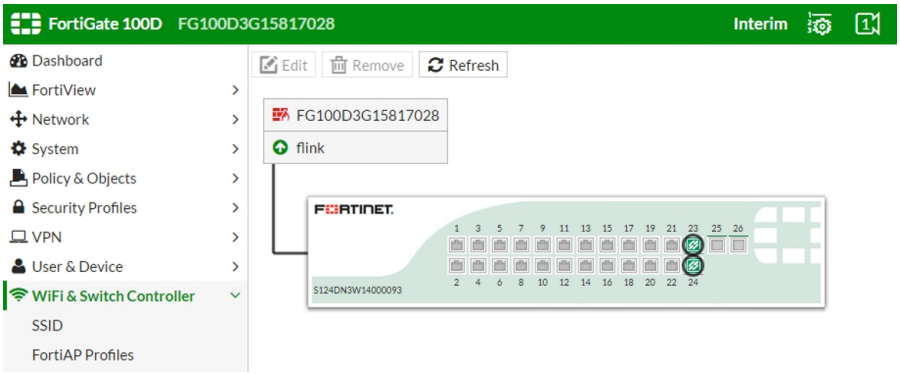
FortiLink as Single Link

The page displays the FortiLink port number on the FortiGate and the FortiLink port is highlighted in green on the FortiSwitch faceplate.



FortiLink as Logical Interface

The page displays the FortiLink interface name on the FortiGate and the FortiLink ports are highlighted in green on the FortiSwitch faceplate.



Edit Managed FortiSwitch

To edit the managed FortiSwitch, perform the following steps:

1. Go to **WiFi & Switch Controller** > **Managed FortiSwitch**.
2. Click on the FortiSwitch faceplate and click **Edit**.
3. In the **Edit Managed FortiSwitch** form, you can input a name and a description for this switch.
4. Click **OK** to save the changes.

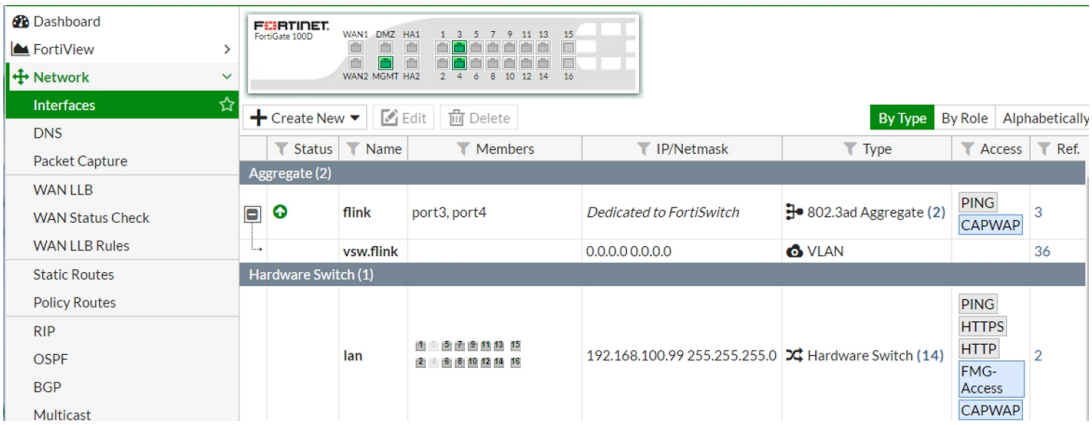
From the **Edit Managed FortiSwitch** form, you can also perform the following actions:

- Click **Restart** to restart the FortiSwitch.
- Click **De-authorize** to stop the FortiSwitch from being managed by this FortiGate.
- Click **Upgrade** to upgrade the switch. The system will prompt you for the new image file to upload and install.

Network Interface Display

In **System** > **Network** > **Interfaces**, the system displays the interface type, and displays **Dedicated to FortiSwitch** in the IP/Netmask field.

The following figure shows the Interfaces table entry for a FortiLink LAG. The table also displays the VLANs associated with the interface.



FortiLink Configuration Using FortiGate CLI

This section describes how to configure FortiLink using the FortiGate CLI. We recommend using the FortiGate GUI, because the CLI steps are more complex (and therefore more prone to error).

If you use one of the auto-discovery FortiSwitch ports, you can establish the FortiLink connection (single port or LAG) with zero configuration steps on the FortiSwitch, and with a few simple configuration steps on the FortiGate.

Summary of the Steps

1. Remove the port(s) from the LAN interface.
2. Configure the FortLink port or create a logical FortLink interface.
3. Configure NTP.
4. Authorize the managed FortiSwitch.
5. Configure DHPC

Configure FortiLink as a Single Link

Configure the FortiLink port on the FortiGate, and authorize the FortiSwitch as a managed switch.

In the following steps, port1 is configured as the FortiLink port.

1. If required, remove port 1 from the **lan** interface:

```
config system virtual-switch
   edit lan
      config port
         delete port1
      end
   end
end
```

2. Configure for port 1 as the FortiLink interface

```
config system interface
   edit port1
      set auto-auth-extension-device enable
      set fortilink enable
   end
end
```

3. Configure an NTP server on port 1.

```
config system ntp
   set server-mode enable
   set interface port1
end
```

4. Authorize the FortiSwitch unit as a managed switch.

```
config switch-controller managed-switch
   edit FS224D3W14000370
      set fsw-wan1-admin enable
```

```
      end
   end
NOTE: FortiSwitch will reboot when you issue the above command.
```

Configure FortiLink as a Logical Interface

You can configure the FortiLink as a logical interface: link-aggregation group (LAG), hardware switch or software switch).

NOTE: LAG is supported on all FortiSwitch models and on FortiGate models FGT-100D and above. Hardware switch is supported on some FortiGate models.

Connect any of the FortiLink-capable ports on the FortiGate to the FortiSwitch. Make sure that you configure auto-discovery on the FortiSwitch ports (unless the port is a default auto-discovery port).

In the following steps, port4 and port5 are configured as a FortiLink LAG.

1. If required, remove the FortiLink ports from the **lan** interface:

```
config system virtual-switch
   edit lan
      config port
         delete port4
         delete port5
      end
   end
end
```

2. Create a trunk with the two ports that you connected to the switch:

```
config system interface
   edit flink1 (enter a name, 11 characters maximum)
      set allowaccess ping capwap https
      set vlanforward enable
      set type aggregate
      set member port4 port5
      set lacp-mode static
      set fortilink enable
      (optional) set fortilink-split-interface enable
   next
end
```

NOTE: you must enable **fortilink-split-interface** if the members of the aggregate interface connect to more than one FortiSwitch.

3. Configure an NTP server on the LAG interface:

```
config system ntp
   set server-mode enable
   set interface flink1
end
```

4. Authorize the FortiSwitch unit as a managed switch.

```
config switch-controller managed-switch
   edit FS224D3W14000370
      set fsw-wan1-admin enable
   end
```

```
end
```

NOTE: FortiSwitch will reboot when you issue the above command.

5. Configure a DHCP server on port 1.

```
config system dhcp server
   edit 0
      set ntp-service local
      set default-gateway 169.254.254.1
      set netmask 255.255.255.252
      set interface flink1
      config ip-range
         edit 1
            set start-ip 169.254.254.2
            set end-ip 169.254.254.2
         end
      set vci-match enable
      set vci-string FortiAP FortiSwitch FortiExtender
   end
end
```

Configuring FortiLink for FortiGate HA

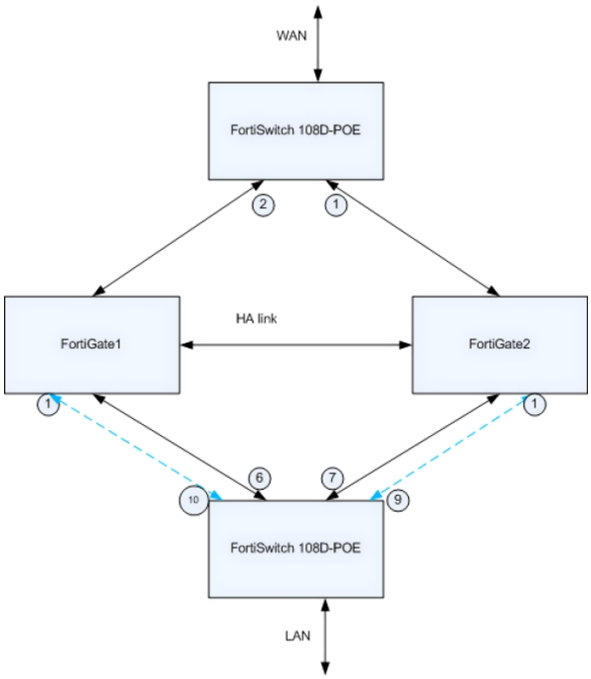
With FortiOS 5.4.0 and later releases, a FortiGate operating in HA mode can use FortiLink (to FortiSwitches running FortiSwitchOS 3.3.0 or later release).

To use FortiLink mode with a pair of FortiGate units in a high-availability cluster, you must connect FortiLink from the switch to both of the FortiGate units.

Highlights of this configuration:

1. No console port or direct management is required on the FortiSwitch.
2. All the actions described here can be performed from FortiCloud if needed
3. All FortiSwitch internal state and counters are visible when in FortiLink managed mode

Example Topology



The LAN and WAN links connect to FortiSwitch ports. The FortiSwitch connects to the active and standby FortiGate units. If the standby FortiGate (for example, FGT2) becomes active, this is transparent to the LAN and WAN ports. FortiLink is automatically established to FGT2, and the active traffic path becomes LAN <-> FGT2<-> WAN.

Note the following points:

1. FortiSwitch connects with FortiLink to both of the FortiGate units.
2. LAN and WAN links can connect to separate FortiSwitches, as shown in the figure. You can also connect them to the same FortiSwitch (and use VLANs to separate the LAN and WAN traffic).
3. Connect the FortiLinks from any two FortiSwitch ports to FGT1 port X and FGT2 port X, where the FortiGate port numbers must match (port1 in the above topology diagram).

4. For a Logical FortiLink interface with two ports, connect Fortilinks from two additional FortiSwitch ports to FGT1 port Y and FGT2 port Y, where the FortiGate port numbers must match.

Adding a Second FortiGate to Existing Single FortiGate

Connect an additional FortiLink from the FortiSwitch to the new FortiGate, and configure HA on both of the FortiGate units.

Configuration Steps

Configuration consists of the following major steps:

1. Configure “auto-discovery-fortilink enable” on the FortiSwitch ports that you will connect to FGT2. This step is not required if the port is auto-fortilink by default.
2. Add cable connections from FGT2 to the directly-connected FortiSwitches (exact duplicate of FGT1 to the FortiSwitches)
3. Connect HA cables between FGT1 and FGT2
4. At FGT1: configure FortiGate High Availability using the GUI. For additional information, refer to the High Availability chapter in the FortiOS Handbook.
5. At FGT2: Configure FortiGate High Availability using the CLI from the console port. The following parameters must be identical to FGT1:
   - HA-mode
   - Priority
   - Group Name and Password
6. At this point, the FGT1 synchronizes with FGT2. This takes several minutes.
7. Verify the configuration at FGT2 using the following commands:

```
get ha status
get system ha status
```

Adding the First Switch to Existing HA FortiGates (single FortiLinks)

Connect one FortiSwitch port to each of the FortiGate units. On FGT1, follow the same FortiLink configuration steps as for the non-HA configuration. FGT1 synchronizes the configuration with FGT2.

Configuration Steps

1. Configure two FortiSwitch ports as “auto-discovery-fortilink enable”. This step is not required for any port is auto-fortilink by default.
2. Connect one port to FGT1 and the other port to FGT2.
   - The FGT1 and FGT2 port numbers must be identical For example:
   - FortiSwitch port21 and port22 connect to FGT1 port4 and FGT2 port4
3. At FGT1, perform the steps to configure FortiLink (as described in FortiLink Configuration Using FortiGate GUI):
   a. Configure a port to be the FortiLink port
   b. Authorize the FortiSwitch
4. At FGT2, run the command "get switch-controller managed-switch" to verify that the FGT1 configuration was synchronized successfully

Adding the First Switch to Existing FGT HA setup (Logical Fortilink Interface)

In this configuration, connect two FortiSwitch ports to each FortiGate unit. Enter the configuration commands on FGT1 (same commands as for the non-HA configuration). The HA feature synchronizes the configuration to FGT2.

Configuration Steps

1. Configure four FortiSwitch ports as “auto-discovery-fortilink enable”. This step is not required for any port is auto-fortilink by default.
2. Connect two ports to FGT1 and the other ports to FGT2
   - the FGT1 and FGT2 port numbers must be the same. For example:
   - FortiSwitch port21 and port22 connect to FGT1 port4 and port5 and FortiSwitch port23 and port24 connect to FGT2 port4 and port5
3. At FGT1, configure the Fortilink interface (as described in FortiLink Configuration Using FortiGate GUI):
   a. Create the FortiLink logical interface and add the physical ports as members
   b. Authorize the FortiSwitch
4. At FGT2, run command "get switch-controller managed-switch" to verify that the FGT1 configuration was synchronized successfully

(Optional) Test the HA Capability

Warning: the following is a destructive test that simulates a FortiGate failure. You should conduct this test only in a lab or test network, not in a production network:

1. Disconnect power from FGT1 to simulate failure
2. From the FGT2 UI:
   Check **Wifi and Switch Controller** > **Managed FortiSwitch**
3. FortiSwitch is now visible from the management interface on FGT2

Network Topologies for Managed FortiSwitch

With releases prior to FortiOS 5.4.1, the FortiGate required a separate FortiLink for each managed FortiSwitch. Starting in release FortiOS 5.4.1, the FortiGate requires only one active FortiLink to manage all of the subtending FortiSwitches. We refer to this new capability as "Stacking".

You can configure the FortiLink as a physical interface or as a logical interface (associated with one or more physical interfaces). Depending on the network topology, you may also configure a standby FortiLink.

For any of the topologies, note the following:

- All of the managed FortiSwitches will function as one Layer-2 stack. The FortiGate manages each FortiSwitch separately.
- The active FortiLink carries data as well as management traffic.

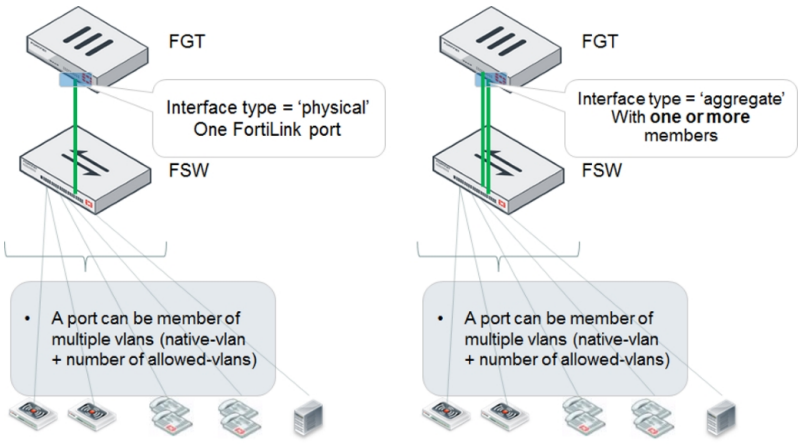
Supported Topologies

Fortinet recommends the following topologies for managed FortiSwitches:

- Single FortiGate managing a single FortiSwitch
- Single FortiGate managing a stack of several FortiSwitches
- HA-mode FortiGate managing a single FortiSwitch
- HA-mode FortiGate managing a stack of several FortiSwitches
- HA-mode FortiGate managing a FortiSwitch two-tier topology
- Single FortiGate managing multiple FortiSwitches (using hardware or software switch interface)
- Enterprise/Office Closet Topology

Single FortiGate managing a single FortiSwitch

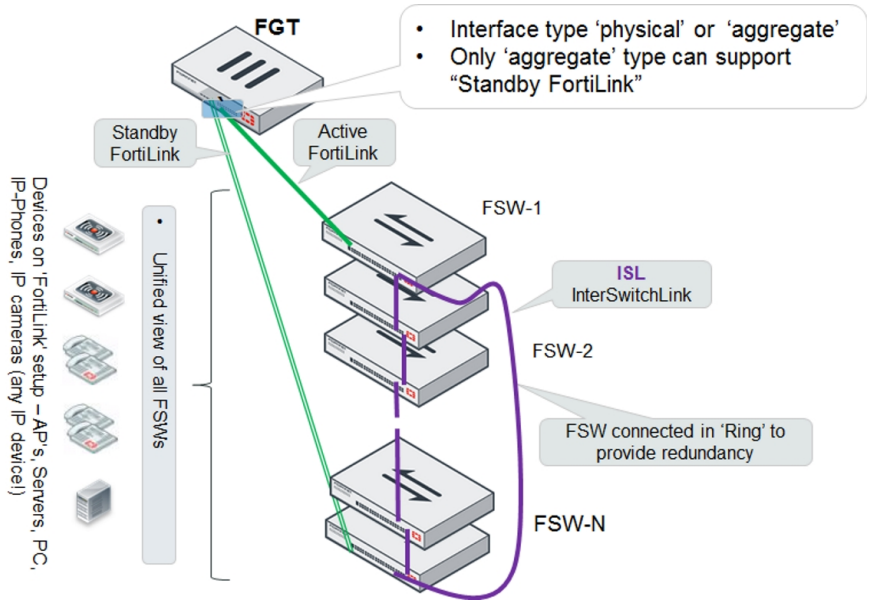
On the FortiGate, the FortiLink interface is configured as physical or aggregate. The 802.3ad aggregate interface type provides a logical grouping of one or more physical interfaces.



Single FortiGate managing a stack of several FortiSwitches

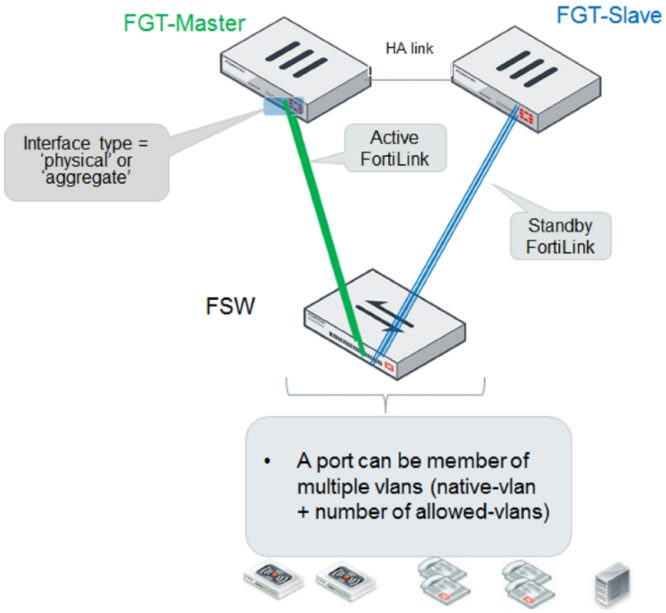
The FortiGate connects directly to one FortiSwitch device using a physical or aggregate interface. The remaining FortiSwitches connect in a ring using inter-switch links.

Optionally, you can connect a standby FortiLink connection to the last FortiSwitch. For this configuration, you create a FortiLink Split-Interface (an aggregate interface which contains one active link and one standby link).



HA-mode FortiGate managing a single FortiSwitch

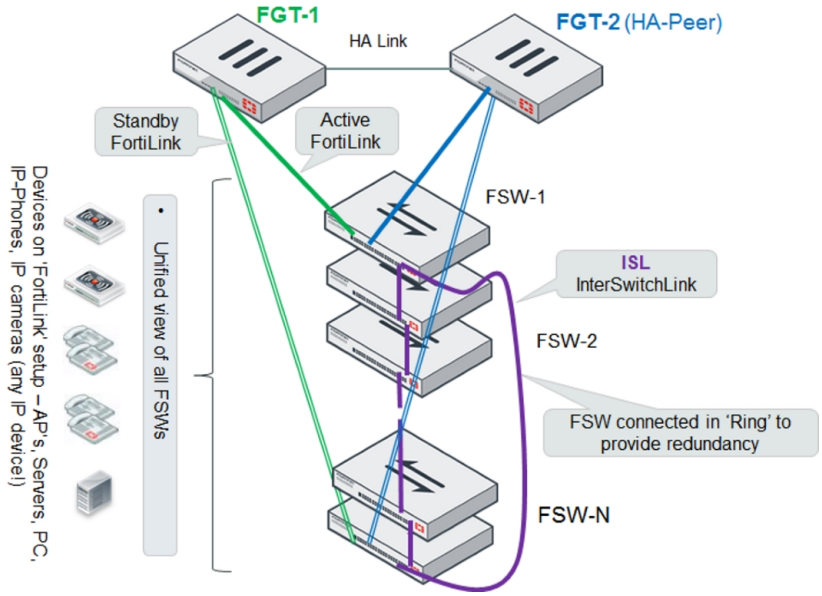
The master and slave FortiGate units both connect a FortiLink to the FortiSwitch. The FortiLink port(s) and interface type must match on the two FortiGate units.



HA-mode FortiGate managing a stack of several FortiSwitches

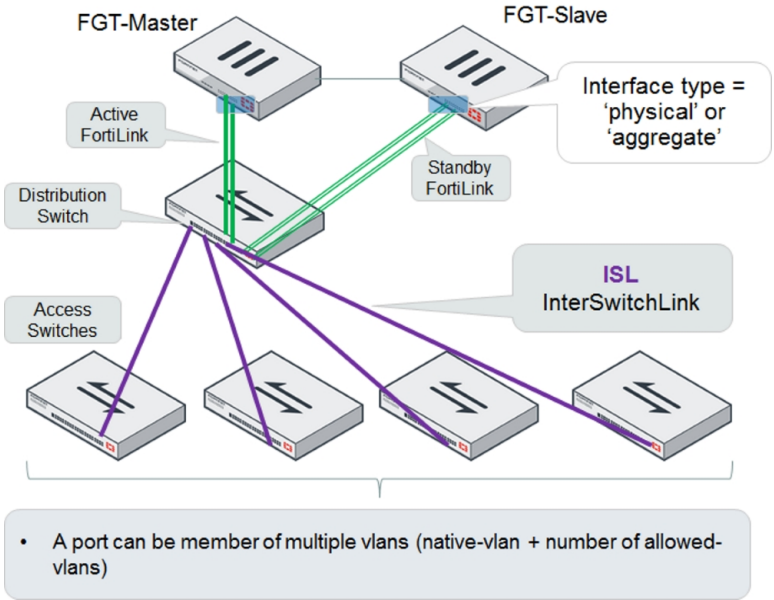
The master and slave FortiGate units both connect a FortiLink to the first FortiSwitch, and (optionally) to the last FortiSwitch. The FortiLink ports and interface type must match on the two FortiGate units.

For the active/standby FortiLink configuration, you create a FortiLink Split-Interface (an aggregate interface which contains one active link and one standby link).



HA-mode FortiGate managing a FortiSwitch two-tier topology

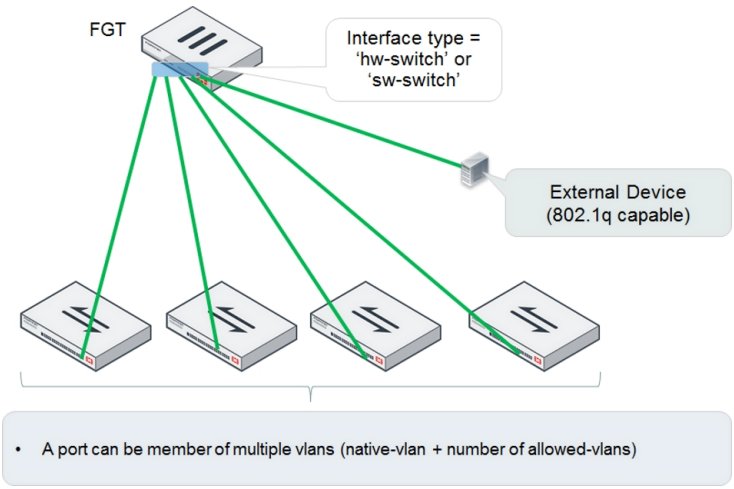
The distribution FortiSwitch connects to the master and slave FortiGate units. The FortiLink port(s) and interface type must match on the two FortiGate units.



Single FortiGate managing multiple FortiSwitches (using hardware or software switch interface)

The FortiGate connects directly to each FortiSwitch. Each of these FortiLink ports is added to the logical hardware-switch or software-switch interface on the FortiGate.

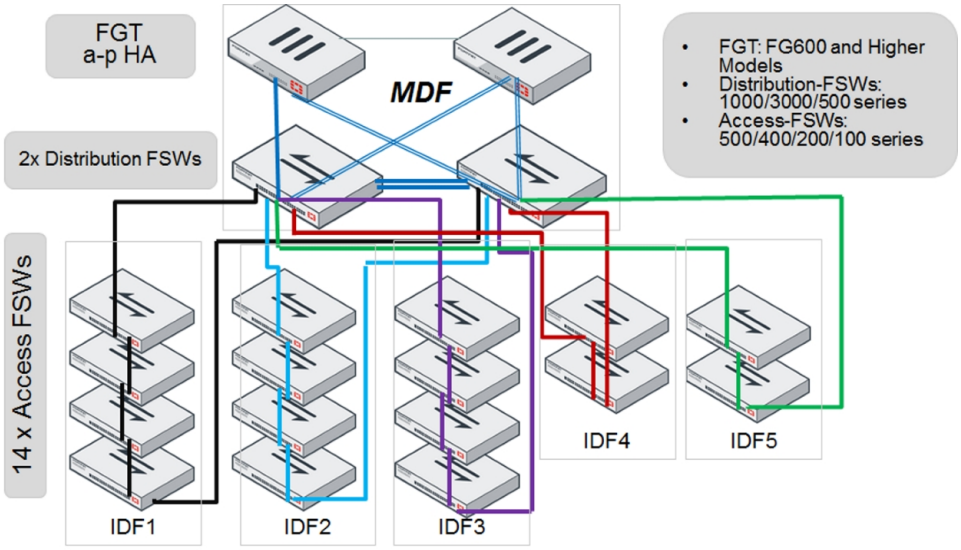
Optionally, you can connect other devices to the FortiGate logical interface. These devices will have Layer 2 connectivity with the FortiSwitch ports. The device must support IEEE 802.1q VLAN tagging.



Enterprise/Office Closet Topology

HA-mode FortiGates connect to redundant distribution FortiSwitches. Access FortiSwitches are arranged in a stack in each IDF, connected to both distribution switches.

For the FortiLink connection to each distribution switch, you create a FortiLink Split-Interface (an aggregate interface which contains one active link and one standby link).



Stacking Configuration

The configuration steps for stacking include:

1. Configure the active FortiLink interface on the FortiGate.
2. (Optional) Configure the standby FortiLink interface.
3. Connect the FortiSwitches together, based on your chosen topology.

1. Configure the Active FortiLink

Configure the FortiLink interface (as described in the FortiLink Configuration section).

When you configure the FortiLink interface, stacking capability is enabled automatically.

2. Configure the Standby FortiLink

Configure the standby FortiLink interface. Depending on your configuration, the standby FortiLink may connect to the same FortiGate as the active Fortilink, or to a different FortiGate.

If the FortiGate receives discovery requests from two FortiSwitches, the link from one FortiSwitch will be selected as active and the link from other FortiSwitch will be selected as standby.

If the active FortiLink fails, FortiGate converts the standby FortiLink to active.

3. Connect the FortiSwitches

Refer to the topology diagrams to see how to connect the FortiSwitches.

Inter-switch links (ISLs) form automatically between the stacked switches.

FortiGate will discover and authorize all of the FortiSwitches that are connected. After this, the FortiGate is ready to manage all of the authorized FortiSwitches.

Disable Stacking

To disable stacking, execute the following command from the FortiGate CLI. In the following example, port4 is the FortiLink interface:

```
config system interface
   edit port4
      set fortilink-stacking disable
   end
end
```

Optional Setup Tasks

This section describes the following tasks:

- Configuring FortiSwitch Management Port
- Converting to FortiSwitch Standalone Mode

Configuring FortiSwitch Management Port

If the FortiSwitch model has a dedicated management port, you can configure remote management to the FortiSwitch. In FortiLink mode, the FortiGate is the default gateway, so you need to configure an explicit route for the FortiSwitch management port.

Using the FortiSwitch Web-based Manager

1. Go to **Routing**
2. Under **Static Routes**, click **Create New**
3. Enter the following fields in the **New Static Route** form:
   a. Destination: enter a subnetwork and mask
   b. Device: select the management interface
   c. Gateway: enter the gateway IP address

Using the FortiSwitch CLI

Enter the following commands:

```
config router static
   edit 1
      set device mgmt
      set gateway <router IP address>
      set dst <router subnet> <subnet mask>
   end
end
```

In the following example, the FortiSwitch management port is connected to a router with IP address 192.168.0.10:

```
config router static
   edit 1
      set device mgmt
      set gateway 192.168.0.10
      set dst 192.168.0.0 255.255.0.0
   end
end
```

Converting to FortiSwitch Standalone Mode

If a FortiSwitch is operating in managed mode, follow these instructions to convert it to standalone mode.

1. From the switch CLI:

```
config system global
   set mgmt-mode local
end
NOTE: FortiSwitch will reboot when you issue the above command.
```

2. From the FortiGate, use the web-based manager or CLI to perform the following commands before the switch reboot has completed:

Using the Web-based manager

a. Navigate to **WiFi & Switch Controller** > **Managed FortiSwitch**.

b. Right-click on the switch and select **De-authorize**.

Using the CLI

```
config switch-controller managed-switch
   edit <switch-id>
      set fsw-wan1-admin disable
   end
end
```

VLAN Configuration

Use Virtual Local Area Networks (VLANs) to logically separate a LAN into smaller broadcast domains. VLANs allow you to define different policies for different types of users and to set finer control on the LAN traffic (traffic is only sent automatically within the VLAN. You must configure routing for traffic between VLANs).

From the FortiGate, you can centrally configure and manage VLANs for the managed FortiSwitches.

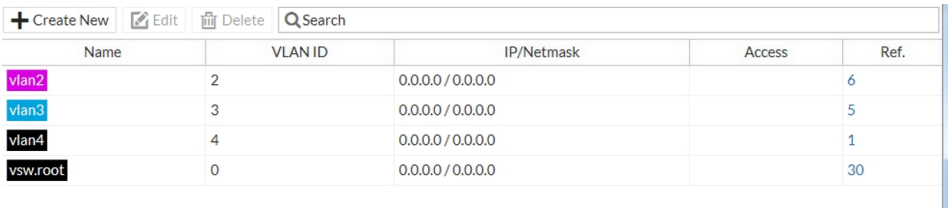
In FortiSwitchOS 3.3.0 and later releases, the FortiSwitch supports untagged and tagged frames in Fortilink mode. The switch supports up to 1023 user-defined VLANs. The user can assign a VLAN number (in the range 1-4095) to each of the VLANs.

You can configure the default VLAN for each FortiSwitch port. You can also configure a set of allowed VLANs for each FortiSwitch port.

FortiSwitch VLANs Display

The **WiFi & Switch Controller** > **FortiSwitch VLANs** page displays VLAN information for the managed switches.

The following figure shows the VLAN page:



Each entry in the VLAN list displays the following information:

- **Name** - name of the VLAN
- **VLAN ID** - the VLAN number.
- **IP/Netmask** - Address and mask of the subnetwork that corresponds to this VLAN
- **Access**
- **Ref** - how many interfaces reference this VLAN.

Creating VLANs

Setting up a VLAN requires:

- Creating the VLAN.
- Assigning FortiSwitch ports to the VLAN.

Using the web-based manager

Creating the VLAN

1. Go to **WiFi & Switch Controller** > **FortiSwitch VLANs** and select **Create New**. Change the following settings:

Interface Name	VLAN name
VLAN ID	Enter a number (1-4094)
Color	Choose a unique color for each VLAN, for ease of visual display.
IP/Network Mask	IP address and network mask for this VLAN.

1. Enable **DHCP Server**. Set the IP range.
2. Set the **Admission Control** options as required.
3. Select **OK**.

Assigning FortiSwitch Ports to the VLAN

1. Go to **WiFi & Switch Controller** > **FortiSwitch Ports**.
2. Click the rows for ports to select them.
3. To change the native VLAN, click the **Native VLAN** column in one of the selected entries.
4. Select a VLAN from the displayed list. The new value is assigned to the selected ports.
5. To change the allowed VLANs, click the **+** icon in the **Allowed VLANs** column.
6. Select one or more of the VLANs from the displayed list. You can also select the value **all**. The new value is assigned to the selected port.

Using the CLI

1. Create the marketing VLAN.

```
config system interface
   edit <vlan name>
      set vlanid <1-4094>
      set color <1-32>
      set interface <fortilink-enabled-interface>
end
```

2. Set the VLAN's IP address.

```
config system interface
   edit <vlan name>
      set ip <IP address> <Network mask>
end
```

3. Enable a DHCP Server.

```
config system dhcp server
   edit 1
      set default-gateway <IP address>
      set dns-service default
      set interface <vlan name>
         config ip-range
            set start-ip <IP address>
            set end-ip <IP address>
         end
      set netmask <Network mask>
end
```

4. Assign ports to the VLAN.

```
config switch-controller managed-switch
   edit <Switch ID>
      config ports
         edit <port name>
            set vlan <vlan name>
            set allowed-vlans <vlan name>
            or
            set allowed-vlans-all enable
         next
      end
end
```

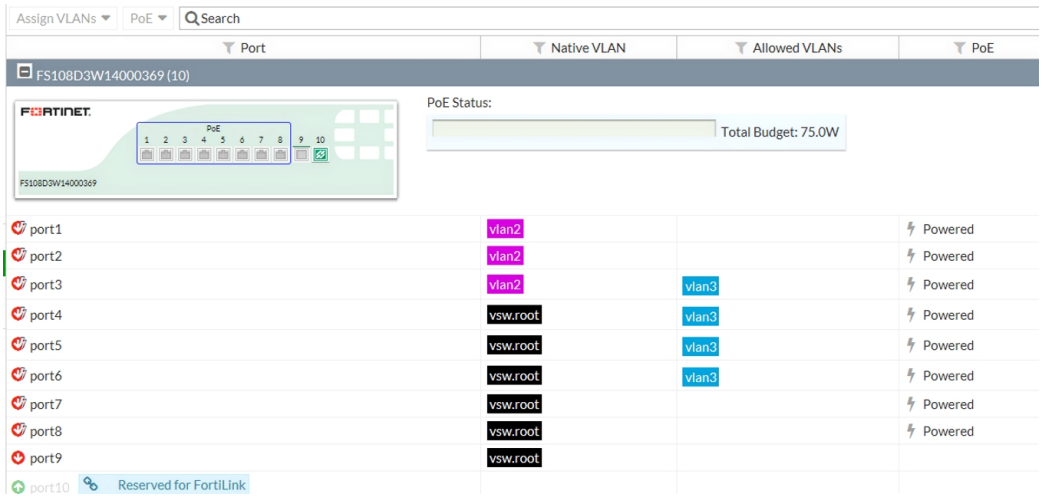
FortiSwitch Port Features

You can configure the FortiSwitch port feature settings from the FortiGate using the FortiGate web-based manager or CLI commands.

FortiSwitch Ports Display

The **WiFi & Switch Controller** > **FortiSwitch Ports** page displays port information about each of the managed switches.

The following figure shows the display for a FortiSwitch 108D-POE:

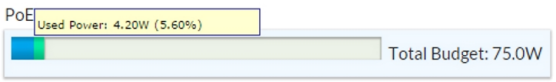


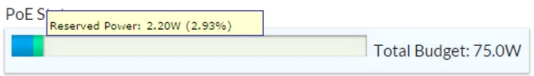
The switch faceplate displays:

- the active ports (green)
- the POE-enabled ports (blue rectangle)
- the FortiLink port (link icon)

The POE Status displays the total power budget, and the actual power currently allocated.

The allocated power displays a blue bar for the used power (currently being consumed) and a green bar for the reserved power (power available for additional devices on the POE ports). See the following figures:





Each entry in the port list displays the following information:

- Port status (red for down, green for up)
- Port name
- Native VLAN
- Allowed VLANs
- POE status

Configuring Ports Using the Web Manager

You can use the web manager to configure VLANs on the port (see VLAN Configuration), or to enable/disable POE on a port.

Enable or Disable POE on a port

Follow these instructions to configure POE on a port:

1. Navigate to **WiFi & Switch Controller** > **FortiSwitch Ports**
2. Click on a row to select the port.
3. Right-click the row, select **POE** and select **Enable POE** or **Disable POE**

Note: when you select a row in the port table, you can also use the **Assign VLANs** and **PoE** menus (located just below the page banner), instead of the right-click menu, to configure the values.

Configuring Ports Using the FortiGate CLI

You can configure the following FortiSwitch port settings using the FortiGate CLI:

- Set port speed and admin status
- Configure vlan on the port (see VLAN Configuration)
- DHCP trust setting
- Enable or disable POE

Configuring Port Speed and Admin Status

Use the following commands to set port speed and other basis port settings:

```
config switch-controller managed-switch
   edit <switch>
      config ports
         edit <port>
            set description <text>
            set speed <speed>
            set status {down | up}
```

Configuring DHCP Snooping

Set the port as a trusted or untrusted DHCP-snooping interface:

```
config switch-controller managed-switch
   edit <switch-id>
      config ports
         edit <port name>
            set dhcp-snooping {trusted | untrusted}
```

Configuring POE

The following POE CLI commands are available starting in FortiSwitchOS 3.3.0:

Enable PoE on the Port

```
config switch-controller managed-switch
   edit <switch-id>
      config ports
         edit <port name>
            set poe-status {enable | disable}
```

Reset the POE port

The following command resets POE on the port

```
execute switch-controller poe-reset <fortiswitch-id> <port>
```

Display general POE status

```
get switch-controller <fortiswitch-id> <port>
```

The following example displays the POE status for port 6 on the specified switch:

```
# get switch-controller poe FS108D3W14000967 port6
Port(6) Power:3.90W, Power-Status: Delivering Power
Power-Up Mode: Normal Mode
Remote Power Device Type: IEEE802.3AT PD
Power Class: 4
Defined Max Power: 30.0W, Priority:3
Voltage: 54.00V
Current: 78mA
```

Configuring STP

Starting in FortiSwitch release 3.4.2, STP is enabled by default for the non-FortiLink ports on the managed FortiSwitches. Use the following commands to enable or disable STP on FortiSwitch ports:

```
config switch-controller managed-switch
   edit <switch-id>
      config ports
         edit <port name>
            set stp-state (enabled | disabled)
```

Additional Capabilities

FortiOS 5.4.1 introduces additional capabilities related to managed FortiSwitch.

FortiSwitch LOG export

You can enable/disable the managed FortiSwitches to export their syslogs to the FortiGate. The setting is global, and the default setting is disabled.

The FortiGate sets the user field to "fortiswitch-syslog" for each entry, to allow a level of filtering.

CLI Command Syntax:

```
config switch-controller switch-log
   status (enable | disable)
   severity [ emergency | alert | critical | error | warning | notification | *information
       | debug ]
end
```

You can override the global log settings for a FortiSwitch, using the following commands:

```
config switch-controller managed-switch
   edit <switch-id>
      config switch-log
         set local-override enable
```

At this point, you can configure the log settings that apply to this specific switch.

FortiSwitch Per-Port Device Visibility

In the FGT GUI, **User & Device** > **Device LIst** displays a list of devices attached to the FortiSwitch ports. For each device, the table displays the IP address of the device, and the interface (FortiSwitch name and port).

From the CLI, the following command displays information about the host devices:

```
diagnose switch-controller dump mac-hosts_switch-ports
```

FortiGate CLI support for FortiSwitch features (on non-FortiLink ports)

You can configure the following FortiSwitch features from the FortiGate CLI.

Configuring LAG

You can configure a link aggregation group for non-fortilink ports on a FortiSwitch. You cannot configure ports from different FortiSwitches in one LAG.

```
config switch-controller managed-switch
   edit <switch-id>
      config ports
         edit <trunk name>
            set type trunk
            set mode < static | lacp > Link Aggreation mode
            set bundle (enable | disable)
```

```
            set min-bundle <int>
            set max-bundle <int>
            set members < port1 port2 ...>
         next
      end
   end
end
```

Configuring Storm Control

Storm control prevents traffic on a LAN from being disrupted by a broadcast, multicast, or unicast storm on a port. Storm control uses the data rate of the link to measure traffic activity.

When the data rate exceeds the configured threshold, storm control drops excess traffic. You can configure the types of traffic to drop: broadcast, unknown unicast, or multicast.

The Rate units is packets per second. The default value is 500.

The Storm Control settings are global to all of the non-FortiLink ports on the managed switches. Use the following CLI commands to configure storm control:

```
config switch-controller storm-control
   set rate <rate>
   set unknown-unicast (enable | disable)
   set unknown-multicast (enable | disable)
   set broadcast (enable | disable)
end
```

You can override the global Storm Control settings for a FortiSwitch, using the following commands:

```
config switch-controller managed-switch
   edit <switch-id>
      config storm-control
         set local-override enable
```

At this point, you can configure the Storm Control settings that apply to this specific switch.

Display Port Statistics

Port stats will be accessed via FSW REST Monitor API.

Execute Custom FortiSwitch Commands

From the FortiGate, you can execute FortiSwitch commands on the managed FortiSwitch.

This feature adds a simple scripting mechanism for users to configure generic commands to be executed on the switch.

Create a command

Use the following syntax to create a command file:

```
config switch-controller custom-command
   edit <cmd-name>
      set command " <FortiSwitch commands>"
```

The following example creates a command file to set the STP max-age parameter:

```
config switch-controller custom-command
   edit "stp-age-10"
      set command "config switch stp setting
         set max-age 10
         end
      "
   next
end
```

Execute a command

After you have created a command file, use the following command on the FortiGate to execute the command file on the target switch:

```
exec switch-controller custom-command <cmd-name> <target-switch>
```

The following example runs command **stp-age-10** on the specified target FortiSwitch:

```
FGT30E3U15003273 # exec switch-controller custom-command stp-age-10 S124DP3X15000118
```

Troubleshooting

If the FortiGate does not establish the Fortilink connection with the switch, perform the following troubleshooting checks.

Troubleshooting FortiLink Issues

Check the FortiGate configuration

Using the FortiGate GUI, check the FortiLink interface configuration:

1. In **Network** > **Interfaces**, double-click the interface used for FortiLink.
2. Ensure that **Dedicated to Extension Device** is set for this interface.

Using the FortiGate CLI, Verify that you have configured the DHCP and NTP settings correctly. Enter the following commands:

1. Verify that the NTP server is enabled, and the Fortilink interface has been added to the list:

```
show system ntp
```

2. Ensure that the DHCP server on the Fortilink interface is configured correctly:

```
show system dhcp
```

Check the FortiSwitch configuration

Use the following FortiSwitch CLI commands to check the FortiSwitch configuration:

1. Verify that the switch system time matches the time on the FortiGate:

```
get system status
```

2. Verify that FortiGate has sent an IP address to the FortiSwitch.
Typically, the IP address will be in the range of 169.254.x.x:

```
get system interfaces
```

3. Verify that you can ping the FortiGate IP address:

```
exec ping x.x.x.x
```

Chapter 22 - Networking

This guide explains how to configure your network. It contains the following sections:

Interfaces explains the concepts of options for setting up interfaces and groupings of subnetworks that can scale to a company's growing requirements.

DNS describes how to set DNS requirements for your network.

DNS Servers explains how to set the FortiGate as a local DNS server.

Packet Capture describes how to use packet capture feature built in the FortiGate, which is useful for troubleshooting purposes.

Advanced Static Routing explains universal and static routing concepts, equal cost multipath (ECMP) and load balancing, policy routing, and routing in transparent mode.

Dynamic Routing Overview provides an overview of dynamic routing, compares static and dynamic routing, and helps you decide which dynamic routing protocol is best for you.

Routing Information Protocol (RIP) describes a distance-vector routing protocol intended for small, relatively homogeneous networks.

Open Shortest Path First (OSPF) provides background on the specific protocol explaining terms used and how the protocol works, as well as providing some troubleshooting information and examples on configuring the protocols in different situations.

Border Gateway Protocol (BGP) describes classless inter-domain routing, and aggregate routes. BGP is the only routing protocol to use TCP for a transport protocol.

Intermediate System to Intermediate System Protocol(IS-IS), which describes the link state protocol, is well-suited to smaller networks and with near universal support on routing hardware. The section also provides troubleshooting information and configuration examples.

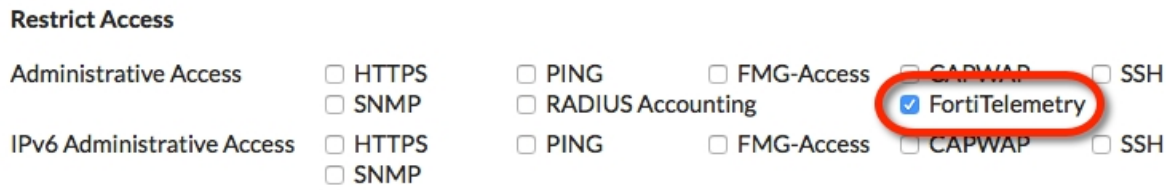
Multicast forwarding provides the concepts and use of multicasting with the FortiGate unit.

What's new for Networking in FortiOS 5.4

New Features in 5.4.1

FortiTelemetry replaces FortiClient Access and other FortiClient interface settings (372945 299371)

To configure an interface to listen for connections from devices with FortiClient installed, enable **FortiTelemetryAdministrative Access**. FortiTelemetry was called FCT-Access or FortiClient Access in FortiOS 5.2.

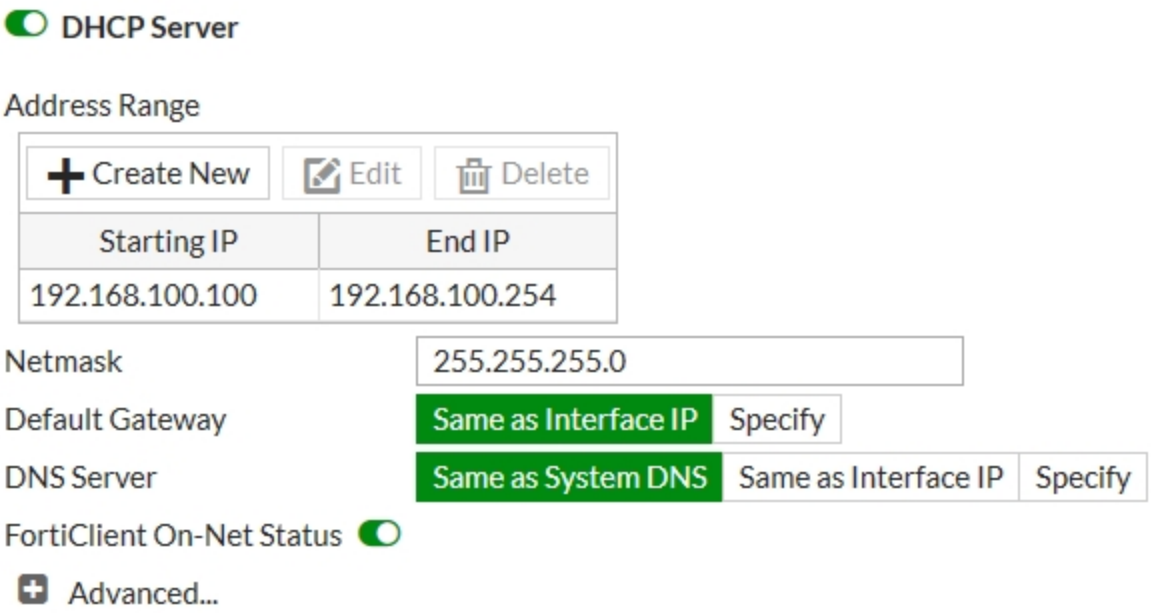


After enabling FortiTelemetry, under **Admission Control** you can select **Enforce FortiTelemetry for all FortiClients** to require clients to have FortiClient installed to be able to get access through the FortiGate. If you enable this feature you should also go to **Security Profiles > FortiClient Profiles** and configure FortiClient Profiles. Then you should add the configured FortiClient Profiles to firewall policies with device detection.

Use the following CLI command to enable FortiHeartBeat on an interface and enable enforcing FortiHeartBeat for all FortiClients:

```
config system interface
   edit port1
      set listen-forticlient-connection enable
      set endpoint-compliance enable
   end
```

After enabling FortiTelemetry, you can also enable **DHCP server** and turn on **FortiClient On-Net Status** to display the on-net status of FortiClient devices on the FortiClient Monitor (go to **Monitor > FortiClient Monitor**).



Use the following CLI command to enable FortiClient on-net status for a DHCP server added to the port1 interface:

```
config system dhcp server
   edit 1
      set interface port1
      set forticlient-on-net-status enable
   end
```

There was a name change involved with this feature. For 5.4.0, it was refered to as FortiHeartBeat, but this only appears in the 5.4.0 GA version of the FortiOS firmware.

TLS support for Dynamic DNS Services (DDNS) (300231)

This feature is available on the FortiGate 140-POE

When clear-text is disable, the FortiGate will use ssl connection to send and receive updates to Dynamic DNS services.

To disable clear-text:

```
config system ddns
   set clear-text disable
   end
```

The ssl-certificate name can also be set in the same location using the command:

```
   set ssl-certificate <cert_name>
```

Defaults:

- clear-text =`enable`
- ssl-certificate = `Fortinet_Factory`

DDNS update override for DHCP (306525 290048)

This feature is available on the FortiGate 140-POE

DHCP server now has an override command option, which allows DHCP server communications to go through DDNS to do updates for the DHCP client.

- This will force a DDNS update of the AA field every time even if the DHCP client does not request it.
- This will allow the support of the allow/ignore/deny client-updates options.

Syntax:

```
config system dhcp server
   edit 0
      set ddns-update_override [enable | disable]
      end
```

disable	Disable DDNS update override for DHCP
enable	Enable DDNS update override for DHCP

Enable or disable individual static and policy routes (174956)

CLI support has been added to [enable | disable] Static and Policy routes.

Syntax for static route in IPv4:

```
config route static
   edit 0
      set status [enable|disable]
      end
```

Syntax for static route in IPv6:

```
config route static6
   edit 0
      set status [enable|disable]
      end
```

Syntax for policy route in IPv4:

```
config router policy
   edit 0
      set status [enable|disable]
      end
```

Syntax for policy route in IPv6:

```
config router policy6
   edit 0
      set status [enable|disable]
      end
```

New option to allow copying of DSCP value in GRE tunnels (306331)

DSCP stands for the Differentiated services code point found in IPv4 and IPv6 headers, used for classifying and managing network traffic such as it relates to Quality of Service. This feature enables the keeping of the DSCP marking in the packets after encapsulation for going through GRE tunnels.

New DHCPv6 Prefix hint feature (302304)

This feature is used to "hint" to upstream DCHPv6 servers a desired prefix length for their subnet to be assigned in response to its request.

There is a possibility of duplicate prefixes being sent by ISP when using a /64 bit subnet because the first 64 bits of the address are derived from the mac address of the interface. This could cause an issue if the system administrator wishes to divide the host networks into 2 /64 bit subnets.

By receiving a /60 bit (for example) network address, the administrator can then divide the internal host works without the danger of creating duplicate subnets.

Also included in the new feature are preferred times for the life and valid life of the DHCP lease.

DHCPv6 hint for the prefix length

`set dhcp6-prefix-hint` <DHCPv6 prefix that will be used as a hint to the upstream DHCPv6 server>

DHCPv6 hint for the preferred life time.

`set dhcp6-prefix-hint-plt` <integer> 1 ~ 4294967295 seconds or "0" for unlimited lease time

DHCPv6 hint for the valid life time.

`set dhcp6-prefix-hint-vlt` <integer> 1 ~ 4294967295 seconds or "0" for unlimited lease tim

The FortiOS DHCP server now has an increased number of DHCP option fields (307342)

In place of specific fields the DHCP server now maintains a table for the potential options. The FortiOS DHCP server supports upto a maximum of 30 custom options.These optional fields are set in the CLI.

To get to the DHCP server:

```
config system dhcp server
   edit <integer - ID of the specific DHCP server>
```

To configure the options:

```
      config options
```

Once in the options context, a few new configuration commands are available. First create an ID for the table entry:

```
edit <integer>
   set code <integer between 0 - 4294967295 to determine the DHCP option>
   set type [ hex | string | ip ]
   set value <option content for DHCP option types hex and string>
   set ip <option content for DHCP option type ip>
end
```

New option to dedicate a FortiGate interface to connect to a managed FortiSwitch (294607)

When setting up an interface, an additional option has been added to the potential addressing modes that dedicates the interface to being the connection to a FortiSwitch.This is covered in more detail in the FortiSwitch section.

New CLI option to change the maximum number of IP route cache entries (363410)

The maximum number of route cache entries is configurable.

Syntax:

```
config system global
   set max-route-cache-size <integer between 0 - 2147483647>
   end
```

Unsetting the field will cause the value to be set to the kernel calculated default.

```
config system global
   unset max-route-cache-size
   end
```

Support for 802.1x fallback and 802.1x dynamic VLANs (308012)

There are 4 modes when enabling 802.1x on a virtual switch interface:

Default	In this mode, it works as it did previously.
Fallback	In fallback mode, the virtual switch will be treated as a master. Only one slave can refer to a fallback master. Those ports in the master virtual switch are always authorized. After passing 802.1x authentication, the ports will be stay authorized and moved to its slave virtual switch.
Dynamic-vlan	In dynamic-vlan mode, the virtual switch will also be treated as a master. However, many slaves can refer to a dynamic-vlan master. Those ports in the master virtual switch are always un-authorized. After passing 802.1x/MAB authentication, the ports will be set to authorized and moved to one of its slave virtual switches.
Slave	In slave mode, a master must be set through security-8021x-master attribute. A slave virtual switch will use its master virtual switch's security-groups settings for authentication.

CLI example for fallback mode

```
config system virtual-switch
   edit "fallsw"
      set physical-switch "sw0"
      config port
   end
   edit "trust"
      set physical-switch "sw0"
   end
config system interface
   edit "fallsw"
      set vdom "root"
      set ip 192.168.20.1 255.255.255.0
      set allowaccess ping https ssh snmp http telnet fgfm auto-ipsec radius-acct probe-
          response capwap
      set type hard-switch
      set security-mode 802.1X
      set security-8021x-mode fallback(fallback mode master switch)
      set security-groups "rds-grp"(the usergroup for 802.1x)
      set snmp-index 10
      next
   edit "trust"
      set vdom "root"
      set ip 192.168.22.1 255.255.255.0
```

```
      set allowaccess ping https ssh snmp http telnet fgfm auto-ipsec radius-acct probe-
          response
      set type hard-switch
      set security-mode 802.1X
      set security-8021x-mode slave(slave mode switch)
      set security-8021x-master "fallsw" (its master switch)
      set snmp-index 6
      next
   end
```

CLI example for dynamic-vlan mode

```
config system virtual-switch
   edit "internal"
      set physical-switch "sw0"
   edit "lan-trust"
      set physical-switch "sw0"
      next
   edit "lan-vlan1000"
      set physical-switch "sw0"
      next
   edit "lan-vlan2000"
      set physical-switch "sw0"
      config port
      edit "internal1" (normally we should not add port in slave switch. This is used if
          user wants to manually add one port in slave)
      end
   end
config system interface
   edit "internal"
      set vdom "root"
      set ip 192.168.11.99 255.255.255.0
      set allowaccess ping https ssh http fgfm capwap
      set type hard-switch
      set security-mode 802.1X
      set security-8021x-mode dynamic-vlan<------dynamic-vlan mode master switch
      set security-groups "rds-grp"<------the usergroup for 802.1x
      set snmp-index 15
      next
   edit "lan-trust"
      set vdom "root"
      set ip 192.168.111.99 255.255.255.0
      set allowaccess ping https ssh snmp http telnet fgfm auto-ipsec radius-acct probe-
          response capwap
      set type hard-switch
      set security-mode 802.1X
      set security-8021x-mode slave<-----slave mode switch
      set security-8021x-master "internal"<-----its master switch
      set snmp-index 7
      next
   edit "lan-vlan1000"
      set vdom "root"
      set ip 192.168.110.1 255.255.255.0
      set allowaccess ping https ssh snmp http telnet fgfm auto-ipsec radius-acct probe-
          response capwap
      set type hard-switch
      set security-mode 802.1X
      set security-8021x-mode slave<-----slave mode switch
```

```
    set security-8021x-master "internal"<-----its master switch
    set security-8021x-dynamic-vlan-id 1000 <-----the matching vlan id for this virtual
        switch
    set snmp-index 16
    next
  edit "lan-vlan2000"
    set vdom "root"
    set ip 192.168.220.1 255.255.255.0
    set allowaccess ping https ssh snmp http telnet fgfm auto-ipsec radius-acct probe-
        response capwap
    set type hard-switch
    set security-mode 802.1X
    set security-8021x-mode slave
    set security-8021x-master "internal"
    set security-8021x-dynamic-vlan-id 2000
    set snmp-index 17
    end
  config user group
    edit "rds-grp"
      set dynamic-vlan-id 4000(default vlan id if there is no vlan attribute return
          from server)
      set member "190"
    end
```

New Features in 5.4.0

Internet-Service database (288672 281333 291858)

Go to ***Policy & Objects > Internet Service Database*** to view the Internet Service Database. The database contains detailed information about services available on the Internet such as DNS servers provided by Adobe, Google, Fortinet, Apple and so on and a wide range of other services. For each service the database includes the IP addresses of the servers that host the service as well as the port and protocol number used by each IP address.

Interfaces assigned to Virtual Wired Pairs don't have "roles" (296519)

Assigning an interface to be part of a virtual wire pairing will remove the "role" value from the interface.

STP (Spanning Tree Protocol) support for models with hardware switches (214901 291953)

STP used to be only available on the old style switch mode for the internal ports. It is now possible to activate STP on the hardware switches found in the newer models. These models use a virtual switch to simulate the old Switch Mode for the Internal ports.

The syntax for enabling STP is as follows:

```
config system interface
  edit lan
  set stp [enable | disable]
  end
```

Command to determine interface transceiver optical signal strength (205138 282307)

The new `get system interface transceiver` command can be used to determine optical signal strength when using SFP/SFP+ modules. The command can be used for trouble shooting fiber optic connections to service providers. This command is hardware dependent and currently supported by FortiGate models that include various SFP/SFP+ interfaces including the FortiGate-100D/200D-POE/400D/500D/900D/1000D/1200D/1500D/3700D/3700DX) models.

New command to get IPv6 multicast router information (267650)

The following command displays IPv6 multicast router information just like the IPv4 version of the command.

```
get router info6 multicast.
```

FortiGate DHCP works with DDNS to allow FQDN connectivity to leased IPs (267043)

As clients are assigned IP addresses, they send back information that would be found in an A record to the FortiGate's DHCP server, which can take this information and passes it back to a corporate DNS server so that even devices using leased IP address can be reached using FQDNs. The settings for this feature are configured through the CLI using the ddns-update command and some other ddns related options.

Fortinet's Dynamic DNS services (FortiDDNS) can be registered to a public IP address (251748)

Fortinet's Dynamic DNS services (FortiDDNS) can be registered to a public IP address even if the FortiGate itself does not have any physical interfaces on the Internet. This is applicable when the FortiGate is behind other networking devices that are employing NAT. This can be configured in the GUI as well as CLI.

Can use firewall addresses for static route destinations (273672)

To help prevent false positive when scanning for duplicate static routes, the dst_addr field is also checked.

Can use firewall addresses for policy route destinations (244101)

When configuring a policy route, firewall addresses and address groups can be used. The only exception for address types that can be used is the URL type of address object.

Enhance TWAMP Light functionality with server/controller functionality (249255)

TWAMP(Two-Way Active Measurement Protocol) Light is a simplified architecture within the TWAMP standard. Its purpose is to measure the round trip IP performance between any two devices within a network that supports the protocol. Now FortiOS operates in more than just the role of responder/reflector.The server/controller functionality has been added.

More information about interface status available from GUI (240285)

The following information is added to the 'hover' details for each port on the GUI FortiGate faceplate:

- MAC address
- Tx/Rx bytes
- Tx/Rx packets
- Tx/Rx errors

In addition, optional columns are added to the interface list to allow users to see all of the above information.

Virtual WAN link fixes (255122)

The firmware now has the following fixes or improvements to Virtual WAN links (VWL):

- Better support for dynamic interfaces (PPPoE and DHCP).
  - It can remove dynamically added routes, and restore these routes once the interfaces are not members.
  - It can count pppoe interface sessions.
  - It can generate a proute for a PPPoE interface. In this proute, the gateway is specified, while the outgoing (PPPoE)interface will not set.
- Adjust the route policy for a manual mode VWL service
- Support HTTP monitor by version 1.1, which obsoletes version 1.0's behavior.
- Apply multiple dst and src new feature for one policy to VWL.
- Improvements to CLI usability:
  - It hides interfaces that are being used in a policy or a zone
  - There is a check when adding an interface to a static route. This check will raise an error if the interface is a member of a VWL.
  - Updates a proute, if based on config change, if the associated link-monitor dies.
  - Fix some inappropriate messages.
  - Revised the minimum value of interval for a link-monitor object. The new value is 1, so it can be compatible with V5.0. When the timeout is 1, and interval is 1.

Router > Static > Settings GUI options available from the CLI only

As part of the new WAN Load Balancing feature, the FortiOS 5.2 **Router > Static > Settings** GUI page has been removed. WAN Load Balancing should be used instead of the 5.2 **ECMP Load Balancing Method** settings. The 5.2 **Link Health Monitor** definitions are now only available from the CLI.

Ports preassigned as sniffer ports by default (261921)

Some models of FortiGate, by default have ports preconfigured as sniffer ports.

The models and ports preconfigered in sniffer mode are as follows:

- FortiGate 300D
  - Port4
  - Port8
- FortiGate 500D
  - Port5
  - Port6
  - Port13
  - Port14

Enable or disable inspecting IPv4 and IPv6 ICMP traffic (258734)

In order for the inspection of assymetric ICMP traffic to not affect TCP and UDP traffic, a pair of settings have been added that can enable/disable the inspection of ICMP traffic being routed assymetricly for both IPv4 and IPv6.

The syntax in the CLI for configuring the setting is:

- IPv4

```
config system settings
   set asymroute-icmp
   end
```

- IPv6

```
config system settings
   set asymroute6-icmp
   end
```

Send GARP on aggregate MAC change (273363)

FortiGates will send out GARP (Gratuitous Address Resolution Protocol) announcements if the MAC address of a link aggregated interface has changed to a new IP pool address due to a link failure or change in ports. This is needed when using networking devices, such as some switches, that don't perform this function when they receive LACP (Link Aggregation Control Protocol) information about changes in the MAC information.

Support split ports (252444)

The 5001D 40 GB can be split into 4 10 GB ports.This is done through a combination of hardware and software configuration. A specific 40 GB connector is used to connect to the 40 GB port and normally, the other end of the fibre optic cable would connect to another 40 GB port but a special cable can be used that is a single 40 GB connector at one end and 4 10 GB connections at the other. To use this set up the port also has to be configured to be a split port.

The configuration option can be found in the CLI:

```
config system global
   set port-split port1 port2
   end
```

The ports will be checked to make sure that they are not in use or referenced by other policy configurations. If in use the command will be aborted. Changing the port to be a split port will require a system reboot.

Add FortiClient enforcement to interfaces (253933)

The use of FortiClient can be enforced on individual interfaces. Go to **Network > Interfaces** and pick the interface of your choice. Under the heading **Admission Control**, you can enable the setting **Allow FortiClient Connections**.Once this setting is enabled, two more options become visible, **Discover Clients (Broadcast)** and **FortiClient Enforcement**. By enabling FortiClient Enforcement you enforce that in order for incoming traffic to pass through that interface it must be initiated by a device running FortiClient.

Once the use of FortiClient is enforced on the interface, FortiClient profiles should also be configured for the incoming connections. You can also set up any exemptions that are needed. Just below the **FortiClient Enforcement** option are fields for **Exempt Sources** and **Exempt Destinations/Services**. These can be selected from address or services object already configured on the FortiGate.

In the CLI the enforcement can be set up as follows:

```
config system interface
   edit port1
      set listen-forticlient-connection [enable|disable]
      set endpoint-compliance [enable|disable]
      end
```

Botnet C&C protection added to interfaces (254959)

The function of Botnet and Command & Control traffic protection is not new but how it can be configured has changed. It is no longer part of the AntiVirus Security profile.

The option to **ScanOutgoing Connections to Botnet Sites** has been added to the Interface page in the GUI.

The options are **Disable**, **Block** and **Monitor.**

In the CLI, the botnet scan can be configured on the interface by entering the following commands:

```
config system interface
   edit <interface>
      set scan-botnet-connections [disable | block | monitor]
      end
```

It is also possible to enable the scanning of botnet and C&C traffic in

- Firewall policies

```
config firewall policy
   edit <policyid>
      set scan-botnet-connections [disable | block | monitor]
      end
```

- Firewall explicit proxy policies

```
config firewall explicit-proxy-policy
   edit <policyid>
      set scan-botnet-connections [disable | block | monitor]
      end
```

- Firewall interface policy

```
config firewall interface-policy
   edit <policyid>
      set scan-botnet-connections [disable | block | monitor]
      end
```

- Firewall sniffer

```
config firewall sniffer
   edit <policyid>
      set scan-botnet-connections [disable | block | monitor]
      end
```

Netflow 9.0 support (167405)

Netflow is a networking feature introduced by Cisco to collect and export information about traffic flow through routers. IPFIX (Internet Protocol Flow Information Export) is the standardized Internet Protocol based on NetFlow version 9. The standards requirements for IPFIX are outlined in RFC 3197 and its basic specifications and other information are documented in RFC 5103, RFC 6759 and RFC 7011 through RFC 7015.

The CLI changes that enable and configure "NetFlow" traffic are:

```
config system netflow
   set collector-ip <collector IP>
   set collector-port <NetFlow collector port>
   set csource-ip <Source IP for NetFlow agent>
   set cactive-flow-timeout <time in minutes of timeout to report active flows>
   set cinactive-flow-timeout <time in seconds of timeout for periodic report of finished
       flows>
   end
```

These setting can also be configured per VDOM by going to:

```
config system vdom-netflow
```

A Netflow sampler will also have to be enabled on specific interfaces.

IPv6 blackhole static routing (220101)

System administrators use black hole routing to divert undesirable traffic, such as packets from a Denial of Service (DoS) attack or communications from an illegal source. The traffic is routed to a dead interface, or a host designed to collect information for investigation. This mitigates the impact of the attack on the network.

The use of blackhole routing is enabled in the CLI as follows:

```
config router static6
   edit <ID #>
      set blackhole enable
   end
```

A collection of Routing changes (261043)

A few new settings have been added to the CLI to assist in the supporting of the IPsec Auto Discovery feature. They are designed for:

- The support of the RIPng (RIP next generation) network command
- Limiting the maximum metric allowed to output for RIPng
- Fix NSM missing kernel address update info

The actual new settings are:

```
config router rip
   set max-out-metric <integer value 1 - 15>
   end

config router ripng
   set max-out-metric <integer value 1 - 15>
   end

config router ripng
   config network
      edit <ID # of network>
         set prefix <IPv6 prefix>
         end
      end
```

DHCPv6 prefix delegation (266061)

Prefix delegation is now support for DHCP for IPv6 addressing. It is not practical to manually provision networks on a large scale in IPv6 networking. The DHCPv6 prefix delegation feature is used to assign a network address prefix, and automate the configuration and provisioning of the public routable addresses for the network.

Enabling the prefix delegation is done only in the CLI as in the following example:

```
config system interface
   edit "wan1"
      config ipv6
         set ip6-mode dhcp
         set ip6-allowaccess ping
```

```
        set dhcp6-prefix-delegation enable
        end
    end
```

Proxy-arp extensions (250651)

The proxy-arp configuration can be extendend to an IP address range rather than a single IP address. A new setting has been added to the CLI. When configuring the proxy-arp, in addtion to setting the IP address, an end-ip address can also be set. If it is not set, the proxy-arp will be a single address as before. An example configuration using the new setting would be a follows:

```
config system proxy-arp
   edit 1
      set interface "internal"
      set ip 192.168.1.100
      set end-ip 192.168.1.102
      end
```

Interfaces

Interfaces, both physical and virtual, enable traffic to flow to and from the internal network, and the Internet and between internal networks. The FortiGate unit has a number of options for setting up interfaces and groupings of subnetworks that can scale to a company's growing requirements.

The following topics are discussed in this section:

Administrative access

Interfaces, especially the public-facing ports can be potentially accessed by those who you may not want access to the FortiGate unit. When setting up the FortiGate unit, you can set the type of protocol an administrator must use to access the FortiGate unit. The options include:

- HTTPS
- SSH
- SNMP
- PING
- CAPWAP
- RADIUS Acounting
- FortiManager Access (FMG-Access)
- FortiTelemetry

You can select as many, or as few, even none, that are accessible by an administrator.

This example adds an IPv4 address 172.20.120.100 to the WAN1 interface as well as the administrative access to HTTPS and SSH. As a good practice, set the administrative access when you are setting the IP address for the port.

To add an IP address on the WAN1 interface - web-based manager

1. Go to **Network > Interface**.
2. Select the WAN1 interface row and select **Edit**.
3. Select the **Addressing Mode** of **Manual**.
4. Enter the IP address for the port of 172.20.120.100/24.
5. For **Administrative Access**, select **HTTPS** and **SSH**.
6. Select **OK**.

To create IP address on the WAN1 interface - CLI

```
config system interface
   edit wan1
      set ip 172.20.120.100/24
      set allowaccess https ssh
end
```

When adding to, or removing a protocol, you must type the entire list again. For example, if you have an access list of HTTPS and SSH, and you want to add PING, typing:

```
set allowaccess ping
```

...only PING will be set. In this case, you must type...

```
set allowaccess https ssh ping
```

Aggregate Interfaces

Link aggregation (IEEE 802.3ad) enables you to bind two or more physical interfaces together to form an aggregated (combined) link. This new link has the bandwidth of all the links combined. If a link in the group fails, traffic is transferred automatically to the remaining interfaces with the only noticeable effect being a reduced bandwidth.

This is similar to redundant interfaces with the major difference being that a redundant interface group only uses one link at a time, where an aggregate link group uses the total bandwidth of the functioning links in the group, up to eight (or more).

Support of the IEEE standard 802.3ad for link aggregation is available on some models.

An interface is available to be an aggregate interface if:

- it is a physical interface, not a VLAN interface or subinterface
- it is not already part of an aggregate or redundant interface
- it is in the same VDOM as the aggregated interface. Aggregate ports cannot span multiple VDOMs
- it does not have an IP address and is not configured for DHCP or PPPoE
- it is not referenced in any security policy, VIP, IP Pool or multicast policy
- it is not an HA heartbeat interface
- it is not one of the FortiGate-5000 series backplane interfaces

Some models of FortiGate units do not support aggregate interfaces. In this case, the aggregate option is not an option in the web-based manager or CLI. As well, you cannot create aggregate interfaces from the interfaces in a switch port.

To see if a port is being used or has other dependencies, use the following diagnose command:

```
diagnose sys checkused system.interface.name <interface_name>
```

When an interface is included in an aggregate interface, it is not listed on the **Network > Interface** page. Interfaces will still appear in the CLI, although configuration for those interfaces will not take affect. You cannot configure the interface individually and it is not available for inclusion in security policies, VIPs, IP pools, or routing.

Example

This example creates an aggregate interface on a FortiGate-3810A using ports 4-6 with an internal IP address of 10.13.101.100, as well as the administrative access to HTTPS and SSH.

To create an aggregate interface - web-based manager

1. Go to **Network > Interface** and select **Create New**, then **Interfaces**
2. Enter the Name as `Aggregate`.
3. For the **Type**, select **802.3ad Aggregate**.
   If this option does not appear, your FortiGate unit does not support aggregate interfaces.
4. In the **Physical Interface Members** click to add interfaces, select port 4, 5 and 6.
5. Select the **Addressing Mode** of **Manual**.
6. Enter the IP address for the port of 10.13.101.100/24.
7. For **Administrative Access** select HTTPS and SSH.
8. Select **OK**.

To create aggregate interface - CLI

```
config system interface
   edit Aggregate
      set type aggregate
      set member port4 port5 port6
      set vdom root
      set ip 172.20.120.100/24
      set allowaccess https ssh
   end
```

DHCP addressing mode on an interface

If you configure an interface to use DHCP, the FortiGate unit automatically broadcasts a DHCP request from the interface. The interface is configured with the IP address and any DNS server addresses and default gateway address that the DHCP server provides.

DHCP IPv6 is similar to DHCP IPv4, however there is:

- no default gateway option defined because a host learns the gateway using router advertisement messages
- no WINS servers because it is obsolete.

For more information about DHCP IPv6, see RFC 3315.

Configure DHCP for an interface in **Network > Interface** and selecting the interface from the list, and selecting **DHCP** in the **Address Mode**. The table describes the DHCP status information when DHCP is configured for an interface.

Addressing mode section of New Interface page for DHCP information	
Status	Displays DHCP status messages as the interface connects to the DHCP server and gets addressing information. Select **Status** to refresh the addressing mode status message. Status can be one of: • **initializing** - No activity. • **connecting** - interface attempts to connect to the DHCP server. • **connected** - interface retrieves an IP address, netmask, and other settings from the DHCP server. • **failed** - interface was unable to retrieve an IP address and other settings from the DHCP server.
Obtained IP/Netmask	The IP address and netmask leased from the DHCP server. Only displayed if **Status** is **connected**.
Renew	Select to renew the DHCP license for this interface. Only displayed if **Status** is **connected**.
Expiry Date	The time and date when the leased IP address and netmask is no longer valid for the interface. The IP address is returned to the pool to be allocated to the next user request for an IP address. Only displayed if **Status** is **connected**.
Default Gateway	The IP address of the gateway defined by the DHCP server. Only displayed if **Status** is **connected**, and if **Receive default gateway from server** is selected.
Distance	Enter the administrative distance for the default gateway retrieved from the DHCP server. The administrative distance, an integer from 1-255, specifies the relative priority of a route when there are multiple routes to the same destination. A lower administrative distance indicates a more preferred route.
Retrieve default gateway from server	Enable to retrieve a default gateway IP address from the DHCP server. The default gateway is added to the static routing table.
Override internal DNS	Enable to use the DNS addresses retrieved from the DHCP server instead of the DNS server IP addresses on the DNS page. When VDOMs are enabled, you can override the internal DNS only on the management VDOM.

DHCP servers and relays

Note that DHCP server options are not available in transparent mode.

A DHCP server provides an address to a client on the network, when requested, from a defined address range.

An interface cannot provide both a server and a relay for connections of the same type (regular or IPsec). However, you can configure a Regular DHCP server on an interface only if the interface is a physical interface with a static IP address. You can configure an IPsec DHCP server on an interface that has either a static or a dynamic IP address.

You can configure one or more DHCP servers on any FortiGate interface. A DHCP server dynamically assigns IP addresses to hosts on the network connected to the interface. The host computers must be configured to obtain their IP addresses using DHCP.

If an interface is connected to multiple networks via routers, you can add a DHCP server for each network. The IP range of each DHCP server must match the network address range. The routers must be configured for DHCP relay.

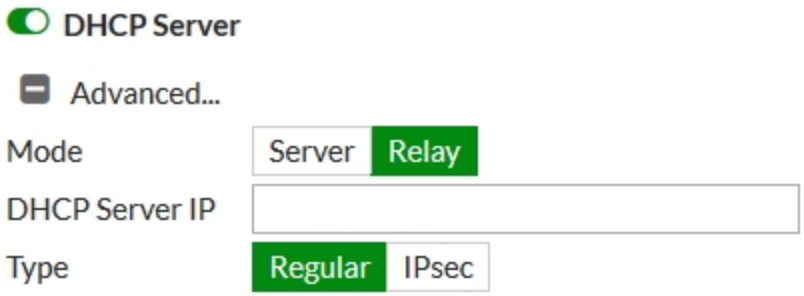
You can configure a FortiGate interface as a DHCP relay. The interface forwards DHCP requests from DHCP clients to an external DHCP server and returns the responses to the DHCP clients. The DHCP server must have appropriate routing so that its response packets to the DHCP clients arrive at the unit.

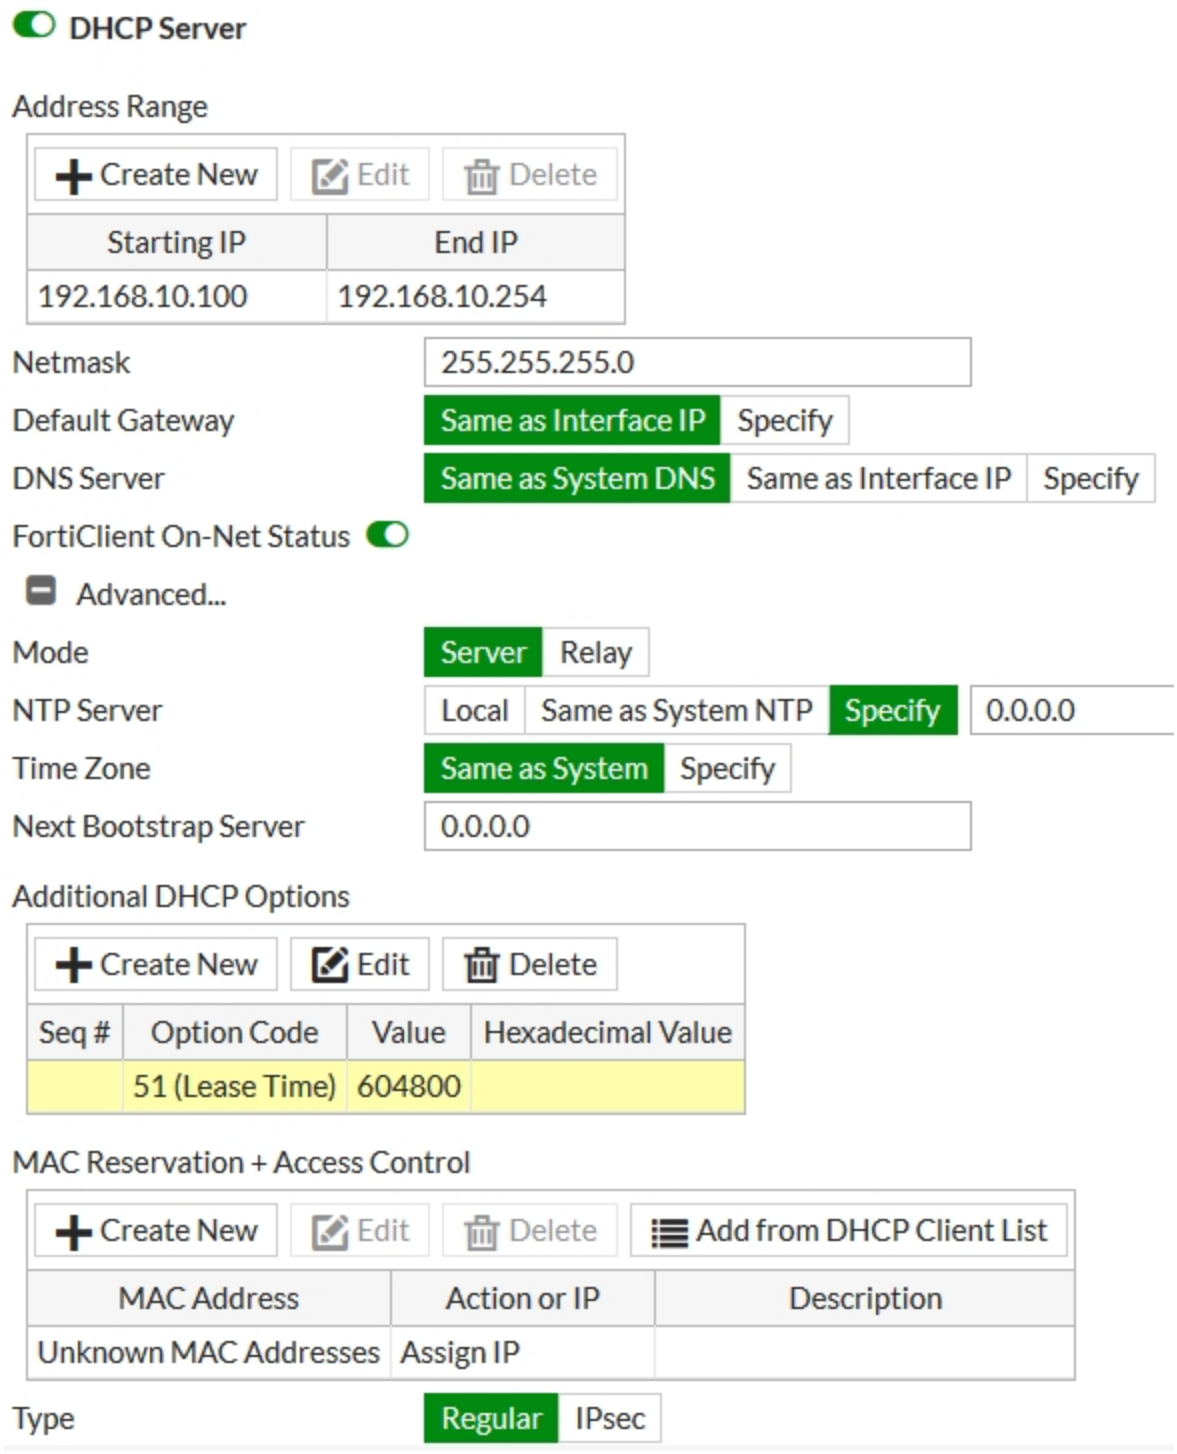
DHCP Server configuration

To add a DHCP server, go to **Network > Interfaces**. Edit the interface, and select **DHCP** in the addressing mode.

Address Range	By default, the FortiGate unit assigns an address range based on the address of the interface for the complete scope of the address. For example, if the interface address is 172.20.120.230, the default range created is 172.20.120.231 to 172.20.120.254. Select the range and select **Edit** to adjust the range as needed, or select **Create New** to add a different range.
Netmask	Enter the netmask of the addresses that the DHCP server assigns.
Default Gateway	Select to either use **Same as Interface IP** or select **Specify** and enter the IP address of the default gateway that the DHCP server assigns to DHCP clients.
DNS Server	Select to use **Same as system DNS**, **Same as Interface IP** or select **Specify** and enter the IP address of the DNS server.
Advanced... (expand to reveal more options)	
Mode	Select the type of DHCP server the FortiGate unit will be. By default, it is a **Server**. Select **Relay** if needed. When **Relay** is selected, the above configuration is replaced by a field to enter the **DHCP Server IP** address.
DHCP Server IP	This appears only when **Mode** is **Relay**. Enter the IP address of the DHCP server where the FortiGate unit obtains the requested IP address.
Type	Select to use the DHCP in **Regular**or **IPsec**mode.
Additional DHCP Options	Use this to create new DHCP options as required.

MAC Address + Access Control	Select to match an IP address from the DHCP server to a specific client or device using its MAC address. In a typical situation, an IP address is assigned ad hoc to a client, and that assignment times out after a specific time of inactivity from the client, known as the lease time. To ensure a client or device always has the same IP address, that is, there is no lease time, use IP reservation.
Add from DHCP Client List	If the client is currently connected and using an IP address from the DHCP server, you can select this option to select the client from the list.





DHCP in IPv6

You can use DHCP with IPv6 using the CLI. To configure DHCP, ensure IPv6 is enabled by going to **System > Feature Select**and enable **IPv6** under the **Basic Features**. Use the CLI command

```
config system dhcp6 server
```

For more information on the configuration options, see the CLI Reference.

Service

On low-end FortiGate units, a DHCP server is configured, by default on the Internal interface:

IP Range	192.168.1.110 to 192.168.1.210
Netmask	255.255.255.0
Default gateway	192.168.1.99
Lease time	7 days
DNS Server 1	192.168.1.99

These settings are appropriate for the default Internal interface IP address of 192.168.1.99. If you change this address to a different network, you need to change the DHCP server settings to match.

Alternatively, after the FortiGate unit assigns an address, you can go to **Monitor > DHCP Monitor**, locate the particular user. Right click and select **Create/Edit IP Reservation**.

Lease time

The lease time determines the length of time an IP address remains assigned to a client. Once the lease expires, the address is released for allocation to the next client request for an IP address The default lease time is seven days. To change the lease time, use the following CLI commands:

```
config system dhcp server
   edit <server_entry_number>
      set lease-time <seconds>
   end
```

To have an unlimited lease time, set the value to zero.

DHCP options

When adding a DHCP server, you have the ability to include DHCP codes and options. The DHCP options are BOOTP vendor information fields that provide additional vendor-independent configuration parameters to manage the DHCP server. For example, you may need to configure a FortiGate DHCP server that gives out a separate option as well as an IP address. For example, an environment that needs to support PXE boot with Windows images.

The option numbers and codes are specific to the particular application. The documentation for the application will indicate the values to use. Option codes are represented in a option value/HEX value pairs. The option is a value 1 and 255.

You can add up to three DHCP code/option pairs per DHCP server.

To configure option 252 with value http://192.168.1.1/wpad.dat - CLI

```
config system dhcp server
   edit <server_entry_number>
      set option1 252 687474703a2f2f3139322e3136382e312e312f777061642e646174
end
```

For detailed information about DHCP options, see RFC 2132, DHCP Options and BOOTP Vendor Extensions.

Exclude addresses in DHCP a range

If you have a large address range for the DHCP server, you can block a range of addresses that will not be included in the available addresses for the connecting users. To do this, go to the CLI and enter the commands:

```
config system dhcp server
   edit <server_entry_number>
      config exclude-range
         edit <sequence_number>
            set start-ip <address>
            set end-ip <address>
         end
      end
   end
```

DHCP Monitor

To view information about DHCP server connections, go to **Monitor > DHCP Monitor**. On this page, you can also add IP address to the reserved IP address list.

Breaking an address lease

Should you need to end an IP address lease, you can break the lease using the CLI. This is useful if you have limited addresses, longer lease times where leases are no longer necessary. For example, with corporate visitors.

To break a lease enter the CLI command:

```
execute dhcp lease-clear <ip_address>
```

Interface MTU packet size

You can change the maximum transmission unit (MTU) of the packets that the FortiGate unit transmits to improve network performance. Ideally, the MTU should be the same as the smallest MTU of all the networks between the FortiGate unit and the destination of the packets. If the packets that the FortiGate unit sends are larger than the smallest MTU, they are broken up or fragmented, which slows down transmission. You can easily experiment by lowering the MTU to find an MTU size for optimum network performance.

- 68 to 1 500 bytes for static mode
- 576 to 1 500 bytes for DHCP mode
- 576 to 1 492 bytes for PPPoE mode
- larger frame sizes if supported by the FortiGate model - up to 9216 bytes for NP2, NP4, and NP6-accelerated interfaces

Only available on physical interfaces. Virtual interfaces associated with a physical interface inherit the physical interface MTU size.

Interfaces on some models support frames larger than the traditional 1500 bytes. Jumbo frames are supported on FortiGate models that have either a SOC2 or NP4lite, except for the FortiGate-30D, as well as on FortiGate-100D series models (for information about your FortiGate unit's hardware, see the Hardware Acceleration guide). For other models, please contact Fortinet Customer Support for the maximum frame size that is supported.

If you need to enable sending larger frames over a route, you need all Ethernet devices on that route to support that larger frame size, otherwise your larger frames will not be recognized and are dropped.

If you have standard size and larger size frame traffic on the same interface, routing alone cannot route them to different routes based only on frame size. However, you can use VLANs to make sure the larger frame traffic is routed over network devices that support that larger size. VLANs will inherit the MTU size from the parent interface. You will need to configure the VLAN to include both ends of the route as well as all switches and routers along the route.

MTU packet size is changed in the CLI. If you select an MTU size larger than your FortiGate unit supports, an error message will indicate this. In this situation, try a smaller MTU size until the value is supported.

In Transparent mode, if you change the MTU of an interface, you must change the MTU of all interfaces on the FortiGate unit to match the new MTU.

To change the MTU size, use the following CLI commands:

```
config system interface
   edit <interface_name>
      set mtu-override enable
      set mtu <byte_size>
end
```

Interface settings

In **Network > Interface**, you configure the interfaces, physical and virtual, for the FortiGate unit. There are different options for configuring interfaces when the FortiGate unit is in NAT mode or transparent mode. On FortiOS Carrier, you can also enable the Gi gatekeeper on each interface for anti-overbilling.

Interface page	
Create New	Select to add a new interface, zone or, in transparent mode, port pair. Depending on the model you can add a VLAN interface, a loopback interface, a IEEE 802.3ad aggregated interface, or a redundant interface. When VDOMs are enabled, you can also add Inter-VDOM links.
Name	The names of the physical interfaces on your FortiGate unit. This includes any alias names that have been configured. When you combine several interfaces into an aggregate or redundant interface, only the aggregate or redundant interface is listed, not the component interfaces. If you have added VLAN interfaces, they also appear in the name list, below the physical or aggregated interface to which they have been added. If you have added loopback interfaces, they also appear in the interface list, below the physical interface to which they have been added. If you have software switch interfaces configured, you will be able to view them. If your FortiGate unit supports AMC modules, the interfaces are named amc-sw1/1, amc-dw1/2, and so on.

Interface page	
Type	The configuration type for the interface.
IP/Netmask	The current IP address and netmask of the interface. In VDOM, when VDOMs are not all in NAT or transparent mode some values may not be available for display and will be displayed as "-".
Access	The administrative access configuration for the interface.
Administrative Status	Indicates if the interface can be accessed for administrative purposes. If the administrative status is a green arrow, and administrator could connect to the interface using the configured access. If the administrative status is a red arrow, the interface is administratively down and cannot be accessed for administrative purposes.
Link Status	The status of the interface physical connection. Link status can be either up (green arrow) or down (red arrow). If link status is up the interface is connected to the network and accepting traffic. If link status is down the interface is not connected to the network or there is a problem with the connection. You cannot change link status from the web-based manager, and typically is indicative of an ethernet cable plugged into the interface. Link status is only displayed for physical interfaces.
MAC	The MAC address of the interface.
Mode	Shows the addressing mode of the interface. The addressing mode can be manual, DHCP, or PPPoE.
Secondary IP	Displays the secondary IP addresses added to the interface.
MTU	The maximum number of bytes per transmission unit (MTU) for the interface.
Virtual Domain	The virtual domain to which the interface belongs. This column is visible when VDOM configuration is enabled.
VLAN ID	The configured VLAN ID for VLAN subinterfaces.

Interface configuration and settings

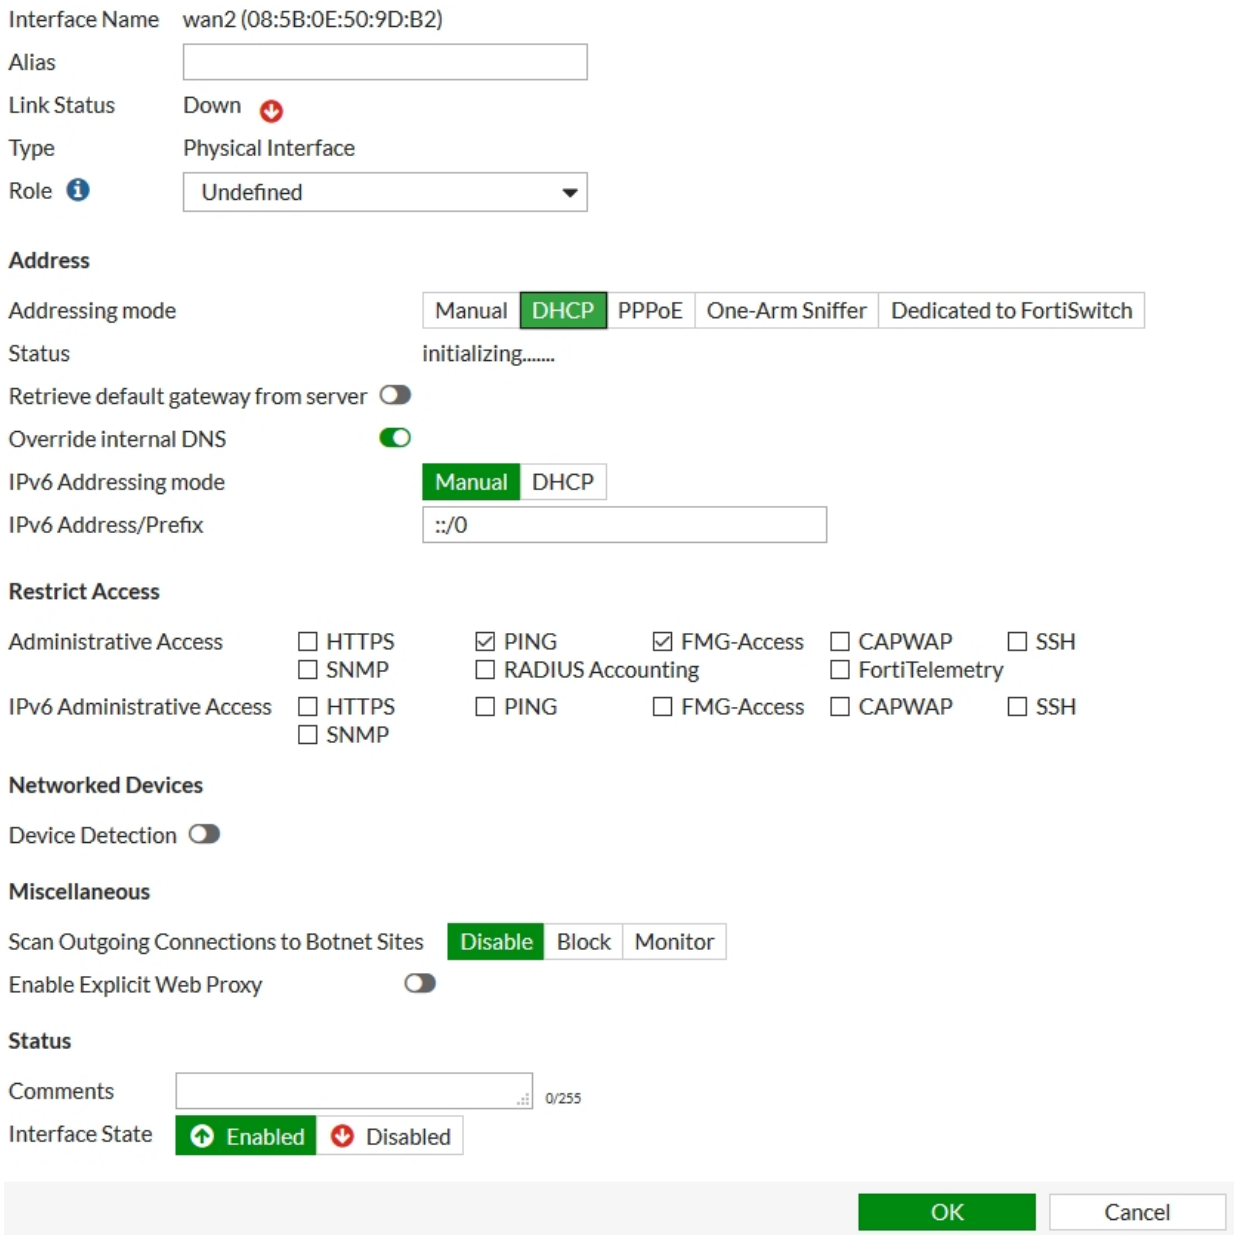
To configure an interface, go to **Network > Interface**and select **Create New**.

Name	Enter a name of the interface. Physical interface names cannot be changed.

Alias	Enter an alternate name for a physical interface on the FortiGate unit. This field appears when editing an existing physical interface. The alias can be a maximum of 25 characters. The alias name will not appears in logs.
Link Status	Indicates whether the interface is connected to a network (link status is **Up**) or not (link status is **Down**). This field appears when editing an existing physical interface.
Type	Select the type of interface that you want to add. On some models you can set **Type** to **802.3ad Aggregate** or **Redundant Interface**.
Interface	Displayed when **Type** is set to **VLAN**. Select the name of the physical interface to which to add a VLAN interface. Once created, the VLAN interface is listed below its physical interface in the Interface list. You cannot change the physical interface of a VLAN interface except when adding a new VLAN interface.
VLAN ID	Displayed when **Type** is set to **VLAN**. Enter the VLAN ID. You cannot change the **VLAN ID** except when adding a new VLAN interface. The VLAN ID can be any number between 1 and 4094 and must match the VLAN ID added by the IEEE 802.1Q-compliant router or switch connected to the VLAN subinterface.
Virtual Domain	Select the virtual domain to add the interface to. Admin accounts with super_admin profile can change the **Virtual Domain**.
Physical Interface Members	This section has two different forms depending on the interface type: • **Software switch interface** - this section is a display-only field showing the interfaces that belong to the software switch virtual interface. • **802.3ad aggregate or Redundant interface** - this section includes available interface and selected interface lists to enable adding or removing interfaces from the interface. Select interfaces from this **Available Interfaces** list and select the right arrow to add an interface to the **Selected Interface** list.

Addressing mode	Select the addressing mode for the interface. • Select **Manual** and add an **IP/Netmask** for the interface. If IPv6 configuration is enabled you can add both a IPv4 and an IPv6 IP address. • Select **DHCP** to get the interface IP address and other network settings from a DHCP server. • Select **PPPoE** to get the interface IP address and other network settings from a PPPoE server. • Select **One-Arm Sniffer** to enable the interface as a means to detect possible traffic threats. This option is available on physical ports not configured for the primary Internet connection. • Select **Dedicate to FortiAP/FortiSwitch** to have a FortiAP unit or FortiSwitch unit connect exclusively to the interface. This option is only available when editing a physical interface, and it has a static IP address. When you enter the IP address, the FortiGate unit automatically creates a DHCP server using the subnet entered. This option is not available on the ADSL interface. The FortiSwitch option is currently only available on the FortiGate-100D.
IP/Netmask	If **Addressing Mode** is set to **Manual**, enter an IPv4 address/subnet mask for the interface. FortiGate interfaces cannot have IP addresses on the same subnet.
IPv6 Address	If **Addressing Mode** is set to **Manual** and IPv6 support is enabled, enter an IPv6 address/subnet mask for the interface. A single interface can have both an IPv4 and IPv6 address or just one or the other.
Administrative Access	Select the types of administrative access permitted for IPv4 connections to this interface.
HTTPS	Allow secure HTTPS connections to the web-based manager through this interface. If configured, this option will enable automatically when selecting the **HTTP** option.
PING	Interface responds to pings. Use this setting to verify your installation and for testing.
HTTP	Allow HTTP connections to the web-based manager through this interface. If configured, this option will also enable the **HTTPS** option.
SSH	Allow SSH connections to the CLI through this interface.
SNMP	Allow a remote SNMP manager to request SNMP information by connecting to this interface.

FMG-Access	Allow FortiManager authorization automatically during the communication exchange between the FortiManager and FortiGate units.
CAPWAP	Allows the FortiGate unit's wireless controller to manage a wireless access point, such as a FortiAP unit.
IPv6 Administrative Access	Select the types of administrative access permitted for IPv6 connections to this interface. These types are the same as for Administrative Access.
Security Mode	Select a captive portal for the interface. When selected, you can define the portal message and look that the user sees when logging into the interface. You can also define one or more user groups that have access to the interface.
DHCP Server	Select to enable a DHCP server for the interface. For more information on configuring a DHCP server on the interface, see DHCP servers and relays.
Device Detection	Select to enable the interface to be used with BYOD hardware such as iPhones. Define the device definitions by going to **User & Device > Device Inventory**.
Enable Explicit Web Proxy	Available when enabling explicit proxy on the **System Information** Dashboard (**System > Dashboard > Status**). This option is not available for a VLAN interface selection. Select to enable explicit web proxying on this interface. When enabled, this interface will be displayed on **System > Network > Explicit Proxy** under **Listen on Interfaces** and web traffic on this interface will be proxied according to the Web Proxy settings.
Secondary IP Address	Add additional IPv4 addresses to this interface. Select the Expand Arrow to expand or hide the section.
Comments	Enter a description up to 63 characters to describe the interface.
Gi Gatekeeper (FortiOS Carrier only)	For FortiOS Carrier, enable Gi Gatekeeper to enable the Gi firewall as part of the anti-overbilling configuration. You must also configure **Gi Gatekeeper Settings** by going to **System > Admin > Settings**.



Loopback interfaces

A loopback interface is a logical interface that is always up (no physical link dependency) and the attached subnet is always present in the routing table.

The FortiGate's loopback IP address does not depend on one specific external port, and is therefore possible to access it through several physical or VLAN interfaces. Multiple loopback interfaces can be configured in either non-VDOM mode or in each VDOM.

Loopback interfaces still require appropriate firewall policies to allow traffic to and from this type of interface.

A loopback interface can be used with:

- Management access
- BGP (TCP) peering
- PIM RP

Loopback interfaces are a good practice for OSPF. Setting the OSPF router ID the same as loopback IP address troubleshooting OSPF easier, and remembering the management IP addresses (ssh to “router ID”).

Dynamic routing protocols can be enabled on loopback interfaces.

For black hole static route, use the black hole route type instead of the loopback interface.

One-armed sniffer

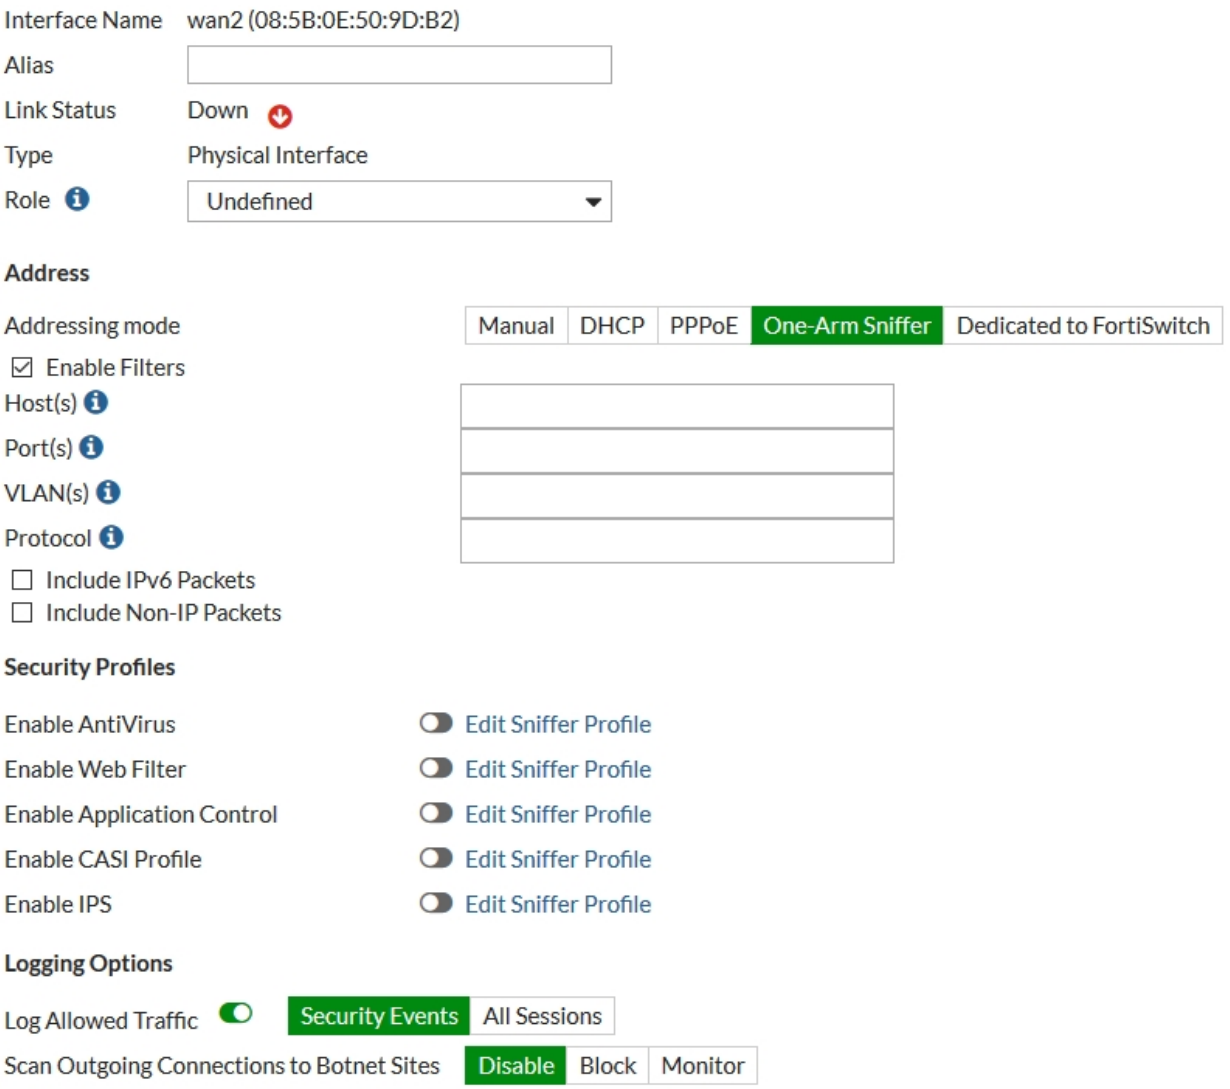
A one-armed sniffer is used to configure a physical interface on the FortiGate unit as a one-arm intrusion detection system (IDS). Traffic sent to the interface is examined for matches to the configured IPS sensor and application control list. Matches are logged and then all received traffic is dropped. Sniffing only reports on attacks. It does not deny or otherwise influence traffic.

Using the one-arm sniffer, you can configure a FortiGate unit to operate as an IDS appliance by sniffing network traffic for attacks without actually processing the packets. To configure one-arm IDS, you enable sniffer mode on a FortiGate interface and connect the interface to a hub or to the SPAN port of a switch that is processing network traffic.

To assign an interface as a sniffer interface, go to **Network > Interface**, edit the interface and select **One-Arm Sniffer**.

If the check box is not available, the interface is in use. Ensure that the interface is not selected in any firewall policies, routes, virtual IPs or other features in which a physical interface is specified.

Enable Filters	Select to include filters to define a more granular sniff of network traffic. Select specific hosts, ports, VLANs and protocols. In all cases, enter a number, or number range, for the filtering type. For Protocol values, standard protocols are: • UDP - 17 • TCP - 6 • ICMP - 1
Include IPv6 Packets	If your network is running a combination of IPv4 and IPv6 addressing, select to sniff both addressing types. Otherwise, the FortiGate unit will only sniff IPv4 traffic.
Include Non-IP Packets	Select for a more intense scan of content in the traffic.
Security Profiles	IPS sensors, and application control lists enable you to select specific sensors and application you want to identify within the traffic.



Physical

FortiGate units have a number of physical ports where you connect ethernet or optical cables. Depending on the model, they can have anywhere from four to 40 physical ports. Some units have a grouping of ports labelled as lan, providing a built-in switch functionality.

In FortiOS, the port names, as labeled on the FortiGate unit, appear in the web-based manager in the **Unit Operation** widget, found on the Dashboard. They also appear when you are configuring the interfaces, by going to **Network > Interface**. As shown below, the FortiGate-100D (Generation 2) has 22 interfaces.

Two of the physical ports on the FortiGate-100D (Generation 2) are SFP ports. These ports share the numbers 15 and 16 with RJ-45 ports. Because of this, when SFP port 15 is used, RJ-45 port 15 cannot be used, and vice versa.

These ports also share the same MAC address.

FortiGate-100D interfaces on the Dashboard

Configuring the FortiGate-100D ports

Normally the internal interface is configured as a single interface shared by all physical interface connections - a switch. The switch mode feature has two states - switch mode and interface mode. Switch mode is the default mode with only one interface and one address for the entire internal switch. Interface mode enables you to configure each of the internal switch physical interface connections separately. This enables you to assign different subnets and netmasks to each of the internal physical interface connections.

The larger FortiGate units can also include Advanced Mezzanine Cards (AMC), which can provide additional interfaces (Ethernet or optical), with throughput enhancements for more efficient handling of specialized traffic. These interfaces appear in FortiOS as port amc/sw1, amc/sw2 and so on.

PPPoE addressing mode on an interface

If you configure the interface to use PPPoE, the FortiGate unit automatically broadcasts a PPPoE request from the interface.

The FortiGate units support many PPPoE RFC features (RFC 2516) including unnumbered IPs, initial discovery timeout and PPPoE Active Discovery Terminate (PADT).

PPPoE is only configurable in the web-based manager on desktop FortiGate units. 1U FortiGates and up must be configured in the CLI using the commands:

```
config system interface
   edit <port_name>
      set mode pppoe
      set username <ISP_username>
      set password <ISP_password>
      set idle-timeout <seconds>
      set distance <integer>
      set ipunnumbered <unumbered-IP>
      set disc-retry-timeout <seconds>
      set padt-retry-timeout <seconds>
      set lcp-echo-interval <seconds>
      set dns-server-override {enable | disable}
end
```

Configure PPPoE on an interface in **Network > Interfaces**. The table describes the PPPoE status information when PPPoE is configured for an interface.

Addressing mode section of New Interface page	
Status	Displays PPPoE status messages as the FortiGate unit connects to the PPPoE server and gets addressing information. Select Status to refresh the addressing mode status message. The status is only displayed if you selected **Edit**. Status can be any one of the following 4 messages.
Initializing	No activity.
Connecting	The interface is attempting to connect to the PPPoE server.
Connected	The interface retrieves an IP address, netmask, and other settings from the PPPoE server. When the status is connected, PPPoE connection information is displayed.
Failed	The interface was unable to retrieve an IP address and other information from the PPPoE server.
Reconnect	Select to reconnect to the PPPoE server. Only displayed if Status is connected.
User Name	The PPPoE account user name.
Password	The PPPoE account password.
Unnumbered IP	Specify the IP address for the interface. If your ISP has assigned you a block of IP addresses, use one of them. Otherwise, this IP address can be the same as the IP address of another interface or can be any IP address.
Initial Disc Timeout	Enter Initial discovery timeout. Enter the time to wait before starting to retry a PPPoE discovery.
Initial PADT timeout	Enter Initial PPPoE Active Discovery Terminate (PADT) timeout in seconds. Use this timeout to shut down the PPPoE session if it is idle for this number of seconds. PADT must be supported by your ISP. Set initial PADT timeout to 0 to disable.
Distance	Enter the administrative distance for the default gateway retrieved from the PPPoE server. The administrative distance, an integer from 1-255, specifies the relative priority of a route when there are multiple routes to the same destination. A lower administrative distance indicates a more preferred route. The default distance for the default gateway is 1.

Addressing mode section of New Interface page	
Retrieve default gateway from server	Enable to retrieve a default gateway IP address from a PPPoE server. The default gateway is added to the static routing table.
Override internal DNS	Enable to replace the DNS server IP addresses on the System DNS page with the DNS addresses retrieved from the PPPoE server. When VDOMs are enabled, you can override the internal DNS only on the management VDOM.

Probing interfaces

Server probes can be used on interfaces. In order for this to occur, the probe response mode must first be configured, then the probe response must be allowed administrative access on the interface. The probe response mode can be:

`none`	Disable probe.
`http-probe`	HTTP probe.
`twamp`	Two way active measurement protocol.

Both steps must be done through the CLI.

Configuring the probe

```
config system probe-response
   set mode http-probe
end
```

Allowing the probe response to have administrative access to the interface

```
config system interface
   edit <port>
      set allowaccess probe-response
   end
```

Redundant interfaces

On some models you can combine two or more physical interfaces to provide link redundancy. This feature enables you to connect to two or more switches to ensure connectivity in the event one physical interface or the equipment on that interface fails.

In a redundant interface, traffic is only going over one interface at any time. This differs from an aggregated interface where traffic is going over all interfaces for distribution of increased bandwidth. This difference means redundant interfaces can have more robust configurations with fewer possible points of failure. This is important in a fully-meshed HA configuration.

An interface is available to be in a redundant interface if:

- it is a physical interface, not a VLAN interface
- it is not already part of an aggregated or redundant interface
- it is in the same VDOM as the redundant interface
- it has no defined IP address
- is not configured for DHCP or PPPoE
- it has no DHCP server or relay configured on it
- it does not have any VLAN subinterfaces
- it is not referenced in any security policy, VIP, or multicast policy
- it is not monitored by HA
- it is not one of the FortiGate-5000 series backplane interfaces

When an interface is included in a redundant interface, it is not listed on the **Network > Interfaces** page. You cannot configure the interface individually and it is not available for inclusion in security policies, VIPs, or routing.

Dual Internet connections (redundant Internet connections)

Dual internet connection, dual WAN, or redundant internet connection refers to using two FortiGate interfaces to connect to the Internet. Dual internet connections can be used in three ways:

- Redundant interfaces, should one interface go down, the second automatically becomes the main internet connection
- For load sharing to ensure better throughput.
- A combination of redundancy and load sharing.

Redundant interfaces

Redundant interfaces, ensures that should your internet access be no longer available through a certain port, the FortiGate unit will use an alternate port to connect to the Internet.

Configuring redundant interfaces

In this scenario, two interfaces, WAN1 and WAN2 are connected to the Internet using two different ISPs. WAN1 is the primary connection. In an event of a failure of WAN1, WAN2 automatically becomes the connection to the Internet. For this configuration to function correctly, you need to configure three specific settings:

- Configure a link health monitor to determine when the primary interface (WAN1) is down and when the connection returns
- Configure a default route for each interface.
- Configure security policies to allow traffic through each interface to the internal network.

Link Health Monitor

Adding a link health monitor is required for routing fail over traffic. A link health monitor will confirm the connectivity of the device's interface

To add a link health monitor

```
config system link-monitor
   edit "Example1"
      set srcint <Interface_sending_probe>
      set server <ISP_IP_address>
```

```
        set protocol <Ping or http>
        set gateway-ip <the_gateway_IP_to_reach_the_server_if_required>
        set failtime <failure_count>
        set interval <seconds>
        set update-cascade-interface enable
        set update-static-route enable
        set status enable
    end
```

Routing

You need to configure a default route for each interface and indicate which route is preferred by specifying the distance. The lower distance is declared active and placed higher in the routing table.

When you have dual WAN interfaces that are configured to provide fail over, you might not be able to connect to the backup WAN interface because the FortiGate unit may not route traffic (even responses) out of the backup interface. The FortiGate unit performs a reverse path lookup to prevent spoofed traffic. If no entry can be found in the routing table which sends the return traffic out the same interface, then the incoming traffic is dropped.

To configure the routing of the two interfaces - GUI

1. Go to **Network > Static Routes** and select **Create New** or **IPv6 Route**.
   For low-end FortiGate units, go to **Network > Static Routes** and select **Create New** or **IPv6 Route**.
2. Set the **Destination IP/Mask** to the address and netmask of 0.0.0.0/0.0.0.0 if it's an IPv4 route. If it's an IPv6 route, set **Destination IP/Mask** to the address and netmask of ::/0
3. Select the **Device** to the primary connection, **WAN1**.
4. Enter the **Gateway** address.
5. Select **Advanced**.
6. Set the **Distance** to `10`.
7. Select **OK**.
8. Repeat steps 1 through 7 setting the **Device** to **WAN2** and a **Distance** of `20`.

To configure the IPv4 routing of the two interfaces - CLI

```
config router static
   edit 0
      set dst 0.0.0.0 0.0.0.0
      set device WAN1
      set gateway <gateway_address>
      set distance 10
   next
   edit 0
      set dst 0.0.0.0 0.0.0.0
      set device WAN2
      set gateway <gateway_address>
      set distance 20
   next
end
```

To configure the IPv6 routing of the two interfaces - CLI

```
config router static6
   edit 0
      set dst ::/0
      set device WAN1
      set gateway <gateway_address>
      set distance 10
   next
   edit 0
      set dst ::/0
      set device WAN2
      set gateway <gateway_address>
      set distance 20
   next
end
```

Security policies

When creating security policies, you need to configure duplicate policies to ensure that after traffic fails over WAN1, regular traffic will be allowed to pass through WAN2 as it did with WAN1. This ensures that fail-over will occur with minimal affect to users. For more information on creating security policies see the Firewall Guide.

Load sharing

Load sharing enables you to use both connections to the internet at the same time, but do not provide fail over support. When configuring for load sharing, you need to ensure routing is configured for both external ports, for example, WAN1 and WAN2, have static routes with the same distance and priority.

For more information on load sharing, see the Advanced Routing Guide.

Link redundancy and load sharing

In this scenario, both links are available to distribute Internet traffic over both links. Should one of the interfaces fail, the FortiGate unit will continue to send traffic over the other active interface. Configuration is similar to the Redundant interfaces configuration, with the main difference being that the configured routes should have equal distance settings.

This means both routes will remain active in the routing table. To make one interface the preferred interface, use a default policy route to indicate the interface that is preferred for accessing the Internet. If traffic matches the security policy, the policy overrides all entries in the routing table, including connected routes. You may need to add a specific policy routes that override these default policy routes.

To redirect traffic over the secondary interface, create policy routes to direct some traffic onto it rather than the primary interface. When adding the policy route, only define the outgoing interface and leave the gateway blank. This ensures that the policy route will not be active when the link is down.

Secondary IP addresses to an interface

If an interface is configured with a manual or static IP address, you can also add secondary static IP addresses to the interface. Adding secondary IP addresses effectively adds multiple IP addresses to the interface. Secondary IP addresses cannot be assigned using DCHP or PPPoE.

All of the IP addresses added to an interface are associated with the single MAC address of the physical interface and all secondary IP addresses are in the same VDOM as the interface that are added to. You configure interface

status detection for gateway load balancing separately for each secondary IP addresses. As with all other interface IP addresses, secondary IP addresses cannot be on the same subnet as any other primary or secondary IP address assigned to a FortiGate interface unless they are in separate VDOMs.

To configure a secondary IP, go to **System > Network > Interface**, select **Edit** or **Create New** and select the **Secondary IP Address** check box.

Software switch

A software switch, or soft switch, is a virtual switch that is implemented at the software, or firmware level, rather than the hardware level. A software switch can be used to simplify communication between devices connected to different FortiGate interfaces. For example, using a software switch, you can place the FortiGate interface connected to an internal network on the same subnet as your wireless interfaces. Then devices on the internal network can communicate with devices on the wireless network without any additional configuration such as additional security policies, on the FortiGate unit.

It can also be useful if you require more hardware ports for the switch on a FortiGate unit. For example, if your FortiGate unit has a 4-port switch, WAN1, WAN2 and DMZ interfaces, and you need one more port, you can create a soft switch that can include the 4-port switch and the DMZ interface all on the same subnet. These types of applications also apply to wireless interfaces and virtual wireless interfaces and physical interfaces such as those with FortiWiFi and FortiAP unit.

Similar to a hardware switch, a software switch functions like a single interface. A software switch has one IP address; all of the interfaces in the software switch are on the same subnet. Traffic between devices connected to each interface are not regulated by security policies, and traffic passing in and out of the switch are affected by the same policy.

There are a few things to consider when setting up a software switch:

- Ensure you create a back up of the configuration.
- Ensure you have at least one port or connection such as the console port to connect to the FortiGate unit. If you accidentally combine too many ports, you will need a way to undo any errors.
- The ports that you include must not have any link or relation to any other aspect of the FortiGate unit. For example, DHCP servers, security policies, and so on.
- For increased security, you can create a captive portal for the switch, allowing only specific user groups access to the resources connected to the switch.

To create a software switch - CLI

```
config system switch-interface
   edit <switch-name>
      set type switch
      set member <interface_list>
end
config system interface
   edit <switch_name>
      set ip <ip_address>
      set allowaccess https ssh ping
end
```

Soft switch example

For this example, the wireless interface (WiFi) needs to be on the same subnet as the DMZ1 interface to facilitate wireless syncing from an iPhone and a local computer. The synching between two subnets is problematic. By putting both interfaces on the same subnet the synching will work. The software switch will accomplish this.

In this example, the soft switch includes a wireless interface. Remember to configure any wireless security before proceeding. If you leave this interface open without any password or other security, it leaves open access to not only the wireless interface but to any other interfaces and devices connected within the software switch.

Clear the interfaces and back up the configuration

First, ensure that the interfaces are not being used with any other security policy or other use on the FortiGate unit. Check the WiFi and DMZ1 ports to ensure DHCP is not enabled on the interface and there are no other dependencies with these interfaces.

Next, save the current configuration, in the event something doesn't work, recovery can be quick.

Merge the interfaces

The plan is to merge the WiFi port and DMZ1 port. This will create a software switch with a name of "synchro" with an IP address of 10.10.21.12. The following steps will create the switch, add the IP and then set the administrative access for HTTPS, SSH and Ping.

To merge the interfaces - CLI

```
config system switch-interface
   edit synchro
      set type switch
      set member dmz1 wifi
end
config system interface
   edit synchro
      set ip 10.10.21.12
      set allowaccess https ssh ping
end
```

Final steps

With the switch set up, you can now add security policies, DHCP servers and any other configuration that you would normally do to configure interfaces on the FortiGate unit.

Virtual Switch

Virtual switch feature enables you create virtual switches on top of the physical switch(es) with designated interfaces/ports so that a virtual switch can build up its forwarding table through learning and forward traffic accordingly. When traffic is forwarded among interfaces belonging to the same virtual switch, the traffic doesn't need to go up to the software stack, but forwarded directly by the switch. When traffic has to be relayed to interfaces not on the virtual switch, the traffic will go through the normal data path and be offloaded to NP4 when possible.

This feature is only available on mid to high end FortiGate units, including the 100D, 600C, 1000C, and 1240B.

To enable and configure the virtual switch, enter the CLI commands:

```
config system virtual-switch
   edit vs1
      set physical-switch sw0
         config port
            edit 1
               set port port1
               set speed xx
               set duplex xx
               set status [up|down]
            edit 2
               set port port2
               set ...
            end
      end
end
```

Zones

Zones are a group of one or more FortiGate interfaces, both physical and virtual, that you can apply security policies to control inbound and outbound traffic. Grouping interfaces and VLAN subinterfaces into zones simplifies the creation of security policies where a number of network segments can use the same policy settings and protection profiles. When you add a zone, you select the names of the interfaces and VLAN subinterfaces to add to the zone. Each interface still has its own address and routing is still done between interfaces, that is, routing is not affected by zones. Security policies can also be created to control the flow of intra-zone traffic.

For example, the network includes three separate groups of users representing different entities on the company network. While each group has its own set of port and VLANs, in each area, they can all use the same security policy and protection profiles to access the Internet. Rather than the administrator making nine separate security policies, he can add the required interfaces to a zone, and create three policies, making administration simpler.

You can configure policies for connections to and from a zone, but not between interfaces in a zone.

This example explains how to set up a zone to include the Internal interface and a VLAN.

To create a zone - web-based manager

1. Go to **Network > Interfaces**.
2. Select the arrow on the **Create New** button and select **Zone**.
3. Enter a zone name of `Zone_1`.
4. Select the required **Interface Members**.
5. Select **OK**.

To create a zone - CLI

```
config system zone
   edit Zone_1
      set interface internal VLAN_1
end
```

Virtual domains

Virtual domains (VDOMs) are a method of dividing a FortiGate unit into two or more virtual units that function as multiple independent units. A single FortiGate unit is then flexible enough to serve multiple departments of an organization, separate organizations, or to act as the basis for a service provider's managed security service.

VDOMs provide separate security domains that allow separate zones, user authentication, security policies, routing, and VPN configurations. By default, each FortiGate unit has a VDOM named root. This VDOM includes all of the FortiGate physical interfaces, modem, VLAN subinterfaces, zones, security policies, routing settings, and VPN settings.

When a packet enters a VDOM, it is confined to that VDOM. In a VDOM, you can create security policies for connections between Virtual LAN (VLAN) subinterfaces or zones in the VDOM. Packets do not cross the virtual domain border internally. To travel between VDOMs, a packet must pass through a firewall on a physical interface. The packet then arrives at another VDOM on a different interface, but it must pass through another firewall before entering the VDOM Both VDOMs are on the same FortiGate unit. Inter-VDOMs change this behavior in that they are internal interfaces; however their packets go through all the same security measures as on physical interfaces.

This example shows how to enable VDOMs on the FortiGate unit and the basic and create a VDOM accounting on the DMZ2 port and assign an administrator to maintain the VDOM. First enable Virtual Domains on the FortiGate unit. When you enable VDOMs, the FortiGate unit will log you out.

For desktop and low-end FortiGate units, VDOMs are enabled using the CLI. On larger FortiGate units, you can enable on the web-based manager or the CLI. Once enabled all further configuration can be made in the web-based manager or CLI.

To enable VDOMs - web-based manager

1. Go to **Dashboard**.
2. In the **System Information** widget, select **Enable**for **Virtual Domain**.

The FortiGate unit logs you out. Once you log back in, you will notice that the menu structure has changed. This reflects the global settings for all Virtual Domains

To enable VDOMs - CLI

```
config system global
   set vdom-admin enable
end
```

Next, add the VDOM called accounting.

To add a VDOM - web-based manager

1. Go to **System > VDOM**, and select **Create New**.
2. Enter the VDOM name `accounting`.
3. Select **OK**.

To add a VDOM - CLI

```
config vdom
   edit <new_vdom_name>
end
```

With the Virtual Domain created, you can assign a physical interface to it, and assign it an IP address.

To assign physical interface to the accounting Virtual Domain - web-based manager

1. Go to **Network > Interfaces**.
2. Select the DMZ2 port row and select **Edit**.
3. For the **Virtual Domain** drop-down list, select **accounting**.
4. Select the **Addressing Mode** of **Manual**.
5. Enter the IP address for the port of 10.13.101.100/24.
6. Set the **Administrative Access** to **HTTPS** and **SSH**.
7. Select **OK**.

To assign physical interface to the accounting Virtual Domain - CLI

```
config global
   config system interface
      edit dmz2
         set vdom accounting
         set ip 10.13.101.100/24
         set allowaccess https ssh
   next
end
```

Wireless

A wireless interface is similar to a physical interface only it does not include a physical connection. The FortiWiFi units enables you to add multiple wireless interfaces that can be available at the same time. On FortiWiFi units, you can configure the device to be either an access point, or a wireless client. As an access point, the FortiWiFi unit can have separate SSIDs, each on their own subnet for wireless access. In client mode, the FortiWiFi only has one SSID, and is used as a receiver, to enable remote users to connect to the existing network using wireless protocols.

Wireless interfaces also require additional security measures to ensure the session does not get hijacked and data tampered or stolen.

For more information on configuring wireless interfaces see the Deploying Wireless Networks Guide.

VLANs

Virtual Local Area Networks (VLANs) multiply the capabilities of your FortiGate unit, and can also provide added network security. Virtual LANs (VLANs) use ID tags to logically separate devices on a network into smaller broadcast domains. These smaller domains forward packets only to devices that are part of that VLAN domain. This reduces traffic and increases network security. The IEEE 802.1Q standard defines VLANs. All layer-2 and layer-3 devices along a route must be 802.1Q-compliant to support VLANs along that route.

A Local Area Network (LAN) is a group of connected computers and devices that are arranged into network broadcast domains. A LAN broadcast domain includes all the computers that receive a packet broadcast from any computer in that broadcast domain. A switch will automatically forward the packets to all of its ports; in contrast, routers do not automatically forward network broadcast packets. This means routers separate broadcast domains. If a network has only switches and no routers, that network is considered one broadcast domain, no

matter how large or small it is. Smaller broadcast domains are more efficient because fewer devices receive unnecessary packets. They are more secure as well because a hacker reading traffic on the network will have access to only a small portion of the network instead of the entire network's traffic.

VLANs reduce the size of the broadcast domains by only forwarding packets to interfaces that are part of that VLAN or part of a VLAN trunk link. Trunk links form switch-to-switch or switch-to-router connections, and forward traffic for all VLANs. This enables a VLAN to include devices that are part of the same broadcast domain, but physically distant from each other.

VLAN ID tags consist of a 4-byte frame extension that switches and routers apply to every packet sent and received in the VLAN. Workstations and desktop computers, which are commonly originators or destinations of network traffic, are not an active part of the VLAN process. All the VLAN tagging and tag removal is done after the packet has left the computer.

Any FortiGate unit without VDOMs enabled can have a maximum of 255 interfaces in transparent operating mode. The same is true for any single VDOM. In NAT mode, the number can range from 255 to 8192 interfaces per VDOM, depending on the FortiGate model. These numbers include VLANs, other virtual interfaces, and physical interfaces. To have more than 255 interfaces configured in transparent operating mode, you need to configure multiple VDOMs that enable you to divide the total number of interfaces over all the VDOMs.

One example of an application of VLANs is a company's accounting department. Accounting computers may be located at both main and branch offices. However, accounting computers need to communicate with each other frequently and require increased security. VLANs allow the accounting network traffic to be sent only to accounting computers and to connect accounting computers in different locations as if they were on the same physical subnet.

This guide uses the term "packet" to refer to both layer-2 frames and layer-3 packets.

On a layer-2 switch, you can have only one VLAN subinterface per physical interface, unless that interface is configured as a trunk link. Trunk links can transport traffic for multiple VLANs to other parts of the network.

On a FortiGate unit, you can add multiple VLANs to the same physical interface. However, VLAN subinterfaces added to the same physical interface cannot have the same VLAN ID or have IP addresses on the same subnet. You can add VLAN subinterfaces with the same VLAN ID to different physical interfaces.

Creating VLAN subinterfaces with the same VLAN ID does not create any internal connection between them. For example a VLAN ID of 300 on port1 and VLAN ID of 300 on port2 are allowed, but they are not connected. Their relationship is the same as between any two FortiGate network interfaces.

FortiGate unit interfaces cannot have overlapping IP addresses, the IP addresses of all interfaces must be on different subnets. This rule applies to both physical interfaces and to virtual interfaces such as VLAN subinterfaces. Each VLAN subinterface must be configured with its own IP address and netmask. This rule helps prevent a broadcast storm or other similar network problems.

This example shows how to add a VLAN, vlan_accounting on the FortiGate unit internal interface with an IP address of 10.13.101.101.

To add a VLAN - web-based manager

1. Go to **Network > Interface** and select **Create NewInterfaces**.
   The **Type** is by default set to VLAN.
2. Enter a name for the **VLAN** to `vlan_accounting`.
3. Select the **Internal** interface.
4. Enter the **VLAN ID**.

The VLAN ID is a number between 1 and 4094 that allow groups of IP addresses with the same VLAN ID to be associated together.

5. Select the **Addressing Mode** of **Manual**.
6. Enter the IP address for the port of 10.13.101.101/24.
7. Set the **Administrative Access** to **HTTPS** and **SSH**.
8. Select **OK**.

To add a VLAN - CLI

```
config system interface
   edit VLAN_1
      set interface internal
      set type vlan
      set vlanid 100
      set ip 10.13.101.101/24
      set allowaccess https ssh
   next
end
```

VLANs in NAT mode

In NAT mode the FortiGate unit functions as a layer-3 device. In this mode, the FortiGate unit controls the flow of packets between VLANs, but can also remove VLAN tags from incoming VLAN packets. The FortiGate unit can also forward untagged packets to other networks, such as the Internet.

In NAT mode, the FortiGate unit supports VLAN trunk links with IEEE 802.1Q-compliant switches, or routers. The trunk link transports VLAN-tagged packets between physical subnets or networks. When you add VLAN sub-interfaces to the FortiGate unit physical interfaces, the VLANs have IDs that match the VLAN IDs of packets on the trunk link. The FortiGate unit directs packets with VLAN IDs to sub-interfaces with matching IDs.

You can define VLAN sub-interfaces on all FortiGate physical interfaces. However, if multiple virtual domains are configured on the FortiGate unit, you will have access to only the physical interfaces on your virtual domain. The FortiGate unit can tag packets leaving on a VLAN subinterface. It can also remove VLAN tags from incoming packets and add a different VLAN tag to outgoing packets.

Normally in VLAN configurations, the FortiGate unit's internal interface is connected to a VLAN trunk, and the external interface connects to an Internet router that is not configured for VLANs. In this configuration the FortiGate unit can apply different policies for traffic on each VLAN interface connected to the internal interface, which results in less network traffic and better security.

Adding VLAN subinterfaces

A VLAN subinterface, also called a VLAN, is a virtual interface on a physical interface. The subinterface allows routing of VLAN tagged packets using that physical interface, but it is separate from any other traffic on the physical interface.

Adding a VLAN subinterface includes configuring:

- Physical interface
- IP address and netmask
- VLAN ID
- VDOM

Physical interface

The term VLAN subinterface correctly implies the VLAN interface is not a complete interface by itself. You add a VLAN subinterface to the physical interface that receives VLAN-tagged packets. The physical interface can belong to a different VDOM than the VLAN, but it must be connected to a network router that is configured for this VLAN. Without that router, the VLAN will not be connected to the network, and VLAN traffic will not be able to access this interface. The traffic on the VLAN is separate from any other traffic on the physical interface.

When you are working with interfaces on your FortiGate unit, use the **Column Settings** on the Interface display to make sure the information you need is displayed. When working with VLANs, it is useful to position the **VLAN ID** column close to the IP address. If you are working with VDOMs, including the **Virtual Domain** column as well will help you troubleshoot problems more quickly.

To view the Interface display, go to **Network > Interfaces**.

IP address and netmask

FortiGate unit interfaces cannot have overlapping IP addresses. The IP addresses of all interfaces must be on different subnets. This rule applies to both physical interfaces and to virtual interfaces such as VLAN subinterfaces. Each VLAN subinterface must be configured with its own IP address and netmask pair. This rule helps prevent a broadcast storm or other similar network problems.

If you are unable to change your existing configurations to prevent IP overlap, enter the CLI command `config system settings` and `set allow-subnet-overlap enable` to allow IP address overlap. If you enter this command, multiple VLAN interfaces can have an IP address that is part of a subnet used by another interface. This command is recommended for advanced users only.

VLAN ID

The VLAN ID is part of the VLAN tag added to the packets by VLAN switches and routers. The VLAN ID is a number between 1 and 4094 that allow groups of IP addresses with the same VLAN ID to be associated together. VLAN ID 0 is used only for high priority frames, and 4095 is reserved.

All devices along a route must support the VLAN ID of the traffic along that route. Otherwise, the traffic will be discarded before reaching its destination. For example, if your computer is part of VLAN_100 and a co-worker on a different floor of your building is also on the same VLAN_100, you can communicate with each other over VLAN_100, only if all the switches and routers support VLANs and are configured to pass along VLAN_100 traffic properly. Otherwise, any traffic you send your co-worker will be blocked or not delivered.

VDOM

If VDOMs are enabled, each VLAN subinterface must belong to a VDOM. This rule also applies for physical interfaces.

Interface-related CLI commands require a VDOM to be specified, regardless of whether the FortiGate unit has VDOMs enabled.

VLAN subinterfaces on separate VDOMs cannot communicate directly with each other. In this situation, the VLAN traffic must exit the FortiGate unit and re-enter the unit again, passing through firewalls in both directions. This situation is the same for physical interfaces.

A VLAN subinterface can belong to a different VDOM than the physical interface it is part of. This is because the traffic on the VLAN is handled separately from the other traffic on that interface. This is one of the main strengths of VLANs.

The following procedure will add a VLAN subinterface called `VLAN_100` to the FortiGate internal interface with a VLAN ID of 100. It will have an IP address and netmask of `172.100.1.1/255.255.255.0`, and allow HTTPS and PING administrative access. Note that in the CLI, you must enter "`set type vlan`" before setting the vlanid, and that the allowaccess protocols are lower case.

To add a VLAN subinterface in NAT mode - web-based manager

1. If **Current VDOM** appears at the bottom left of the screen, select **Global** from the list of VDOMs.
2. Go to **Network > Interface**.
3. Select **Create New** to add a VLAN subinterface.
4. Enter the following:

VLAN Name	VLAN_100
Type	VLAN
Interface	internal
VLAN ID	100
Addressing Mod	Manual
IP/Netmask	172.100.1.1/255.255.255.0
Administrative Access	HTTPS, PING, TELNET

5. Select **OK**.

To view the new VLAN subinterface, select the expand arrow next to the parent physical interface (the internal interface). This will expand the display to show all VLAN subinterfaces on this physical interface. If there is no expand arrow displayed, there are no subinterfaces configured on that physical interface.

For each VLAN, the list displays the name of the VLAN, and, depending on column settings, its IP address, the Administrative access you selected for it, the VLAN ID number, and which VDOM it belongs to if VDOMs are enabled.

To add a VLAN subinterface in NAT mode - CLI

```
config system interface
   edit VLAN_100
      set interface internal
      set type vlan
      set vlanid 100
      set ip 172.100.1.1 255.255.255.0
      set allowaccess https ping
end
```

Configuring security policies and routing

Once you have created a VLAN subinterface on the FortiGate unit, you need to configure security policies and routing for that VLAN. Without these, the FortiGate unit will not pass VLAN traffic to its intended destination. Security policies direct traffic through the FortiGate unit between interfaces. Routing directs traffic across the network.

Configuring security policies

Security policies permit communication between the FortiGate unit's network interfaces based on source and destination IP addresses. Interfaces that communicate with the VLAN interface need security policies to permit traffic to pass between them and the VLAN interface.

Each VLAN needs a security policy for each of the following connections the VLAN will be using:

- From this VLAN to an external network
- From an external network to this VLAN
- From this VLAN to another VLAN in the same virtual domain on the FortiGate unit
- From another VLAN to this VLAN in the same virtual domain on the FortiGate unit.

The packets on each VLAN are subject to antivirus scans and other security profiles measures as they pass through the FortiGate unit.

Configuring routing

As a minimum, you need to configure a default static route to a gateway with access to an external network for outbound packets. In more complex cases, you will have to configure different static or dynamic routes based on packet source and destination addresses.

As with firewalls, you need to configure routes for VLAN traffic. VLANs need routing and a gateway configured to send and receive packets outside their local subnet just as physical interfaces do. The type of routing you configure, static or dynamic, will depend on the routing used by the subnet and interfaces you are connecting to. Dynamic routing can be routing information protocol (RIP), border gateway protocol (BGP), open shortest path first (OSPF), or multicast.

If you enable SSH, PING, HTTPS and HTTP on the VLAN, you can use those protocols to troubleshoot your routing and test that it is properly configured. Enabling logging on the interfaces and using CLI diagnose commands such as `diagnose sniff packet <interface_name>` can also help locate any possible configuration or hardware issues.

VLANs in transparent mode

In transparent mode, the FortiGate unit behaves like a layer-2 bridge but can still provide services such as antivirus scanning, web filtering, spam filtering and intrusion protection to traffic. There are some limitations in transparent mode in that you cannot use SSL VPN, PPTP/L2TP VPN, DHCP server, or easily perform NAT on traffic. The limits in transparent mode apply to IEEE 802.1Q VLAN trunks passing through the unit.

VLANs and transparent mode

You can insert the FortiGate unit operating in transparent mode into the VLAN trunk without making changes to your network. In a typical configuration, the FortiGate unit internal interface accepts VLAN packets on a VLAN trunk from a VLAN switch or router connected to internal network VLANs. The FortiGate external interface forwards VLAN-tagged packets through another VLAN trunk to an external VLAN switch or router and on to

external networks such as the Internet. You can configure the unit to apply different policies for traffic on each VLAN in the trunk.

To pass VLAN traffic through the FortiGate unit, you add two VLAN subinterfaces with the same VLAN ID, one to the internal interface and the other to the external interface. You then create a security policy to permit packets to flow from the internal VLAN interface to the external VLAN interface. If required, you create another security policy to permit packets to flow from the external VLAN interface to the internal VLAN interface. Typically in transparent mode, you do not permit packets to move between different VLANs. Network protection features, such as spam filtering, web filtering and anti-virus scanning, are applied through the Security Profiles specified in each security policy, enabling very detailed control over traffic.

When the FortiGate unit receives a VLAN-tagged packet at a physical interface, it directs the packet to the VLAN subinterface with the matching VLAN ID. The VLAN tag is removed from the packet, and the FortiGate unit then applies security policies using the same method it uses for non-VLAN packets. If the packet exits the FortiGate unit through a VLAN subinterface, the VLAN ID for that subinterface is added to the packet and the packet is sent to the corresponding physical interface.

General configuration steps

There are two essential steps to configure your FortiGate unit to work with VLANs in transparent mode:

- Add VLAN subinterfaces
- Create security policies

You can also configure the Security Profiles that manage antivirus scanning, web filtering and spam filtering. For more information on Security Profiles, see the Security Profiles Guide.

Add VLAN subinterfaces

The VLAN ID of each VLAN subinterface must match the VLAN ID added by the IEEE 802.1Q-compliant router or switch. The VLAN ID can be any number between 1 and 4094, with 0 being used only for high priority frames and 4095 being reserved. You add VLAN subinterfaces to the physical interface that receives VLAN-tagged packets.

For this example, we are creating a VLAN called internal_v225 on the internal interface, with a VLAN ID of 225. Administrative access is enabled for HTTPS and SSH. VDOMs are not enabled.

To add VLAN subinterfaces in transparent mode - web-based manager

1. Go to **Network > Interfaces**.
2. Select **Create New** and click on **Interfaces**.
3. Enter the following information and select **OK**.

Name	internal_v225
Type	VLAN
Interface	internal
VLAN ID	225
Administrative Access	Enable HTTPS, and SSH. These are very secure access methods.

The FortiGate unit adds the new subinterface to the interface that you selected.

Repeat steps 2 and 3 to add additional VLANs. You will need to change the **VLAN ID**, **Name**, and possibly **Interface** when adding additional VLANs.

To add VLAN subinterfaces in transparent mode - CLI

```
config system interface
   edit internal_v225
      set interface internal
      set vlanid 225
      set allowaccess HTTPS SSH
      set description "VLAN 225 on internal interface"
      set vdom root
end
```

Create security policies

In transparent mode, the FortiGate unit performs antivirus and antispam scanning on each VLAN's packets as they pass through the unit. You need security policies to permit packets to pass from the VLAN interface where they enter the unit to the VLAN interface where they exit the unit. If there are no security policies configured, no packets will be allowed to pass from one interface to another.

To add security policies for VLAN subinterfaces - web based manager

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New** to add firewall addresses that match the source and destination IP addresses of VLAN packets.
3. Go to **Policy & Objects > IPv4 Policy** or **Policy & Objects > IPv6Policy** and select **Create New**.
4. From the **Incoming Interface/Zone** list, select the VLAN interface where packets enter the unit.
5. From the **Outgoing Interface/Zone** list, select the VLAN interface where packets exit the unit.
6. Select the **Source** and **Destination** Address names that you added in step 2.
7. Select **OK**.

To add security policies for VLAN subinterfaces - CLI

```
config firewall address
   edit incoming_VLAN_address
      set associated-interface <incoming_VLAN_interface>
      set type ipmask
      set subnet <IPv4_address_mask)
   next
   edit outgoing_VLAN_address
      set associated-interface <outgoing_VLAN_interface>
      set type ipmask
      set subnet <IPv4_address_mask>
   next
end
config firewall policy or config firewall policy6
   edit <unused_policy_number>
      set srcintf <incoming_VLAN_interface>
      set srcaddr incoming_VLAN_address
      set destintf <outgoing_VLAN_interface>
      set destaddr outgoing_VLAN_address
      set schedule always
      set service <protocol_to_allow_on VLAN>
```

```
        set action ACCEPT
    next
end
```

VLAN switching and routing

VLAN switching takes place on the OSI model layer-2, just like other network switching. VLAN routing takes place on the OSI model layer-3. The difference between them is that during VLAN switching, VLAN packets are simply forwarded to their destination. This is different from VLAN routing where devices can open the VLAN packets and change their VLAN ID tags to route the packets to a new destination.

VLAN layer-2 switching

Ethernet switches are layer-2 devices, and generally are 802.1Q compliant. Layer 2 refers to the second layer of the seven layer Open Systems Interconnect (OSI) basic networking model; the Data Link layer. FortiGate units act as layer-2 switches or bridges when they are in transparent mode. The units simply tag and forward the VLAN traffic or receive and remove the tags from the packets. A layer-2 device does not inspect incoming packets or change their contents; it only adds or removes tags and routes the packet.

A VLAN can have any number of physical interfaces assigned to it. Multiple VLANs can be assigned to the same physical interface. Typically two or more physical interfaces are assigned to a VLAN, one for incoming and one for outgoing traffic. Multiple VLANs can be configured on one FortiGate unit, including trunk links.

VLAN layer-3 routing

Routers are layer-3 devices. Layer 3 refers to the third layer of the OSI networking model, the Network layer. FortiGate units in NAT mode act as layer-3 devices. As with layer 2, FortiGate units acting as layer-3 devices are 802.1Q-compliant.

The main difference between layer-2 and layer-3 devices is how they process VLAN tags. Layer-2 switches just add, read and remove the tags. They do not alter the tags or do any other high-level actions. Layer-3 routers not only add, read and remove tags but also analyze the data frame and its contents. This analysis allows layer-3 routers to change the VLAN tag if it is appropriate and send the data frame out on a different VLAN.

In a layer-3 environment, the 802.1Q-compliant router receives the data frame and assigns a VLAN ID. The router then forwards the data frame to other members of the same VLAN broadcast domain. The broadcast domain can include local ports, layer-2 devices and layer-3 devices such as routers and firewalls. When a layer-3 device receives the data frame, the device removes the VLAN tag and examines its contents to decide what to do with the data frame. The layer-3 device considers:

- Source and destination addresses
- Protocol
- Port number

The data frame may be forwarded to another VLAN, sent to a regular non-VLAN-tagged network or just forwarded to the same VLAN as a layer-2 switch would do. Or, the data frame may be discarded if the proper security policy has been configured to do so.

Layer-2 and Arp traffic

By default, FortiGate units do not pass layer-2 traffic. If there are layer-2 protocols such as IPX, PPTP or L2TP in use on your network, you need to configure your FortiGate unit interfaces to pass these protocols without blocking. Another type of layer-2 traffic is ARP traffic.

You can allow these layer-2 protocols using the CLI command:

```
config system interface
   edit <name_str>
      set l2forward enable
   end
```

where `<name_str>` is the name of an interface.

If VDOMs are enabled, this command is per VDOM. You must set it for each VDOM that has the problem as following:

```
config vdom
   edit <vdom_name>
      config system interface
      edit <name_str>
      set l2forward enable
   end
end
```

If you enable layer-2 traffic, you may experience a problem if packets are allowed to repeatedly loop through the network. This repeated looping, very similar to a broadcast storm, occurs when you have more than one layer-2 path to a destination. Traffic may overflow and bring your network to a halt. You can break the loop by enabling Spanning Tree Protocol (STP) on your network's switches and routers.

STP forwarding

The FortiGate unit does not participate in the Spanning Tree Protocol (STP). STP is an IEEE 802.1 protocol that ensures there are no layer-2 loops on the network. Loops are created when there is more than one route for traffic to take and that traffic is broadcast back to the original switch. This loop floods the network with traffic, reducing available bandwidth to nothing.

If you use your FortiGate unit in a network topology that relies on STP for network loop protection, you need to make changes to your FortiGate configuration. Otherwise, STP recognizes your FortiGate unit as a blocked link and forwards the data to another path. By default, your FortiGate unit blocks STP as well as other non-IP protocol traffic.

Using the CLI, you can enable forwarding of STP and other layer-2 protocols through the interface. In this example, layer-2 forwarding is enabled on the external interface:

```
config system interface
   edit external
      set l2forward enable
      set stpforward enable
end
```

By substituting different commands for `stpforward enable`, you can also allow layer-2 protocols such as IPX, PPTP or L2TP to be used on the network.

ARP traffic

Address Resolution Protocol (ARP) packets are vital to communication on a network, and ARP support is enabled on FortiGate unit interfaces by default. Normally you want ARP packets to pass through the FortiGate unit, especially if it is sitting between a client and a server or between a client and a router.

ARP traffic can cause problems, especially in transparent mode where ARP packets arriving on one interface are sent to all other interfaces including VLAN subinterfaces. Some layer-2 switches become unstable when they detect the same MAC address originating on more than one switch interface or from more than one VLAN. This

instability can occur if the layer-2 switch does not maintain separate MAC address tables for each VLAN. Unstable switches may reset and cause network traffic to slow down considerably.

The default ARP timeout value is 5 minutes (300 seconds). So usually ARP entries are removed after 5 minutes. However, some conditions can cause arp entries to remain on the list for a longer time. This is not a configurable value. Enter the `get system arp` CLI command to view the ARP list.

Multiple VDOMs solution

By default, physical interfaces are in the root domain. If you do not configure any of your VLANs in the root VDOM, it will not matter how many interfaces are in the root VDOM.

The multiple VDOMs solution is to configure multiple VDOMs on the FortiGate unit, one for each VLAN. In this solution, you configure one inbound and one outbound VLAN interface in each VDOM. ARP packets are not forwarded between VDOMs. This configuration limits the VLANs in a VDOM and correspondingly reduces the administration needed per VDOM.

As a result of this configuration, the switches do not receive multiple ARP packets with duplicate MACs. Instead, the switches receive ARP packets with different VLAN IDs and different MACs. Your switches are stable.

However, you should **not** use the multiple VDOMs solution under any of the following conditions:

- You have more VLANs than licensed VDOMs
- You do not have enough physical interfaces

Instead, use one of two possible solutions, depending on which operation mode you are using:

- In NAT mode, you can use the `vlanforward` CLI command.
- In transparent mode, you can use the `forward-domain` CLI command. But you still need to be careful in some rare configurations.

Vlanforward solution

If you are using NAT mode, the solution is to use the `vlanforward` CLI command for the interface in question. By default, this command is enabled and will forward VLAN traffic to all VLANs on this interface. When disabled, each VLAN on this physical interface can send traffic only to the same VLAN. There is no cross-talk between VLANs, and ARP packets are forced to take one path along the network which prevents the multiple paths problem.

In the following example, `vlanforward` is disabled on port1. All VLANs configured on port1 will be separate and will not forward any traffic to each other.

```
config system interface
   edit port1
      set vlanforward disable
end
```

Forward-domain solution

If you are using transparent mode, the solution is to use the `forward-domain` CLI command. This command tags VLAN traffic as belonging to a particular collision group, and only VLANs tagged as part of that collision group receive that traffic. It is like an additional set of VLANs. By default, all interfaces and VLANs are part of forward-domain collision group 0. The many benefits of this solution include reduced administration, the need for fewer physical interfaces, and the availability of more flexible network solutions.

In the following example, forward-domain collision group 340 includes VLAN 340 traffic on port1 and untagged traffic on port 2. Forward-domain collision group 341 includes VLAN 341 traffic on port 1 and untagged traffic on port 3. All other interfaces are part of forward-domain collision group 0 by default. This configuration separates VLANs 340 and 341 from each other on port 1.

Use these CLI commands:

```
config system interface
   edit port2
      set forward_domain 340
   next
   edit port3
      set forward_domain 341
   next
   edit port1-340
      set forward_domain 340
      set interface port1
      set vlanid 340
   next
   edit port1-341
      set forward_domain 341
      set interface port1
      set vlanid 341
end
```

You may experience connection issues with layer-2 traffic, such as ping, if your network configuration has:

- Packets going through the FortiGate unit in transparent mode more than once
- More than one forwarding domain (such as incoming on one forwarding domain and outgoing on another)
- IPS and AV enabled.

Now IPS and AV is applied the first time packets go through the FortiGate unit, but not on subsequent passes. Only applying IPS and AV to this first pass fixes the network layer-2 related connection issues.

Asymmetric routing

You might discover unexpectedly that hosts on some networks are unable to reach certain other networks. This occurs when request and response packets follow different paths. If the FortiGate unit recognizes the response packets, but not the requests, it blocks the packets as invalid. Also, if the FortiGate unit recognizes the same packets repeated on multiple interfaces, it blocks the session as a potential attack.

This is asymmetric routing. By default, the FortiGate unit blocks packets or drops the session when this happens. You can configure the FortiGate unit to permit asymmetric routing by using the following CLI commands:

```
config system settings
   set asymroute enable
end
```

If VDOMs are enabled, this command is per VDOM. You must set it for each VDOM that has the problem as following:

```
config vdom
   edit <vdom_name>
      config system settings
      set asymroute enable
   end
end
```

If this solves your blocked traffic issue, you know that asymmetric routing is the cause. But allowing asymmetric routing is not the best solution, because it reduces the security of your network.

For a long-term solution, it is better to change your routing configuration or change how your FortiGate unit connects to your network.

If you enable asymmetric routing, antivirus and intrusion prevention systems will not be effective. Your FortiGate unit will be unaware of connections and treat each packet individually. It will become a stateless firewall.

NetBIOS

Computers running Microsoft Windows operating systems that are connected through a network rely on a WINS server to resolve host names to IP addresses. The hosts communicate with the WINS server by using the NetBIOS protocol.

To support this type of network, you need to enable the forwarding of NetBIOS requests to a WINS server. The following example will forward NetBIOS requests on the internal interface for the WINS server located at an IP address of 192.168.111.222.

```
config system interface
   edit internal
      set netbios_forward enable
      set wins-ip 192.168.111.222
end
```

These commands apply only in NAT mode. If VDOMs are enabled, these commands are per VDOM. You must set them for each VDOM that has the problem.

Too many VLAN interfaces

Any virtual domain can have a maximum of 255 interfaces in transparent mode. This includes VLANs, other virtual interfaces, and physical interfaces. NAT mode supports from 255 to 8192 depending on the FortiGate model. This total number of interfaces includes VLANs, other virtual interfaces, and physical interfaces.

Your FortiGate unit may allow you to configure more interfaces than this. However, if you configure more than 255 interfaces, your system will become unstable and, over time, will not work properly. As all interfaces are used, they will overflow the routing table that stores the interface information, and connections will fail. When you try to add more interfaces, an error message will state that the maximum limit has already been reached.

If you see this error message, chances are you already have too many VLANs on your system and your routing has become unstable. To verify, delete a VLAN and try to add it back. If you have too many, you will not be able to add it back on to the system. In this case, you will need to remove enough interfaces (including VLANs) so that the total number of interfaces drops to 255 or less. After doing this, you should also reboot your FortiGate unit to clean up its memory and buffers, or you will continue to experience unstable behavior.

To configure more than 255 interfaces on your FortiGate unit in transparent mode, you have to configure multiple VDOMs, each with many VLANs. However, if you want to create more than the default 10 VDOMs (or a maximum of 2550 interfaces), you must buy a license for additional VDOMs and your FortiGate must be able to be licensed for more than 10 VDOMs.

With these extra licenses, you can configure up to 500 VDOMs, with each VDOM containing up to 255 VLANs in transparent mode. This is a theoretical maximum of over 127 500 interfaces. However, system resources will

quickly get used up before reaching that theoretical maximum. To achieve the maximum number of VDOMs, you need to have top-end hardware with the most resources possible.

In NAT mode, if you have a top-end model, the maximum interfaces per VDOM can be as high as 8192, enough for all the VLANs in your configuration.

Your FortiGate unit has limited resources, such as CPU load and memory, that are divided between all configured VDOMs. When running 250 or more VDOMs, you may need to monitor the system resources to ensure there is enough to support the configured traffic processing.

Troubleshooting VLAN issues

Several problems can occur with your VLANs. Since VLANs are interfaces with IP addresses, they behave as interfaces and can have similar problems that you can diagnose with tools such as ping, traceroute, packet sniffing, and diag debug.

DNS

A DNS server is a public service that converts symbolic node names to IP addresses. A Domain Name System (DNS) server implements the protocol. In simple terms, it acts as a phone book for the Internet. A DNS server matches domain names with the computer IP address. This enables you to use readable locations, such as fortinet.com when browsing the Internet. FortiOS supports DNS configuration for both IPv4 and IPv6 addressing.

The FortiGate unit includes default DNS server addresses. However, these should be changed to those provided by your Internet Service Provider. The defaults are DNS proxies and are not as reliable as those from your ISP.

Within FortiOS, there are two DNS configuration options; each provide a specific service, and can work together to provide a complete DNS solution.

DNS settings

Basic DNS queries are configured on interfaces that connect to the Internet. When a web site is requested, for example, the FortiGate unit will look to the configured DNS servers to provide the IP address to know which server to contact to complete the transaction.

DNS server addresses are configured by going to **Network > DNS**. Here you specify the DNS server addresses. Typically, these addresses are supplied by your ISP. An additional option is available if you have local Microsoft domains on the network, by entering a domain name in the **Local Domain Name** field.

In a situation where all three fields are configured, the FortiGate unit will first look to the local domain. If no match is found, a request is sent to the external DNS servers.

If virtual domains are enabled, you create a DNS database in each VDOM. All of the interfaces in a VDOM share the DNS database in that VDOM.

Additional DNS CLI configuration

Further options are available from the CLI with the command `config system dns`. Within this command you can set the following commands:

- `dns-cache-limit` - enables you to set how many DNS entries are stored in the cache. Entries that remain in the cache provide a quicker response to requests than going out to the Internet to get the same information.
- `dns-cache-ttl` - enables you to set how long entries remain in the cache in seconds, between 60 and 86,400 (24 hours).
- `cache-notfound-responses` - when enabled, any DNS requests that are returned with NOT FOUND can be stored in the cache.
- `source-ip` - enables you to define a dedicated IP address for communications with the DNS server.

Dynamic DNS

If your ISP changes your external IP address on a regular basis, and you have a static domain name, you can configure the external interface to use a dynamic DNS service to ensure external users and/or customers can always connect to your company firewall.

If you have a FortiGuard subscription, you can use FortiGuard as your DDNS server. To configure dynamic DNS in the web-based manager, go to **Network > DNS**, select **Enable FortiGuard DDNS**, and enter the relevant information for the interface communicating to the server, and which server to use, and relevant information.

If you do not have a FortiGuard subscription, or want to use an alternate server, you can configure dynamic DNS in the CLI use the commands below. Within the CLI you can configure a DDNS for each interface. Only the first configured port appears in the web-based manager. Additional commands vary with the DDNS server you select.

```
config system ddns
   edit <instance_value>
      set monitor-interface <external_interface>
      set ddns-server <ddns_server_selection>
end
```

You can also use FortiGuard (when subscribed) as a DDNS as well. To configure, use the CLI commands:

```
config system fortiguard
   set ddns-server-ip
   set ddns-server-port
end
```

DNS Servers

You can also create local DNS servers for your network. Depending on your requirements, you can manually maintain your entries (master DNS server), or use it as a jumping point, where the server refers to an outside source (slave DNS server). A local master DNS server works similarly to the DNS server addresses configured in **Network > DNS**, but all entries must be added manually. This enables you to add a local DNS server to include specific URL/IP address combinations.

The DNS server options are not visible in the web-based manager by default. To enable the server, go to **System > Feature Select**and select **DNS Database.**

While a master DNS server is an easy method of including regularly used addresses to save on going to an outside DNS server, it is not recommended to make it the authoritative DNS server. IP addresses may change, and maintaining any type of list can quickly become labor-intensive.

A FortiGate master DNS server is best set for local services. For example, if your company has a web server on the DMZ that is accessed by internal employees as well as external users, such as customers or remote users. In

this situation, the internal users when accessing the site would send a request for website.example.com, that would go out to the DNS server on the web, to return an IP address or virtual IP. With an internal DNS, the same site request is resolved internally to the internal web server IP address, minimizing inbound/outbound traffic and access time.

As a slave, DNS server, the FortiGate server refers to an external or alternate source as way to obtain the url/IP combination. This useful if there is a master DNS server for a large company where a list is maintained. Satellite offices can then connect to the master DNS server to obtain the correct addressing.

The DNS server entries does not allow CNAME entries, as per RFC 1912, section 2.4.

To configure a master DNS server - web-based manager

1. Go to **Network > DNS Servers**, and select **Create New** for **DNS Database**.
2. Select the **Type** of **Master**.
3. Select the **View** as **Shadow**.
4. The view is the accessibility of the DNS server. Selecting **Public**, external users can access, or use, the DNS server. Selecting **Shadow**, only internal users can use it.
5. Enter the DNS **Zone**, for example, `WebServer`.
6. Enter the domain name for the zone, for example `example.com`.
7. Enter the hostname of the DNS server, for example, `Corporate`.
8. Enter the contact address for the administrator, for example, `admin@example.com`.
9. Set **Authoritative** to **Disable**.
10. Select **OK**.
11. Enter the DNS entries for the server by selecting **Create New**.
12. Select the **Type**, for example, **Address (A)**.
13. Enter the **Hostname**, for example `web.example.com`.
14. Enter the remaining information, which varies depending on the **Type** selected.
15. Select **OK**.

To configure a DNS server - CLI

```
config system dns-database
   edit WebServer
      set domain example.com
      set type master
      set view shadow
      set ttl 86400
      set primary-name corporate
      set contact admin@exmple.com
      set authoritative disable
         config dns-entry
            edit 1
               set hostname web.example.com
               set type A
               set ip 192.168.21.12
               set status enable
         end
      end
```

Recursive DNS

You can set an option to ensure these types of DNS server is not the authoritative server. When configured, the FortiGate unit will check its internal DNS server (Master or Slave). If the request cannot be fulfilled, it will look to the external DNS servers. This is known as a split DNS configuration.

You can also have the FortiGate unit look to an internal server should the Master or Slave not fulfill the request by using the CLI commands:

```
config system dns-database
   edit example.com
      ...
      set view shadow
end
```

For this behavior to work completely, for the external port, you must set the DNS query for the external interface to be recursive.

To configure a recursive DNS - web-based manager

1. Go to **Network > DNS Servers**, and select **Create New** for **DNS Service on Interface**.
2. Select the **Interface**.
3. Select the **Mode** to **Recursive**.
4. Select **OK**.

To set the DNS query - CLI

```
config system dns-server
   edit wan1
      set mode recursive
end
```

Packet Capture

When troubleshooting networks, it helps to look inside the header of the packets. This helps to determine if the packets, route, and destination are all what you expect. Packet capture can also be called a network tap, packet sniffing, or logic analyzing.

To use the packet capture.

1. Go to **Network > Packet Capture**.
2. Select **Create New** or select an existing entry if you've already made one that fits your needs.
3. Select the interface to monitor and select the number of packets to keep.
4. Select **Enable Filters**.
5. Enter the information you want to gather from the packet capture.
6. Select **OK**.

To run the capture, select the play button in the progress column in the packet capture list. If not active, **Not Running** will also appear in the column cell. The progress bar will indicate the status of the capture. You can stop and restart it at any time.

When the capture is complete, select the **Download** icon to save the packet capture file to your hard disk for further analysis.

Packet capture tells you what is happening on the network at a low level. This can be very useful for troubleshooting problems, such as:

- finding missing traffic
- seeing if sessions are setting up properly
- locating ARP problems such as broadcast storm sources and causes
- confirming which address a computer is using on the network if they have multiple addresses or are on multiple networks
- confirming routing is working as you expect
- wireless client connection problems
- intermittent missing PING packets
- a particular type of packet is having problems, such as UDP, which is commonly used for streaming video

If you are running a constant traffic application such as ping, packet capture can tell you if the traffic is reaching the destination, how the port enters and exits the FortiGate unit, if the ARP resolution is correct, and if the traffic is returning to the source as expected. You can also use packet switching to verify that NAT or other configuration is translating addresses or routing traffic the way that you want it to.

Before you start capturing packets, you need to have a good idea of what you are looking for. Capture is used to confirm or deny your ideas about what is happening on the network. If you try capture without a plan to narrow your search, you could end up with too much data to effectively analyze. On the other hand, you need to capture enough packets to really understand all of the patterns and behavior that you are looking for.

Advanced Static Routing

Advanced static routing includes features and concepts that are used in more complex networks.

This section includes:

Routing concepts

Many routing concepts apply to static routing. However without first understanding these basic concepts, it is difficult to understand the more complex dynamic routing.

This section includes:

- Routing in VDOMs
- Default route
- Adding a static route
- Routing table
- Building the routing table
- Static routing security
- Multipath routing and determining the best route
- Route priority
- Troubleshooting static routing

Routing in VDOMs

Routing on FortiGate units is configured per-VDOM. This means if VDOMs are enabled, you must enter a VDOM to do any routing configuration. This allows each VDOM to operate independently, with its own default routes and routing configuration.

In this guide, the procedures assume your FortiGate unit has VDOMs disabled. This is stated in the assumptions for the examples. If you have VDOMs enabled you will need to perform the following steps in addition to the procedure's steps.

To route in VDOMs - web-based manager

Select the VDOM that you want to view or configure at the bottom of the main menu.

To route in VDOMs - CLI

Before following any CLI routing procedures with VDOMs enabled, enter the following commands. For this example, it is assumed you will be working in the root VDOM. Change root to the name of your selected VDOM as needed.

```
config vdom
   edit root
```

Following these commands, you can enter any routing CLI commands as normal.

Default route

The default route is used if either there are no other routes in the routing table or if none of the other routes apply to a destination. Including the gateway in the default route gives all traffic a next-hop address to use when leaving the local network. The gateway address is normally another router on the edge of the local network.

All routers, including FortiGate units, are shipped with default routes in place. This allows customers to set up and become operational more quickly. Beginner administrators can use the default route settings until a more advanced configuration is warranted.

Adding a static route

To add or edit a static route, go to **Network > Static Routes** and select **Create New**.

Destination IP / Mask	Enter the destination IP address and netmask. A value of `0.0.0.0/0.0.0.0` is universal.
Device	Select the name of the interface which the static route will connect through.
Gateway	Enter the gateway IP address.
Distance	Enter the distance value, which will affect which routes are selected first by different protocols for route management or load balancing. The default is 10.
Priority	Enter the priority if desired, which will artificially weight the route during route selection. The higher the number, the less likely the route is to be selected over others. The default is 0.

Routing table

When two computers are directly connected, there is no need for routing because each computer knows exactly where to find the other computer. They communicate directly.

Networking computers allows many computers to communicate with each other. This requires each computer to have an IP address to identify its location to the other computers. This is much like a mailing address - you will not receive your postal mail at home if you do not have an address for people to send mail to. The routing table on a computer is much like an address book used to mail letters to people in that the routing table maintains a list of how to reach computers. Routing tables may also include information about the quality of service (QoS) of the route, and the interface associated with the route if the device has multiple interfaces.

Looking at routing as delivering letters is more simple than reality. In reality, routers loose power or have bad cabling, network equipment is moved without warning, and other such events happen that prevent static routes from reaching their destinations. When any changes such as these happen along a static route, traffic can no longer reach the destination — the route goes down. Dynamic routing can address these changes to ensure traffic still reaches its destination. The process of realizing there is a problem, backtracking and finding a route that is operational is called convergence. If there is fast convergence in a network, users won't even know that re-routing is taking place.

The routing table for any device on the network has a limited size. For this reason, routes that aren't used are replaced by new routes. This method ensures the routing table is always populated with the most current and most used routes—the routes that have the best chance of being reused. Another method used to maintain the

routing table's size is if a route in the table and a new route are to the same destination, one of the routes is selected as the best route to that destination and the other route is discarded.

Routing tables are also used in unicast reverse path forwarding (uRPF). In uRPF, the router not only looks up the destination information, but also the source information to ensure that it exists. If there is no source to be found, then that packet is dropped because the router assumes it to be an error or an attack on the network.

The routing table is used to store routes that are learned. The routing table for any device on the network has a limited size. For this reason, routes that aren't used are replaced by new routes. This method ensures the routing table is always populated with the most current and most used routes — the routes that have the best chance of being reused. Another method used to maintain the routing table's size is if a route in the table and a new route are to the same destination, one of the routes is selected as the best route to that destination and the other route is discarded.

Some actions you can perform on the routing table include:

- Viewing the routing table in the web-based manager
- Viewing the routing table in the CLI
- Searching the routing table

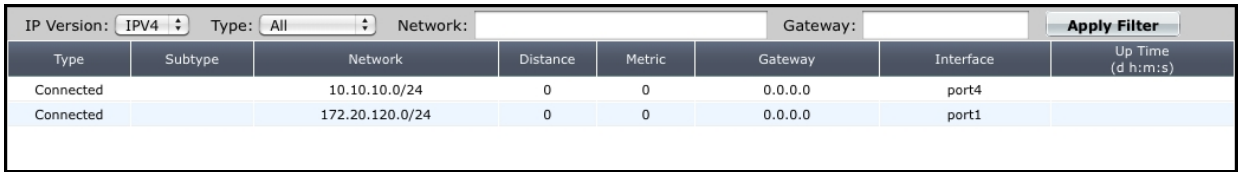
Viewing the routing table in the web-based manager

By default, all routes are displayed in the Routing Monitor list. The default static route is defined as 0.0.0.0/0, which matches the destination IP address of "any/all" packets.

To display the routes in the routing table, go to **Monitor > Routing Monitor**.

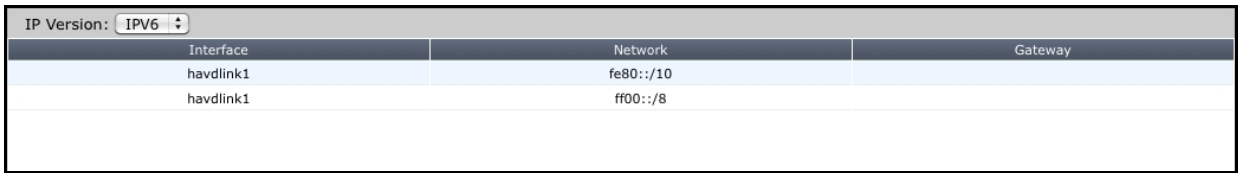
The figure below shows the Routing Monitor list belonging to a FortiGate unit that has interfaces named "port1" and "port4". The names of the interfaces on your FortiGate unit may be different.

Routing Monitor list - IPv4



The following figure shows the Routing Monitor list when IPv6 has been selected. Note that the information available for IPv6 is limited.

Routing Monitor list - IPv6



IP Version	Select IPv4 or IPv6. This is available only when IPv6 is enabled in the web-based manager. The fields displayed in the table depend on which IP version is selected.

Type	The type values assigned to FortiGate unit routes (Static, Connected, RIP, OSPF, or BGP). **All** — all routes recorded in the routing table. **Connected** — all routes associated with direct connections to FortiGate unit interfaces. **Static** — the static routes that have been added to the routing table manually. **RIP** — all routes learned through RIP. For more information see Routing Information Protocol (RIP) on page 2387. **RIPNG** — all routes learned through RIP version 6 (which enables the sharing of routes through IPv6 networks). **BGP** — all routes learned through BGP. For more information see Border Gateway Protocol (BGP) on page 2465. **OSPF** — all routes learned through OSPF. For more information see Open Shortest Path First (OSPF) on page 2424. **OSPF6** — all routes learned through OSPF version 6 (which enables the sharing of routes through IPv6 networks). **IS-IS** — all routes learned through IS-IS. For more information see Intermediate System to Intermediate System Protocol(IS-IS) on page 2502. **HA** — RIP, OSPF, and BGP routes synchronized between the primary unit and the subordinate units of a high availability (HA) cluster. HA routes are maintained on subordinate units and are visible only if you are viewing the router monitor from a virtual domain that is configured as a subordinate virtual domain in a virtual cluster. Not displayed when IPv6 is selected. For details about HA routing synchronization, see the FortiGate HA User Guide.

Subtype	If applicable, the subtype classification assigned to OSPF routes. An empty string implies an intra-area route. The destination is in an area to which the FortiGate unit is connected. **OSPF inter area** — the destination is in the OSPF AS, but the FortiGate unit is not connected to that area. **External 1** — the destination is outside the OSPF AS. This is known as OSPF E1 type. The metric of a redistributed route is calculated by adding the external cost and the OSPF cost together. **External 2** — the destination is outside the OSPF AS. This is known as OSPF E2 type. In this case, the metric of the redistributed route is equivalent to the external cost only, expressed as an OSPF cost. **OSPF NSSA 1** — same as External 1, but the route was received through a not-so-stubby area (NSSA). **OSPF NSSA 2** — same as External 2, but the route was received through a not-so-stubby area. For more information on OSPF subtypes, see Open Shortest Path First (OSPF) on page 2424. Not displayed when IP version 6 is selected.
Network	The IP addresses and network masks of destination networks that the FortiGate unit can reach.
Gateway	The IP addresses of gateways to the destination networks.
Interface	The interface through which packets are forwarded to the gateway of the destination network.
Up Time	The total accumulated amount of time that a route learned through RIP, OSPF, or BGP has been reachable. Not displayed when IP version IPv6 is selected.
Distance	The administrative distance associated with the route. A value of 0 means the route is preferable compared to other routes to the same destination, and the FortiGate unit may routinely use the route to communicate with neighboring routers and access servers. Modifying this distance for dynamic routes is route distribution. See Border Gateway Protocol (BGP) on page 2465. Not displayed when IP version 6 is selected.

Metric	The metric associated with the route type. The metric of a route influences how the FortiGate unit dynamically adds it to the routing table. The following are types of metrics and the protocols they are applied to. **Hop count** — routes learned through RIP. **Relative cost** — routes learned through OSPF. **Multi-Exit Discriminator (MED)** — routes learned through BGP. However, several attributes in addition to MED determine the best path to a destination network. For more information on BGP attributes, see Border Gateway Protocol (BGP) on page 2465. By default, the MED value associated with a BGP route is zero. However, the MED value can be modified dynamically. If the value was changed from the default, the Metric column will display a non-zero value. Not displayed when IP version 6 is selected.

Viewing the routing table in the CLI

In the CLI, you can easily view the static routing table just as in the web-based manager or you can view the full routing table.

When viewing the list of static routes using the CLI command `get router static`, it is the configured static routes that are displayed. When viewing the routing table using the CLI command `get router info routing-table all`, it is the entire routing table information that is displayed including configured and learned routes of all types. The two are different information in different formats.

If VDOMs are enabled on your FortiGate unit, all routing related CLI commands must be performed within a VDOM and not in the global context.

To view the routing table

```
# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
O  - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
i  - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
*  - candidate default

S*  0.0.0.0/0 [10/0] via 192.168.183.254, port2
S    1.0.0.0/8 [10/0] via 192.168.183.254, port2
S   2.0.0.0/8 [10/0] via 192.168.183.254, port2
C   10.142.0.0/23 is directly connected, port3
B   10.160.0.0/23 [20/0] via 10.142.0.74, port3, 2d18h02m
C 192.168.182.0/23 is directly connected, port2
```

Examining an entry:

```
B 10.160.0.0/23 [20/0] via 10.142.0.74, port3, 2d18h02m
```

B	BGP. The routing protocol used.
10.160.0.0/23	The destination of this route including netmask.
[20/0]	20 indicates and administrative distance of 20 out of a range of 0 to 255. 0 is an additional metric associated with this route, such as in OSPF
10.142.0.74	The gateway, or next hop.
port3	The interface used by this route.
2d18h02m	How old this route is, in this case almost three days old.

To view the kernel routing table

```
# get router info kernel

tab=254 vf=0 scope=253 type=1 proto=2 prio=0 0.0.0.0/0.0.0.0/0->10.11.201.0/24
    pref=10.11.201.4 gwy=0.0.0.0 dev=5(external1)

tab=254 vf=0 scope=253 type=1 proto=2 prio=0 0.0.0.0/0.0.0.0/0->172.20.120.0/24
    pref=172.20.120.146 gwy=0.0.0.0 dev=6(internal)
```

The parts of the routing table entry are:

tab	Table number. This will be either 254 (unicast) or 255 (multicast).
vf	Virtual domain of the firewall. This is the vdom index number. If vdoms are not enabled, this number will be 0.
type	Type of routing connection. Valid values include: 0 - unspecific 1 - unicast 2 - local 3 - broadcast 4 - anycast 5 - multicast 6 - blackhole 7 - unreachable 8 - prohibited

proto	Type of installation. This indicates where the route came from. Valid values include: 0 - unspecific 2 - kernel 11 - ZebOS routing module 14 - FortiOS 15 - HA 16 - authentication based 17 - HA1
prio	Priority of the route. Lower priorities are preferred.
->10.11.201.0/24 **(->x.x.x.x/mask)**	The IP address and subnet mask of the destination
pref	Preferred next hop along this route
gwy	Gateway - the address of the gateway this route will use
dev	Outgoing interface index. This number is associated with the interface for this route, and if VDOMs are enabled the VDOM will be included here as well. If an interface alias is set for this interface it will also be displayed here.

Searching the routing table

You can apply a filter to search the routing table and display certain routes only. For example, you can display one or more static routes, connected routes, routes learned through RIP, OSPF, or BGP, and routes associated with the network or gateway that you specify.

If you want to search the routing table by route type and further limit the display according to network or gateway, all of the values that you specify as search criteria must match corresponding values in the same routing table entry in order for that entry to be displayed — an implicit AND condition is applied to all of the search parameters you specify.

For example, if the FortiGate unit is connected to network 172.16.14.0/24 and you want to display all directly connected routes to network 172.16.14.0/24, you must select **Connected** from the **Type** list, type `172.16.14.0/24` in the **Network** field, and then select **Apply Filter** to display the associated routing table entry or entries. Any entry that contains the word “Connected” in its **Type** field and the specified value in the **Gateway** field will be displayed.

In this example, you will apply a filter to search for an entry for static route to 10.10.10.10/24

To search the FortiGate unit routing table in the web-based manager

1. Go to **Monitor > Routing Monitor**.
2. From the **Type** list, select the type of route to display. In our example, select **Static**.
3. If you want to display routes to a specific network, type the IP address and netmask of the network in the Networks field. In our example, enter `10.10.10.10/24`.

4. If you want to display routes to a specific gateway, type the IP address of the gateway in the **Gateway** field.
5. Select **Apply Filter**.

All of the values that you specify as search criteria must match corresponding values in the same routing table entry in order for that entry to be displayed.

To search the FortiGate unit routing table in the CLI

```
FGT # get router info routing-table details 10.10.10.10
Routing entry for 10.10.10.10/24
   Known via "static", distance 10, metric 0, best
```

If there are multiple routes that match your filter, they will all be listed, with the best match at the top of the list as indicated by the word best.

Building the routing table

In the factory default configuration, the FortiGate unit routing table contains a single static default route. You can add routing information to the routing table by defining additional static routes.

It is possible that the routing table is faced with several different routes to the same destination—the IP addresses of the next-hop router specified in those routes or the FortiGate interfaces associated with those routes may vary. In this situation, the “best” route is selected from the table.

The FortiGate unit selects the “best” route for a packet by evaluating the information in the routing table. The “best” route to a destination is typically associated with the shortest distance between the FortiGate unit and the closest gateway, also known as a next-hop router. In some cases, the next best route may be selected if the best route is unavailable.

The FortiGate unit installs the best available routes in the unit’s forwarding table, which is a subset of the unit’s routing table. Packets are forwarded according to the information in the forwarding table.

Static routing security

Securing the information on your company network is a top priority for network administrators. Security is also required as the routing protocols used are internationally known standards that typically provide little or no inherent security by themselves.

The two reasons for securing your network are the sensitive and proprietary information on your network, and also your external bandwidth. Hackers not only can steal your information, but they can also steal your bandwidth. Routing is a good low level way to secure your network, even before UTM features are applied.

Routing provides security to your network in a number of ways including obscuring internal network addresses with NAT and blackhole routing, using RPF to validate traffic sources, and maintaining an access control list (ACL) to limit access to the network.

This section includes:

- Network Address Translation (NAT)
- Access Control List (ACL)
- Blackhole Route
- Reverse path lookup

Network Address Translation (NAT)

Network address translation (NAT) is a method of changing the address from which traffic appears to originate. This practice is used to hide the IP address on a company's internal networks, and helps prevent malicious attacks that use those specific addresses.

This is accomplished by the router connected to that local network changing all the IP addresses to its externally connected IP address before sending the traffic out to the other networks, such as the Internet. Incoming traffic uses the established sessions to determine which traffic goes to which internal IP address. This also has the benefit of requiring only the router to be very secure against external attacks, instead of the whole internal network as would be the case without NAT. Securing the network is much cheaper and easier to maintain.

1. Configuring NAT on your FortiGate unit includes the following steps.
2. Configure your internal network. For example use the `10.11.101.0` subnet.
3. Connect your internal subnet to an interface on your FortiGate unit. For example use `port1`.
4. Connect your external connection, for example an ISP gateway of `172.20.120.2`, to another interface on your Fortigate unit, for example `port2`.

Configure security policies to allow traffic between port1 and port2 on your FortiGate unit, ensuring that the NAT feature is enabled.

The above steps show that traffic from your internal network will originate on the 10.11.101.0 subnet and pass on to the 172.20.120.0 network. The FortiGate unit moves the traffic to the proper subnet. In doing that, the traffic appears to originate from the FortiGate unit interface on that subnet — it does not appear to originate from where it actually came from.

NAT "hides" the internal network from the external network. This provides security through obscurity. If a hacker tries to directly access your network, they will find the Fortigate unit, but will not know about your internal network. The hacker would have to get past the security-hardened FortiGate unit to gain access to your internal network. NAT will not prevent hacking attempts that piggy back on valid connections between the internal network and the outside world. However other UTM security measures can deal with these attempts.

Another security aspect of NAT is that many programs and services have problems with NAT. Consider if someone on the Internet tries to initiate a chat with someone on the internal network. The outsider only can access the FortiGate unit's external interface unless the security policy allows the traffic through to the internal network. If allowed in, the proper internal user would respond to the chat. However if its not allowed, the request to chat will be refused or time-out. This is accomplished in the security policy by allowing or denying different protocols.

Access Control List (ACL)

An access control list (ACL) is a table of addresses that have permission to send and receive data over a router's interface or interfaces. The router maintains an ACL, and when traffic comes in on a particular interface it is buffered, while the router looks up in the ACL if that traffic is allowed over that port or not. If it is allowed on that incoming interface, then the next step is to check the ACL for the destination interface. If the traffic passes that check as well the buffered traffic is delivered to its accentuation. If either of those steps fail the ACL check, the traffic is dropped and an error message may be sent to the sender. The ACL ensures that traffic follows expected paths, and any unexpected traffic is not delivered. This stops many network attacks. However, to be effective the ACL must be kept up to date —when employees or computers are removed from the internal network their IP addresses must also be removed from the ACL. For more information on the ACL, see the router chapter of the FortiGate CLI Reference.

Blackhole Route

A blackhole route is a route that drops all traffic sent to it. It is very much like /dev/null in Linux programming.

Blackhole routes are used to dispose of packets instead of responding to suspicious inquiries. This provides added security since the originator will not discover any information from the target network.

Blackhole routes can also limit traffic on a subnet. If some subnet addresses are not in use, traffic to those addresses (traffic which may be valid or malicious) can be directed to a blackhole for added security and to reduce traffic on the subnet.

The loopback interface, a virtual interface that does not forward traffic, was added to enable easier configuration of blackhole routing. Similar to a normal interface, this loopback interface has fewer parameters to configure, and all traffic sent to it stops there. Since it cannot have hardware connection or link status problems, it is always available, making it useful for other dynamic routing roles. Once configured, you can use a loopback interface in security policies, routing, and other places that refer to interfaces. You configure this feature only from the CLI. For more information, see the system chapter of the FortiGate CLI Reference.

Reverse path lookup

Whenever a packet arrives at one of the FortiGate unit's interfaces, the unit determines whether the packet was received on a legitimate interface by doing a reverse lookup using the source IP address in the packet header. This is also called anti-spoofing. If the FortiGate unit cannot communicate with the computer at the source IP address through the interface on which the packet was received, the FortiGate unit drops the packet as it is likely a hacking attempt.

If the destination address can be matched to a local address (and the local configuration permits delivery), the FortiGate unit delivers the packet to the local network. If the packet is destined for another network, the Fortigate unit forwards the packet to a next-hop router according to a policy route and the information stored in the FortiGate forwarding table.

Multipath routing and determining the best route

Multipath routing occurs when more than one entry to the same destination is present in the routing table. When multipath routing happens, the FortiGate unit may have several possible destinations for an incoming packet, forcing the FortiGate unit to decide which next-hop is the best one.

It should be noted that some IP addresses will be rejected by routing protocols. These are called Martian addresses. They are typically IP addresses that are invalid and not routable because they have been assigned an address by a misconfigured system, or are spoofed addresses.

Two methods to manually resolve multiple routes to the same destination are to lower the administrative distance of one route or to set the priority of both routes. For the FortiGate unit to select a primary (preferred) route, manually lower the administrative distance associated with one of the possible routes. Setting the priority on the routes is a FortiGate unit feature and may not be supported by non-Fortinet routers.

Administrative distance is based on the expected reliability of a given route. It is determined through a combination of the number of hops from the source and the protocol used. A hop is when traffic moves from one router to the next. More hops from the source means more possible points of failure. The administrative distance can be from 1 to 255, with lower numbers being preferred. A distance of 255 is seen as infinite and will not be installed in the routing table.

Here is an example to illustrate how administration distance works — if there are two possible routes traffic can take between two destinations with administration distances of 5 (always up) and 31 (sometimes not available),

the traffic will use the route with an administrative distance of 5. If for some reasons the preferred route (admin distance of 5) is not available, the other route will be used as a backup.

Different routing protocols have different default administrative distances. These different administrative distances are based on a number of factors of each protocol such as reliability, speed, and so on. The default administrative distances for any of these routing protocols are configurable.

Default administrative distances for routing protocols and connections

Routing protocol	Default administrative distance
Direct physical connection	1
Static	10
EBGP	20
OSPF	110
IS-IS	115
RIP	120
IBGP	200

Another method to determine the best route is to manually change the priority of both routes in question. If the next-hop administrative distances of two routes on the FortiGate unit are equal, it may not be clear which route the packet will take. Manually configuring the priority for each of those routes will make it clear which next-hop will be used in the case of a tie. The priority for a route be set in the CLI, or when editing a specific static route, as described in the next section. Lower priority routes are preferred. Priority is a Fortinet value that may or may not be present in other brands of routers.

All entries in the routing table are associated with an administrative distance. If the routing table contains several entries that point to the same destination (the entries may have different gateways or interface associations), the FortiGate unit compares the administrative distances of those entries first, selects the entries having the lowest distances, and installs them as routes in the FortiGate unit forwarding table. As a result, the FortiGate unit forwarding table contains only those routes having the lowest distances to every possible destination. While only static routing uses administrative distance as its routing metric, other routing protocols such as RIP can use metrics that are similar to administrative distance.

Route priority

After the FortiGate unit selects static routes for the forwarding table based on their administrative distances, the priority field of those routes determines routing preference. Priority is a Fortinet value that may or may not be present in other brands of routers.

You can configure the priority field through the CLI or the web-based manager. Priority values can range from 0 to 4 294 967 295. The route with the lowest value in the priority field is considered the best route. It is also the primary route.

To change the priority of a route - web-based manager

1. Go to **Network > Static Routes**.
2. Select the route entry, and select **Edit**.
3. Select **Advanced Options**.
4. Enter the **Priority** value.
5. Select **OK**.

To change the priority of a route - CLI

The following command changes the priority to 5 for a route to the address `10.10.10.1` on the `port1` interface.

```
config router static
   edit 1
      set device port1
      set gateway 10.10.10.10
      set dst 10.10.10.1
      set priority 5
   end
```

If there are other routes set to priority 10, the route set to priority 5 will be preferred. If there are routes set to priorities less than 5, those other routes will be preferred instead.

In summary, because you can use the CLI to specify which sequence numbers or priority field settings to use when defining static routes, you can prioritize routes to the same destination according to their priority field settings. For a static route to be the preferred route, you must create the route using the `config router static` CLI command and specify a low priority for the route. If two routes have the same administrative distance and the same priority, then they are equal cost multipath (ECMP) routes.

Since this means there is more than one route to the same destination, it can be confusing which route or routes to install and use. However, if you have enabled load balancing with ECMP routes, then different sessions will resolve this problem by using different routes to the same address.

Troubleshooting static routing

When there are problems with your network that you believe to be static routing related, there are a few basic tools available to locate the problem.

These tools include:

- Ping
- Traceroute
- Examine routing table contents

Ping

Beyond the basic connectivity information, ping can tell you the amount of packet loss (if any), how long it takes the packet to make the round trip, and the variation in that time from packet to packet.

If there is no packet loss detected, your basic network connectivity is OK.

If there is some packet loss detected, you should investigate:

- Possible ECMP, split horizon, network loops
- Cabling to ensure no loose connections

If there is total packet loss, you should investigate:

- Hardware - ensure cabling is correct, and all equipment between the two locations is accounted for
- Addresses and routes - ensure all IP addresses and routing information along the route is configured as expected
- Firewalls - ensure all firewalls are set to allow PING to pass through

To ping from a Windows PC

1. Go to a DOS prompt. Typically you go to **Start > Run**, enter `cmd` and select **OK**.
2. Enter `ping 10.11.101.100` to ping the default internal interface of the FortiGate unit with four packets.

To ping from an Apple computer

1. Open the Terminal.
2. Enter `ping 10.11.101.100`.
3. If the ping fails, it will stop after a set number of attempts. If it succeeds, it will continue to ping repeatedly. Press `Control+C` to end the attempt and see gathered data.

To ping from a Linux PC

1. Go to a command line prompt.
2. Enter "`/bin/etc/ping 10.11.101.101`".

Traceroute

Where ping will only tell you if it reached its destination and came back successfully, traceroute will show each step of its journey to its destination and how long each step takes. If ping finds an outage between two points, traceroute can be used to locate exactly where the problem is.

To use traceroute on an Windows PC

1. Go to a DOS prompt. Typically you go to **Start > Run**, enter "`cmd`" and select **OK**.
2. Enter "`tracert fortinet.com`" to trace the route from the PC to the Fortinet website.

To use traceroute from an Apple computer

1. Open the Terminal.
2. Enter `traceroute fortinet.com`.
3. The terminal will list the number of steps made. Upon reaching the destination, it will list three asterisks per line. Press `Control+C` to end the attempt.

To use traceroute on a Linux PC

1. Go to a command line prompt.
2. Enter "`/bin/etc/traceroute fortinet.com`".
   The Linux traceroute output is very similar to the MS Windows traceroute output.

Examine routing table contents

The first place to look for information is the routing table.

The routing table is where all the currently used routes are stored for both static and dynamic protocols. If a route is in the routing table, it saves the time and resources of a lookup. If a route isn't used for a while and a new route needs to be added, the oldest least used route is bumped if the routing table is full. This ensures the most recently used routes stay in the table. Note that if your FortiGate unit is in Transparent mode, you are unable to perform this step.

If the FortiGate is running in NAT mode, verify that all desired routes are in the routing table: local subnets, default routes, specific static routes, and dynamic routing protocols.

To check the routing table in the web-based manager, use the Routing Monitor — go to **Monitor > Routing Monitor**. In the CLI, use the command `get router info routing-table all`.

Static routing tips

When your network goes beyond basic static routing, here are some tips to help you plan and manage your static routing.

Always configure a default route

The first thing configured on a router on your network should be the default route. And where possible the default routes should point to either one or very few gateways. This makes it easier to locate and correct problems in the network. By comparison, if one router uses a second router as its gateway which uses a fourth for its gateway and so on, one failure in that chain will appear as an outage for all the devices downstream. By using one or very few addresses as gateways, if there is an outage on the network it will either be very localized or network-wide — either is easy to troubleshoot.

Have an updated network plan

A network plan lists different subnets, user groups, and different servers. Essentially is puts all your resources on the network, and shows how the parts of your network are connected. Keeping your plan updated will also help you troubleshoot problems more quickly when they arise.

A network plan helps your static routing by eliminating potential bottlenecks, and helping troubleshoot any routing problems that come up. Also you can use it to plan for the future and act on any changes to your needs or resources more quickly.

Plan for expansion

No network remains the same size. At some time, all networks grow. If you take future growth into account, there will be less disruption to your existing network when that growth happens. For example allocating a block of addresses for servers can easily prevent having to re-assign IP addresses to multiple servers due to a new server.

With static routing, if you group parts of your network properly you can easily use network masks to address each part of your network separately. This will reduce the amount of administration required both to maintain the routing, and to troubleshoot any problems.

Configure as much security as possible

Securing your network through static routing methods is a good low level method to defend both your important information and your network bandwidth.

- Implement NAT to obscure your IP address is an excellent first step.
- Implement black hole routing to hide which IP addresses are in use or not on your local network.
- Configure and use access control list (ACL) to help ensure you know only valid users are using the network.

All three features limit access to the people who should be using your network, and obscure your network information from the outside world and potential hackers.

Policy routing

Policy routing enables you to redirect traffic away from a static route. This can be useful if you want to route certain types of network traffic differently. You can use incoming traffic's protocol, source address or interface, destination address, or port number to determine where to send the traffic. For example, generally network traffic would go to the router of a subnet, but you might want to direct SMTP or POP3 traffic directly to the mail server on that subnet.

If you have configured the FortiGate unit with routing policies and a packet arrives at the FortiGate unit, the FortiGate unit starts at the top of the Policy Route list and attempts to match the packet with a policy. If a match is found and the policy contains enough information to route the packet (a minimum of the IP address of the next-hop router and the FortiGate interface for forwarding packets to it), the FortiGate unit routes the packet using the information in the policy. If no policy route matches the packet, the FortiGate unit routes the packet using the routing table.

Most policy settings are optional, and a matching policy alone might not provide enough information for forwarding the packet. In fact, the FortiGate almost always requires a matching route in the routing table in order to use a policy route. The FortiGate unit will refer to the routing table in an attempt to match the information in the packet header with a route in the routing table.

Policy route options define which attributes of a incoming packet cause policy routing to occur. If the attributes of a packet match all the specified conditions, the FortiGate unit routes the packet through the specified interface to the specified gateway.

To view policy routes go to **Network > Policy Routes**.

Create New	Add a policy route. See Adding a policy route on page 2359.
Edit	Edit the selected policy route.
Delete	Delete the selected policy route.
Move To	Move the selected policy route. Enter the new position and select **OK**. For more information, see Moving a policy route on page 2361.

#	The ID numbers of configured route policies. These numbers are sequential unless policies have been moved within the table.
Incoming	The interfaces on which packets subjected to route policies are received.
Outgoing	The interfaces through which policy routed packets are routed.
Source	The IP source addresses and network masks that cause policy routing to occur.
Destination	The IP destination addresses and network masks that cause policy routing to occur.

Adding a policy route

To add a policy route, go to **Network > Policy Route** and select **Create New**.

Protocol	Select from existing or specify the protocol number to match. The Internet Protocol Number is found in the IP packet header. RFC 5237 describes protocol numbers and you can find a list of the assigned protocol numbers here. The range is from 0 to 255. A value of `0` disables the feature. Commonly used **Protocol** settings include 6 for TCP sessions, 17 for UDP sessions, 1 for ICMP sessions, 47 for GRE sessions, and 92 for multicast sessions.
Incoming Interface	Select the name of the interface through which incoming packets subjected to the policy are received.
Source Address / Mask	To perform policy routing based on IP source address, type the source address and network mask to match. A value of `0.0.0.0/0.0.0.0` disables the feature.
Destination Address / Mask	To perform policy routing based on the IP destination address of the packet, type the destination address and network mask to match. A value of `0.0.0.0/0.0.0.0` disables the feature.
Destination Ports	To perform policy routing based on the port on which the packet is received, type the same port number in the From and To fields. To apply policy routing to a range of ports, type the starting port number in the From field and the ending port number in the To field. A value of 0 disables this feature. The Destination Ports fields are only used for TCP and UDP protocols. The ports are skipped over for all other protocols.
Type of Service	Use a two digit hexadecimal bit pattern to match the service, or use a two digit hexadecimal bit mask to mask out. For more information, see Type of Service on page 2360.

Outgoing Interface	Select the name of the interface through which packets affected by the policy will be routed.
Gateway Address	Type the IP address of the next-hop router that the FortiGate unit can access through the specified interface.

Example policy route

Configure the following policy route to send all FTP traffic received at `port1` out the `port10` interface and to a next hop router at IP address `172.20.120.23`. To route FTP traffic set protocol to 6 (for TCP) and set both of the destination ports to 21, the FTP port.

Protocol	6
Incoming interface	port1
Source address / mask	0.0.0.0/0.0.0.0
Destination address / mask	0.0.0.0/0.0.0.0
Destination Ports	From 21 to 21
Type of Service	bit pattern: 00 (hex) bit mask: 00 (hex)
Outgoing interface	port10
Gateway Address	172.20.120.23

Type of Service

Type of service (TOS) is an 8-bit field in the IP header that enables you to determine how the IP datagram should be delivered, with such qualities as delay, priority, reliability, and minimum cost.

Each quality helps gateways determine the best way to route datagrams. A router maintains a ToS value for each route in its routing table. The lowest priority TOS is 0, the highest is 7 - when bits 3, 4, and 5 are all set to 1. The router tries to match the TOS of the datagram to the TOS on one of the possible routes to the destination. If there is no match, the datagram is sent over a zero TOS route.

Using increased quality may increase the cost of delivery because better performance may consume limited network resources. For more information, see RFC 791 and RFC 1349.

The role of each bit in the IP header TOS 8-bit field

bits 0, 1, 2	**Precedence**	Some networks treat high precedence traffic as more important traffic. Precedence should only be used within a network, and can be used differently in each network. Typically you do not care about these bits.
bit 3	**Delay**	When set to 1, this bit indicates low delay is a priority. This is useful for such services as VoIP where delays degrade the quality of the sound.

bit 4	**Throughput**	When set to 1, this bit indicates high throughput is a priority. This is useful for services that require lots of bandwidth such as video conferencing.
bit 5	**Reliability**	When set to 1, this bit indicates high reliability is a priority. This is useful when a service must always be available such as with DNS servers.
bit 6	**Cost**	When set to 1, this bit indicates low cost is a priority. Generally there is a higher delivery cost associated with enabling bits 3,4, or 5, and bit 6 indicates to use the lowest cost route.
bit 7	**Reserved for future use**	Not used at this time.

For example, if you want to assign low delay, and high reliability, say for a VoIP application where delays are unacceptable, you would use a bit pattern of xxx1x1xx where an 'x' indicates that bit can be any value. Since all bits are not set, this is a good use for the bit mask; if the mask is set to 0x14, it will match any TOS packets that are set to low delay and high reliability.

Moving a policy route

A routing policy is added to the bottom of the routing table when it is created. If you prefer to use one policy over another, you may want to move it to a different location in the routing policy table.

The option to use one of two routes happens when both routes are a match, for example `172.20.0.0/255.255.0.0` and `172.20.120.0/255.255.255.0`. If both of these routes are in the policy table, both can match a route to `172.20.120.112` but you consider the second one as a better match. In that case the best match route should be positioned before the other route in the policy table.

To change the position of a policy route in the table, go to **Network> Policy Routes** and select **Move To** for the policy route you want to move.

Before/After	Select Before to place the selected Policy Route before the indicated route. Select After to place it following the indicated route.
Policy route ID	Enter the Policy route ID of the route in the Policy route table to move the selected route before or after.

Transparent mode static routing

FortiOS operating modes allow you to change the configuration of your FortiGate unit depending on the role it needs to fill in your network.

NAT/Route operating mode is the standard mode where all interfaces are accessed individually, and traffic can be routed between ports to travel from one network to another.

In transparent operating mode, all physical interfaces act like one interface. The FortiGate unit essentially becomes a bridge — traffic coming in over any interface is broadcast back out over all the interfaces on the FortiGate unit.

In transparent mode, there is no entry for routing at the main level of the menu on the web-based manager display as there is in NAT/Route mode. Routing is instead accessed through the network menu option.

To view the routing table in transparent mode, go to **Network > Routing Table**.

When viewing or creating a static route entry in transparent mode there are only three fields available.

Destination IP / Mask	The destination of the traffic being routed. The first entry is attempted first for a match, then the next, and so on until a match is found or the last entry is reached. If no match is found, the traffic will not be routed. Use 0.0.0.0 to match all traffic destinations. This is the default route.
Gateway	Specifies the next hop for the traffic. Generally the gateway is the address of a router on the edge of your network.
Priority	The priority is used if there is more than one match for a route. This allows multiple routes to be used, with one preferred. If the preferred route is unavailable the other routes can be used instead. Valid range of priority can be from 0 to 4 294 967 295. If more than one route matches and they have the same priority it becomes an ECMP situation and traffic is shared among those routes. See Transparent mode static routing on page 2361.

When configuring routing on a FortiGate unit in transparent mode, remember that all interfaces must be connected to the same subnet. That means all traffic will be coming from and leaving on the same subnet. This is important because it limits your static routing options to only the gateways attached to this subnet. For example, if you only have one router connecting your network to the Internet then all static routing on the FortiGate unit will use that gateway. For this reason static routing on FortiGate units in transparent mode may be a bit different, but it is not as complex as routing in NAT/Route mode.

Static routing example

This is an example of a typical small network configuration that uses only static routing.

This network is in a dentist office that includes a number of dentists, assistants, and office staff. The size of the office is not expected to grow significantly in the near future, and the network usage is very stable—there are no new applications being added to the network.

The users on the network are:

- Admin staff - access to local patient records, and perform online billing
- Dentists - access and update local patient records, research online from desk
- Assistants - access and update local patient records in exam rooms

The distinction here is mainly that only the admin staff and dentist's office need access to the Internet—all the other traffic is local and doesn't need to leave the local network. Routing is only required for the outbound traffic, and the computers that have valid outbound traffic.

Configuring routing only on computers that need it acts as an additional layer of security by helping prevent malicious traffic from leaving the network.

This section includes the following topics:

- Network layout and assumptions
- General configuration steps
- Configure FortiGate unit
- Configure Admin PC and Dentist PCs
- Testing network configuration

Network layout and assumptions

The computers on the network are admin staff computers, dentist office computers, and dental exam room computers. While there are other devices on the local network such as printers, they do not need Internet access or any routing.

This networked office equipment includes 1 admin staff PC, 3 dentist PCs, and 5 exam room PCs. There are also a network printer, and a router on the network as well.

Assumptions about these computers, and network include:

- The FortiGate unit is a model with interfaces labeled port1 and port2.
- The FortiGate unit has been installed and is configured in NAT/Route mode.
- VDOMs are not enabled.
- The computers on the network are running MS Windows software.
- Any hubs required in the network are not shown in the network diagram.
- The network administrator has access to the ISP IP addresses, and is the super_admin administrator on the FortiGate unit.

Static routing example device names, IP addresses, and level of access

Device Name(s)	IP address	Need external access?
Router	192.168.10.1	YES
Admin	192.168.10.11	YES
Dentist1-3	192.168.10.21-23	YES
Exam1-5	192.168.10.31-35	NO
Printer	192.168.10.41	NO

General configuration steps

The steps to configuring routing on this network are:

1. Get your ISP information such as DNS, gateway, etc.
2. Configure FortiGate unit
3. Configure Admin PC and Dentist PCs
4. Testing network configuration

Get your ISP information such as DNS, gateway, etc.

Your local network connects to the Internet through your Internet Service Provider (ISP). They have IP addresses that you need to configure your network and routing.

The addresses needed for routing are your assigned IP address, DNS servers, and the gateway.

Configure FortiGate unit

The FortiGate unit will have two interfaces in use—one connected to the internal network and one connected to the external network. Port1 will be the internal interface, and port2 will be the external interface.

To configure the FortiGate unit:

1. Configure the internal interface (port1)
2. Configure the external interface (port2)
3. Configure networking information
4. Configure basic security policies
5. Configure static routing

Configure the internal interface (port1)

To configure the internal interface (port1) - web based manager

1. Go to **Network > Interfaces**. Highlight **port1** and select **Edit**.
2. Enter the following:

Addressing Mode	Manual
IP/Netmask	172.100.1.1/255.255.255.0
Administrative Access	HTTPS, PING, TELNET
Description	Internal network

To configure the internal interface (port1) - CLI

```
config system interface
   edit port1
      set IP 192.168.10.1 255.255.255.0
      set allowaccess https ping telnet
      set description "internal network"
   end
end
```

Configure the external interface (port2)

The external interface connects to your ISP's network. You need to know the IP addresses in their network that you should connect to. Use their addresses when you get them, however for this example we will assume the address your ISP gave you is 172.100.20.20 will connect to the gateway at 172.100.20.5 on their network, and their DNS servers are 172.11.22.33 and 172.11.22.34.

To configure the internal interface (port2) - web based manager

1. Go to **Network > Interfaces**. Highlight **port2** and select **Edit**.
2. Enter the following:

Addressing Mode	Manual
IP/Netmask	172.100.20.20/255.255.255.0
Administrative Access	HTTPS, PING, TELNET
Description	Internal network

To configure the internal interface (port2) - CLI

```
configure system interface
   edit port2
      set IP 172.100.20.20 255.255.255.0
      set allowaccess https ping telnet
      set description "internal network"
   end
end
```

Configure networking information

Networking information includes the gateway, and DNS servers. Your FortiGate unit requires a connection to the Internet for antivirus and other periodic updates.

To configure networking information - web-based manager

1. Go to **Network > DNS**.
2. Enter the primary and secondary DNS addresses.
3. Select **Apply**.

To configure networking information - CLI

```
config system global
   set dns_1 172.11.22.33
   set dns_2 172.11.22.34
end
```

Configure basic security policies

For traffic to flow between the internal and external ports in both directions, two security policies are required as a minimum. More can be used to farther limit or direct traffic as needed, but will not be included here.

Before configuring the security policies, a firewall address group is configured for the PCs that are allowed Internet access. This prevents PC without Internet privileges from accessing the Internet.

The security policy assumptions are:

- Only the basic networking services have been listed as allowed for added security. Others can easily be added as the users require them.

- In this example to keep things simple, both incoming and outgoing security policies are the same. In a real network there are applications that are allowed out but not in, and vice versa.
- Endpoint control has been enabled to ensure that all computers on the local network are running FortiClient and those installs are up to date. This feature ensures added security on your local network without the need for the network administrator to continually bother users to update their software. The FortiGate unit can store an up to date copy of the FortiClient software and offer a URL to it for users to install it if they need to.

To configure security policies - web-based manager

1. Go to **Policy & Objects > Objects > Addresses**.
2. Create a new Firewall Address entry for each of:

PC Name	IP Address	Interface
Admin	192.168.10.11	port1
Dentist1	192.168.10.21	port1
Dentist2	192.168.10.22	port1
Dentist3	192.168.10.23	port1

3. Go to **Policy & Objects > Objects > Addresses**.
4. Select the dropdown arrow next to **Create New** and select **Address Group**.
5. Name the group Internet_PCs.
6. Add Admin, Dentist1, Dentist2, and Dentist3 as members of the group.
7. Select **OK**.
8. Go to **Policy & Objects > Policy > IPv4**.
9. Select **Create New**.
10. Enter the following: DH - port2(external) -> port1(internal)

Incoming Interface	port2
Source Address	all
Outgoing Interface	port1
Destination Address	Internet_PCs
Schedule	always
Service	Multiple. Select **DHCP, DNS,FTP, HTTP, HTTPS, NTP, POP3, SMTP, SSH.**
Action	ACCEPT
Log Allowed Traffic	Enabled

11. Select **OK**.
12. Select **Create New**.

13. Enter the following:

Incoming Interface	port1
Source Address	Internet_PCs
Outgoing Interface	port2
Destination Address	all
Schedule	always
Service	Multiple. Select **DHCP, DNS,FTP, HTTP, HTTPS, NTP, POP3, SMTP, SSH.**
Action	ACCEPT
Log Allowed Traffic	Enabled

14. Select **OK**.

To configure security policies - CLI

```
config firewall address
   edit "Admin"
      set associated-interface "port1"
      set subnet 192.168.10.11 255.255.255.255
   next
   edit "Dentist1"
      set associated-interface "port1"
      set subnet 192.168.10.21 255.255.255.255
   next
   edit "Dentist2"
      set associated-interface "port1"
      set subnet 192.168.10.22 255.255.255.255
   next
   edit "Dentist3"
      set associated-interface "port1"
      set subnet 192.168.10.23 255.255.255.255
   end
config firewall addrgrp
   edit Internet_PCs
      set member Admin Dentist1 Dentist2 Dentist3
   end
config firewall policy
   edit 1
      set srcintf port1
      set dstintf port2
      set srcaddr Internet_PCs
      set dstaddr all
      set action accept
      set schedule always
      set service "DHCP" "DNS" "FTP" "HTTP" "HTTPS" "NTP" "POP3" "SMTP" "SSH"
      set logtraffic enable
      set label "Section2"
```

```
        set endpoint-restrict-check no-av db-outdated
      next
      edit 2
        set srcintf port2
        set dstintf port1
        set srcaddr all
        set dstaddr Internet_PCs
        set action accept
        set schedule always
        set service "DHCP" "DNS" "FTP" "HTTP" "HTTPS" "NTP" "POP3" "SMTP" "SSH"
        set logtraffic enable
        set label "Section2"
        set endpoint-restrict-check no-av db-outdated
      end
    end
```

Configure static routing

With the rest of the FortiGate unit configured, static routing is the last step before moving on to the rest of the local network. All traffic on the local network will be routed according to this static routing entry.

To configure Fortinet unit static routing - web-based manager

1. Go to **Network > Static Routes**.
2. Select **Edit** for the top route on the page.
3. Enter the following:

Destination IP/Mask	172.100.20.5
Device	port2
Gateway	172.100.20.5
Distance	10

4. Select **OK**.

To configure Fortinet unit static routing - CLI

```
config router static
  edit 1
    set gateway 172.100.20.5
    set distance 10
    set device port2
    set dst 0.0.0.0
  end
end
```

Configure Admin PC and Dentist PCs

With the router configured, next we need to configure the computers that need Internet access. These computers need routing to be configured on them. As the other computers do not require routing, they are not included here.

The procedure to configure these computers is the same. Repeat the following procedure for the corresponding PCs.

The Windows CLI procedure does not configure the DNS entries. It just adds the static routes.

To configure routing and DNS on Admin and Dentist PCs - Windows GUI

1. On PC, select **Start > Control Panel > Network Connections**.
2. Right click on the network connection to your local network that has a status of Connected, and select **Properties**.
3. Under the **General** tab, from the list select **TCP/IP**, and **Properties**.
4. Under **Gateway**, enter the FortiGate unit address (192.168.10.1).
5. Enter the primary and secondary DNS server addresses from your ISP (172.11.22.33 and 172.11.22.34).
6. Select **OK**.

To configure routing on Admin and Dentist PCs - Windows CLI

1. On PC, select **Start > Run**, enter "`cmd`", and select **OK**.
2. At the command prompt, type
   ```
   route ADD 0.0.0.0 MASK 0.0.0.0 172.100.20.5 METRIC 10
   route ADD 192.168.10.0 MASK 255.255.255.0 192.168.10.1 METRIC 5
   ```
3. Confirm these routes have been added. Type:
   ```
   route PRINT
   ```
   If you do not see the two routes you added, try adding them again paying attention to avoid spelling mistakes.
4. Test that you can communicate with other computers on the local network, and with the Internet. If there are no other computers on the local network, connect to the FortiGate unit.

Configure other PCs on the local network

The PCs on the local network without Internet access (the exam room PCs) can be configured now.

As this step does not require any routing, details have not been included.

Testing network configuration

There are three tests to run on the network to ensure proper connectivity.

- To test that PCs on the local network can communicate
- Test that Internet_PCs on the local network can access the Internet
- Test that non-Internet_PCs can not access the Internet

Test that PCs on the local network can communicate

1. Select any two PCs on the local network, such as Exam4 and Dentist3.
2. On the Exam4 PC, at the command prompt enter `ping 192.168.10.23.`
   The output from this command should appear similar to the following.
   ```
   Pinging 192.168.10.23 with 32 bytes of data:

   Reply from 192.168.10.23: bytes=32 time<1m TTL=255
   ```

```
Reply from 192.168.10.23: bytes=32 time<1m TTL=255
Reply from 192.168.10.23: bytes=32 time<1m TTL=255
```

3. At the command prompt enter `exit` to close the window.
4. On the Dentist3 PC, at the command prompt enter `ping 192.168.10.34.`
   The output from this command should appear similar to the following.

```
Pinging 192.168.10.34 with 32 bytes of data:

Reply from 192.168.10.34: bytes=32 time<1m TTL=255
Reply from 192.168.10.34: bytes=32 time<1m TTL=255
Reply from 192.168.10.34: bytes=32 time<1m TTL=255
```

5. At the command prompt enter `exit` to close the window.
6. Repeat these steps for all PCs on the local network.
   If the output does not appear similar to above, there is a problem with the network configuration between these two PCs.

To test that Internet_PCs on the local network can access the Internet

The easiest way to access the Internet is with an Internet browser. However, if that doesn't work its best to do a traceroute to see at what point the problem is. This can help determine if it is a networking problem such as cabling, or if its an access problem such as this PC not having Internet access.

1. Select any PC on the local network that is supposed to have Internet access, such as Admin.
2. On the Admin PC, open an Internet browser and attempt to access a website on the Internet such as http://www.fortinet.com.
   If this is successful, this PC has Internet access.
3. If step2 was not successful, at the command prompt on the PC enter `traceroute 22.11.22.33.`
   The output from this command should appear similar to:

```
Pinging 22.11.22.33 with 32 bytes of data:

Reply from 22.11.22.33: bytes=32 time<1m TTL=255
Reply from 22.11.22.33: bytes=32 time<1m TTL=255
Reply from 22.11.22.33: bytes=32 time<1m TTL=255
```

Dynamic Routing Overview

This section provides an overview of dynamic routing, and how it compares to static routing. For details on various dynamic routing protocols, see the following chapters for detailed information.

The following topics are included in this section:

What is dynamic routing?

Dynamic routing uses a dynamic routing protocol to automatically select the best route to put into the routing table. So instead of manually entering static routes in the routing table, dynamic routing automatically receives routing updates, and dynamically decides which routes are best to go into the routing table. Its this intelligent and hands-off approach that makes dynamic routing so useful.

Dynamic routing protocols vary in many ways and this is reflected in the various administrative distances assigned to routes learned from dynamic routing. These variations take into account differences in reliability, speed of convergence, and other similar factors. For more information on these administrative distances, see Advanced Static Routing on page 2343.

This section includes:

- Comparing static and dynamic routing
- Dynamic routing protocols
- Minimum configuration for dynamic routing

Comparing static and dynamic routing

A common term used to describe dynamic routing is convergence. Convergence is the ability to work around network problems and outages — for the routing to come together despite obstacles. For example, if the main router between two end points goes down, convergence is the ability to find a way around that failed router and reach the destination. Static routing has zero convergence beyond trying the next route in its limited local routing table — if a network administrator doesn't fix a routing problem manually, it may never be fixed, resulting in a downed network. Dynamic routing solves this problem by involving routers along the route in the decision-making about the optimal route, and using the routing tables of these routers for potential routes around the outage. In general, dynamic routing has better scalability, robustness, and convergence. However, the cost of these added benefits include more complexity and some overhead: the routing protocol uses some bandwidth for its own administration.

Comparing static and dynamic routing

Feature	Static Routing	Dynamic Routing
Hardware support	Supported by all routing hardware	May require special, more expensive routers
Router Memory Required	Minimal	Can require considerable memory for larger tables

Feature	Static Routing	Dynamic Routing
Complexity	Simple	Complex
Overhead	None	Varying amounts of bandwidth used for routing protocol updates
Scalability	Limited to small networks	Very scalable, better for larger networks
Robustness	None - if a route fails it has to be fixed manually	Robust - traffic routed around failures automatically
Convergence	None	Varies from good to excellent

Dynamic routing protocols

A dynamic routing protocol is an agreed-on method of routing that the sender, receiver, and all routers along the path (route) support. Typically the routing protocol involves a process running on all computers and routers along that route to enable each router to handle routes in the same way as the others. The routing protocol determines how the routing tables are populated along that route, how the data is formatted for transmission, and what information about a route is included with that route. For example RIP, and BGP use distance vector algorithms, where OSPF uses a shortest path first algorithm. Each routing protocol has different strengths and weaknesses — one protocol may have fast convergence, while another may be very reliable, and a third is very popular for certain businesses like Internet Service Providers (ISPs).

Dynamic routing protocols are different from each other in a number of ways, such as:

- Classful versus classless routing protocols
- Interior versus exterior routing protocols
- Distance vector versus link-state protocols

Classful versus classless routing protocols

Classful or classless routing refers to how the routing protocol handes the IP addresses. In classful addresses there is the specific address, and the host address of the server that address is connected to. Classless addresses use a combination of IP address and netmask.

Classless Inter-Domain Routing (CIDR) was introduced in 1993 (originally with RFC 1519 and most recently with RFC 4632) to keep routing tables from getting too large. With Classful routing, each IP address requires its own entry in the routing table. With Classless routing, a series of addresses can be combined into one entry potentially saving vast amounts of space in routing tables.

Current routing protocols that support classless routing out of necessity include RIPv2, BGP, IS-IS, and OSPF. Older protocols such as RIPv1 do not support CIDR addresses.

Interior versus exterior routing protocols

The names **interior** and **exterior** are very descriptive. Interior routing protocols are designed for use within a contained network of limited size, whereas exterior routing protocols are designed to link multiple networks together. They can be used in combination in order to simplify network administration. For example, a network can be built with only border routers of a network running the exterior routing protocol, while all the routers on the network run the interior protocol, which prevents them from connecting outside the network without passing

through the border. Exterior routers in such a configuration must have both exterior and interior protocols, to communicate with the interior routers and outside the network.

Nearly all routing protocols are interior routing protocols. Only BGP is commonly used as an exterior routing protocol.

You may see interior gateway protocol (IGP) used to refer to interior routing protocols, and exterior gateway protocol (EGP) used to refer to interior routing protocols.

Distance vector versus link-state protocols

Every routing protocol determines the best route between two addresses using a different method. However, there are two main algorithms for determining the best route — Distance vector and Link-state.

Distance vector protocols

In distance vector protocols, routers are told about remote networks through neighboring routers. The distance part refers to the number of hops to the destination, and in more advanced routing protocols these hops can be weighted by factors such as available bandwidth and delay. The vector part determines which router is the next step along the path for this route. This information is passed along from neighboring routers with routing update packets that keep the routing tables up to date. Using this method, an outage along a route is reported back along to the start of that route, ideally before the outage is encountered.

On distance vector protocols, RFC 1058 which defines RIP v1 states the following:

> *Distance vector algorithms are based on the exchange of only a small amount of information. Each entity (gateway or host) that participates in the routing protocol is assumed to keep information about all of the destinations within the system. Generally, information about all entities connected to one network is summarized by a single entry, which describes the route to all destinations on that network.*

There are four main weaknesses inherent in the distance vector method. Firstly, the routing information is not discovered by the router itself, but is instead reported information that must be relied on to be accurate and up-to-date. The second weakness is that it can take a while for the information to make its way to all the routers who need the information — in other words it can have slow convergence. The third weakness is the amount of overhead involved in passing these updates all the time. The number of updates between routers in a larger network can significantly reduce the available bandwidth. The fourth weakness is that distance vector protocols can end up with routing-loops. Routing loops are when packets are routed for ever around a network, and often occur with slow convergence. The bandwidth required by these infinite loops will slow your network to a halt. There are methods of preventing these loops however, so this weakness is not as serious as it may first appear.

Link-state protocols

Link-state protocols are also known as shortest path first protocols. Where distance vector uses information passed along that may or may not be current and accurate, in link-state protocols each router passes along only information about networks and devices directly connected to it. This results in a more accurate picture of the network topology around your router, allowing it to make better routing decisions. This information is passed between routers using link-state advertisements (LSAs). To reduce the overhead, LSAs are only sent out when information changes, compared to distance vector sending updates at regular intervals even if no information has changed. The more accurate network picture in link-state protocols greatly speed up convergence and avoid problems such as routing-loops.

Minimum configuration for dynamic routing

Dynamic routing protocols do not pay attention to routing updates from other sources, unless you specifically configure them to do so using CLI redistribute commands within each routing protocol.

The minimum configuration for any dynamic routing to function is to have dynamic routing configured on one interface on the FortiGate unit, and one other router configured as well. Some protocols require larger networks to function as designed.

Minimum configuration based on dynamic protocol

	BGP	RIP	OSPF / IS-IS
Interface	yes	yes	yes
Network	yes	yes	yes
AS	local and neighbor	no	yes
Neighbors	at least one	at least one	at least one
Version	no	yes	no
Router ID	no	no	yes

Comparison of dynamic routing protocols

Each dynamic routing protocol was designed to meet a specific routing need. Each protocol does some things well, and other things not so well. For this reason, choosing the right dynamic routing protocol for your situation is not an easy task.

Features of dynamic routing protocols

Each protocol is better suited for some situations over others.

Choosing the best dynamic routing protocol depends on the size of your network, speed of convergence required, the level of network maintenance resources available, what protocols the networks you connect to are using, and so on. For more information on these dynamic routing protocols, see Routing Information Protocol (RIP) on page 2387, Border Gateway Protocol (BGP) on page 2465, Open Shortest Path First (OSPF) on page 2424, and Intermediate System to Intermediate System Protocol(IS-IS) on page 2502.

Comparing RIP, BGP, and OSPF dynamic routing protocols

Protocol	RIP	BGP	OSPF / IS-IS
Routing algorithm	Distance Vector, basic	Distance Vector, advanced	Link-state

Protocol	RIP	BGP	OSPF / IS-IS
Common uses	Small non-complex networks	Network backbone, ties multinational offices together	Common in large, complex enterprise networks
Strengths	Fast and simple to implement Near universal support Good when no redundant paths	Graceful restart BFD support Only needed on border routers Summarize routes	Fast convergence Robust Little management overhead No hop count limitation Scalable
Weakness	Frequent updates can flood network Slow convergence Maximum 15 hops may limit network configuration	Required full mesh in large networks can cause floods Route flap Load-balance multi-homed networks Not available on low-end routers	Complex No support for unequal cost multipath routing Route summary can require network changes
Authentication	Optional authentication using text string or MD5 password. (RIP v1 has no authentication)		
IPv6 Support	Only in RIPng	Only in BGP4+	Only in OSPF6 / Integrated IS-IS

Routing protocols

- **Routing Information Protocol (RIP)** uses classful routing, as well as incorporating various methods to stop incorrect route information from propagating, such as the poisoned horizon method. However, on larger networks its frequent updates can flood the network and its slow convergence can be a problem.
- **Border Gateway Protocol (BGP)** has been the core Internet backbone routing protocol since the mid 1990s, and is the most used interior gateway protocol (IGP). However, some configurations require full mesh connections which flood the network, and there can be route flap and load balancing issues for multihomed networks.
- **Open Shortest Path First (OSPF)** is commonly used in large enterprise networks. It is the protocol of choice mainly due to its fast convergence. However, it can be complicated to setup properly.
- **Intermediate System to Intermediate System (IS-IS) Protocol** allows routing of ISO's OSI protocol stack Connectionless Network Service (CLNS). IS-IS is an Interior Gateway Protocol (IGP) not intended to be used between Autonomous Systems (ASes). IS-IS is a link state protocol well-suited to smaller networks that is in widespread use and has near universal support on routing hardware.

- **Multicast** addressing is used to broadcast from one source to many destinations efficiently. Protocol Independent Multicast (PIM) is the protocol commonly used in enterprises, multimedia content delivery, and stock exchanges.

Routing algorithm

Each protocol uses a slightly different algorithm for choosing the best route between two addresses on the network. The algorithm is the “intelligent” part of a dynamic protocol because the algorithm is responsible for deciding which route is best and should be added to the local routing table. RIP and BGP use distance vector algorithms, where OSPF and IS-IS use link-state or a shortest path first algorithm.

Vector algorithms are essentially based on the number of hops between the originator and the destination in a route, possibly weighting hops based on how reliable, fast, and error-free they are.

The link-state algorithm used by OSPF and IS-IS is called the Dijkstra algorithm. Link-state treats each interface as a link, and records information about the state of the interface. The Dijkstra algorithm creates trees to find the shortest paths to the routes it needs based on the total cost of the parts of the routes in the tree.

For more information on the routing algorithm used, see Comparison of dynamic routing protocols on page 2374.

Authentication

If an attacker gains access to your network, they can masquerade as a router on your network to either gain information about your network or disrupt network traffic. If you have a high quality firewall configured, it will help your network security and stop many of this type of threat. However, the main method for protecting your routing information is to use authentication in your routing protocol. Using authentication on your FortiGate unit and other routers prevents access by attackers — all routers must authenticate with passwords, such as MD5 hash passwords, to ensure they are legitimate routers.

When configuring authentication on your network, ensure you configure it the same on all devices on the network. Failure to do so will create errors and outages as those forgotten devices fail to connect to the rest of the network.

For example, to configure an MD5 key of `123` on an OSPF interface called `ospf_test`, enter the following CLI command:

```
config router ospf
   config ospf-interface
      edit ospf_test
         set authentication md5
         set md5-key 123
      end
   end
```

Convergence

Convergence is the ability of a networking protocol to re-route around network outages. Static routing cannot do this. Dynamic routing protocols can all converge, but take various amounts of time to do this. Slow convergence can cause problems such as network loops which degrade network performance.

You may also hear robustness and redundancy used to describe networking protocols. In many ways they are the same thing as convergence. Robustness is the ability to keep working even though there are problems, including configuration problems as well as network outages. Redundancy involves having duplicate parts that can continue to function in the event of some malfunction, error, or outage. It is relatively easy to configure dynamic routing protocols to have backup routers and configurations that will continue to function no matter the network problem short of a total network failure.

IPv6 Support

IPv4 addressing is in common use everywhere around the world. IPv6 has much larger addresses and it is used by many large companies and government departments. IPv6 is not as common as IPv4 yet, but more companies are adopting it.

If your network uses IPv6, your dynamic routing protocol must support it. None of the dynamic routing protocols originally supported IPv6, but they all have additions, expansions, or new versions that do support IPv6. For more information, see Routing Information Protocol (RIP) on page 2387, Border Gateway Protocol (BGP) on page 2465, Open Shortest Path First (OSPF) on page 2424, or Intermediate System to Intermediate System Protocol (IS-IS) on page 2502.

When to adopt dynamic routing

Static routing is more than enough to meet your networking needs when you have a small network. However, as your network grows, the question you need to answer is at what point do you adopt dynamic routing in your networking plan and start using it in your network? The main factors in this decision are typically:

- Budget
- Current network size and topology
- Expected network growth
- Available resources for ongoing maintenance

Budget

When making any business decision, the budget must always be considered. Static routing does not involve special hardware, fancy software, or expensive training courses.

Dynamic routing can include all of these extra expenses. Any new hardware, such as routers and switches, will need to support your chosen routing protocols. Network management software and routing protocol drivers may be necessary as well to help configure and maintain your more complex network. If the network administrators are not well versed in dynamic routing, either a training course or some hands-on learning time must be budgeted so they can administer the new network with confidence. Together, these factors can impact your budget.

Additionally, people will always account for network starting costs in the budgets, but usually leave out the ongoing cost of network maintenance. Any budget must provide for the hours that will be spent on updating the network routing equipment, and fixing any problems. Without that money in the budget, you may end up back at static routing before you know it.

Current network size and topology

As stated earlier static routing works well on small networks. At those networks get larger, routing takes longer, routing tables get very large, and general performance isn't what it could be.

Topology is a concern as well. If all your computers are in one building, its much easier to stay with static routing longer. However, connecting a number of locations will be easier with the move to dynamic routing.

If you have a network of 20 computers, you can still likely use static routing. If those computers are in two or three locations, static routing will still be a good choice for connecting them. Also, if you just connect to your ISP and don't worry about any special routing to do that, you are likely safe with just static routing.

If you have a network of 100 computers in one location, you can use static routing but it will be getting slower, more complex, and there won't be much room for expansion. If those 100 computers are spread across three or more locations, dynamic routing is the way to go.

If you have 1000 computers, you definitely need to use dynamic routing no matter how many locations you have.

Hopefully this section has given you an idea of what results you will likely experience from different sized networks using different routing protocols. Your choice of which dynamic routing protocol to use is partly determined by the network size, and topology.

Expected network growth

You may not be sure if your current network is ready for dynamic routing. However, if you are expecting rapid growth in the near future, it is a good idea to start planning for that growth now so you are ready for the coming expansion.

Static routing is very labor intensive. Each network device's routing table needs to be configured and maintained manually. If there is a large number of new computers being added to the network, they each need to have the static routing table configured and maintained. If devices are being moved around the network frequently, they must also be updated each time.

Instead, consider putting dynamic routing in place before those new computers are installed on the network. The installation issues can be worked out with a smaller and less complex network, and when those new computers or routers are added to the network there will be nowhere near the level of manual configuration required. Depending on the level of growth, this labor savings can be significant. For example, in an emergency you can drop a new router into a network or AS, wait for it to receive the routing updates from its neighbors, and then remove one of the neighbors. While the routes will not be the most effective possible, this method is much less work than static routing in the same situation, with less chance of mistakes.

Also, as your network grows and you add more routers, those new routers can help share the load in most dynamic routing configurations. For example if you have 4 OSPF routers and 20,000 external routes those few routers will be overwhelmed. But in a network with 15 OSPF routers they will better be able to handle that number of routes. Be aware though that adding more routers to your network will increase the amount of updates sent between the routers, which will use up a greater part of your bandwidth and use more bandwidth overall.

Available resources for ongoing maintenance

As touched on in the budget section, there must be resources dedicated to ongoing network maintenance, upgrades, and troubleshooting. These resources include administrator hours to configure and maintain the network, training for the administrator if needed, extra hardware and software as needed, and possible extra staff to help the administrator in emergencies. Without these resources, you will quickly find the network reverting to static routing out of necessity. This is because:

- Routing software updates will require time.
- Routing hardware updates will require time.
- Office reorganizations or significant personnel movement will require time from a networking point of view.
- Networking problems that occur, such as failed hardware, require time to locate and fix the problem.

If the resources to accomplish these tasks are not budgeted, they will either not happen or not happen at the required level to continue operation. This will result in both the network administration staff and the network users being very frustrated.

A lack of maintenance budget will also result in increasingly heavy reliance on static routing as the network administrators are forced to use quick fixes for problems that come up. This invariably involves going to static routing, and dropping the more complex and time-consuming dynamic routing.

Choosing a routing protocol

One of that hardest decisions in routing can be choosing which routing protocol to use on your network. It can be easy to decide when static routing will not meet your needs, but how can you tell which dynamic routing protocol is best for your network and situation?

Here is a brief look at the routing protocols including their strongest and weakest points. The steps to choosing your routing protocol are:

1. Answer questions about your network
2. Evaluate your chosen protocol
3. Implement your dynamic routing protocol

Answer questions about your network

Before you can decide what is best for your situation, you need to examine what the details of your situation are such as what you have for budget, equipment, and users.

The following questions will help you form a clear idea of your routing needs:

How many computers or devices are on your network?

It matters if you only have a few computers, or if you have many and if they are all at one location or not as well. All routing protocols can be run on any sized network, however it can be inefficient to run some on very small networks. However, routers and network hardware that support dynamic routing can be more expensive than more generic routers for static routing.

What applications typically run over the network?

Finding out what application your users are running will help you determine their needs and the needs of the network regarding bandwidth, quality of service, and other such issues.

What level of service do the users expect from the network?

Different network users have different expectations of the network. Its not critical for someone surfing the Internet to have 100% uptime, but it is required for a stock exchange network or a hospital.

Is there network expansion in your near future?

You may have a small network now, but if it will be growing quickly, you should plan for the expected size so you don't have to chance technologies again down the road.

What routing protocols do your networks connect to?

This is most often how routing protocol decisions are made. You need to be able to communicate easily with your service provider and neighbors, so often people simply use what everyone else is using.

Is security a major concern?

Some routing protocols have levels of authentication and other security features built in. Others do not. If security is important to you, be aware of this.

What is your budget — both initial and maintenance?

More robust and feature laden routing protocols generally mean more resources are required to keep them working well. Also more secure configurations require still more resources. This includes both set up costs, as well as ongoing maintenance costs. Ignore these costs at the risk of having to drop the adoption of the new routing protocol mid-change.

Evaluate your chosen protocol

Once you have examined the features of the routing protocols listed above and chosen the one that best meets your needs, you can set up an evaluation or test install of that protocol.

The test install is generally set up in a sandbox configuration so it will not affect critical network traffic. The aim of the test install is to prove that it will work on a larger scale on your network. So be sure that the test install mirrors your larger network well enough for you to discover any problems. If its too simplistic, these problems may not appear.

If your chosen protocol does not meet your goals choose a different protocol and repeat the evaluation process until either a protocol meets your needs, or you change your criteria.

Implement your dynamic routing protocol

You have examined your needs, selected the best matching dynamic routing protocol, tested it, and now you are ready to implement it with confidence.

This guide will help you configure your FortiGate unit to support your chosen dynamic routing protocol. Refer to the various sections in this guide as needed during your implementation to help ensure a smooth transition. Examples for each protocol have been included to show proper configurations for different types of networks.

Dynamic routing terminology

Dynamic routing is a complex subject. There are many routers on different networks and all can be configured differently. It become even more complicated when you add to this each routing protocol having slightly different names for similar features, and many configurable features for each protocol.

To better understand dynamic routing, here are some explanations of common dynamic routing terms.

- Aggregated routes and addresses
- Autonomous system (AS)
- Area border router (ABR)
- Neighbor routers
- Route maps
- Access lists
- Bi-directional forwarding detection (BFD)

For more details on a term as it applies to a dynamic routing protocol, see one of Border Gateway Protocol (BGP) on page 2465, Routing Information Protocol (RIP) on page 2387, or Open Shortest Path First (OSPF) on page 2424.

Aggregated routes and addresses

Just as an aggregate interface combines multiple interfaces into one virtual interface, an aggregate route combines multiple routes into one. This reduces the amount of space those routes require in the routing tables of

the routers along that route. The trade-off is a small amount of processing to aggregate and de-aggregate the routes at either end.

The benefit of this method is that you can combine many addresses into one, potentially reducing the routing table size immensely. The weakness of this method is if there are holes in the address range you are aggregating you need to decide if its better to break it into multiple ranges, or accept the possibility of failed routes to the missing addresses.

For information on aggregated routes in BGP, see Border Gateway Protocol (BGP) on page 2465, and Border Gateway Protocol (BGP) on page 2465.

To manually aggregate the range of IP addresses from 192.168.1.100 to 192.168.1.103

1. Convert the addresses to binary
   ```
   192.168.1.100 = 11000000 10101000 00000001 01100100
   192.168.1.101 = 11000000 10101000 00000001 01100101
   192.168.1.102 = 11000000 10101000 00000001 01100110
   192.168.1.103 = 11000000 10101000 00000001 01100111
   ```
2. Determine the maximum number of matching bits common to the addresses.
   There are 30-bits in common, with only the last 2-bits being different.
3. Record the common part of the address.
   ```
   11000000 10101000 00000001 0110010X = 192.168.1.100
   ```
4. For the netmask, assume all the bits in the netmask are 1 except those that are different which are 0.
   ```
   11111111 11111111 11111111 11111100 = 255.255.255.252
   ```
5. Combine the common address bits and the netmask.
   ```
   192.168.1.100/255.255.255.252
   ```
   Alternately the IP mask may be written as a single number:
   ```
   192.168.1.100/2
   ```
6. As required, set variables and attributes to declare the routes have been aggregated, and what router did the aggregating.

Autonomous system (AS)

An Autonomous System (AS) is one or more connected networks that use the same routing protocol, and appear to be a single unit to any externally connected networks. For example an ISP may have a number of customer networks connected to it, but to any networks connected externally to the ISP it appears as one system or AS. An AS may also be referred to as a routing domain.

It should be noted that while OSPF routing takes place within one AS, the only part of OSPF that deals with the AS is the AS border router (ASBR).

There are multiple types of AS defined by how they are connected to other ASes. A multihomed AS is connected to at least two other ASes and has the benefit of redundancy — if one of those ASes goes down, your AS can still reach the Internet through its other connection. A stub AS only has one connection, and can be useful in specific configurations where limited access is desirable.

Each AS has a number assigned to it, known as an ASN. In an internal network, you can assign any ASN you like (a private AS number), but for networks connected to the Internet (public AS) you need to have an officially

registered ASN from Internet Assigned Numbers Authority (IANA). ASNs from 1 to 64,511 are designated for public use.

NAs of January 2010, AS numbers are 4 bytes long instead of the former 2 bytes. RFC 4893 introduced 32-bit ASNs, which FortiGate units support for BGP and OSPF.

Do you need your own AS?

The main factors in deciding if you need your own AS or if you should be part of someone else's are:

- exchanging external routing information
- many prefixes should exist in one AS as long as they use the same routing policy
- when you use a different routing protocol than your border gateway peers (for example your ISP uses BGP, and you use OSPF)
- connected to multiple other AS (multi-homed)

You should not create an AS for each prefix on your network. Neither should you be forced into an AS just so someone else can make AS-based policy decisions on your traffic.

There can be only one AS for any prefix on the Internet. This is to prevent routing issues.

What AS number to use?

In addition to overseeing IP address allocation and Domain Name Systems (DNS), the Internet Assigned Numbers Authority (IANA) assigns public AS numbers. The public AS numbers are from 1 to 64,511. The ASNs 0, 54272–64511, and 65535 are reserved by the IANA. These ASNs should not be used.

ASNs are assigned in blocks by the Internet Assigned Numbers Authority (IANA) to Regional Internet Registries (RIRs) who then assign ASNs to companies within that RIRs geographic area. Usually these companies are ISPs, and to receive an ASN you must complete the application process of the local RIR and be approved before being assigned an ASN. The RIRs names and regions are:

AFRINIC	Serves the African continent
APNIC	Asia-Pacific including China, India, and Japan
ARIN	American registry including Canada and United States
LACNIC	Latin America, including Mexico, Caribbean, Central and South America
RIPE NCC	Europe, the Middle East, former USSR, and parts of Central Asia

AS numbers from 64512 to 65534 are reserved for private use. Private AS numbers can be used for any internal networks with no outside connections to the Internet such as test networks, classroom labs, or other internal-only networks that do not access the outside world. You can also configure border routers to filter out any private ASNs before routing traffic to the outside world. If you must use private ASNs with public networks, this is the only way to configure them. However, it is risky because many other private networks could be using the same ASNs and conflicts will happen. It would be very much like your local 192.168.0.0 network being made public — the resulting problems would be widespread.

In 1996, when RFC 1930 was written only 5,100 ASes had been allocated and a little under 600 ASes were actively routed in the global Internet. Since that time many more public ASNs have been assigned, leaving only a small number. For this reason 32-bit ASNs (four-octet ASNs) were defined to provide more public ASNs. RFC 4893 defines 32-bit ASNs, and FortiGate units support these larger ASNs.

Area border router (ABR)

Routers within an AS advertise updates internally and only to each other. However, routers on the edge of the AS must communicate both with routers inside their AS and with routers external to their AS, often running a different routing protocol. These routers are called Area Border Routers (ABRs) or edge routers. Often ABRs run multiple routing protocols to be able to redistribute traffic between different ASes that are running different protocols, such as the edge between an ISP's IS-IS routing network and a large company's OSPF network.

OSPF defines ABRs differently from other routers. In OSPF, an ABR is an OSPF router that connects another AS to the backbone AS, and is a member of all the areas it connects to. An OSPF ABR maintains a LSA database for each area that it is connected to. The concept of the edge router is present, but its the edge of the backbone instead of the edge of the OSPF supported ASes.

Neighbor routers

Routing involves routers communicating with each other. To do this, routers need to know information about each other. These routers are called neighbor routers, and are configured in each routing protocol. Each neighbor has custom settings since some routers may have functionality others routers lack. Neighbor routers are sometimes called peers.

Generally neighbor routers must be configured, and discovered by the rest of the network before they can be integrated to the routing calculations. This is a combination of the network administrator configuring the new router with its neighbor router addresses, and the routing network discovering the new router, such as the hello packets in OSPF. That discovery initiates communication between the new router and the rest of the network.

Route maps

Route maps are a way for the FortiGate unit to evaluate optimum routes for forwarding packets or suppressing the routing of packets to particular destinations. Compared to access lists, route maps support enhanced packet-matching criteria. In addition, route maps can be configured to permit or deny the addition of routes to the FortiGate unit routing table and make changes to routing information dynamically as defined through route-map rules.

Route maps can be used for limiting both received route updates, and sent route updates. This can include the redistribution of routes learned from other types of routing. For example if you don't want to advertise local static routes to external networks, you could use a route map to accomplish this.

The FortiGate unit compares the rules in a route map to the attributes of a route. The rules are examined in ascending order until one or more of the rules in the route map are found to match one or more of the route attributes.

As an administrator, route maps allow you to group a set of addresses together and assign them a meaningful name. Then during your configuration, you can use these route-maps to speed up configuration. The meaningful names ensure fewer mistakes during configuration as well.

The default rule in the route map (which the FortiGate unit applies last) denies all routes. For a route map to take effect, it must be called by a FortiGate unit routing process.

The syntax for route maps are:

```
config router route-map
   edit <route_map_name>
      set comments
      config rule
         edit <route_map_rule_id>
            set action
            set match-*
            set set-*
            ...
         end
```

The `match-*` commands allow you to match various parts of a route. The `set-*` commands allow you to set routing information once a route is matched.

For an example of how route maps can be used to create receiving or sending “groups” in routing, see Border Gateway Protocol (BGP) on page 2465.

Access lists

Use this command to add, edit, or delete access lists. Access lists are filters used by FortiGate unit routing processes. For an access list to take effect, it must be called by a FortiGate unit routing process (for example, a process that supports RIP or OSPF). Use `access-list6` for IPv6 routing.

Access lists can be used to filter which updates are passed between routers, or which routes are redistributed to different networks and routing protocols. You can create lists of rules that will match all routes for a specific router or group of routers.

Each rule in an access list consists of a prefix (IP address and netmask), the action to take for this prefix (permit or deny), and whether to match the prefix exactly or to match the prefix and any more specific prefix.

If you are setting a prefix of 128.0.0.0, use the format 128.0.0.0/1. The default route, 0.0.0.0/0 can not be exactly matched with an access-list. A prefix-list must be used for this purpose.

The FortiGate unit attempts to match a packet against the rules in an access list starting at the top of the list. If it finds a match for the prefix, it takes the action specified for that prefix. If no match is found the default action is deny.

The syntax for access lists is:

```
config router access-list, access-list6
   edit <access_list_name>
      set comments
      config rule
      edit <access_list_id>
         set action
         set exact-match
         set prefix
         set prefix6
         set wildcard
```

For an example of how access lists can be used to create receiving or sending “groups” in routing, see Border Gateway Protocol (BGP) on page 2465.

Bi-directional forwarding detection (BFD)

Bi-directional Forwarding Detection (BFD) is a protocol used to quickly locate hardware failures in the network. Routers running BFD send packets to each other at a negotiated rate. If packets from a BFD-protected router fail to arrive, then that router is declared down. BFD communicates this information to the routing protocol and the routing information is updated.

BFD neighbors establish if BFD is enabled in OSPF or BFP routers that establish as neighbors.

The CLI commands associated with BFD include:

```
config router bgp
   config neighbor
      set bfd
end
config router ospf
   set bfd
end
```

Per-VDOM configuration:

```
config system settings
   set bfd
   set bfd-desired-min-tx
   set bfd-required-min-rx
   set bfd-detect-mult
   set bfd-dont-enforce-src-port
end
```

Per-interface (override) configuration:

```
config system interface
   edit <interface_name>
      set bfd enable
      set bfd-desired-min-tx
      set bfd-detect-mult
      set bfd-required-min-rx
   end
```

For more information about BFD in BGP, see Border Gateway Protocol (BGP) on page 2465.

IPv6 in dynamic routing

Unless otherwise stated, routing protocols apply to IPv4 addressing. This is the standard address format used. However, IPv6 is becoming more popular and new versions of the dynamic routing protocols have been introduced.

Dynamic routing supports IPv6 on your FortiGate unit. The new versions of these protocols and the corresponding RFCs are:

- **RIP next generation (RIPng)** — RFC 2080 - Routing Information Protocol next generation (RIPng). See RIP and IPv6.
- **BGP4+** — RFC 2545, and RFC 2858 Multiprotocol Extensions for IPv6 Inter-Domain Routing, and Multiprotocol Extensions for BGP-4 (MP-BGP) respectively. See BGP and IPv6.
- **OSPFv3** — RFC 2740 Open Shortest Path First version 3 (OSPFv3) for IPv6 support. See OSPFv3 and IPv6.
- **Integrated IS-IS** — RFC 5308 for IPv6 support. See Integrated IS-IS.

As with most advanced routing features on your FortiGate unit, IPv6 settings for dynamic routing protocols must be enabled before they will be visible in the GUI. To enable IPv6 configuration in the GUI, enable it in **System >**

Feature Select. Alternatively, you can directly configure IPv6 for RIP, BGP, or OSPF protocols using CLI commands.

Routing Information Protocol (RIP)

This section describes the Routing Information Protocol (RIP).

The following topics are included in this section:

RIP background and concepts

This section contains:

- Background
- Parts and terminology of RIP
- How RIP works

Background

Routing Information Protocol (RIP) is a distance-vector routing protocol intended for small, relatively homogeneous networks. Its widespread use started when an early version of RIP was included with BSD v4.3 Linux as the routed daemon. The routing algorithm used by RIP, the Bellman–Ford algorithm, first saw widespread use as the initial routing algorithm of the ARPANET.

RIP benefits include being well suited to smaller networks, is in widespread use, near universal support on routing hardware, quick to configure, and works well if there are no redundant paths. However, RIP updates are sent out node-by-node so it can be slow to find a path around network outages. RIP also lacks good authentication, can not choose routes based on different quality of service methods, and can create network loops if you are not careful.

The FortiGate implementation of RIP supports RIP version 1 (see RFC 1058), RIP version 2 (see RFC 2453), and the IPv6 version RIPng (see RFC 2080).

RIP v1

In 1988 RIP version 1, defined in RFC 1058, was released. The RFC even states that RIP v1 is based on Linux routed due to it being a “defacto standard”.

It uses classful addressing and uses broadcasting to send out updates to router neighbors. There is no subnet information included in the routing updates in classful routing, and it does not support CIDR addressing — subnets must all be the same size. Also, route summarization is not possible.

RIP v1 has no router authentication method, so it is vulnerable to attacks through packet sniffing, and spoofing.

RIP v2

In 1993, RIP version 2 was developed to deal with the limitations of RIP v1. It was not standardized until 1998. This new version supports classless routing, and subnets of various sizes.

Router authentication was added in RIP v2 — it supports MD5. MD5 hashes are an older encryption method, but this is much improved over no security at all.

In RIP v2 the hop count limit remained at 15 to be backwards compatible with RIP v1.

RIP v2 uses multicasting to send the entire routing table to router neighbors, thereby reducing the traffic for devices that are not participating in RIP routing.

Routing tags were added as well, which allow internal routes or redistributed routes to be identified as such.

RIPng

RIPng, defined in RFC 2080, is an extension of RIP2 designed to support IPv6. However, RIPng varies from RIPv2 in that it is not fully backwards compatible with RIPv1.

- RIPng does not support RIPv1 update authentication, it relies on IPsec
- RIPng does not allow attaching tags to routes as in RIPv2
- RIPng requires specific encoding of the next hop for a set of route entries, unlike RIPv2 that encodes the next-hop into each route entry.

Parts and terminology of RIP

Before you can understand how RIP functions, you need to understand some of the main concepts and parts of RIP.

This section includes:

- RIP and IPv6
- Default information originate option
- Update, Timeout, and Garbage timers
- Authentication and key-chain
- Access Lists

RIP and IPv6

RIP Next Generation (RIPng) is a new version of RIP was released that includes support for IPv6.

The FortiGate unit command `config router ripng` is almost the same as `config router rip`, except that IPv6 addresses are used. Also if you are going to use prefix or access lists with RIPng, you must use the `config router access-list6` or `config prefix-list6` versions of those commands.

If you want to troubleshoot RIPng, it is the same as with RIP but specify the different protocol, and use IPv6 addresses. This applies to commands such as `get router info6` when you want to see the routing table, or other related information.

If you want to route IPv4 traffic over an IPv6 network, you can use the command `config system ip6-tunnel` to configure the FortiGate unit to do this. The IPv6 interface is configured under `config system interface`. All subnets between the source and destination addresses must support IPv6. This command is not supported in Transparent mode.

For example, you want to set up a tunnel on the port1 interface starting at 2002:C0A8:3201:: on your local network and tunnel it to address 2002:A0A:A01:: where it will need access to an IPv4 network again. Use the following command:

```
config system ipv6-tunnel
   edit test_tunnel
      set destination 2002:A0A:A01::
      set interface port1
      set source 2002:C0A8:3201::
   end
```

```
end
```

The CLI commands associated with RIPng include:

```
config router ripng
config router access-list6
config router prefix-list6
config system ipv6-tunnel
get router info6 *
```

Default information originate option

This is the second advanced option for RIP in the web-based manager, right after metric. Enabling default-information-originate will generate and advertise a default route into the FortiGate unit's RIP-enabled networks. The generated route may be based on routes learned through a dynamic routing protocol, routes in the routing table, or both. RIP does not create the default route unless you use the always option.

Select **Disable** if you experience any issues or if you wish to advertise your own static routes into RIP updates.

You can enable or disable default-information-originate in **Network > RIP**, under **Advanced Options**, or use the CLI.

The CLI commands associated with default information originate include:

```
config router rip
   set default-information-originate
end
```

Update, Timeout, and Garbage timers

RIP uses various timers to regulate its performance including an update timer, a timeout timer, and a garbage timer. The FortiGate unit default timer settings (30, 180, and 120 seconds respectively) are effective in most configurations — if you change these settings, ensure that the new settings are compatible with local routers and access servers.

The Timeout period should be at least three times longer than the Update period. If the Update timer is smaller than Timeout or Garbage timers, you will experience an error.

You can set the three RIP timers in **Network > RIP**, under **Advanced Options**, or use the CLI.

The CLI commands associated with garbage, timeout, and update timers include:

```
config router rip
   set timeout-timer
   set update-timer
   set garbage-timer
end
```

Update timer

The update timer determines the interval between routing updates. Generally, this value is set to 30 seconds. There is some randomness added to help prevent network traffic congestion, which could result from all routers simultaneously attempting to update their neighbors. The update timer should be at least three times smaller than the timeout timer, otherwise you will experience an error.

If you are experiencing significant RIP traffic on your network, you can increase this interval to send fewer updates per minute. However, ensure you increase the interval for all the routers on your network or you will experience time outs that will degrade your network speed.

Timeout timer

The timeout timer is the maximum amount of time (in seconds) that a route is considered reachable while no updates are received for the route. This is the maximum time the FortiGate unit will keep a reachable route in the routing table while no updates for that route are received. If the FortiGate unit receives an update for the route before the timeout period expires, the timer is restarted. The timeout period should be at least three times longer than the depute period, otherwise you will experience an error.

If you are experiencing problems with routers not responding in time to updates, increase this timer. However, remember that longer timeout intervals result in longer overall update periods — it may be considerable time before the time the FortiGate unit is done waiting for all the timers to expire on unresponsive routes.

Garbage timer

The garbage timer is the amount of time (in seconds) that the FortiGate unit will advertise a route as being unreachable before deleting the route from the routing table. If this timer is shorter, it will keep more up-to-date routes in the routing table and remove old ones faster. This will result in a smaller routing table which is useful if you have a very large network, or if your network changes frequently.

Authentication and key-chain

RIP version 2 uses authentication keys to ensure that the routing information exchanged between routers is reliable. RIP version 1 has no authentication. For authentication to work both the sending and receiving routers must be set to use authentication, and must be configured with the same keys.

The sending and receiving routers need to have their system dates and times synchronized to ensure both ends are using the same keys at the proper times. However, you can overlap the key lifetimes to ensure that a key is always available even if there is some difference in the system times.

A key chain is a list of one or more authentication keys including the send and receive lifetimes for each key. Keys are used for authenticating routing packets only during the specified lifetimes. The FortiGate unit migrates from one key to the next according to the scheduled send and receive lifetimes.

Key-chain is a CLI router command. You use this command to manage RIP version 2 authentication keys. You can add, edit or delete keys identified by the specified key number.

This example shows how to configure a key-chain with two keys that are valid sequentially in time. This example creates a key-chain called “rip_key” that has a password of “fortinet”. The accepted and send lifetimes are both set to the same values — a start time of 9:00am February 23, 2010 and an end time of 9:00am March 17, 2010. A second key is configured with a password of “my_fortigate” that is valid from March 17, 2010 9:01am to April 1 2010 9:00am. This “rip_key” keychain is then used on the port1 interface in RIP.

```
config router key-chain
   edit "rip_key"
      config key
      edit 1
         set accept-lifetime 09:00:00 23 02 2010 09:00:00 17 03 2010
         set key-string "fortinet"
         set send-lifetime 09:00:00 23 02 2010 09:00:00 17 03 2010
      next
      edit 2
```

```
            set accept-lifetime 09:01:00 17 03 2010 09:00:00 1 04 2010
            set key-string "my_fortigate"
            set send-lifetime 09:01:00 17 03 2010 09:00:00 1 04 2010
         next
         end
      end
   config router rip
      config interface
         edit port1
            set auth-keychain "rip_key"
         end
      end
```

The CLI commands associated with authentication keys include:

```
config router key-chain

config router rip
   config interface
      edit <interface>
         set auth-keychain
         set auth-mode
         set auth-string
      end
   end
```

Access Lists

Access lists are filters used by FortiGate unit RIP and OSPF routing. An access list provides a list of IP addresses and the action to take for them — essentially an access list makes it easy to group addresses that will be treated the same into the same group, independent of their subnets or other matching qualities. You add a rule for each address or subnet that you want to include, specifying the action to take for it. For example if you wanted all traffic from one department to be routed a particular way, even in different buildings, you can add all the addresses to an access list and then handle that list all at once.

Each rule in an access list consists of a prefix (IP address and netmask), the action to take for this prefix (permit or deny), and whether to match the prefix exactly or to match the prefix and any more specific prefix.

The FortiGate unit attempts to match a packet against the rules in an access list starting at the top of the list. If it finds a match for the prefix, it takes the action specified for that prefix. If no match is found the default action is deny.

Access lists greatly speed up configuration and network management. When there is a problem, you can check each list instead of individual addresses. Also its easier to troubleshoot since if all addresses on one list have problems, it eliminates many possible causes right away.

If you are using the RIPng or OSPF+ IPv6 protocols you will need to use access-list6, the IPv6 version of access list. The only difference is that access-list6 uses IPv6 addresses.

For example, if you want to create an access list called `test_list` that only allows an exact match of `10.10.10.10` and `11.11.11.11`, enter the command:

```
config router access-list
   edit test_list
      config rule
         edit 1
            set prefix 10.10.10.10 255.255.255.255
            set action allow
```

```
            set exact-match enable
         next
         edit 2
            set prefix 11.11.11.11 255.255.255.255
            set action allow
            set exact-match enable
         end
      end
```

Another example is if you want to deny ranges of addresses in IPv6 that start with the IPv6 equivalents of 10.10.10.10 and 11.11.11.11, enter the command access-list6 as follows:

```
config router access-list6
   edit test_list_ip6
      config rule
         edit 1
            set prefix6 2002:A0A:A0A:0:0:0:0:0:/48
            set action deny
         next
         edit 2
            set prefix6 2002:B0B:B0B:0:0:0:0:0/48
            set action deny
         end
      end
```

To use an access_list, you must call it from a routing protocol such as RIP. The following example uses the access_list from the earlier example called test_list to match routes coming in on the port1 interface. When there is a match, it will add 3 to the hop count metric for those routes to artificially increase . Enter the following command:

```
config router rip
   config offset-list
      edit 5
         set access-list test_list
         set direction in
         set interface port1
         set offset 3
         set status enable
      end
```

If you are setting a prefix of 128.0.0.0, use the format 128.0.0.0/1. The default route, 0.0.0.0/0 can not be exactly matched with an access-list. A prefix-list must be used for this purpose

How RIP works

As one of the original modern dynamic routing protocols, RIP is straightforward. Its routing algorithm is not complex, there are some options to allow fine tuning, and it's relatively simple to configure RIP on FortiGate units.

From RFC 1058:

> *Distance vector algorithms are based on the exchange of only a small amount of information. Each entity (gateway or host) that participates in the routing protocol is assumed to keep information about all of the destinations within the system. Generally, information about all entities connected to one network is summarized by a single entry, which describes the route to all destinations on that network.*

This section includes:

- RIP versus static routing
- RIP metric — hop count
- The Bellman–Ford routing algorithm
- Passive versus active RIP interfaces
- RIP packet structure

RIP versus static routing

RIP was one of the earliest dynamic routing protocols to work with IP addresses. As such, it is not as complex as more recent protocols. However, RIP is a big step forward from simple static routing.

While RIP may be slow in response to network outages, static routing has zero response. The same is true for convergence — static routing has zero convergence. Both RIP and static routing have the limited hop count, so its not a strength or a weakness. Count to infinity can be a problem, but typically can be fixed as it happens or is the result of a network outage that would cause even worse problems on static routing network.

This compares to static routing where each time a packet needs to be routed, the FortiGate unit can only send it to the next hop towards the destination. That next hop then forwards it, and so on until it arrives at its destination. RIP keeps more routing information on each router so your FortiGate unit can send the packet farther towards its destination before it has to be routed again towards its destination. RIP reduces the amount of table lookups and therefore fewer network resources than static routing. Also since RIP is updated on neighboring routes it is aware of new routes or dead routes that static routing would not be aware of.

Overall, RIP is a large step forward when compared to static routing.

RIP metric — hop count

RIP uses hop count as the metric for choosing the best route. A hop count of 1 represents a network that is connected directly to the FortiGate unit, while a hop count of 16 represents a network that cannot be reached. Each network that a packet travels through to reach its destination usually counts as one hop. When the FortiGate unit compares two routes to the same destination, it adds the route having the lowest hop count to the routing table. As you can see in RIP packet structure on page 2397, the hop count is part of a RIP v2 packet.

Similarly, when RIP is enabled on an interface, the FortiGate unit sends RIP responses to neighboring routers on a regular basis. The updates provide information about the routes in the FortiGate unit's routing table, subject to the rules that you specify for advertising those routes. You can specify how often the FortiGate unit sends updates, the period of time a route can be kept in the routing table without being updated, and for routes that are not updated regularly you can specify the period of time that the unit advertises a route as unreachable before it is removed from the routing table.

If hops are weighted higher than one, it becomes very easy to reach the upper limit. This higher weighting will effectively limit the size of your network depending on the numbers used. Merely changing from the default of 1.0 to 1.5 will lower the effective hop count from 15 to 10. This is acceptable for smaller networks, but can be a problem as your network expands over time.

In RIP, you can use the offset command to artificially increase the hop count of a route. Doing this will make this route less preferred, and in turn it will get less traffic. Offsetting routes is useful when you have network connections of different bandwidths, different levels of reliability, or different costs. In each of these situations you still want the redundancy of multiple route access, but you don't want the bulk of your traffic using these less preferred routes. For an example of RIP offset, see Access Lists on page 2391.

The Bellman–Ford routing algorithm

The routing algorithm used by RIP was first used in 1967 as the initial routing algorithm of the ARPANET. The Bellman–Ford algorithm is distributed because it involves a number of nodes (routers) within an Autonomous system, and consists of the following steps:

1. Each node calculates the distances between itself and all other nodes within the AS and stores this information as a table.
2. Each node sends its table to all neighboring nodes.
3. When a node receives distance tables from its neighbors, it calculates the shortest routes to all other nodes and updates its own table to reflect any changes.

To examine how this algorithm functions let's look at a network with 4 routers — routers 1 through 4. The distance from router1 to router2 is 2 hops, 1 to 3 is 3 hops, and 2 to 3 is 4 hops. Router4 is only connected to routers 2 and 3, each distance being 2 hops.

1. Router1 finds all the distance to the other three routers — router 2 is 2, router 3 is 3. Router1 doesn't have a route to router 4.
2. Routers 2 through 4 do the same calculations from their point of views.
3. Once router 1 gets an update from router 2 or 3, it will get their route to router 4. At that point it now has a route to router 4 and installs that in its local table.
4. If router1 gets an update from router3 first, it has a hop count of 5 to reach router4. But when router2 sends its update, router1 will go with router2's shorter 4 hops to reach router4. Future updates don't change this unless they are shorter than 4 hops, or the routing table route goes down.

RIP algorithm example in 4 steps

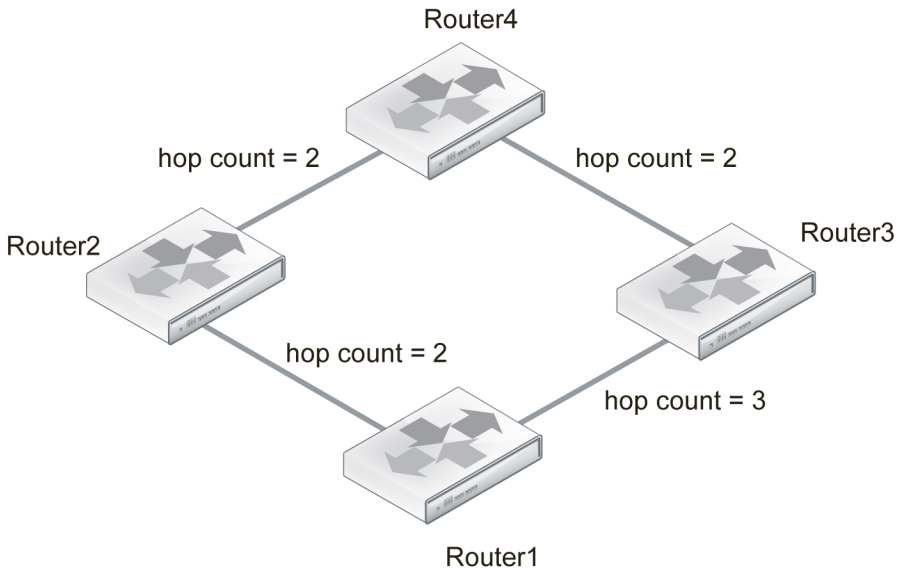
Step 1

Router1 finds the distance to other routers in the network.

It currently has no route to Router4.

Router1 routing table:

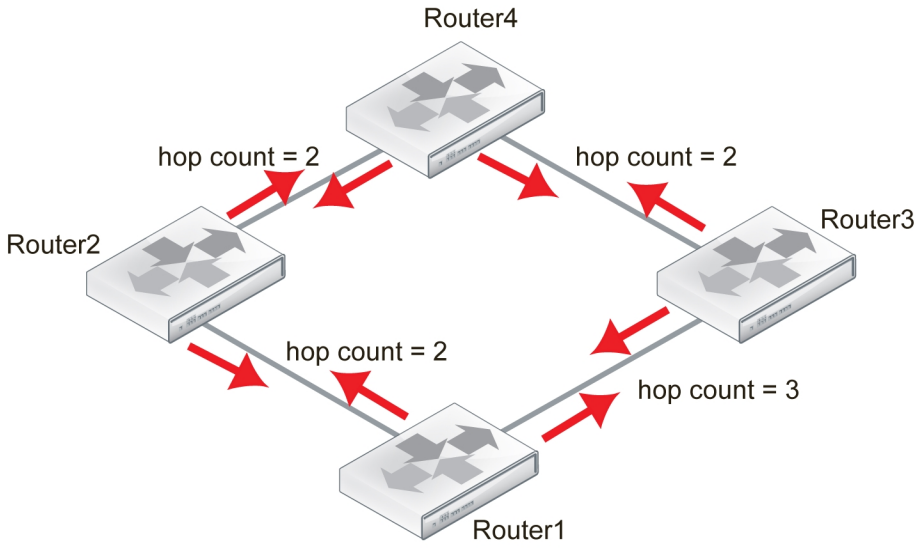
- Distance to Router2 = 2 hops.
- Distance to Router3 = 3 hops.



Step 2

All routers do the same as Router1, and send out updates containing their routing table.

Note that Router1 and Router4 do not update each other, but rely on Router2 and Router3 to pass along accurate updates.

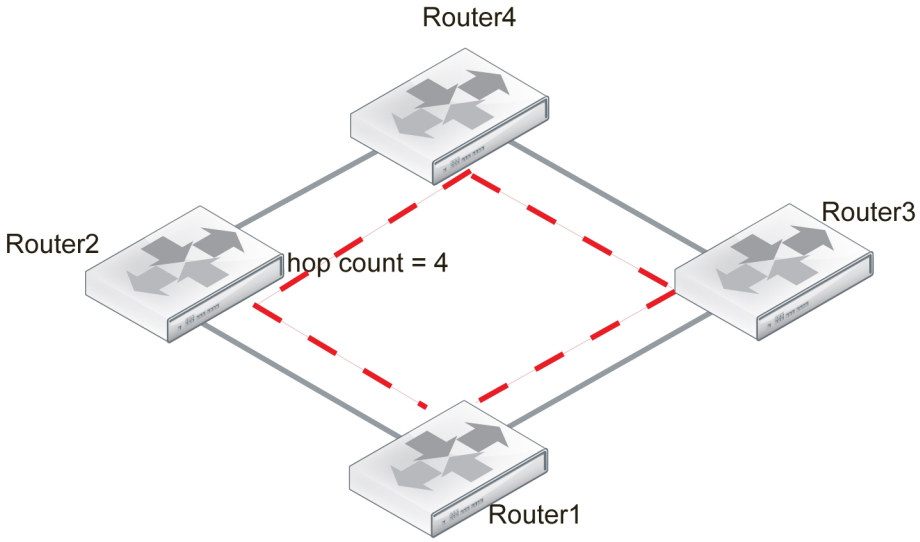


Step 3

Each router looks at the updates it has received, and adds any new or shorter routes to its table.

Router1 updated table:

- Distance to Router2 = 2 hops.
- Distance to Router3 = 3 hops.
- Distance to Router4 = 4 or 5 hops.

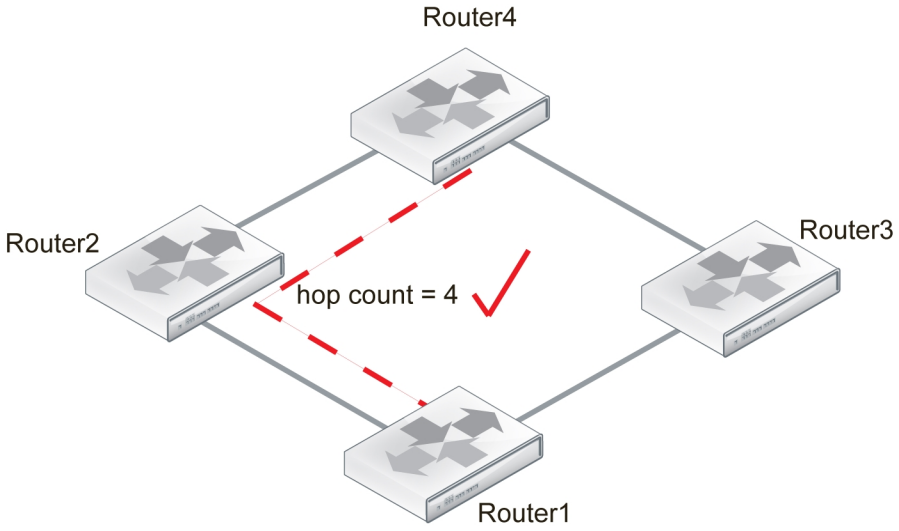


Step 4

Router1 installs the shortest route to Router4, and the other routes to it are removed from the routing table.

Router1 complete table:

- Distance to Router2 = 2 hops.
- Distance to Router3 = 3 hops.
- Distance to Router4 = 4 hops.



The good part about the Bellman-Ford algorithm in RIP is that the router only uses the information it needs from the update. If there are no newer, better routes than the ones the router already has in its routing table, there is no need to change its routing table. And no change means no additional update, so less traffic. But even when there is update traffic, the RIP packets are very small so it takes many updates to affect overall network bandwidth. For more information about RIP packets, see RIP packet structure on page 2397.

The main disadvantage of the Bellman–Ford algorithm in RIP is that it doesn't take weightings into consideration. While it is possible to assign different weights to routes in RIP, doing so severely limits the effective network size

by reducing the hop count limit. Also other dynamic routing protocols can take route qualities, such as reliability or delay, into consideration to provide not only the physically shortest but also the fastest or more reliable routes as you choose.

Another disadvantage of the Bellman-Ford algorithm is due to the slow updates passed from one RIP router to the next. This results in a slow response to changes in the network topology, which in turn results in more attempts to use routes that are down, which wastes time and network resources.

Passive versus active RIP interfaces

Normally the FortiGate unit's routing table is kept up to date by periodically asking the neighbors for routes, and sending your routing updates out. This has the downside of generating a lot of extra traffic for large networks. The solution to this problem is passive interfaces.

An standard interface that supports RIP is active by default — it both sends and receives updates by actively communicating with its neighbors. A passive RIP interface does not send out updates — it just listens to the updates of other routers. This is useful in reducing network traffic, and if there are redundant routers in the network that would be sending out essentially the same updates all the time.

The following example shows how to create a passive RIP v2 interface on port1, using MD5 authentication and a key-chain called `passiveRIPv2` that has already been configured. Note that in the CLI, you enable passive by disabling `send-version2-broadcast`.

To create a passive RIP interface - web-based manager

1. Go to **Network > RIP**.
2. Next to **Interfaces**, select **Create**.
3. Select port1 as the **Interface**.
4. Select 2 as both the **Send Version** and **Receive Version**.
5. Select MD5 for **Authentication**.
6. Select the `passiveRIPv2` **Key-chain**.
7. Select **Passive Interface**.
8. Select **OK** to accept this configuration, and return to the main RIP display page.

To create a passive RIP v2 interface on port1 using MD5 authentication- CLI

```
config router rip
   config interface
      edit port1
         set send-version2-broadcast disable
         set auth-keychain "passiveRIPv2"
         set auth-mode md5
         set receive-version 2
         set send-version 2
      end
   end
```

RIP packet structure

It is hard to fully understand a routing protocol without knowing what information is carried in its packets. Knowing what information is exchanged between routers and how will help you better understand the RIP protocol, and better configure your network for it.

This section provides information on the contents of RIP 1 and RIP 2 packets.

RIP version 1

RIP version 1, or RIP IP packets are 24 bytes in length, with some empty areas left for future expansion.

RIP IP packets

1-byte command	1-byte version	2-byte zero field	2-byte AFI	2-byte zero field
4-byte IP address	4-byte zero field	4-byte zero field	4-byte metric	

A RIP 1 packet contains the following fields:

- **Command** — Indicates whether the packet is a request or a response. The request asks that a router send all or part of its routing table. The response can be an unsolicited regular routing update or a reply to a request. Responses contain routing table entries. Multiple RIP packets are used to convey information from large routing tables.
- **Version** — Specifies the RIP version used. This field can signal different potentially incompatible versions.
- **Zero field** — This field defaults to zero, and is not used by RFC 1058 RIP.
- **Address-family identifier (AFI)** — Specifies the address family used. RIP is designed to carry routing information for several different protocols. Each entry has an address-family identifier to indicate the type of address being specified. The AFI for IP is 2.
- **IP Address** — Specifies the IP address for the entry.
- **Metric** — This is the number of hops or routers traversed along the route on its trip to the destination. The metric is between 1 and 15 for that number of hops. If the route is unreachable the metric is 16.

RIP version 2

RIP version 2 has more features than RIP 1, which is reflected in its packets which carry more information. All but one of the empty zero fields in RIP 1 packets are used in RIP 2.

RIP 2 packets

1-byte command	1-byte version	2-byte unused	2-byte AFI	2-byte route tag
4-byte IP address	4-byte subnet	4-byte next hop	4-byte metric	

A RIP 2 packet contains fields described above in RIP 1, as well as the following:

- **Unused** — Has a value set to zero, and is intended for future use
- **Route tag** — Provides a method for distinguishing between internal routes learned by RIP and external routes learned from other protocols.
- **Subnet mask** — Contains the subnet mask for the entry. If this field is zero, no subnet mask has been specified for the entry.
- **Next hop** — Indicates the IP address of the next hop to which packets for the entry should be forwarded.

Troubleshooting RIP

This section is about troubleshooting RIP. For general troubleshooting information, see the FortiOS Handbook Troubleshooting chapter.

This section includes:

- Routing Loops
- Holddowns and Triggers for updates
- Split horizon and Poison reverse updates
- Debugging IPv6 on RIPng

Routing Loops

Normally in routing, a path between two addresses is chosen and traffic is routed along that path from one address to the other. When there is a routing loop, that normal path doubles back on itself creating a loop. When there are loops, the network has problems getting information to its destination and also prevents it from returning to the source to report the inaccessible destination.

A routing loop happens when a normally functioning network has an outage, and one or more routers are offline. When packets encounter this, an alternate route is attempted to maneuver around the outage. During this phase it is possible for a route to be attempted that involves going back a hop, and trying a different hop forward. If that hop forward is blocked by the outage as well, a hop back and possibly the original hop forward may be selected. You can see if this continues, how it can consume not only network bandwidth but also many resources on those routers affected. The worst part is this situation will continue until the network administrator changes the router settings, or the downed routers come back online.

Routing loops' effect on the network

In addition to this "traffic jam" of routed packets, every time the routing table for a router changes that router sends an update out to all of the RIP routers connected to it. In a network loop, its possible for a router to change its routes very quickly as it tries and fails along these new routes. This can quickly result in a flood of updates being sent out, which can effectively grind the network to a halt until the problem is fixed.

How can you spot a routing loop

Any time network traffic slows down, you will be asking yourself if it is a network loop or not. Often slowdowns are normal, they are not a full stoppage, and normal traffic resumes in a short period of time.

If the slow down is a full halt of traffic or a major slowdown does not return to normal quickly, you need to do serious troubleshooting quickly.

If you aren't running SNMP, dead gateway detection, or you have non-Fortinet routers in your network, you can use networking tools such as ping and traceroute to define the outage on your network and begin to fix it. Ping, traceroute, and other basic troubleshooting tools are largely the same between static and dynamic, and are covered in Advanced Static Routing on page 2343.

Check your logs

If your routers log events to a central location, it can be easy to check the logs for your network for any outages.

On your FortiGate unit, go to **Log & Report**. You will want to look at both event logs and traffic logs. Events to look for will generally fall under CPU and memory usage, interfaces going offline (due to dead gateway detection), and other similar system events.

Once you have found and fixed your network problem, you can go back to the logs and create a report to better see how things developed during the problem. This type of forensics analysis can better help you prepare for next time.

Use SNMP network monitoring

If your network had no problems one minute and slows to a halt the next, chances are something changed to cause that problem. Most of the time an offline router is the cause, and once you find that router and bring it back online, things will return to normal.

If you can enable a hardware monitoring system such as SNMP or sFlow on your routers, you can be notified of the outage and where it is exactly as soon as it happens.

Ideally you can configure SNMP on all your FortiGate routers and be alerted to all outages as they occur.

To use SNMP to detect potential routing loops

1. Go to **System > SNMP**.
2. Enable **SMTP Agent** and select **Apply**.
   Optionally enter the **Description**, **Location**, and **Contact** information for this device for easier location of the problem report.
3. Under **SNMP v1/v2** or **SNMP v3** as appropriate, select **Create New**.
   SNMP v3

User Name	Enter the SNMP user ID.
Security Level	Select authentication or privacy as desired. Select the authentication or privacy algorithms to use and enter the required passwords.
Notification Host	Enter the IP addresses of up to 16 hosts to notify.
Enable Query	Select. The **Port** should be 161. Ensure that your security policies allow ports 161 and 162 (SNMP queries and traps) to pass.

   SNMP v1/v2

Hosts	Enter the IP addresses of up to 8 hosts to notify. You can also specify the network **Interface**, or leave it as **ANY**.
Queries	Enable **v1** and/or **v2** as needed. The **Port** should be 161. Ensure that your security policies allow port 161 to pass.
Traps	Enable v1 and/or v2 as needed. The Port should be 162. Ensure that your security policies allow port 162 to pass.

4. Select the events for which you want notification. For routing loops this should include **CPU usage is high**, **Memory is low**, and possibly **Log disk space is low**.If there are problems the log will be filling up quickly, and the FortiGate unit's resources will be overused.

5. Configure SNMP host (manager) software on your administration computer. This will monitor the SNMP information sent out by the FortiGate unit. Typically you can configure this software to alert you to outages or CPU spikes that may indicate a routing loop.

Use Link Health Monitor and e-mail alerts

Another tool available to you on FortiGate units is the Link Health Monitor, useful in dead gateway detection. This feature allows the FortiGate unit to ping a gateway at regular intervals to ensure it is online and working. When the gateway is not accessible, that interface is marked as down.

To detect possible routing loops with Link Health Monitor and e-mail alerts

Use the following command to configure dead gateway detection:

```
config system link-monitor
   edit "test"
      set srcintf "internal4"
      set server "8.8.8.8"
      set interval 5
      set failtime 1
   end
```

Set the `Interval` (how often to send a ping) and `failtime` (how many lost pings is considered a failure). A smaller interval and smaller number of lost pings will result in faster detection, but will create more traffic on your network.

To configure notification of failed gateways

1. Go to **Log & Report > Local Report**and enable **Email Generated Reports**.
2. Enter your email details.
3. Select **Apply**.

You might also want to log CPU and Memory usage as a network outage will cause your CPU activity to spike.

If you have VDOMs configured, you will have to enter the basic SMTP server information in the Global section, and the rest of the configuration within the VDOM that includes this interface.

After this configuration, when this interface on the FortiGate unit cannot connect to the next router, the FortiGate unit will bring down the interface and alert you with an email about the outage.

Look at the packet flow

If you want to see what is happening on your network, look at the packets travelling on the network. This is same idea as police pulling over a car and asking the driver where they have been, and what the conditions were like.

The method used in the troubleshooting sections Debugging IPv6 on RIPng on page 2403 and on debugging the packet flow apply here as well. In this situation, you are looking for routes that have metrics higher than 15 as that indicates they are unreachable.

Ideally if you debug the flow of the packets, and record the routes that are unreachable, you can create an accurate picture of the network outage.

Action to take on discovering a routing loop

Once you have mapped the problem on your network, and determined it is in fact a routing loop there are a number of steps to take in correcting it.

1. Get any offline routers back online. This may be a simple reboot, or you may have to replace hardware. Often this first step will restore your network to its normal operation, once the routing tables finish being updated.
2. Change your routing configuration on the edges of the outage. Even if step 1 brought your network back online, you should consider making changes to improve your network before the next outage occurs. These changes can include configuring features like holddowns and triggers for updates, split horizon, and poison reverse updates.

Holddowns and Triggers for updates

One of the potential problems with RIP is the frequent routing table updates that are sent every time there is a change to the routing table. If your network has many RIP routers, these updates can start to slow down your network. Also if you have a particular route that has bad hardware, it might be going up and down frequently, which will generate an overload of routing table updates.

One of the most common solutions to this problem is to use holddown timers and triggers for updates. These slow down the updates that are sent out, and help prevent a potential flood.

Holddown Timers

The holddown timer activates when a route is marked down. Until the timer expires, the router does not accept any new information about that route. This is very useful if you have a flapping route because it will prevent your router from sending out updates and being part of the problem in flooding the network. The potential down side is if the route comes back up while the timer has not expired, that route will be unavailable for that period of time. This is only a problem if this is a major route used by the majority of your traffic. Otherwise, this is a minor problem as traffic can be re-routed around the outage.

Triggers

Triggered RIP is an alternate update structure that is based around limiting updates to only specific circumstances. The most basic difference is that the routing table will only be updated when a specific request is sent to update, as opposed to every time the routing table changes. Updates are also triggered when a unit is ‘powered on’, which can include addition of new interfaces or devices to the routing structure, or devices returning to being available after being unreachable.

Split horizon and Poison reverse updates

Split horizon is best explained with an example. You have three routers linked serially, let’s call them A, B, and C. A is only linked to B, C is only linked to B, and B is linked to both A and C. To get to C, A must go through B. If the link to C goes down, it is possible that B will try to use A’s route to get to C. This route is A-B-C, so it will loop endlessly between A and B.

This situation is called a split horizon because from B’s point of view the horizon stretches out in each direction, but in reality it only is on one side.

Poison reverse is the method used to prevent routes from running into split horizon problems. Poison reverse “poisons” routes away from the destination that use the current router in their route to the destination. This “poisoned” route is marked as unreachable for routers that cannot use it. In RIP this means that route is marked with a distance of 16.

Debugging IPv6 on RIPng

The debug commands are very useful to see what is happening on the network at the packet level. There are a few changes to debugging the packet flow when debugging IPv6.

The following CLI commands specify both IPv6 and RIP, so only RIPng packets will be reported. The output from these commands will show you the RIPng traffic on your FortiGate unit including RECV, SEND, and UPDATE actions.

The addresses are in IPv6 format.

```
diagnose debug enable
diagnose ipv6 router rip level info
diagnose ipv6 router rip all enable
```

These three commands will:

- turn on debugging in general
- set the debug level to information, a verbose reporting level
- turn on all rip router settings

Part of the information displayed from the debugging is the metric (hop count). If the metric is 16, then that destination is unreachable since the maximum hop count is 15.

In general, you should see an update announcement, followed by the routing table being sent out, and a received reply in response.

For more information, see Troubleshooting RIP on page 2399.

Simple RIP example

This is an example of a typical medium sized network configuration using RIP routing.

Your company has 3 small local networks, one for each department. These networks are connected by RIP, and then connected to the Internet. Each subnet has more than one route, for redundancy. There are two central routers that are both connected to the Internet, and to the other networks. If one of those routers goes down, the whole network can continue to function normally.

The ISP is running RIP, so no importing or exporting routes is required on the side of the network. However, since the internal networks have static networking running those will need to be redistributed through the RIP network.

To keep the example simple, there will be no authentication of router traffic.

With RIP properly configured, if the device fails or temporarily goes offline, the routes will change and traffic will continue to flow. RIP is good for a smaller network due to its lack of complex configurations.

This section includes the following topics:

- Network layout and assumptions
- General configuration steps
- Configuring the FortiGate units system information
- Configuring other networking devices
- Testing network configuration

Network layout and assumptions

Basic network layout

Your company has 3 departments each with their own network — Sales, R&D, and Accounting. Each network has routers that are not running RIP as well as FortiGate units running RIP.

The R&D network has two RIP routers, and each is connected to both other departments as well as being connected to the Internet through the ISP router. The links to the Internet are indicated in black.

The three internal networks do not run RIP. They use static routing because they are small networks. This means the FortiGate units have to redistribute any static routes they learn so that the internal networks can communicate with each other.

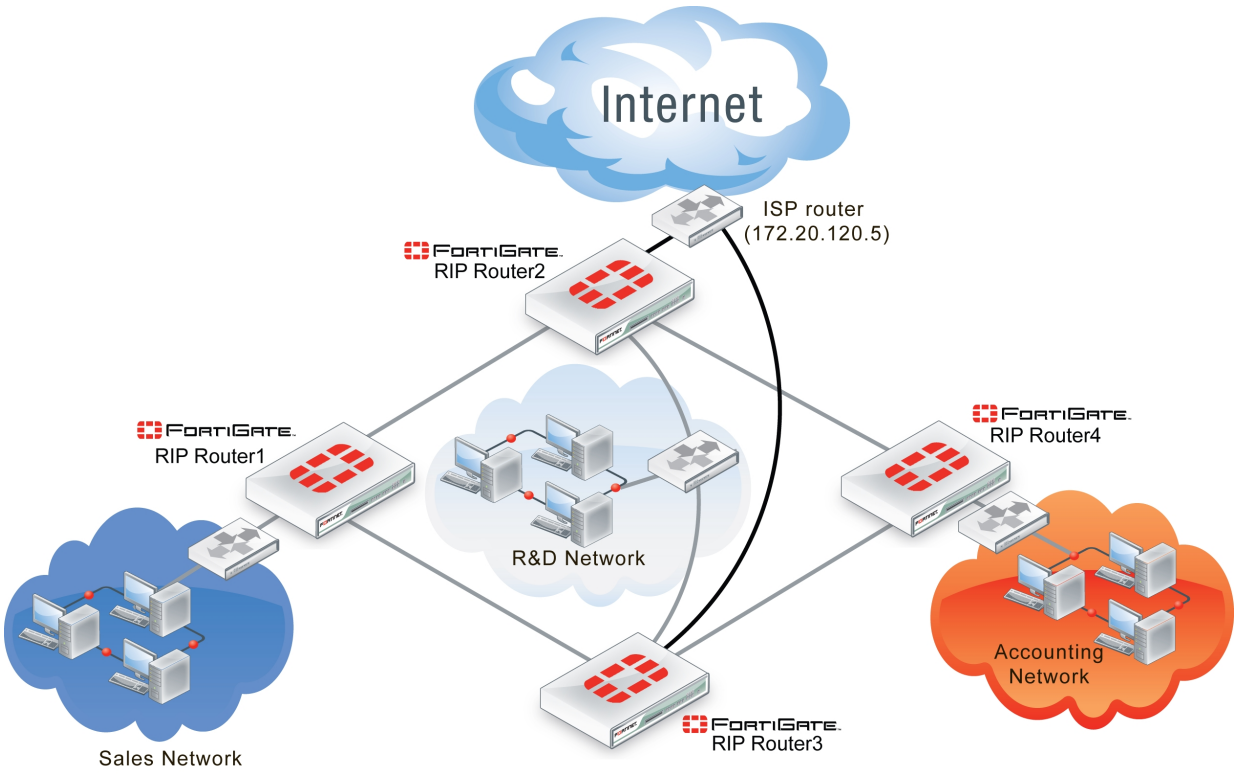
Where possible in this example, the default values will be used or the most general settings. This is intended to provide an easier configuration that will require less troubleshooting.

In this example the routers, networks, interfaces used, and IP addresses are as follows. Note that the Interfaces that connect Router2 and Router3 also connect to the R&D network.

RIP example network topology

Network	Router	Interface & Alias	IP address
Sales	Router1	port1 (internal)	10.11.101.101
		port2 (router2)	10.11.201.101
		port3 (router3)	10.11.202.101
R&D	Router2	port1 (internal)	10.12.101.102
		port2 (router1)	10.11.201.102
		port3 (router4)	10.14.201.102
		port4 (ISP)	172.20.120.102
	Router3	port1 (internal)	10.12.101.103
		port2 (router1)	10.11.201.103
		port3 (router4)	10.14.202.103
		port4 (ISP)	172.20.120.103
Accounting	Router4	port1 (internal)	10.14.101.104
		port2 (router2)	10.14.201.104
		port3 (router3)	10.14.202.104

Network topology for the simple RIP example



Assumptions

The following assumptions have been made concerning this example.

- All FortiGate units have 5.0 firmware, and are running factory default settings.
- All CLI and web-based manager navigation assumes the unit is running in NAT/Route operating mode, with VDOMs disabled.
- All FortiGate units have interfaces labelled port1 through port4 as required.
- All firewalls have been configured for each FortiGate unit to allow the required traffic to flow across interfaces.
- Only FortiGate units are running RIP on the internal networks.
- Router2 and Router3 are connected through the internal network for R&D.
- Router2 and Router3 each have their own connection to the Internet, indicated in black in the diagram above.

General configuration steps

This example is very straight forward. The only steps involved are:

- Configuring the FortiGate units system information
- Configuring FortiGate unit RIP router information
- Configuring other networking devices
- Testing network configuration

Configuring the FortiGate units system information

Each FortiGate unit needs their hostname, and interfaces configured.

For IP numbering, Router2 and Router3 use the other routers numbering where needed.

Router2 and Router3 have dead gateway detection enabled on the ISP interfaces using Ping. Remember to contact the ISP and confirm their server has ping enabled.

Configure the hostname, interfaces, and default route

To configure Router1 system information - web-based manager

1. Go to **Dashboard > System Information**.
2. Next to **Host Name** select **Change**, and enter “Router1”.
3. Go to **Network > Static Routes**.
4. Edit the default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port2 (router2)
Gateway	172.20.120.5/255.255.255.0
Distance	40

5. Enter a second default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port3 (router3)
Gateway	172.20.120.5/255.255.255.0
Distance	40

6. Go to **Network > Interfaces**.
7. Edit port1 (internal) interface.
8. Set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.11.101.101/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Internal sales network
Administrative Status	Up

9. Edit port2 (router2) interface.
10. Set the following information, and select **OK**.

Alias	router2

IP/Network Mask	10.11.201.101/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to R&D network & Internet through Router2
Administrative Status	Up

11. Edit port3 (router3) interface.
12. Set the following information, and select **OK**.

Alias	router3
IP/Network Mask	10.11.202.101/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to R&D network and Internet through Router3
Administrative Status	Up

To configure Router1 system information - CLI

```
config system global
   set hostname Router1
end

config router static
   edit 1
      set device "port2"
      set distance 45
      set gateway 10.11.201.102
   next
   edit 2
      set device "port3"
      set distance 45
      set gateway 10.11.202.103
   end
end

config system interface
   edit port1
      set alias internal
      set ip 10.11.101.101/255.255.255.0
      set allowaccess https ssh ping
      set description "Internal sales network"
   next
   edit port2
      set alias ISP
      set allowaccess https ssh ping
      set ip 10.11.201.101/255.255.255.0
      set description "Link to R&D network & Internet through Router2"
   next
   edit port3
      set alias router3
```

```
      set ip 10.11.202.101/255.255.255.0
      set allowaccess https ssh ping
      set description "Link to R&D network & Internet through Router2"
   end
end
```

To configure Router2 system information - web-based manager

1. Go to **Dashboard > System Information**.
2. Next to **Host Name** select **Change**, and enter “Router2”.
3. Go to **Network > Static Routes**.
4. Edit the default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port4 (ISP)
Gateway	172.20.120.5/255.255.255.0
Distance	5

5. Go to **Network > Interfaces**.
6. Edit port1 (internal) interface.
7. Set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.12.101.102/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	R&D internal network and Router3
Administrative Status	Up

8. Edit port2 (router1) interface.
9. Set the following information, and select **OK**.

Alias	router1
IP/Network Mask	10.12.201.102/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to Router1 and the Sales network
Administrative Status	Up

10. Edit port3 (router4) interface.
11. Set the following information, and select **OK**.

Alias	router4
IP/Network Mask	10.12.301.102/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to Router4 and the accounting network
Administrative Status	Up

12. Edit port4 (ISP) interface.
13. Set the following information, and select **OK**.

Alias	ISP
IP/Network Mask	172.20.120.102/255.255.255.0
Administrative Access	HTTPS SSH PING
Detect and Identify Devices	enable
Description	Internet through ISP
Administrative Status	Up

To configure Router2 system information - CLI

```
config system global
   set hostname Router2
end
config router static
   edit 1
      set device "port4"
      set distance 5
      set gateway 172.20.130.5
   end
end
config system interface
   edit port1
      set alias internal
      set ip 10.11.101.102/255.255.255.0
      set allowaccess https ssh ping
      set description "Internal RnD network and Router3"
   next
   edit port2
      set alias router1
      set allowaccess https ssh ping
      set ip 10.11.201.102/255.255.255.0
      set description "Link to Router1"
   next
   edit port3
      set alias router3
      set ip 10.14.202.102/255.255.255.0
      set allowaccess https ssh ping
      set description "Link to Router4"
   next
```

```
    edit port4
       set alias ISP
       set ip 172.20.120.102/255.255.255.0
       set allowaccess https ssh ping
       set description "ISP and Internet"
    end
end
```

To configure Router3 system information - web-based manager

1. Go to **Dashboard > System Information**.
2. Next to **Host Name** select **Change**, and enter “Router3”.
3. Go to **Network > Static Routes**.
4. Edit the default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port4 (ISP)
Gateway	172.20.120.5/255.255.255.0
Distance	5

5. Go to **System > Network > Interfaces**.
6. Edit port1 (internal) interface.
7. Set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.12.101.103/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	R&D internal network and Router2
Administrative Status	Up

8. Edit port2 (router1) interface.
9. Set the following information, and select **OK**.

Alias	router1
IP/Network Mask	10.13.201.103/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to Router1 and Sales network
Administrative Status	Up

10. Edit port3 (router4) interface.
11. Set the following information, and select **OK**.

Alias	router4
IP/Network Mask	10.13.301.103/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to Router4 and accounting network
Administrative Status	Up

12. Edit port4 (ISP) interface.
13. Set the following information, and select **OK**.

Alias	ISP
IP/Network Mask	172.20.120.103/255.255.255.0
Administrative Access	HTTPS SSH PING
Detect and Identify Devices	enable
Description	Internet and ISP
Administrative Status	Up

To configure Router3 system information - CLI

```
config system global
   set hostname Router3
end
config router static
   edit 1
      set device "port4"
      set distance 5
      set gateway 172.20.130.5
   end
end
config system interface
   edit port1
      set alias internal
      set ip 10.12.101.103/255.255.255.0
      set allowaccess https ssh ping
      set description “Internal RnD network and Router2”
   next
   edit port2
      set alias ISP
      set allowaccess https ssh ping
      set ip 10.11.201.103/255.255.255.0
      set description “Link to Router1”
   next
   edit port3
      set alias router3
      set ip 10.14.202.103/255.255.255.0
      set allowaccess https ssh ping
      set description “Link to Router4”
   next
```

```
    edit port4
       set alias ISP
       set ip 172.20.120.103/255.255.255.0
       set allowaccess https ssh ping
       set description "ISP and Internet"
    end
end
```

To configure Router4 system information - web-based manager

1. Go to **Dashboard > System Information**.
2. Next to **Host Name** select **Change**, and enter "Router4".
3. Go to **Network > Static Routes**.
4. Edit the default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port2 (router2)
Gateway	172.20.120.5/255.255.255.0
Distance	40

5. Enter a second default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port3 (router3)
Gateway	172.20.120.5/255.255.255.0
Distance	40

6. Go to **Network > Interfaces**.
7. Edit port 1 (internal) interface.
8. Set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.14.101.104/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Internal accounting network
Administrative Status	Up

9. Edit port 2 (router2) interface.
10. Set the following information, and select **OK**.

Alias	router2

IP/Network Mask	10.14.201.104/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to R&D network & Internet through Router2
Administrative Status	Up

11. Edit port 3 (router3) interface.
12. Set the following information, and select **OK**.

Alias	router3
IP/Network Mask	10.14.301.104/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to R&D network and Internet through Router3
Administrative Status	Up

To configure Router4 system information - CLI

```
config system global
   set hostname Router4
end
config router static
   edit 1
      set device "port2"
      set distance 45
      set gateway 10.14.201.102
   next
   edit 2
      set device "port3"
      set distance 45
      set gateway 10.14.202.103
   end
end
config system interface
   edit port1
      set alias internal
      set ip 10.14.101.104/255.255.255.0
      set allowaccess https ssh ping
      set description "Internal sales network"
   next
   edit port2
      set alias router2
      set allowaccess https ssh ping
      set ip 10.14.201.104/255.255.255.0
      set description "Link to R&D network & Internet through Router2"
   next
   edit port3
      set alias router3
      set ip 10.14.202.104/255.255.255.0
      set allowaccess https ssh ping
```

```
        set description "Link to R&D network & Internet through Router2"
    end
end
```

Configuring FortiGate unit RIP router information

With the interfaces configured, RIP can now be configured on the FortiGate units.

For each FortiGate unit the following steps will be taken:

- Configure RIP version used
- Redistribute static networks
- Add networks serviced by RIP
- Add interfaces that support RIP on the FortiGate unit

Router1 and Router4 are configured the same. Router2 and Router3 are configured the same. These routers will be grouped accordingly for the following procedures — repeat the procedures once for each FortiGate unit.

Configure RIP settings on Router1 and Router4 - web-based manager

1. Go to **Network > RIP**.
2. Select **2** for **RIP Version**.
3. In **Advanced Options**, under **Redistribute** enable **Static**.
4. Leave the other Advanced Options at default values.
5. Enter the following networks, and select **Add** after each:
   - 10.11.0.0/255.255.0.0
   - 10.12.0.0/255.255.0.0
   - 10.14.0.0/255.255.0.0
   - 172.20.120.0/255.255.255.0
6. For interface, select **Create** and set the following information.

Interface	port1 (internal)
Send Version	Both
Receive Version	Both
Authentication	None
Passive Interface	disabled

7. For interface, select **Create** and set the following information.

Interface	port2 (router2)
Send Version	Both
Receive Version	Both
Authentication	None
Passive Interface	disabled

8. For interface, select **Create** and set the following information.

Interface	port3 (router3)
Send Version	Both
Receive Version	Both
Authentication	None
Passive Interface	disabled

Configure RIP settings on Router1 and Router4 - CLI

```
config router rip
   set version 2
   config interface
      edit "port1"
         set receive-version 1 2
         set send-version 1 2
      next
      edit "port2"
         set receive-version 1 2
         set send-version 1 2
      next
      edit "port3"
         set receive-version 1 2
         set send-version 1 2
      end
   config network
      edit 1
         set prefix 10.11.0.0 255.255.0.0
      next
      edit 2
         set prefix 10.12.0.0 255.255.0.0
      next
      edit 3
         set prefix 10.14.0.0 255.255.0.0
      next
      edit 4
         set prefix 172.20.120.0 255.255.255.0
      end
   config redistribute "static"
      set status enable
   end
end
```

Configure RIP settings on Router2 and Router3- web-based manager

1. Go to **Network > RIP**.
2. Select **2** for **RIP Version**.
3. In **Advanced Options**, under **Redistribute** enable **Static**.
4. Leave the other Advanced Options at default values.
5. Enter the following networks, and select **Add** after each:

- 10.11.0.0/255.255.0.0
- 10.12.0.0/255.255.0.0
- 10.14.0.0/255.255.0.0
- 172.20.120.0/255.255.255.0

6. For interface, select **Create** and set the following information.

Interface	port1 (internal)
Send Version	Both
Receive Version	Both
Authentication	None
Passive Interface	disabled

7. For interface, select **Create** and set the following information.

Interface	port2 (router1)
Send Version	Both
Receive Version	Both
Authentication	None
Passive Interface	disabled

8. For interface, select **Create** and set the following information.

Interface	port3 (router4)
Send Version	Both
Receive Version	Both
Authentication	None
Passive Interface	disabled

9. For interface, select **Create** and set the following information.

Interface	port4 (ISP)
Send Version	Both
Receive Version	Both
Authentication	None
Passive Interface	disabled

Configure RIP settings on Router2 and Router3- web-based manager

```
config router rip
   set version 2
   config interface
      edit "port1"
         set receive-version 1 2
         set send-version 1 2
      next
      edit "port2"
         set receive-version 1 2
         set send-version 1 2
      next
      edit "port3"
         set receive-version 1 2
         set send-version 1 2
      end
      edit "port4"
         set receive-version 1 2
         set send-version 1 2
      end
   config network
      edit 1
         set prefix 10.11.0.0 255.255.0.0
      next
      edit 2
         set prefix 10.12.0.0 255.255.0.0
      next
      edit 3
         set prefix 10.14.0.0 255.255.0.0
      next
      edit 4
         set prefix 172.20.120.0 255.255.255.0
      end
   config redistribute "static"
      set status enable
   end
end
```

Configuring other networking devices

In this example there are two groups of other devices on the the network — internal devices, and the ISP.

The first is the internal network devices on the Sales, R&D, and Accounting networks. This includes simple static routers, computers, printers and other network devices. Once the FortiGate units are configured, the internal static routers need to be configured using the internal network IP addresses. Otherwise there should be no configuration required.

The second group of devices is the ISP. This consists of the RIP router the FortiGate routers 2 and 3 connect to. You need to contact your ISP and ensure they have your information for your network such as the IP addresses of the connecting RIP routers, what version of RIP your network supports, and what authentication (if any) is used.

Testing network configuration

Once the network has been configured, you need to test that it works as expected.

The two series of tests you need to run are to test the internal networks can communicate with each other, and that the internal networks can reach the Internet.

Use ping, traceroute, and other networking tools to run these tests.

If you encounter problems, for troubleshooting help consult Simple RIP example on page 2403.

RIPng — RIP and IPv6

RIP next generation, or RIPng, is the version of RIP that supports IPv6.

This is an example of a typical small network configuration using RIPng routing.

Your internal R&D network is working on a project for a large international telecom company that uses IPv6. For this reason, you have to run IPv6 on your internal network and you have decided to use only IPv6 addresses.

Your network has two FortiGate units running the RIPng dynamic routing protocol. Both FortiGate units are connected to the ISP router and the internal network. This configuration provides some redundancy for the R&D internal network enabling it to reach the Internet at all times.

This section includes the following topics:

- Network layout and assumptions
- Configuring the FortiGate units system information
- Configuring RIPng on FortiGate units
- Configuring other network devices
- Testing the configuration

Network layout and assumptions

Basic network layout

Your internal R&D network is working on a project for a large international telecom company that uses IPv6. For this reason, you have to run IPv6 on your internal network and you have decided to use only IPv6 addresses.

Your network has two FortiGate units running the RIPng dynamic routing protocol. Both FortiGate units are connected to the ISP router and the internal network. This configuration provides some redundancy for the R&D internal network enabling it to reach the Internet at all times.

All internal computers use RIP routing, so no static routing is required. And all internal computers use IPv6 addresses.

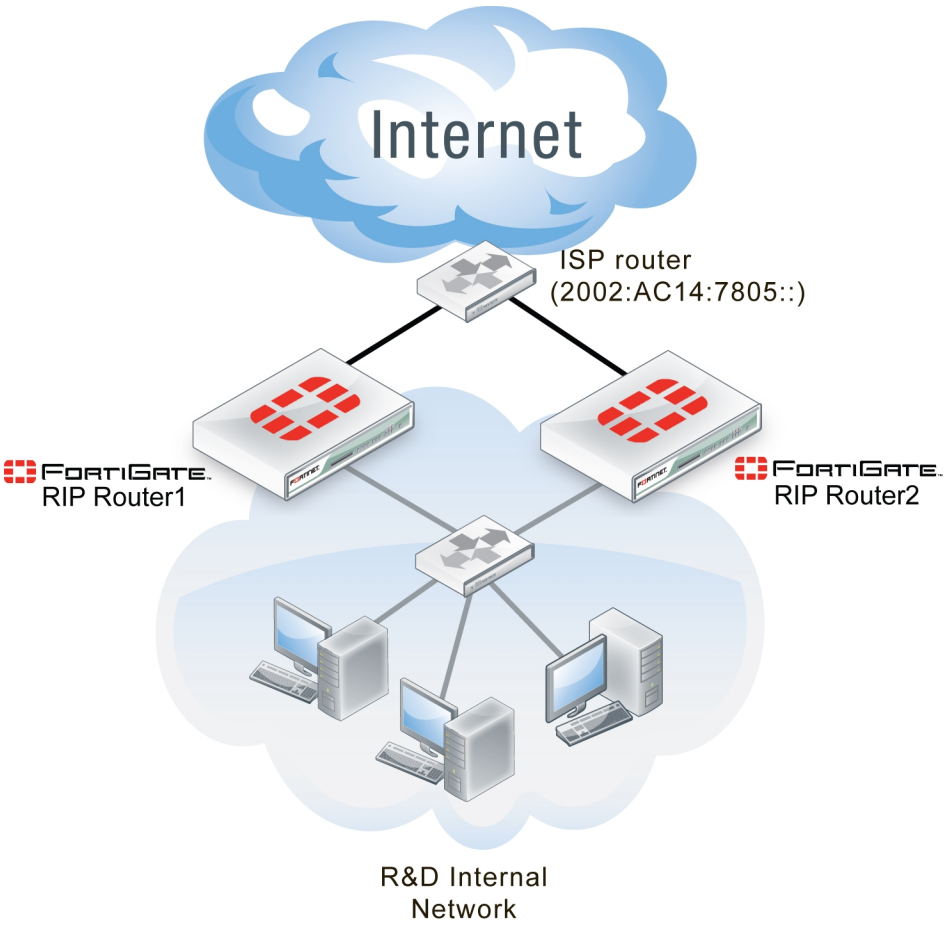
Where possible in this example, the default values will be used or the most general settings. This is intended to provide an easier configuration that will require less troubleshooting.

In this example the routers, networks, interfaces used, and IP addresses are as follows.

RIP example network topology

Network	Router	Interface & Alias	IPv6 address
R&D	Router1	port1 (internal)	2002:A0B:6565:0:0:0:0:0
		port2 (ISP)	2002:AC14:7865:0:0:0:0:0
	Router2	port1 (internal)	2002:A0B:6566:0:0:0:0:0
		port2 (ISP)	2002:AC14:7866:0:0:0:0:0

Network topology for the IPV6 RIPng example



Assumptions

The following assumptions have been made concerning this example.

- All FortiGate units have 5.0 firmware, and are running factory default settings.
- All CLI and web-based manager navigation assumes the unit is running in NAT/Route operating mode, with VDOMs disabled.
- All FortiGate units have interfaces labelled port1 and port2 as required.

- All firewalls have been configured for each FortiGate unit to allow the required traffic to flow across interfaces.
- All network devices are support IPv6 and are running RIPng.

Configuring the FortiGate units system information

Each FortiGate unit needs IPv6 enabled, a new hostname, and interfaces configured.

To configure system information on Router1 - web-based manager

1. Go to **Dashboard > System Information**.
2. For **Host name**, select **Change**.
3. Enter “Router1”.
4. Go to **System > Feature Select**.
5. In **Basic Features**, enable **IPv6**, and select **Apply**.
6. Go to **Network > Interfaces**.
7. Edit port1 (internal) interface.
8. Set the following information, and select **OK**.

Alias	internal
IP/Network Mask	2002:A0B:6565::/0
Administrative Access	HTTPS SSH PING
Description	Internal RnD network
Administrative Status	Up

9. Edit port2 (ISP) interface.
10. Set the following information, and select **OK**.

Alias	ISP
IP/Network Mask	2002:AC14:7865::/0
Administrative Access	HTTPS SSH PING
Description	ISP and Internet
Administrative Status	Up

To configure system information on Router1 - CLI

```
config system global
   set hostname Router1
   set gui-ipv6 enable
end
config system interface
   edit port1
      set alias internal
      set allowaccess https ping ssh
      set description “Internal RnD network”
      config ipv6
```

```
      set ip6-address 2002:a0b:6565::/0
   end
next
edit port2
   set alias ISP
   set allowaccess https ping ssh
   set description "ISP and Internet"
   config ipv6
      set ip6-address 2002:AC14:7865::
   end
end
```

To configure system information on Router2 - web-based manager

1. Go to **Dashboard > System Information**.
2. For **Host name**, select **Change**.
3. Enter "Router2".
4. Go to **System > Feature Select**.
5. In **Basic Features**, enable **IPv6**, and select **Apply**.
6. Go to **Network > Interfaces**.
7. Edit port1 (internal) interface.
8. Set the following information, and select **OK**.

Alias	internal
IP/Network Mask	2002:A0B:6566::/0
Administrative Access	HTTPS SSH PING
Description	Internal RnD network
Administrative Status	Up

9. Edit port2 (ISP) interface.
10. Set the following information, and select **OK**.

Alias	ISP
IP/Network Mask	2002:AC14:7866::/0
Administrative Access	HTTPS SSH PING
Description	ISP and Internet
Administrative Status	Up

To configure system information on Router2 - CLI

```
config system global
   set hostname Router2
   set gui-ipv6 enable
end
config system interface
```

```
edit port1
   set alias internal
   set allowaccess https ping ssh
   set description "Internal RnD network"
   config ipv6
      set ip6-address 2002:a0b:6566::/0
   end
next
edit port2
   set alias ISP
   set allowaccess https ping ssh
   set description "ISP and Internet"
   config ipv6
      set ip6-address 2002:AC14:7866::
   end
end
```

Configuring RIPng on FortiGate units

Now that the interfaces are configured, you can configure RIPng on the FortiGate units.

There are only two networks and two interfaces to include — the internal network, and the ISP network. There is no redistribution, and no authentication. In RIPng there is no specific command to include a subnet in the RIP broadcasts. There is also no information required for the interfaces beyond including their name.

As this is a CLI only configuration, configure the ISP router and the other FortiGate unit as neighbors. This was not part of the previous example as this feature is not offered in the web-based manager. Declaring neighbors in the configuration like this will reduce the discovery traffic when the routers start up.

Since RIPng is not supported in the web-based manager, this section will only be entered in the CLI.

To configure RIPng on Router1 - CLI

```
config router ripng
   config interface
      edit port1
      next
      edit port2
      end
   config neighbor
      edit 1
         set interface port1
         set ipv6 2002:a0b:6566::/0
      next
      edit 2
         set interface port2
         set ipv6 2002:AC14:7805::/0
      end
```

To configure RIPng on Router2 - CLI

```
config router ripng
   config interface
      edit port1
      next
      edit port2
      end
```

```
config neighbor
   edit 1
      set interface port1
      set ipv6 2002:a0b:6565::/0
   next
   edit 2
      set interface port2
      set ipv6 2002:AC14:7805::/0
   end
```

Configuring other network devices

The other devices on the internal network all support IPv6, and are running RIPng where applicable. They only need to know the internal interface network addresses of the FortiGate units.

The ISP routers need to know the FortiGate unit information such as IPv6 addresses.

Testing the configuration

In addition to normal testing of your network configuration, you must also test the IPv6 part of this example.

For troubleshooting problems with your network, see the FortiOS Handbook Troubleshooting chapter.

For troubleshooting problems with RIP, see RIPng — RIP and IPv6 on page 2418.

Testing the IPv6 RIPng information

There are some commands to use when checking that your RIPng information is correct on your network. These are useful to check on your RIPng FortiGate units on your network. Comparing the output between devices will help you understand your network better, and also track down any problems.

```
diagnose ipv6 address list
```

View the local scope IPv6 addresses used as next-hops by RIPng on the FortiGate unit.

```
diagnose ipv6 route list
```

View ipv6 addresses that are installed in the routing table.

```
get router info6 routing-table
```

View the routing table. This information is almost the same as the previous command (diagnose ipv6 route list) however it is presented in an easier to read format.

```
get router info6 rip interface external
```

View brief output on the RIP information for the interface listed. The information includes if the interface is up or down, what routing protocol is being used, and whether passive interface or split horizon are enabled.

```
get router info6 neighbor-cache list
```

View the IPv6/MAC address mapping. This also displays the interface index and name associated with the address.

Open Shortest Path First (OSPF)

This section describes OSPF routing.

The following topics are included in this section:

OSPF Background and concepts

OSPF (Open Shortest Path First) is a link-state interior routing protocol, that is widely used in large enterprise organizations. It only routes packets within a single autonomous system (AS). This is different from BGP as BGP can communicate between ASes.

This section includes:

- Background
- The parts and terminology of OSPF
- How OSPF works

Background

OSPF version 2 was defined in 1998 in RFC 2328. OSPF was designed to support classless IP addressing, and variable subnet masks. This was a shortcoming of the earlier RIP protocols.

Updates to OSPF version 2 are included in OSPF version 3 defined in 2008 in RFC 5340. OSPF3 includes support for IPv6 addressing where previously OSPF2 only supports IPv4 addressing.

The main benefit of OSPF is that it detects link failures in the network quickly and within seconds has converged network traffic successfully without any networking loops. Also OSPF has many features to control which routes are propagated and which are not, maintaining smaller routing tables. OSPF can also provide better load-balancing on external links than other interior routing protocols.

The parts and terminology of OSPF

Parts and terminology of OSPF includes:

- OSPFv3 and IPv6
- Router ID
- Adjacency
- Designated router (DR) and backup router (BDR)
- Area
- Authentication
- Hello and dead intervals
- Access Lists

OSPFv3 and IPv6

OSPFv3 (OSPF version 3) includes support for IPv6. Generally, all IP addresses are in IPv6 format instead of IPv4. However, OSPFv3 area numbers use the same 32-bit numbering system as OSPFv2, as described in RFC 2740. Likewise, the router ID and area ID are in the same format as OSPFv2.

As with most advanced routing features on your FortiGate unit, IPv6 settings for dynamic routing protocols must be enabled before they will be visible in the GUI. To enable IPv6 configuration in the GUI, enable it in **System > Config > Features**.

For IPv6, the main difference in OSPFv3 is that, rather than using a network statement to enable OSPFv3 on an interface, you define OSPF6 (OSPF for IPv6) interfaces, which are bound to interface and area. This configuration must be done in the CLI, as follows (with sample interfaces and addresses):

```
config router ospf6
   config area
      edit 0.0.0.0
   next
end
config ospf6-interface
   edit "tunnel"
   set interface "to_FGT300A-7"
next
   edit "internal_lan"
   set interface "port1"
next
   set router-id 10.174.0.113
end
```

Note that OSPFv3 neighbors use link-local IPv6 addresses, but with broadcast and point-to-point network types, neighbors are automatically discovered. You only have to manually configure neighbors when using non-broadcast network types.

Router ID

In OSPF, each router has a unique 32-bit number called its Router ID. Often this 32-bit number is written the same as a 32-bit IPv4 address would be written in dotted decimal notation. However some brands of routers, such as Cisco routers, support a router ID entered as an integer instead of an IP address.

It is a good idea to not use IP address in use on the router for the router ID number. The router ID does not have to be a particular IP address on the router. By choosing a different number, it will be harder to get confused which number you are looking at. A good idea can be to use the as much of the area's number as possible. For example if you have 15 routers in area 0.0.0.0 they could be numbered from 0.0.0.1 to 0.0.0.15. If you have an area 1.1.1.1, then routers in that area could start at 1.1.1.10 for example.

You can manually set the router ID on your FortiGate unit.

To manually set an OSPF router ID of 0.0.1.1 - web-based manager

1. Go to **Network > OSPF**.
2. For **Router ID**, enter `0.0.1.1`.
3. Select **Apply**.

To manually set an OSPF router ID of 0.0.1.1 - CLI

```
config router ospf
   set router-id 0.0.1.1
end
```

Adjacency

In an OSPF routing network, when an OSPF router boots up it sends out OSPF Hello packets to find any neighbors, routers that have access to the same network as the router booting up. Once neighbors are discovered and Hello packets are exchanged, updates are sent, and the Link State databases of both neighbors are synchronized. At this point these neighbors are said to be adjacent.

For two OSPF routers to become neighbors, the following conditions must be met.

- The subnet mask used on both routers must be the same subnet.
- The subnet number derived using the subnet mask and each router's interface IP address must match.
- The Hello interval & The Dead interval must match.
- The routers must have the same OSPF area ID. If they are in different areas, they are not neighbors.
- If authentication is used, they must pass authentication checks.

If any of these parameters are different between the two routers, the routers do not become OSPF neighbors and cannot be adjacent. If the routers become neighbors, they are adjacent.

Adjacency and neighbors

Neighbor routers can be in a Two-Way state, and not be adjacent. Adjacent routers normally have a neighbor state of FULL. Neighbors only exchange Hello packets, and do not exchange routing updates. Adjacent routers exchange LSAs (LSDB information) as well as Hello packets. A good example of an adjacent pair of routers is the DR and BDR.

You can check on the state of an OSPF neighbor using the CLI command `get router info ospf neighbor all`. See OSPF Background and concepts on page 2424.

Why adjacency is important

It is important to have adjacent pairs of routers in the OSPF routing domain because routing protocol packets are only passed between adjacent routers. This means adjacency is required for two OSPF routers to exchange routes.

If there is no adjacency between two routers, such as one on the 172.20.120.0 network and another on the 10.11.101.0 network, the routers do not exchange routes. This makes sense because if all OSPF routers on the OSPF domain exchanged updates it would flood the network.

Also, it is better for updates to progress through adjacent routers to ensure there are no outages along the way. Otherwise, updates could skip over routers that are potentially offline, causing longer routing outages and delays while the OSPF domain learns of this outage later on.

If the OSPF network has multiple border routers and multiple connections to external networks, the designated router (DR) determines which router pairs become adjacent. The DR can accomplish this because it maintains the complete topology of the OSPF domain, including which router pairs are adjacent.

The BDR also has this information in case the DR goes offline.

Designated router (DR) and backup router (BDR)

In OSPF a router can have a number of different roles to play.

A designated router (DR) is the designated broadcasting router interface for an AS. It looks after all the initial contact and other routing administration traffic. Having only one router do all this greatly reduces the network traffic and collisions.

If something happens and the designated router goes offline, the backup designated router (BDR) takes over. An OSPF FortiGate unit interface can become either a DR or BDR. Both the DR and the BDR cover the same area, and are elected at the same time. The election process doesn't have many rules, but the exceptions can become complex.

Benefits

The OSPF concept of the designated router is a big step above RIP. With all RIP routers doing their own updates all the time, RIP suffers from frequent and sometimes unnecessary updates that can slow down your network. With OSPF, not only do routing changes only happen when a link-state changes instead of any tiny change to the routing table, but the designated router reduces this overhead traffic even more.

However, smaller network topologies may only have a couple routers besides the designated router. This may seem excessive, but it maintains the proper OSPF form and it will still reduce the administration traffic but to a lesser extent than on a large network. Also, your network topology will be ready whenever you choose to expand your network.

DR and BDR election

An election chooses the DR and BDR from all the available routers. The election is primarily based on the priority setting of the routers—the highest priority becomes the DR, and the second highest becomes BDR. To resolve any ties, the router with the highest router ID wins. For example 192.168.0.1 would win over 10.1.1.2.

The router priority can vary from 0 to 255, but at 0 a router will never become a DR or BDR. If a router with a higher priority comes on line after the election, it must wait until after the DR and BDR go offline before it would become the DR.

If the original DR goes offline, but then is available when the BDR goes offline later on, the original DR will be promoted back to DR without an election leaving the new BDR as it is.

With your FortiGate unit, to configure the port1 interface to be a potential OSPF designated router or backup designed router called `ospf_DR` on the network, you need to raise the priority of the router to a very high number such as 250 out of 255. This will ensure the interface has a chance to be a DR, but will not guarantee that it will be one. Give the interface a low numbered IP address—such as 10.1.1.1 instead of 192.168.1.1—to help ensure it becomes a DR, but that is not part of this example. Enter the following command:

```
config router ospf
   config ospf-interface
   edit "ospf_DR"
      set priority 250
   end
end
```

Area

An OSPF area is a smaller part of the larger OSPF AS. Areas are used to limit the link-state updates that are sent out. The flooding used for these updates would overwhelm a large network, so it is divided into these smaller areas for manageability.

Within an area if there are two or more routers that are viable, there will always be a designated router (DR) and a backup DR (BDR). For more on these router roles, see Designated router (DR) and backup router (BDR) on page 2426.

Defining a private OSPF area, involves:

- Assigning a 32-bit number to the area that is unique on your network
- Defining the characteristics of one or more OSPF areas
- Creating associations between the OSPF areas that you defined and the local networks to include in the OSPF area
- If required, adjusting the settings of OSPF-enabled interfaces.

IPv6 OSPF area numbers use the same 32-bit number notation as IPv4 OSPF.

If you are using the web-based manager to perform these tasks, follow the procedures summarized below.

FortiGate units support the four main types of OSPF area:

- Backbone area
- Stub area
- NSSA
- Regular area

Backbone area

Every OSPF network has at least one AS, and every OSPF network has a backbone area. The backbone is the main area, or possibly the only area. All other OSPF areas are connected to a backbone area. This means if two areas want to pass routing information back and forth, that routing information will go through the backbone on its way between those areas. For this reason the backbone not only has to connect to all other areas in the network, but also be uninterrupted to be able to pass traffic to all points of the network.

The backbone area is referred to as area 0 because it has an IP address of 0.0.0.0.

Stub area

A stub area is an OSPF area that receives no outside routes advertised into it, and all routing in it is based on a default route. This essentially isolates it from outside areas.

Stub areas are useful for small networks that are part of a larger organization, especially if the networking equipment can't handle routing large amounts of traffic passing through, or there are other reasons to prevent outside traffic, such as security. For example most organizations don't want their accounting department to be the center of their network with everyone's traffic passing through there. It would increase the security risks, slow down their network, and it generally doesn't make sense.

A variation on the stub area is the totally stubby area. It is a stub area that does not allow summarized routes.

NSSA

A not-so-stubby-area (NSSA) is a stub area that allows for external routes to be injected into it. While it still does not allow routes from external areas, it is not limited to only using he default route for internal routing.

Regular area

A regular area is what all the other ASes are, all the non-backbone, non-stub, non-NSSA areas. A regular area generally has a connection to the backbone, does receive advertisements of outside routes, and does not have an area number of 0.0.0.0.

Authentication

In the OSPF packet header are two authentication related fields —AuType, and Authentication.

All OSPF packet traffic is authenticated. Multiple types of authentication are supported in OSPFv2. However in OSPFv3, there is no authentication built-in but it is assumed that IPsec will be used for authentication instead.

Packets that fail authentication are discarded.

Null authentication

Null authentication indicates there is no authentication being used. In this case the 16-byte Authentication field is not checked, and can be any value. However checksumming is still used to locate errors. On your FortiGate this is the `none` option for authentication.

Simple Password authentication

Simple password refers to a standard plain text string of characters. The same password is used for all transactions on a network. The main use of this type of authentication is to prevent routers from accidently joining the network. Simple password authentication is vulnerable to many forms of attack, and is not recommended as a secure form of authentication.

Cryptographic authentication

Cryptographic authentication involves the use of a shared secret key to authenticate all router traffic on a network. The key is never sent over the network in the clear—a packet is sent and a condensed and encrypted form of the packet is appended to the end of the packet. A non-repeating sequence number is included in the OSPF packet to protect against replay attacks that could try to use already sent packets to disrupt the network. When a packet is accepted as authentic the authentication sequence number is set to the packet sequence number. If a replay attack is attempted, the packet sent will be out of sequence and ignored.

Your FortiGate unit supports all three levels of authentication through the authentication keyword associated with creating an OSPF interface .

For example to create an OSPF interface called `Accounting` on the port1 interface that is a broadcast interface, has a hello interval of 10 seconds, has a dead interval of 40 seconds, uses text authentication (simple password) with a password of “ospf_test”, enter the command:

```
config router ospf
   config ospf-interface
   edit Accounting
      set interface port1
      set network-type broadcast
      set hello-interval 10
      set dead-interval 40
      set authentication text
      set authentication-key "ospf_test"
   end
end
```

Hello and dead intervals

The OSPF Hello protocol is used to discover and maintain communications with neighboring routers.

Hello packets are sent out at a regular interval for this purpose. The DR sends out the Hello packets. In a broadcast network, the multicast address of 224.0.0.5 is used to send out Hello packets. New routers on the network listen for and reply to these packets to join the OSPF area. If a new router never receives a Hello packet, other routers will not know it is there and will not communicate with it. However, once a new router is discovered the DR adds it to the list of routers in that area and it is integrated into the routing calculations.

Dead interval is the time other routers will wait before declaring a neighbor dead (offline). Setting a reasonable dead interval is very important. If this interval is too short, routers will be declared offline when they are just slow or momentarily inaccessible, and link-state updates will happen more than they need to, using more bandwidth. If the dead interval is too long, it will slow down network traffic overall if online routers attempt to contact offline ones instead of re-routing traffic.

FortiOS also supports OSPF fast-hello, which provides a way of sending multiple Hello packets per second. This is achieved by setting a dead-interval to one second. The hello-multiplier, which can be any number between 4 and 10, determines the number of Hello packets that will be sent every second. The CLI syntax for OSPF fast-hello follows:

```
config ospf-interface
   edit ospf1
      set interface port1
      set network-type broadcast
      set dead-interval 1
      set hello-multiplier 4
end
```

Access Lists

Access lists are filters used by FortiGate unit OSPF routing. An access list provides a list of IP addresses and the action to take for them — essentially an access list makes it easy to group addresses that will be treated the same into the same group, independent of their subnets or other matching qualities. You add a rule for each address or subnet that you want to include, specifying the action to take for it. For example if you wanted all traffic from one department to be routed a particular way, even in different buildings, you can add all the addresses to an access list and then handle that list all at once.

Each rule in an access list consists of a prefix (IP address and netmask), the action to take for this prefix (permit or deny), and whether to match the prefix exactly or to match the prefix and any more specific prefix.

The FortiGate unit attempts to match a packet against the rules in an access list starting at the top of the list. If it finds a match for the prefix, it takes the action specified for that prefix. If no match is found the default action is deny.

Access lists greatly speed up configuration and network management. When there is a problem, you can check each list instead of individual addresses. Also, it eases troubleshooting since if all addresses on one list have problems, it eliminates many possible causes right away.

If you are using the OSPF+ IPv6 protocols you will need to use access-list6, the IPv6 version of access list. The only difference is that access-list6 uses IPv6 addresses.

For example, if you want to create an access list called `test_list` that only allows an exact match of `10.10.10.10` and `11.11.11.11`, enter the command:

```
config router access-list
   edit test_list
```

```
    config rule
       edit 1
          set prefix 10.10.10.10 255.255.255.255
          set action allow
          set exact-match enable
       next
       edit 2
          set prefix 11.11.11.11 255.255.255.255
          set action allow
          set exact-match enable
       end
    end
```

Another example is if you want to deny ranges of addresses in IPv6 that start with the IPv6 equivalents of 10.10.10.10 and 11.11.11.11, enter the command access-list6 as follows:

```
config router access-list6
   edit test_list_ip6
      config rule
         edit 1
            set prefix6 2002:A0A:A0A:0:0:0:0:0:/48
            set action deny
         next
         edit 2
            set prefix6 2002:B0B:B0B:0:0:0:0:0/48
            set action deny
         end
```

To use an access_list, you must call it from a routing protocol such as RIP. The following example uses the access_list from the earlier example called test_list to match routes coming in on the port1 interface. When there is a match, it will add 3 to the hop count metric for those routes to artificially decrease their priority. Enter the following command:

```
config router ospf
   config distribute-list
      edit 5
         set access-list test_list
         set protocol connected
      end
```

If you are setting a prefix of 128.0.0.0, use the format 128.0.0.0/1. The default route 0.0.0.0/0 can not be exactly matched with an access-list. A prefix-list must be used for this purpose.

How OSPF works

An OSPF installation consists of one or more areas. An OSPF area is typically divided into logical areas linked by Area Border Routers. A group of contiguous networks form an area. An Area Border Router (ABR) links one or more areas to the OSPF network backbone (area ID 0). See Dynamic Routing Overview on page 2371.

OSPF is an interior routing protocol. It includes a backbone AS, and possibly additional ASes. The DR and BDR are elected from potential routers with the highest priorities. The DR handles much of the administration to lower the network traffic required. New routers are discovered through hello packets sent from the DR using the multicast address of 224.0.0.5. If the DR goes offline at any time, the BDR has a complete table of routes that is uses when it takes over as the DR router.

OSPF does not use UDP or TCP, but is encapsulated directly in IP datagrams as protocol 89. This is in contrast to RIP, or BGP. OSPF handles its own error detection and correction functions.

The OSPF protocol, when running on IPv4, can operate securely between routers, optionally using a variety of authentication methods to allow only trusted routers to participate in routing. OSPFv3, running on IPv6, no longer supports protocol-internal authentication. Instead, it relies on IPv6 protocol security (IPsec).

Other important parts of how OSPF works includes:

- OSPF router discovery
- How OSPF works on FortiGate units
- External routes
- Link-state Database (LSDB) and route updates
- OSPF packets

OSPF router discovery

OSPF-enabled routers generate Link-State Advertisements (LSA) and send them to their neighbors whenever the status of a neighbor changes or a new neighbor comes online. As long as the OSPF network is stable, LSAs between OSPF neighbors do not occur. An LSA identifies the interfaces of all OSPF-enabled routers in an area, and provides information that enables OSPF-enabled routers to select the shortest path to a destination. All LSA exchanges between OSPF-enabled routers are authenticated.

When a network of OSPF routers comes online, the follow steps occur.

1. When OSPF routers come online, they send out Hello packets to find other OSPF routers on their network segment.
2. When they discover other routers on their network segment, generally they become adjacent. Adjacent routers can exchange routing updates. See Adjacency on page 2426.
3. A DR and BDR are elected from the available routers using priority settings, and router ID. See Designated router (DR) and backup router (BDR) on page 2426, and OSPF Background and concepts on page 2424.
4. Link state updates are sent between adjacent routers to map the topology of the OSPF area.
5. Once complete, the DR floods the network with the updates to ensure all OSPF routers in the area have the same OSPF route database. After the initial update, there are very few required updates if the network is stable.

How OSPF works on FortiGate units

When a FortiGate unit interface is connected to an OSPF area, that unit can participate in OSPF communications. FortiGate units use the OSPF Hello protocol to acquire neighbors in an area. A neighbor is any router that is directly connected to the same area as the FortiGate unit, and ideally is adjacent with a state of Full. After initial contact, the FortiGate unit exchanges Hello packets with its OSPF neighbors regularly to confirm that the neighbors can be reached.

The number of routes that a FortiGate unit can learn through OSPF depends on the network topology. A single unit can support tens of thousands of routes if the OSPF network is configured properly.

External routes

OSPF is an internal routing protocol. OSPF external routes are routes where the destination using a routing protocol other than OSPF. OSPF handles external routes by adjusting the cost of the route to include the cost of the other routing protocol. There are two methods of calculating this cost, used for OSPF E1 and OSPF E2.

OSPF external1 (E1)

In OSPF E1 the destination is outside of the OSPF domain. This requires a different metric to be used beyond the normal OSPF metrics. The new metric of a redistributed route is calculated by adding the external cost and the OSPF cost together.

OSPF external2 (E2)

OSPF E2 is the default external type when routes are redistributed outside of OSPF. With OSPF E2, the metric of the redistributed route is equivalent to the external cost only, expressed as an OSPF cost. Dropping the OSPF portion can be useful in a number of situations, on border routers that have no OSPF portion for example or where the OSPF routing cost is negligible compared to the external routing cost.

Comparing E1 and E2

The best way to understand OSPF E1 and E2 routes is to check routing tables on OSPF routers. If you look at the routes on an OSPF border router, the redistributed routes will have an associated cost that represents only the external route, as there is no OSPF cost to the route due to it already being on the edge of the OSPF domain. However, if you look at that same route on a different OSPF router inside the OSPF routing domain, it will have a higher associated cost - essentially the external cost plus the cost over the OSPF domain to that border router. The border router uses OSPF E2, where the internal OSPF router uses OSPF E1 for the same route.

Viewing external routes

When you are trying to determine the costs for routes in your network to predict how traffic will be routed, you need to see the external OSPF routes and their associated costs. On your FortiGate unit, you find this information through your CLI.

To view external routes - CLI

You can view the whole routing table using `get router info routing-table all` to see all the routes including the OSPF external routes, or for a shorter list you can use the command `get router info routing-table ospf`. The letter at the left will be either E1 or E2 for external OSPF routes. The output of will look similar to the following, depending on what routes are in your routing table.

```
FGT620B# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
* - candidate default

O*E2   0.0.0.0/0 [110/10] via 10.1.1.3, tunnel_wan2, 00:02:11
O      10.0.0.1/32 [110/300] via 10.1.1.3, tunnel_wan2, 00:02:11
S      0.0.0.0/0 [10/0] via 192.168.183.254, port2
S      1.0.0.0/8 [10/0] via 192.168.183.254, port2
```

Link-state Database (LSDB) and route updates

OSPF is based on links. The links between adjacent neighbor routers allow updates to be passed along the network. Network links allow the DR to flood the area with Link-state database (LSDB) updates. External links

allow the OSPF area to connect to destinations outside the OSPF autonomous system. Information about these links is passed throughout the OSPF network as link-state updates.

The LSDB contains the information that defines the complete OSPF area, but the LSDB is not the routing table. It contains the information from all the link-state updates passed along the network. When there are no more changes required, and the network is stable then the LSDB on each router in the network will be the same. The DR will flood the LSDB to the area to ensure each router has the same LSDB.

To calculate the best route (shortest path) to a destination, the FortiGate unit applies the Shortest Path First (SPF) algorithm, based on Dijkstra's algorithm, to the accumulated link-state information. OSPF uses relative path cost metric for choosing the best route. The path cost can be any metric, but is typically the bandwidth of the path, how fast traffic will get from one point to another.

The path cost, similar to "distance" for RIP, imposes a penalty on the outgoing direction of a FortiGate unit interface. The path cost of a route is calculated by adding together all of the costs associated with the outgoing interfaces along the path to the destination. The lowest overall path cost indicates the best route, and generally the fastest route. Some brands of OSPF routers, such as Cisco, implement cost as a direct result of bandwidth between the routers. Generally this is a good cost metric because larger bandwidth means more traffic can travel without slowing down. To achieve this type of cost metric on FortiGate units, you need to set the cost for each interface manually in the CLI.

The inter-area routes may not be calculated when a Cisco type ABR has no fully adjacent neighbor in the backbone area. In this situation, the router considers summary-LSAs from all Actively summary-LSAs from all Actively Attached areas (RFC 3509).

The FortiGate unit dynamically updates its routing table based on the results of the SPF calculation to ensure that an OSPF packet will be routed using the shortest path to its destination. Depending on the network topology, the entries in the FortiGate unit routing table may include:

- The addresses of networks in the local OSPF area (to which packets are sent directly)
- Routes to OSPF area border routers (to which packets destined for another area are sent)
- If the network contains OSPF areas and non-OSPF domains, routes to area boundary routers, which reside on the OSPF network backbone and are configured to forward packets to destinations outside the OSPF AS.

OSPF Route updates

Once the OSPF domain is established, there should be few updates required on a stable network. When updates occur and a decision is required concerning a new route, this is the general procedure.

Our router gets a new route, and needs to decide if it should go in the routing table.

The router has an up to date LSDB of the entire area, containing information about each router, the next hop to it, and most importantly the cost to get there.

Our router, turns the LSDB into a shortest path first (SPF) tree using Dijkstra's algorithm. It doesn't matter if there is more than one path to a router on the network, the SPF tree only cares about the shortest path to that router.

Once the SPF tree has been created, and shows the shortest paths to all the OSPF routers on the network, the work is done. If the new route is the best route, it will be part of that tree. If it is not the shortest route, it will not be included in the LSDB.

If there has been a change from the initial LSDB to the new SPF tree, a link state update will be sent out to let the other routers know about the change so they can update their LSDBs as well. This is vital since all routers on the OSPF area must have the same LSDB.

If there was no change between the LSDB and the SPF tree, no action is taken.

OSPF packets

Every OSPF packet starts with a standard 24-byte header, and another 24 bytes of information or more. The header contains all the information necessary to determine whether the packet should be accepted for further processing.

OSPF packet

1-byte Version field	1-byte Type field	2-byte Packet length	3-byte Router ID
4-byte Area ID	2-byte Checksum	2-byte Auth Type	8-byte Authentication
4-byte Network Mask	2-byte Hello interval	1-byte Options field	1-byte Router Priority
4-byte Dead Router interval	4-byte DR field	4-byte BDR field	4-byte Neighbor ID

The following descriptions summarize the OSPF packet header fields.

Version field — The OSPF version number. This specification documents version 2 of the protocol.

Type field — There are 5 OSPF packet types. From one to five, respectively, they are Hello, Database Description, Link State Request, Link State Update, and Link State Acknowledgment.

Packet length — The length of the OSPF protocol packet in bytes. This length includes the standard OSPF 24-byte header, so all OSPF packets are at 24-bytes long.

Router ID — The Router ID of the packet's source.

Area ID — A 32-bit number identifying the area that this packet belongs to. All OSPF packets are associated with a single area. Most travel a single hop only. Packets travelling over a virtual link are labelled with the backbone Area ID of 0.0.0.0.

Checksum — The standard IP checksum of the entire contents of the packet, starting with the OSPF packet header but excluding the 64-bit authentication field. This checksum is calculated as the 16-bit one's complement of the one's complement sum of all the 16-bit words in the packet, excepting the authentication field. If the packet's length is not an integral number of 16-bit words, the packet is padded with a byte of zero before checksumming. The checksum is considered to be part of the packet authentication procedure; for some authentication types the checksum calculation is omitted.

Auth Type — Identifies the authentication procedure to be used for the packet. Authentication types include Null authentication (0), Simple password (1), Cryptographic authentication (2), and all others are reserved for future use.

Authentication — A 64-bit field for use by the authentication scheme. When AuType indicates no authentication is being used, the Authentication fields is not checked and can be any value. When AuType is set to 2 (Cryptographic authentication), the 64-bit authentication field is split into the following four fields: Zero field, Key ID field, Authentication data length field, and Cryptographic sequence field.

The Key ID field indicates the key and algorithm used to create the message digest appended to the packet. The authentication data length field indicates how many bytes long the message digest is, and the cryptographic sequence number is at non-decreasing number that is set when the packet is received and authenticated to prevent replay attacks.

Network Mask — The subnet where this packet is valid.

Hello interval — The period of time between sending out Hello packets. See Hello and dead intervals on page 2430.

Options field — The OSPF protocol defines several optional capabilities. A router indicates the optional capabilities that it supports in its OSPF Hello packets, Database Description packets and in its LSAs. This enables routers supporting a mix of optional capabilities to coexist in a single Autonomous System.

Router priority — The priority between 0 and 255 that determines which routers become the DR and BDR. See Designated router (DR) and backup router (BDR) on page 2426.

Dead router interval — The period of time when there is no response from a router before it is declared dead. See Hello and dead intervals on page 2430.

DR and BDR fields — The DR and BDR fields each list the router that fills that role on this network, generally the routers with the highest priorities. See Designated router (DR) and backup router (BDR) on page 2426.

Neighbor ID — The ID number of a neighboring router. This ID is used to discover new routers and respond to them.

Troubleshooting OSPF

As with other dynamic routing protocols, OSPF has some issues that may need troubleshooting from time to time. For basic troubleshooting, see the FortiOS Handbook Troubleshooting chapter.

The more common issues include:

- Clearing OSPF routes from the routing table
- Checking the state of OSPF neighbors
- Passive interface problems
- Timer problems
- Bi-directional Forwarding Detection (BFD)
- Authentication issues
- DR and BDR election issues

Clearing OSPF routes from the routing table

If you think the wrong route has been added to your routing table and you want to check it out, you first have to remove that route from your table before seeing if it is added back in or not. You can clear all or some OSPF neighbor connections (sessions) using the `execute router clear ospf` command. The exec router clear command is much more limiting for OSPF than it is for BGP. See Border Gateway Protocol (BGP) on page 2465.

For example, if you have routes in the OSPF routing table and you want to clear the specific route to IP address 10.10.10.1, you will have to clear all the OSPF entries. Enter the command:

```
execute router clear ospf process
```

Checking the state of OSPF neighbors

In OSPF each router sends out link state advertisements to find other routers on its network segment, and to create adjacencies with some of those routers. This is important because routing updates are only passed between adjacent routers. If two routers you believe to be adjacent are not, that can be the source of routing failures.

To identify this problem, you need to check the state of the OSPF neighbors of your FortiGate unit. Use the CLI command `get router info ospf neighbor all` to see all the neighbors for your FortiGate unit. You will see output in the form of:

```
FGT1 # get router info ospf neighbor
OSPF process 0:
Neighbor ID  Pri  State    Dead Time Address Interface
10.0.0.2     1    Full/ -  00:00:39 10.1.1.2 tunnel_wan1
10.0.0.2     1    Full/ -  00:00:34 10.1.1.4 tunnel_wan2
```

The important information here is the `State` column. Any neighbors that are not adjacent to your FortiGate unit will be reported in this column as something other than `Full`. If the state is `Down`, that router is offline.

Passive interface problems

A passive OSPF interface doesn't send out any updates. This means it can't be a DR, BDR, or an area border router among other things. It will depend on other neighbor routers to update its link-state table.

Passive interfaces can cause problems when they aren't receiving the routing updates you expect from their neighbors. This will result in the passive OSPF FortiGate unit interface having an incomplete or out-of-date link-state database, and it will not be able to properly route its traffic. It is possible that the passive interface is causing a hole in the network where no routers are passing updates to each other, however this is a rare situation.

If a passive interface is causing problems, there are simple methods to determine it is the cause. The easiest method is to make it an active interface, and if the issues disappear, then that was the cause. Another method is to examine the OSPF routing table and related information to see if it is incomplete compared to other neighbor routers. If this is the case, you can clear the routing table, reset the device and allow it to repopulate the table.

If you cannot make the interface active for some reason, you will have to change your network to fix the "hole" by adding more routers, or changing the relationship between the passive router's neighbors to provide better coverage.

Timer problems

A timer mismatch is when two routers have different values set for the same timer. For example if one router declares a router dead after 45 seconds and another waits for 4 minutes that difference in time will result in those two routers being out of synch for that period of time—one will still see that offline router as being online.

The easiest method to check the timers is to check the configuration on each router. Another method is to sniff some packets, and read the timer values in the packets themselves from different routers. Each packet contains the hello interval, and dead interval periods, so you can compare them easily enough.

Bi-directional Forwarding Detection (BFD)

Bi-directional Forwarding Detection (BFD) is a protocol used to quickly locate hardware failures in the network. Routers running BFD communicate with each other, and if a timer runs out on a connection then that router is declared down. BFD then communicates this information to the routing protocol and the routing information is updated.

Authentication issues

OSPF has a number of authentication methods you can choose from. You may encounter problems with routers not authenticating as you expect. This will likely appear simply as one or more routers that have a blind spot in their routing - they won't acknowledge a router. This can be a problem if that router connects areas to the backbone as it will appear to be offline and unusable.

To confirm this is the issue, the easiest method is to turn off authentication on the neighboring routers. With no authentication between any routers, everything should flow normally.

Another method to confirm that authentication is the problem is to sniff packets, and look at their contents. The authentication type and password are right in the packets which makes it easy to confirm they are what you expect during real time. Its possible one or more routers is not configured as you expect and may be using the wrong authentication. This method is especially useful if there are a group of routers with these problems—it may only be one router causing the problem that is seen in multiple routers.

Once you have confirmed the problem is authentication related, you can decide how to handle it. You can turn off authentication and take your time to determine how to get your preferred authentication type back online. You can try another type of authentication, such as text instead of md5, which may have more success and still provide some level of protection. The important part is that once you confirm the problem, you can decide how to fix it properly.

DR and BDR election issues

You can force a particular router to become the DR and BDR by setting their priorities higher than any other OSPF routers in the area. This is a good idea when those routers have more resources to handle the traffic and extra work of the DR and BDR roles, since not all routers may be able to handle all that traffic.

However, if you set all the other routers to not have a chance at being elected, a priority of zero, you can run into problems if the DR and BDR go offline. The good part is that you will have some warning generally as the DR goes offline and the BDR is promoted to the DR position. But if the network segment with both the DR and BDR goes down, your network will have no way to send hello packets, send updates, or the other tasks the DR performs.

The solution to this is to always allow routers to have a chance at being promoted, even if you set their priority to one. In that case they would be the last choice, but if there are no other candidates you want that router to become the DR. Most networks would have already alerted you to the equipment problems, so this would be a temporary measure to keep the network traffic moving until you can find and fix the problem to get the real DR back online.

Basic OSPF example

This example sets up an OSPF network at a small office. There are 3 routers, all running OSPF v2. The border router connects to a BGP network.

All three routers in this example are FortiGate units. Router1 will be the designated router (DR) and router2 will be the backup DR (BDR) due to their priorities. Router3 will not be considered for either the DR or BDR elections. Instead, Router3 is the area border router (ASBR) routing all traffic to the ISP's BGP router on its way to the Internet.

Router2 has a modem connected that provides dialup access to the Internet as well, at a reduced bandwidth. This is a PPPoE connection to a DSL modem. This provides an alternate route to the Internet if the other route goes down. The DSL connection is slow, and is charged by the amount of traffic. For these reasons OSPF will highly favor Router3's Internet access.

The DSL connection connects to an OSPF network with the ISP, so no redistribution of routes is required. The ISP network does have to be added to that router's configuration however.

This section includes the following topics:

- Network layout and assumptions
- Configuring the FortiGate units
- Configuring OSPF on the FortiGate units
- Configuring other networking devices
- Testing network configuration

Network layout and assumptions

There are three FortiGate units acting as OSPF v2 routers on the network—Router1, Router2, and Router3. Router1 will be the designated router (DR), and Router 2 the BDR. Router3 is the area border router (ASBR) that connects to the external ISP router running BGP. Router2 has a PPPoE DSL connection that can access the Internet.

The Head Office network is connected to Router1 and Router2 on the 10.11.101.0 subnet.

Router1 and Router3 are connected over the 10.11.103.0 subnet.

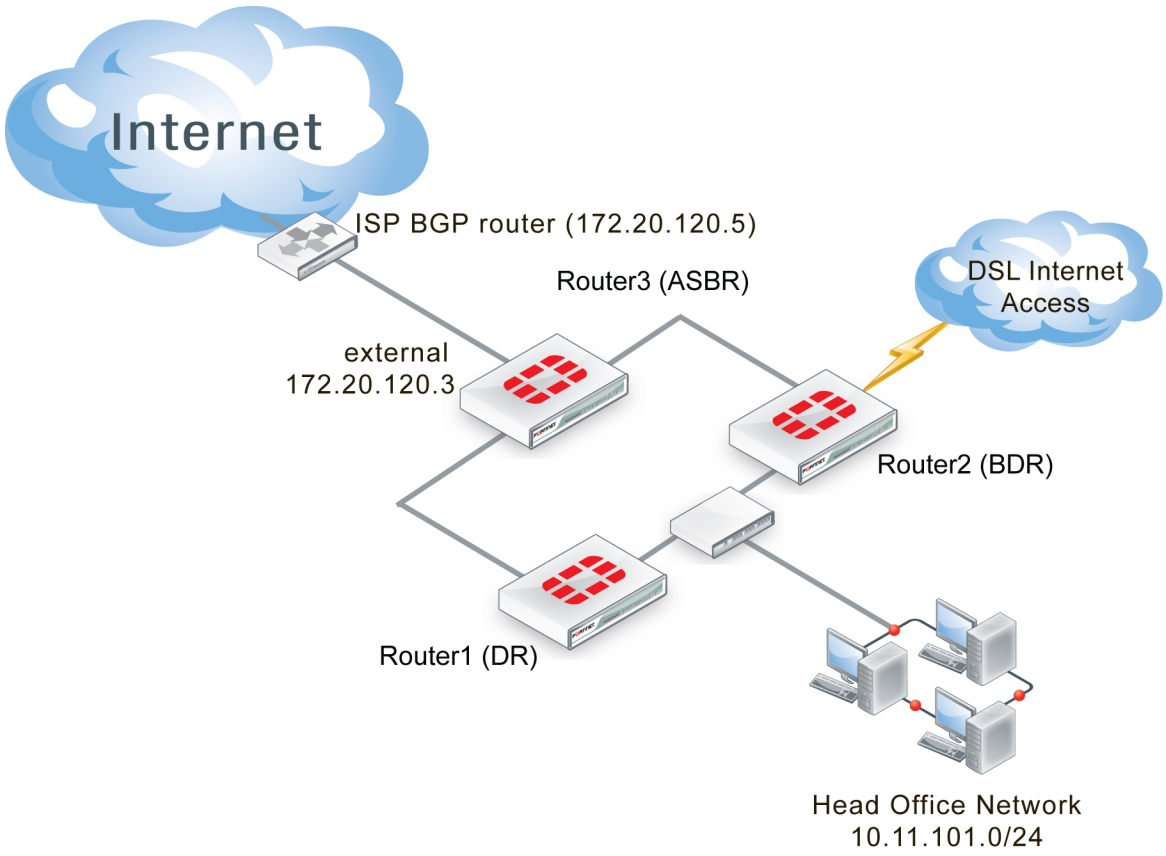
Router2 and Router3 are connected over the 10.11.102.0 subnet.

The following table lists the router, interface, address, and role it is assigned.

Routers, interfaces, and IP addresses for basic OSPF example network

Router name	Interface	IP address	Interface is connected to:
Router1 (DR)	Internal (port1)	10.11.101.1	Head office network, and Router2
	External (port2)	10.11.102.1	Router3
Router2 (BDR)	Internal (port1)	10.11.101.2	Head office network, and Router1
	External (port2)	10.11.103.2	Router3
	DSL (port3)	10.12.101.2	PPPoE DSL access
	Internal1 (port1)	10.11.102.3	Router1
Router3 (ASBR)	Internal2 (port2)	10.11.103.3	Router2
	External (port3)	172.20.120.3	ISP's BGP network

Basic OSPF network topology



Note that other subnets can be added to the internal interfaces without changing the configuration.

Assumptions

- The FortiGate units used in this example have interfaces named port1, port2, and port3.
- All FortiGate units in this example have factory default configuration with FortiOS 4.0 MR2 firmware installed, and are in NAT/Route operation mode.
- Basic firewalls are in place to allow unfiltered traffic between all connected interfaces in both directions.
- This OSPF network is not connected to any other OSPF networks.
- Both Internet connections are always available.
- The modem connection is very slow and expensive.
- Other devices may be on the network, but do not affect this basic configuration.
- Router3 is responsible for redistributing all routes into and out of the OSPF AS.

Configuring the FortiGate units

Each FortiGate unit needs the interfaces, and basic system information such as hostname configured.

This section includes:

- Configuring Router1
- Configuring Router2

- Configuring Router3

Configuring Router1

Router1 has two interfaces connected to the network—internal (port1) and external (port2). Its host name must be changed to Router1.

To configure Router1 interfaces - web-based manager

1. Go to **Dashboard > System Information**.
2. Beside the host name, select **Change**.
3. Enter a hostname of `Router1`, and select **OK**.
4. Go to **Network > Interfaces**, edit port1, set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.11.101.1/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Head office and Router2
Administrative Status	Up

5. Edit port2, set the following information, and select **OK**.

Alias	External
IP/Network Mask	10.11.102.1/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router3
Administrative Status	Up

Configuring Router2

Router2 configuration is the same as Router1, except Router2 also has the DSL interface to configure.

The DSL interface is configured with a username of “user1” and a password of “ospf_example”. The default gateway will be retrieved from the ISP, and the defaults will be used for the rest of the PPPoE settings.

To configure Router2 interfaces - web-based manager

1. Go to **Dashboard > System Information**.
2. Beside the host name, select **Change**.
3. Enter a hostname of `Router2`, and select **OK**.
4. Go to **Network > Interfaces**, edit port1, set the following information, and select **OK**.

Alias	internal

IP/Network Mask	10.11.101.2/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Head office and Router1
Administrative Status	Up

5. Edit port2, set the following information, and select **OK**.

Alias	External
IP/Network Mask	10.11.103.2/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router3
Administrative Status	Up

6. Edit DSL (port3), set the following information, and select **OK**.

Alias	DSL
Addressing Mode	PPPoE
Username	user1
Password	ospf_example
Unnumbered IP	10.12.101.2/255.255.255.0
Retrieve default gateway from server	Enable
Administrative Access	HTTPS SSH PING
Description	DSL
Administrative Status	Up

Configuring Router3

Router3 is similar to Router1 and Router2 configurations. The main difference is the External (port3) interface connected to the ISP BGP network which has no administration access enabled for security reasons.

To configure Router3 interfaces - web-based manager

1. Go to **Dashboard > System Information**.
2. Next to hostname, select **Change**.
3. Enter a hostname of `Router3`, and select **OK**.
4. Go to **Network > Interfaces, e**dit port1, set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.11.102.3/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router1
Administrative Status	Up

5. Edit port2, set the following information, and select **OK**.

Alias	Internal2
IP/Network Mask	10.11.103.3/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router2
Administrative Status	Up

6. Edit port3, set the following information, and select **OK**.

Alias	External
IP/Network Mask	172.20.120.3/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	ISP BGP
Administrative Status	Up

Configuring OSPF on the FortiGate units

With the interfaces configured, now the FortiGate units can be configured for OSPF on those interfaces. All routers are part of the backbone 0.0.0.0 area, so there is no inter-area communications needed.

For a simple configuration there will be no authentication, no graceful restart or other advanced features, and timers will be left at their defaults. Also the costs for all interfaces will be left at 10, except for the modem and ISP interfaces where cost will be used to load balance traffic. Nearly all advanced features of OSPF are only available from the CLI.

The network that is defined covers all the subnets used in this example - 10.11.101.0, 10.11.102.0, and 10.11.103.0. All routes for these subnets will be advertised. If there are other interfaces on the FortiGate units that you do not want included in the OSPF routes, ensure those interfaces use a different subnet outside of the 10.11.0.0 network. If you want all interfaces to be advertised you can use an OSPF network of 0.0.0.0 .

Each router will configure:

- Router ID
- Area
- Network

- Two or three interfaces depending on the router
- Priority for DR (Router1) and BDR (Router2)
- Redistribute for ASBR (Router3)

This section includes:

- Configuring OSPF on Router1
- Configuring OSPF on Router2
- Configuring OSPF on Router3

Configuring OSPF on Router1

Router1 has a very high priority to ensure it becomes the DR for this area. Also Router1 has the lowest IP address to help ensure it will win in case there is a tie at some point. Otherwise it is a standard OSPF configuration. Setting the priority can only be done in the CLI, and it is for a specific OSPF interface.

To configure OSPF on Router1 - web-based manager

1. Go to **Network > OSPF**.
2. Set **Router ID** to `10.11.101.1` and select **Apply**.
3. In **Areas**, select **Create New,** set the following information, and select **OK**.

Area	0.0.0.0
Type	Regular
Authentication	none

4. In **Networks**, select **Create New**, set the following information, and select **OK**.

IP/Netmask	10.11.0.0/255.255.0.0
Area	0.0.0.0

5. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name		Router1-Internal-DR
Interface		port1 (Internal)
IP		0.0.0.0
Authentication		none
Timers (seconds)		
	Hello Interval	10
	Dead Interval	40

6. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name		Router1-External
Interface		port2 (External)
IP		0.0.0.0
Authentication		none
Timers (seconds)		
	Hello Interval	10
	Dead Interval	40

7. Using the CLI, enter the following commands to set the priority for the Router1-Internal OSPF interface to maximum, ensuring this interface becomes the DR.

```
config router ospf
   config ospf-interface
      edit Router1-Internal-DR
         set priority 255
      end
```

To configure OSPF on Router1 - CLI

```
config router ospf
   set router-id 10.11.101.1
   config area
      edit 0.0.0.0
      next
   end
   config network
      edit 1
         set prefix 10.11.0.0/255.255.255.0
      next
   end
   config ospf-interface
      edit "Router1-Internal"
         set interface "port1"
         set priority 255
      next
      edit "Router1-External"
         set interface "port2"
      next
   end
end
```

Configuring OSPF on Router2

Router2 has a high priority to ensure it becomes the BDR for this area, and configures the DSL interface slightly differently—assume this will be a slower connection resulting in the need for longer timers, and a higher cost for this route.

Otherwise it is a standard OSPF configuration.

To configure OSPF on Router2 - web-based manager

1. Go to **Network > OSPF**.
2. Set **Router ID** to `10.11.101.2` and select **Apply**.
3. In **Areas**, select **Create New**, set the following information, and select **OK**.

Area	0.0.0.0
Type	Regular
Authentication	none

4. In **Networks**, select **Create New**, set the following information, and select **OK**.

IP/Netmask	10.11.0.0/255.255.0.0
Area	0.0.0.0

5. In **Interfaces**, select **Create New,** set the following information, and select **OK**.

Name	Router2-Internal
Interface	port1 (Internal)
IP	0.0.0.0
Authentication	none
Timers (seconds)	
Hello Interval	10
Dead Interval	40

6. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name	Router2-External
Interface	port2 (External)
IP	0.0.0.0
Authentication	none
Timers (seconds)	
Hello Interval	10
Dead Interval	40

7. In **Interfaces**, select **Create New,** set the following information, and select **OK**.

Name		Router2-DSL
Interface		port3 (DSL)
IP		0.0.0.0
Authentication		none
Cost		50
Timers (seconds)		
	Hello Interval	20
	Dead Interval	80

8. Using the CLI, enter the following commands to set the priority for the Router2-Internal OSPF interface to ensure this interface will become the BDR:

```
config router ospf
   config ospf-interface
      edit Router2-Internal
         set priority 250
      next
   end
```

To configure OSPF on Router2 - CLI

```
config router ospf
   set router-id 10.11.101.2
   config area
      edit 0.0.0.0
      next
   end
   config network
      edit 1
         set prefix 10.11.0.0/255.255.0.0
      next
   end
   config ospf-interface
      edit "Router2-Internal"
         set interface "port1"
         set priority 255
      next
      edit "Router2-External"
         set interface "port2"
      next
      edit "Router2-DSL"
         set interface "port3"
         set cost 50
      next
   end
end
```

Configuring OSPF on Router3

Router3 is more complex than the other two routers. The interfaces are straightforward, but this router has to import and export routes between OSPF and BGP. That requirement makes Router3 a border router or ASBR. Also Router3 needs a lower cost on its route to encourage all traffic to the Internet to route through it.

In the advanced OSPF options, Redistribute is enabled for Router3. It allows different types of routes, learned outside of OSPF, to be used in OSPF. Different metrics are assigned to these other types of routes to make them more or less preferred to regular OSPF routes.

To configure OSPF on Router3 - web-based manager

1. Go to **Network > OSPF**.
2. Set **Router ID** to `10.11.101.2` and select **Apply**.
3. Expand **Advanced Options**.
4. In **Redistribute**, set the following information, and select **OK**.

Route type	Redistribute	Metric
Connected	Enable	15
Static	Enable	15
RIP	Disable	n/a
BGP	Enable	5

5. In **Areas**, select **Create New**, set the following information, and select **OK**.

Area	0.0.0.0
Type	Regular
Authentication	none

6. In **Networks**, select **Create New**, set the following information, and select **OK**.

IP/Netmask	10.11.0.0/255.255.0.0
Area	0.0.0.0

7. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name	Router3-Internal
Interface	port1 (Internal)
IP	0.0.0.0
Authentication	none

Timers (seconds)		
	Hello Interval	10
	Dead Interval	40

8. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name		Router3-Internal2
Interface		port2 (Internal2)
IP		0.0.0.0
Authentication		none
Timers (seconds)		
	Hello Interval	10
	Dead Interval	40

9. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name		Router3-ISP-BGP
Interface		port3 (ISP-BGP)
IP		0.0.0.0
Authentication		none
Cost		2
Timers (seconds)		
	Hello Interval	20
	Dead Interval	80

10. Using the CLI, enter the following commands to set the priority for the Router3-Internal OSPF interface to ensure this interface will become the BDR.

```
config router ospf
   config ospf-interface
   edit Router3-Internal
      set priority 250
   next
end
```

To configure OSPF on Router3 - CLI

```
config router ospf
   set router-id 10.11.102.3
   config area
      edit 0.0.0.0
```

```
      next
    end
    config network
      edit 1
        set prefix 10.11.0.0/255.255.255.0
      next
      edit 2
        set prefix 172.20.120.0/255.255.255.0
      next
    end
    config ospf-interface
      edit "Router3-Internal"
        set interface "port1"
        set priority 255
      next
      edit "Router3-External"
        set interface "port2"
      next
      edit "Router3-ISP-BGP"
        set interface "port3"
        set cost 2
      next
    end
  end
```

Configuring other networking devices

The other networking devices required in this configuration are on the two ISP networks, the BGP network for the main Internet connection, and the DSL backup connection.

In both cases, the ISPs need to be notified of the OSPF network settings including router IP addresses, timer settings, and so on. The ISP will use this information to configure its routers that connect to this OSPF network.

Testing network configuration

Testing the network configuration involves two parts: testing the network connectivity, and testing the OSPF routing.

To test the network connectivity use ping, traceroute, and other network tools.

To test the OSPF routing in this example, refer to the troubleshooting outlined in Basic OSPF example on page 2438.

Advanced inter-area OSPF example

This example sets up an OSPF network at a large office. There are three areas, each with two routers. Typically OSPF areas would not be this small, and if they were the areas would be combined into one bigger area. However, the stub area services the accounting department which is very sensitive about their network and do not want any of their network information broadcast through the rest of the company. The backbone area contains the bulk of the company network devices. The regular area was established for various reasons such as hosting the company servers on a separate area with extra security.

One area is a small stub area that has no independent Internet connection, and only one connection to the backbone area. That connection between the stub area and the backbone area is only through a default route. No routes outside the stub area are advertised into that area. Another area is the backbone, which is connected to

the other two areas. The third area has the Internet connection, and all traffic to and from the Internet must use that area's connection. If that traffic comes from the stub area, then that traffic is treating the backbone like a transit area that only uses it to get to another area.

In the stub area, a subnet of computers is running the RIP routing protocol and those routes must be redistributed into the OSPF areas.

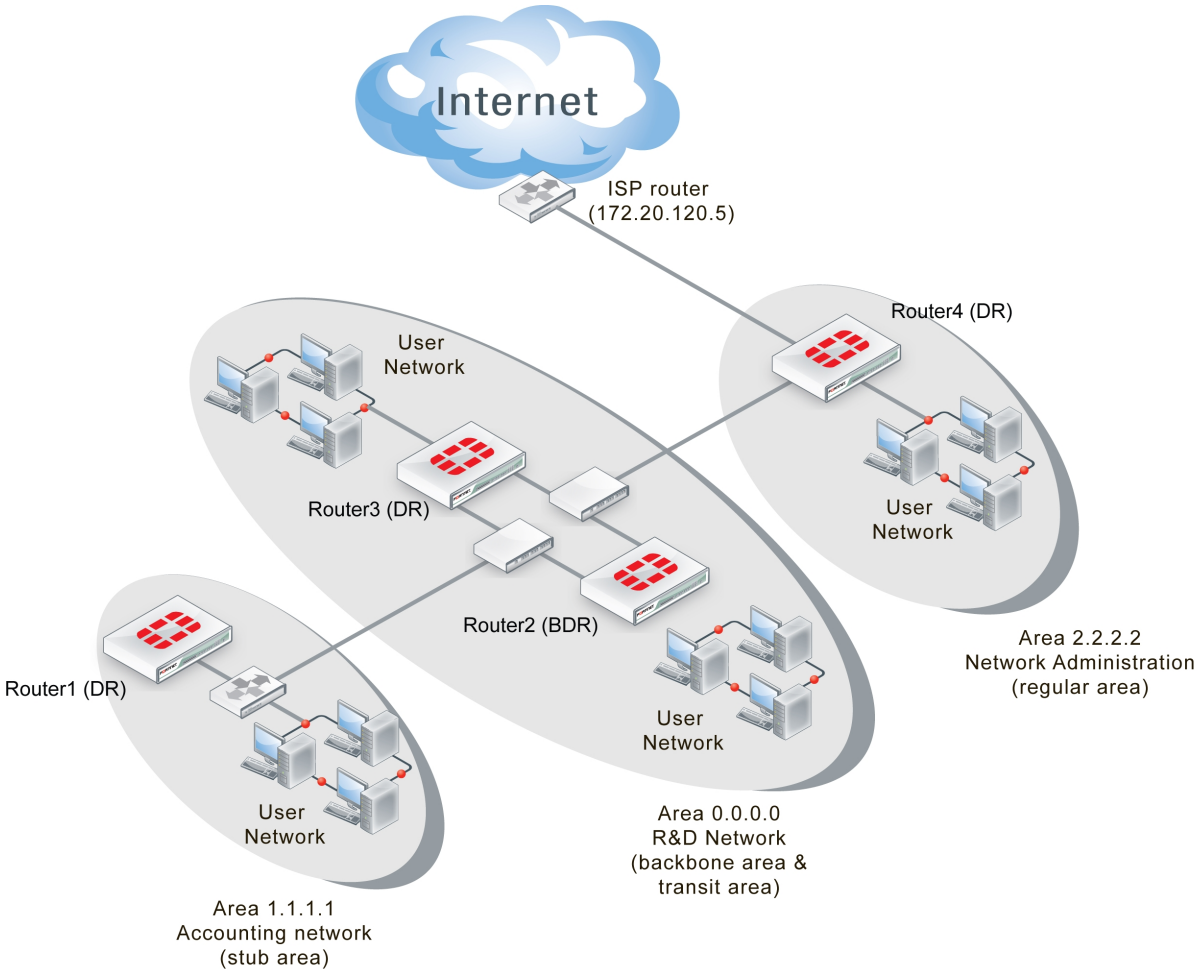
This section includes the following topics:

- Network layout and assumptions
- Configuring the FortiGate units
- Configuring OSPF on the FortiGate units
- Configuring other networking devices
- Testing network configuration

Network layout and assumptions

There are four FortiGate units in this network topology acting as OSPF routers:

Advanced inter-area OSPF network topology



Area 1.1.1.1 is a stub area with one FortiGate unit OSPF router called Router1 (DR). Its only access outside of that area is a default route to the backbone area, which is how it accesses the Internet. Traffic must go from the stub area, through the backbone, to the third area to reach the Internet. The backbone area in this configuration is called a transit area. Also in area 1.1.1.1 there is a RIP router that will be providing routes to the OSPF area through redistribution.

Area 0.0.0.0 is the backbone area, and has two FortiGate unit routers named Router2 (BDR) and Router3 (DR).

Area 2.2.2.2 is a regular area that has an Internet connection accessed by both the other two OSPF areas. There is only one FortiGate unit router in this area called Router4 (DR). This area is more secure and requires MD5 authentication by routers.

All areas have user networks connected, but they are not important for configuring the network layout for this example.

Internal interfaces are connected to internal user networks only. External1 interfaces are connected to the 10.11.110.0 network, joining Area 1.1.1.1 and Area 0.0.0.0.

External2 interfaces are connected to the 10.11.111.0 network, joining Area 0.0.0.0 and Area 2.2.2.2. The ISP interface is called ISP.

Routers, areas, interfaces, IP addresses for advanced OSPF network

Router name	Area number and type	Interface	IP address
Router1 (DR)	1.1.1.1 - stub area (Accounting)	port1 (internal)	10.11.101.1
		port2 (external1)	10.11.110.1
Router2 (BDR)	0.0.0.0 - backbone area (R&D Network)	port1 (internal)	10.11.102.2
		port2 (external1)	10.11.110.2
		port3 (external2)	10.11.111.2
Router3 (DR)	0.0.0.0 - backbone area (R&D Network)	port1 (internal)	10.11.103.3
		port2 (external1)	10.11.110.3
		port3 (external2)	10.11.111.3
Router4 (DR)	2.2.2.2 - regular area (Network Admin)	port1 (internal)	10.11.104.4
		port2 (external2)	10.11.111.4
		port3 (ISP)	172.20.120.4

Note that other subnets can be added to the internal interfaces without changing the configuration.

Assumptions

- The FortiGate units used in this example have interfaces named port1, port2, and port3.
- All FortiGate units in this example have factory default configuration with FortiOS 4.0 MR2 firmware installed, and are in NAT/Route operation mode.
- During configuration, if settings are not directly referred to they will be left at default settings.
- Basic firewalls are in place to allow unfiltered traffic between all connected interfaces in both directions.
- This OSPF network is not connected to any other OSPF areas outside of this example.
- The Internet connection is always available.
- Other devices may be on the network, but do not affect this configuration.

Configuring the FortiGate units

This section configures the basic settings on the FortiGate units to be OSPF routers. These configurations include multiple interface settings, and hostname.

There are four FortiGate units in this example. The two units in the backbone area can be configured exactly the same except for IP addresses, so only router3 (the DR) configuration will be given with notes indicating router2 (the BDR) IP addresses.

Configuring the FortiGate units includes:

- Configuring Router1
- Configuring Router2
- Configuring Router3
- Configuring Router4

Configuring Router1

Router1 is part of the Accounting network stub area (1.1.1.1).

To configure Router1 interfaces - web-based manager

1. Go to **Dashboard > System Information**.
2. Next to hostname, select **Change**.
3. Enter a hostname of `Router1`, and select **OK**.
4. Go to **Network > Interfaces,** edit port1, set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.11.101.1/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Accounting network
Administrative Status	Up

5. Edit port2, set the following information, and select **OK**.

Alias	External1
IP/Network Mask	10.11.110.1/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Backbone network and Internet
Administrative Status	Up

Configuring Router2

Router2 is part of the R&D network backbone area (0.0.0.0). Router2 and Router3 are in this area. They provide a redundant connection between area 1.1.1.1 and area 2.2.2.2.

Router2 has three interfaces configured; one to the internal network, and two to Router3 for redundancy.

To configure Router2 interfaces - web-based manager

1. Go to **Dashboard > System Information**.
2. Next to hostname, select **Change**.
3. Enter a hostname of `Router2`, and select **OK**.
4. Go to **Network > Interfaces**, edit port1 (internal), set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.11.102.2/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Internal RnD network
Administrative Status	Up

5. Edit port2 (external1), set the following information, and select **OK**.

Alias	external1
IP/Network Mask	10.11.110.2/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router3 first connection
Administrative Status	Up

6. Edit port3 (external2), set the following information, and select **OK**.

Alias	external2
IP/Network Mask	10.11.111.2/255.255.255.0

Administrative Access	HTTPS SSH PING
Description	Router3 second connection
Administrative Status	Up

Configuring Router3

Router3 is part of the R&D network backbone area (0.0.0.0). Router2 and Router3 are in this area. They provide a redundant connection between area 1.1.1.1 and area 2.2.2.2.

To configure Router3 interfaces - web-based manager

1. Go to **Dashboard > System Information**.
2. Next to hostname, select **Change**.
3. Enter a hostname of `Router3`, and select **OK**.
4. Go to **Network > Interfaces**, edit port1 (internal), set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.11.103.3/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Internal RnD network
Administrative Status	Up

5. Edit port2 (external1), set the following information, and select **OK**.

Alias	external1
IP/Network Mask	10.11.110.3/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router2 first connection
Administrative Status	Up

6. Edit port3 (external2), set the following information, and select **OK**.

Alias	external2
IP/Network Mask	10.11.111.3/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router2 second connection
Administrative Status	Up

Configuring Router4

Router4 is part of the Network Administration regular area (2.2.2.2). This area provides Internet access for both area 1.1.1.1 and the backbone area.

This section configures interfaces and hostname.

To configure Router4 interfaces - web-based manager

1. Go to **Dashboard > System Information**.
2. Next to hostname, select **Change**.
3. Enter a hostname of `Router4`, and select **OK**.
4. Go to **Network > Interfaces**.
5. Edit port1 (internal).
6. Set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.11.101.4/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Accounting network
Administrative Status	Up

7. Edit port2 (external2).
8. Set the following information, and select **OK**.

Alias	external2
IP/Network Mask	10.11.110.4/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Backbone and Accounting network
Administrative Status	Up

9. Edit port3 (ISP).
10. Set the following information, and select **OK**.

Alias	ISP
IP/Network Mask	172.20.120.4/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	ISP and Internet
Administrative Status	Up

Configuring OSPF on the FortiGate units

Three of the routers are designated routers (DR) and one is a backup DR (BDR). This is achieved through the lowest router ID numbers, or OSPF priority settings.

Also each area needs to be configured as each respective type of area - stub, backbone, or regular. This affects how routes are advertised into the area.

To configure OSPF on Router1 - web-based manager

1. Go to **Network > OSPF**.
2. Enter `10.11.101.1` for the **Router ID** and select **Apply**.
3. In **Areas**, select **Create New,** set the following information, and select **OK**.

Area	1.1.1.1
Type	Stub
Authentication	None

4. In **Networks**, select **Create New,** set the following information, and select **OK**.

IP/Netmask	10.11.101.0/255.255.255.0
Area	1.1.1.1

5. In **Interfaces**, select **Create New,** set the following information, and select **OK**.

Name	Accounting
Interface	port1 (internal)
IP	10.11.101.1
Authentication	None

6. In **Interfaces**, select **Create New,** set the following information, and select **OK**.

Name	Backbone1
Interface	port2 (external1)
IP	10.11.110.1
Authentication	None

To configure OSPF on Router2 - web-based manager

1. Go to **Network > OSPF**.
2. Enter `10.11.102.2` for the **Router ID** and select **Apply**.
3. In **Areas**, select **Create New,** set the following information, and select **OK**.

Area	0.0.0.0
Type	Regular
Authentication	None

4. In **Networks**, select **Create New,** set the following information, and select **OK**.

IP/Netmask	10.11.102.2/255.255.255.0
Area	0.0.0.0

5. In **Networks**, select **Create New,** set the following information, and select **OK**.

IP/Netmask	10.11.110.2/255.255.255.0
Area	0.0.0.0

6. In **Networks**, select **Create New,** set the following information, and select **OK**.

IP/Netmask	10.11.111.2/255.255.255.0
Area	0.0.0.0

7. In **Interfaces**, select **Create New,** set the following information, and select **OK**.

Name	RnD network
Interface	port1 (internal)
IP	10.11.102.2
Authentication	None

8. In **Interfaces**, select **Create New,** set the following information, and select **OK**.

Name	Backbone1
Interface	port2 (external1)
IP	10.11.110.2
Authentication	None

9. In **Interfaces**, select **Create New,** set the following information, and select **OK**.

Name	Backbone2
Interface	port3 (external2)

IP	10.11.111.2
Authentication	None

To configure OSPF on Router3 - web-based manager

1. Go to **Network > OSPF**.
2. Enter `10.11.103.3` for the **Router ID** and then select **Apply**.
3. In **Areas**, select **Create New, s**et the following information, and then select **OK**.

Area	0.0.0.0
Type	Regular
Authentication	None

4. In **Networks**, select **Create New,** set the following information, and select **OK**.

IP/Netmask	10.11.102.3/255.255.255.0
Area	0.0.0.0

5. In **Networks**, select **Create New,** set the following information, and select **OK**.

IP/Netmask	10.11.110.3/255.255.255.0
Area	0.0.0.0

6. In **Networks**, select **Create New,** set the following information, and select **OK**.

IP/Netmask	10.11.111.3/255.255.255.0
Area	0.0.0.0

7. In **Interfaces**, select **Create New,** set the following information, and select **OK**.

Name	RnD network
Interface	port1 (internal)
IP	10.11.103.3
Authentication	None

8. In **Interfaces**, select **Create New,** set the following information, and select **OK**.

Name	Backbone1
Interface	port2 (external1)

IP	10.11.110.3
Authentication	None

9. In **Interfaces**, select **Create New,** set the following information, and select **OK**.

Name	Backbone2
Interface	port3 (external2)
IP	10.11.111.3
Authentication	None

To configure OSPF on Router4 - web-based manager

1. Go to **Network > OSPF**.
2. Enter `10.11.104.4` for the **Router ID** and then select **Apply**.
3. In **Areas**, select **Create New**.
4. Set the following information, and select **OK**.

Area	2.2.2.2
Type	Regular
Authentication	None

5. In **Networks**, select **Create New,** set the following information, and select **OK**.

IP/Netmask	10.11.104.0/255.255.255.0
Area	0.0.0.0

6. In **Networks**, select **Create New**, set the following information, and select **OK**.

IP/Netmask	10.11.111.0/255.255.255.0
Area	0.0.0.0

7. In **Networks**, select **Create New**, set the following information, and select **OK**.

IP/Netmask	172.20.120.0/255.255.255.0
Area	0.0.0.0

8. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name	Network Admin network

Interface	port1 (internal)
IP	10.11.104.4
Authentication	None

9. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name	Backbone2
Interface	port2 (external2)
IP	10.11.111.4
Authentication	None

10. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name	ISP
Interface	port3 (ISP)
IP	172.20.120.4
Authentication	None

Configuring other networking devices

All network devices on this network are running OSPF routing. The user networks (Accounting, R&D, and Network Administration) are part of one of the three areas.

The ISP needs to be notified of your network configuration for area 2.2.2.2. Your ISP will not advertise your areas externally as they are intended as internal areas. External areas have assigned unique numbers. The area numbers used in this example are similar to the 10.0.0.0 and 192.168.0.0 subnets used in internal networking.

Testing network configuration

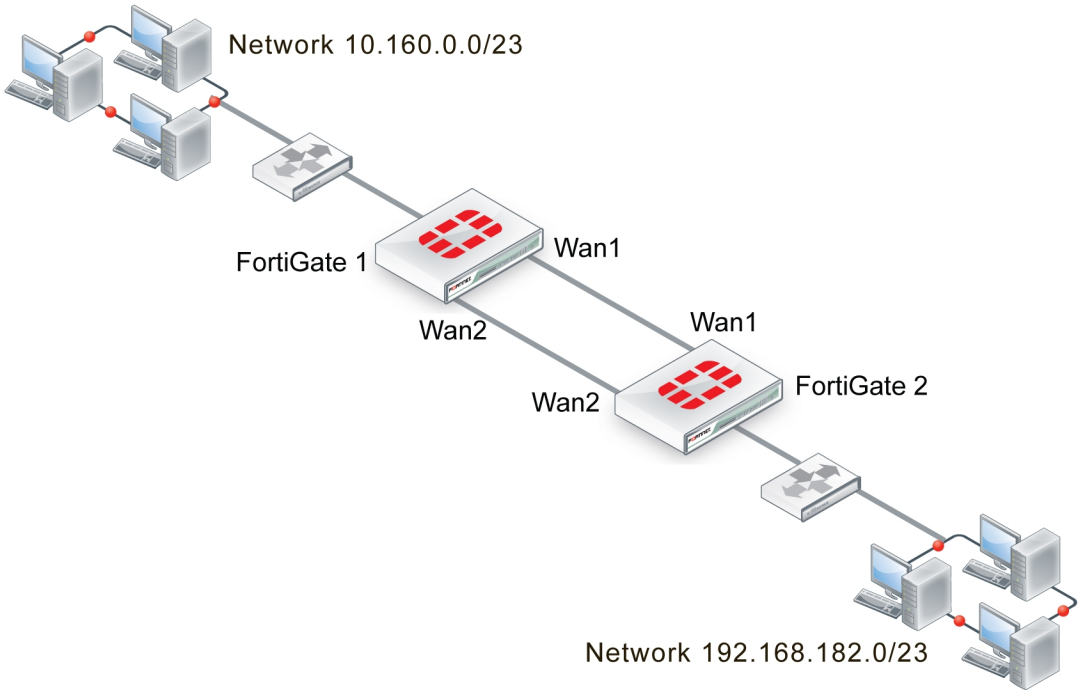
There are two main areas to test in this network configuration; network connectivity, and OSPF routing.

To test the network connectivity, see if computers on the Accounting or R&D networks can access the Internet. If you need to troubleshoot network connectivity, see the FortiOS Handbook Troubleshooting chapter.

To test the OSPF routing, check the routing tables on the FortiGate units to ensure the expected OSPF routes are present. If you need help troubleshooting OSPF routing, see Advanced inter-area OSPF example on page 2450.

Controlling redundant links by cost

In this scenario, two FortiGate units have redundant links: one link between their WAN1 interfaces and another between their WAN2 interfaces.



FortiGate 1 should learn the route to network 192.168.182.0 and FortiGate 2 should learn the route to network 10.160.0.0. Under normal conditions, they should learn these routes through the WAN1 link. The WAN2 link should be used only as a backup.

With the default settings, each FortiGate unit learns these routes from both WAN1 and WAN2.

FortiGate 1:

```
FGT1 # get router info ospf neighbor
OSPF process 0:
Neighbor ID Pri State Dead Time Address Interface
10.2.2.2 1 Full/Backup 00:00:33 10.182.0.187 wan1
10.2.2.2 1 Full/Backup 00:00:31 10.183.0.187 wan2
FGT1 # get router info routing-table ospf
O*E2 0.0.0.0/0 [110/10] via 10.183.0.187, wan2, 00:00:01
[110/10] via 10.182.0.187, wan1, 00:00:01
O 192.168.182.0/23 [110/20] via 10.183.0.187, wan2, 00:02:04
[110/20] via 10.182.0.187, wan1, 00:02:04
```

FortiGate 2:

```
FGT2 # get router info ospf neighbor
OSPF process 0:
Neighbor ID Pri State Dead Time Address Interface
10.1.1.1 1 Full/DR 00:00:38 10.182.0.57 wan1
10.1.1.1 1 Full/DR 00:00:38 10.183.0.57 wan2
FGT2 # get router info routing-table ospf
O 10.160.0.0/23 [110/20] via 10.183.0.57, wan2, 00:00:39
[110/20] via 10.182.0.57, wan1, 00:00:39
```

Adjusting the route costs

On both FortiGate units, the cost of the route through WAN2 is adjusted higher so that this route will only be used if the route through WAN1 is unavailable. The default cost is 10. The WAN2 route will be changed to a cost of 200.

On both FortiGate units:

```
config router ospf
   config ospf-interface
      edit "WAN2_higher_cost"
         set cost 200
         set interface "wan2"
      end
```

Now both FortiGate units use only the WAN1 route:

FortiGate 1:

```
FGT1 # get router info routing-table ospf
O*E2 0.0.0.0/0 [110/10] via 10.182.0.187, wan1, 00:00:40
O 192.168.182.0/23 [110/20] via 10.182.0.187, wan1, 00:00:40
```

FortiGate 2:

```
FGT2 # get router info routing-table ospf
O 10.160.0.0/23 [110/20] via 10.182.0.57, wan1, 00:09:37
```

LSDB check on FortiGate 1:

```
FGT1 # get router info ospf database router lsa
Router Link States (Area 0.0.0.0)

   (Link ID) Network/subnet number: 192.168.182.0
   (Link Data) Network Mask: 255.255.254.0
   Number of TOS metrics: 0
   TOS 0 Metric: 10

   Link connected to: a Transit Network
   (Link ID) Designated Router address: 10.183.0.187
   (Link Data) Router Interface address: 10.183.0.187
   Number of TOS metrics: 0
   TOS 0 Metric: 200

   Link connected to: a Transit Network
   (Link ID) Designated Router address: 10.182.0.57
   (Link Data) Router Interface address: 10.182.0.187
   Number of TOS metrics: 0
   TOS 0 Metric: 10
```

Verifying route redundancy

Bring down WAN1 and then check the routes on the two FortiGate units.

FortiGate 1:

```
FGT1 # get router info routing-table ospf
FGT1 # get router info routing-table ospf
O*E2 0.0.0.0/0 [110/10] via 10.183.0.187, wan2, 00:00:06
O 192.168.182.0/23 [110/210] via 10.183.0.187, wan2, 00:00:06
```

FortiGate 2:

```
FGT2 # get router info routing-table ospf
O 10.160.0.0/23 [110/210] via 10.183.0.57, wan2, 00:00:14
```

The WAN2 interface is now in use on both units.

Border Gateway Protocol (BGP)

This section describes Border Gateway Protocol (BGP).

The following topics are included in this section:

BGP background and concepts

The border gateway protocol contains two distinct subsets — internal BGP (iBGP) and external BGP (eBGP). iBGP is intended for use within your own networks. eBGP is used to connect many different networks together, and is the main routing protocol for the Internet backbone. FortiGate units support iBGP, and eBGP only for communities.

The following topics are included in this section:

- Background
- Parts and terminology of BGP
- How BGP works

Background

BGP was first used in 1989. The current version, BGP-4, was released in 1995 and is defined in RFC 1771. That RFC has since been replaced by the more recent RFC 4271. The main benefits of BGP-4 are classless inter-domain routing, and aggregate routes. BGP is the only routing protocol to use TCP for a transport protocol. Other routing protocols use UDP.

BGP makes routing decisions based on path, network policies and rulesets instead of the hop-count metric as RIP does, or cost-factor metrics as OSPF does.

BGP-4+ supports IPv6. It was introduced in RFC 2858 and RFC 2545.

BGP is the routing protocol used on the Internet. It was designed to replace the old Exterior Gateway Protocol (EGP) which had been around since 1982, and was very limited. In doing so, BGP enabled more networks to take part in the Internet backbone to effectively decentralize it and make the Internet more robust, and less dependent on a single ISP or backbone network.

Parts and terminology of BGP

In a BGP network, there are some terms that need to be explained before going ahead. Some parts of BGP are not explained here as they are common to other dynamic routing protocols as well. When determining your network topology, note that the number of available or supported routes is not set by the configuration but depends on your FortiGate's available memory. For more information on parts of BGP that are not listed here, see Dynamic Routing Overview on page 2371.

BGP and IPv6

FortiGate units support IPv6 over BGP using the same `config router bgp` command as IPv4, but different subcommands.

The main CLI keywords have IPv6 equivalents that are identified by the “6” on the end of the keyword, such as with `config network6` or `set allowas-in6`. For more information about IPv6 BGP keywords, see the FortiGate CLI Reference.

IPv6 BGP commands include:

```
config router bgp
   set activate6 {enable | disable}
   set allowas-in6 <max_num_AS_integer>
   set allowas-in-enable6 {enable | disable}
   set as-override6 {enable | disable}
   set attribute-unchanged6 [as-path] [med] [next-hop]
   set capability-default-originate6 {enable | disable}
   set capability-graceful-restart6 {enable | disable}
   set capability-orf6 {both | none | receive | send}
   set default-originate-route-map6 <routemap_str>
   set distribute-list-in6 <access-list-name_str>
   set distribute-list-out6 <access-list-name_str>
   set filter-list-in6 <aspath-list-name_str>
   set filter-list-out6 <aspath-list-name_str>
   set maximum-prefix6 <prefix_integer>
   set maximum-prefix-threshold6 <percentage_integer>
   set maximum-prefix-warning-only6 {enable | disable}
   set next-hop-self6 {enable | disable}
   set prefix-list-in6 <prefix-list-name_str>
   set prefix-list-out6 <prefix-list-name_str>
   set remove-private-as6 {enable | disable}
   set route-map-in6 <routemap-name_str>
   set route-map-out6 <routemap-name_str>
   set route-reflector-client6 {enable | disable}
   set route-server-client6 {enable | disable}
   set send-community6 {both | disable | extended | standard}
   set soft-reconfiguration6 {enable | disable}
   set unsuppress-map6 <route-map-name_str>
   config network6
   config redistribute6
end
```

Roles of routers in BGP networks

Dynamic routing has a number of different roles routers can fill such as those covered in Dynamic Routing Overview on page 2371. BGP has a number of custom roles that routers can fill. These include:

- Speaker routers
- Peer routers or neighbors
- Route reflectors (RR)

Speaker routers

Any router configured for BGP is considered a BGP speaker. This means that a speaker router advertises BGP routes to its peers.

Any routers on the network that are not speaker routers, are not treated as BGP routers.

Peer routers or neighbors

In a BGP network, all neighboring BGP routers or peer routers are routers that are connected to your FortiGate unit. Your FortiGate unit learns about all other routers through these peers.

You need to manually configure BGP peers on your FortiGate unit as neighbors. Otherwise these routers will not be seen as peers, but instead as simply other routers on the network that don't support BGP. You can optionally use MD5 authentication to password protect BGP sessions with those neighbors. (see RFC 2385).

You can configure up to 1000 BGP neighbors on your FortiGate unit. You can clear all or some BGP neighbor connections (sessions) using the `execute router clear bgp` command.

For example, if you have 10 routes in the BGP routing table and you want to clear the specific route to IP address 10.10.10.1, enter the command:

```
execute router clear bgp ip 10.10.10.1
```

To remove all routes for AS number 650001, enter the command:

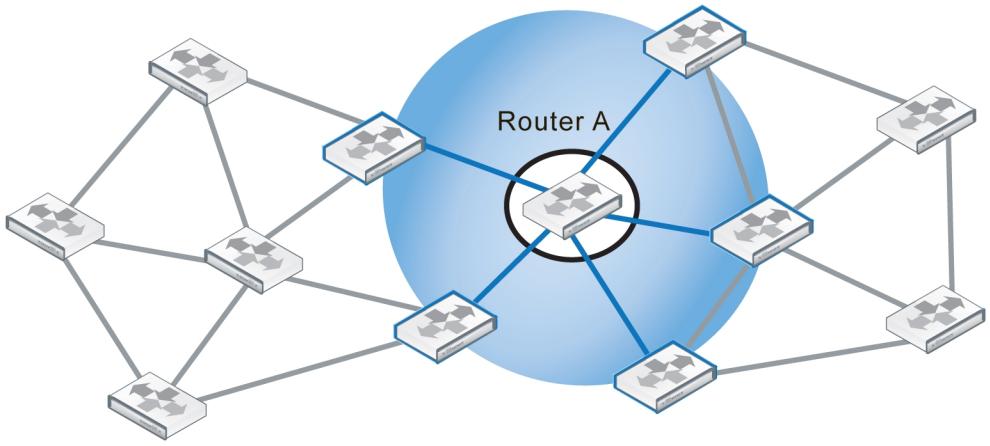
```
execute router clear bgp as 650001
```

To remove route flap dampening information for the 10.10.0.0/16 subnet, enter the command:

```
execute router clear bgp dampening 10.10.0.0/16
```

In Figure 1, Router A is directly connected to five other routers in a network that contains 12 routers overall. These routers, the ones in the blue circle, are Router A's peers or neighbors.

Router A and its 5 peer routers



As a minimum, when configuring BGP neighbors you must enter their IP address, and the AS number (remote-as). This is all the information the web-based manager interface allows you to enter for a neighbor.

The BGP commands related to neighbors are quite extensive and include:

```
config router bgp
   config neighbor
      edit <neighbor_address_ipv4>
         set activate {enable | disable}
         set advertisement-interval <seconds_integer>
         set allowas-in <max_num_AS_integer>
         set allowas-in-enable {enable | disable}
         set as-override {enable | disable}
         set attribute-unchanged [as-path] [med] [next-hop]
         set bfd {enable | disable}
```

```
            set capability-default-originate {enable | disable}
            set capability-dynamic {enable | disable}
            set capability-graceful-restart {enable | disable}
            set capability-orf {both | none | receive | send}
            set capability-route-refresh {enable | disable}
            set connect-timer <seconds_integer>
            set description <text_str>
            set distribute-list-in <access-list-name_str>
            set distribute-list-out <access-list-name_str>
            set dont-capability-negotiate {enable | disable}
            set ebgp-enforce-multihop {enable | disable}
            set ebgp-multihop {enable | disable}
            set ebgp-multihop-ttl <seconds_integer>
            set filter-list-in <aspath-list-name_str>
            set filter-list-out <aspath-list-name_str>
            set holdtime-timer <seconds_integer>
            set interface <interface-name_str>
            set keep-alive-timer <seconds_integer>
            set maximum-prefix <prefix_integer>
            set maximum-prefix-threshold <percentage_integer>
            set maximum-prefix-warning-only {enable | disable}
            set next-hop-self {enable | disable}
            set passive {enable | disable}
            set password <string>
            set prefix-list-in <prefix-list-name_str>
            set prefix-list-out <prefix-list-name_str>
            set remote-as <id_integer>
            set remove-private-as {enable | disable}
            set retain-stale-time <seconds_integer>
            set route-map-in <routemap-name_str>
            set route-map-out <routemap-name_str>
            set route-reflector-client {enable | disable}
            set route-server-client {enable | disable}
            set send-community {both | disable | extended | standard}
            set shutdown {enable | disable}
            set soft-reconfiguration {enable | disable}
            set strict-capability-match {enable | disable}
            set unsuppress-map <route-map-name_str>
            set update-source <interface-name_str>
            set weight <weight_integer>
        end
    end
end
```

Route reflectors (RR)

Route reflectors in BGP concentrate route updates so other routers need only talk to the route reflectors to get all the updates. This results in smaller routing tables, fewer connections between routers, faster responses to network topology changes, and less administration bandwidth. BGP route reflectors are defined in RFC 1966.

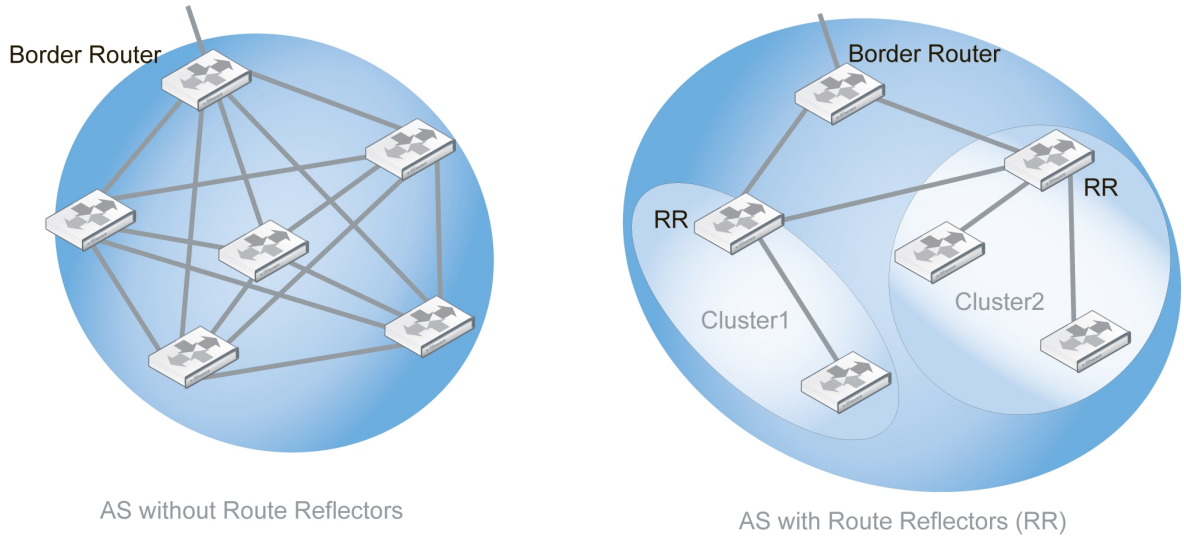
In a BGP route reflector configuration, the AS is divided into different clusters that each include client and reflector routers. The client routers supply the reflector routers with the client's route updates. The reflectors pass this information along to other route reflectors and border routers. Only the reflectors need to be configured, not the clients — the clients will find the closest reflector and communicate with it automatically. The reflectors communicate with each other as peers. FortiGate units can be configured as either reflectors or clients.

Since route reflectors are processing more than the client routers, the reflectors should have more resources to handle the extra workload.

Smaller networks running BGP typically don't require route reflectors (RR). However, RR is a useful feature for large companies, where their AS may include 100 routers or more. For example, for a full mesh 20 router configuration within an AS, there would have to be 190 unique BGP sessions — just for routing updates within the AS. The number of sessions jumps to 435 sessions for just 30 routers, or 4950 sessions for 100 routers. From these numbers, its plain that updating this many sessions will quickly consume the limited bandwidth and processing resources of the routers involved.

The following diagram illustrates how route reflectors can improve the situation when only six routers are involved. The AS without route reflectors requires 15 sessions between the routers. In the AS with route reflectors, the two route reflectors receive route updates from the reflector clients (unlabeled routers in the diagram) in their cluster as well as other route reflectors and pass them on to the border router. The RR configuration only require six sessions. This example shows a reduction of 60% in the number of required sessions.

Required sessions within an AS with and without route reflectors



The BGP commands related to route reflectors includes:

```
config router bgp
   config neighbor
      set route-reflector-client {enable | disable}
      set route-server-client {enable | disable}
   end
end
```

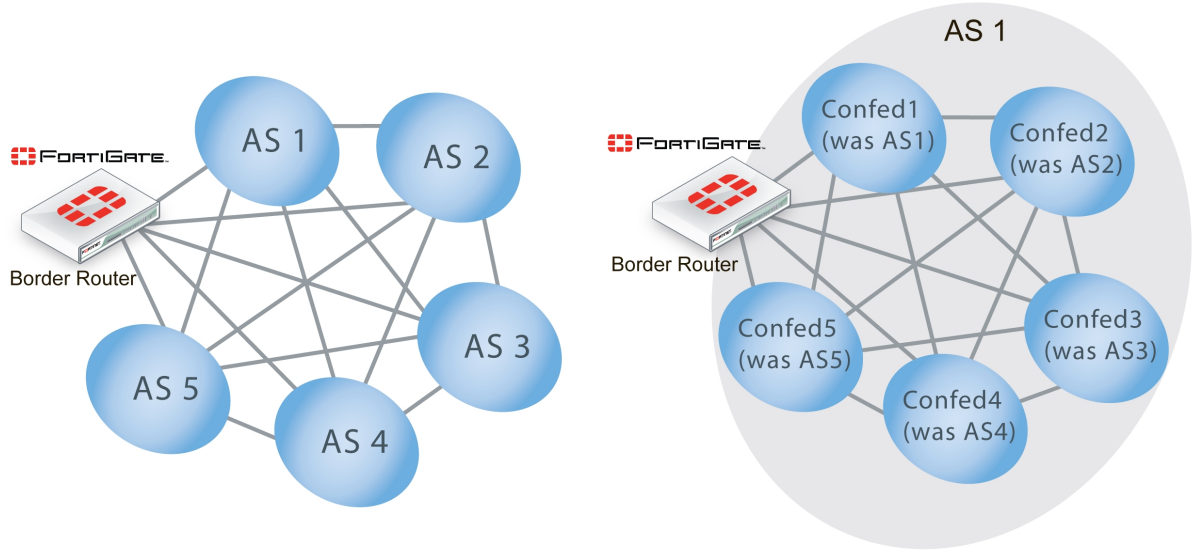
Confederations

Confederations were introduced to reduce the number of BGP advertisements on a segment of the network, and reduce the size of the routing tables. Confederations essentially break up an AS into smaller units. Confederations are defined in RFC 3065 and RFC 1965.

Within a confederation, all routers communicate with each other in a full mesh arrangement. Communications between confederations is more like inter-AS communications in that many of the attributes are changed as they would be for BGP communications leaving the AS, or eBGP.

Confederations are useful when merging ASs. Each AS being merged can easily become a confederation, requiring few changes. Any additional permanent changes can then be implemented over time as required. The figure below shows the group of ASs before merging, and the corresponding confederations afterward as part of the single AS with the addition of a new border router. It should be noted that after merging if the border router becomes a route reflector, then each confederation only needs to communicate with one other router, instead of five others.

AS merging using confederations



Multiple ASes before merging

Combined AS with confederations and new FortiGate unit border router

Confederations and route reflectors perform similar functions — they both sub-divide large ASes for more efficient operation. They differ in that route reflector clusters can include routers that are not members of a cluster, where routers in a confederation must belong to that confederation. Also, confederations place their confederation numbers in the AS_PATH attribute making it easier to trace.

It is important to note that while confederations essentially create sub-ASs, all the confederations within an AS appear as a single AS to external ASs.

Confederation related BGP commands include:

```
config router bgp
   set confederation-identifier <peerid_integer>
end
```

BGP conditional advertisements

Normally, routes are propagated regardless of the existence of a different path. The BGP conditional advertisement feature allows a route not to be advertised based on existence or non-existence of other routes.

With this new feature, a child table under bgp.neighbor is introduced. Any route matched by one of the route-map specified in the table will be advertised to the peer based on the corresponding condition route-map.

You can enable and disable conditional advertisements using the CLI.

To configure BGP conditional advertisements - CLI:

```
config router bgp
   set as 3
      config neighbor
         edit "10.10.10.10"
            set remote-as 3
               config conditional-advertise
                  edit "route-map-to-match-sending"
                     set condition-routemap "route-map-to-match-condition"
                     set condition-type [exist | non-exist]
                  next
               end
            next
         end
```

BGP Neighbor Groups

The BGP Neighbor Groups feature allows a large number of neighbors to be configured automatically based on a range of neighbors' source addresses.

To configure BGP Neighbor Groups - CLI:

Start by adding a BGP neighbor group:

```
config router bgp
   config neighbor-group
      edit <neighbor-group-name>
         set remote-as 100
   ...
```

(All options for BGP neighbor are supported except `password`.)

```
end
```

Then add a BGP neighbor range:

```
config router bgp
   config neighbor-range
      edit 1
         set prefix 192.168.1.0/24
         set max-neighbor-num 100
         set neighbor-group <neighbor-group-name>
      next
   end
```

Network Layer Reachability Information (NLRI)

Network Layer Reachability Information (NLRI) is unique to BGP-4. It is sent as part of the update messages sent between BGP routers, and contains information necessary to supernet, or aggregate route, information. The NLRI includes the length and prefix that when combined are the address of the aggregated routes referred to.

There is only one NLRI entry per BGP update message.

BGP attributes

Each route in a BGP network has a set of attributes associated with it. These attributes define the route, and are modified as required along the route.

BGP can work well with mostly default settings, but if you are going to change settings you need to understand the roles of each attribute and how they affect those settings.

The BGP attributes include:

AS_PATH	A list of ASes a route has passed through. See AS_PATH on page 2472.
MULTI_EXIT_DESC (MED)	Which router to use to exit an AS with more than one external connection. See MULTI_EXIT_DESC (MED) on page 2473.
COMMUNITY	Used to apply attributes to a group of routes. See COMMUNITY on page 2473.
NEXT_HOP	Where the IP packets should be forwarded to, like a gateway in static routing. See NEXT_HOP on page 2474.
ATOMIC_AGGREGATE	Used when routes have been summarized to tell downstream routers not to de-aggregate the route. See ATOMIC_AGGREGATE on page 2474.
ORIGIN	Used to determine if the route is from the local AS or not. See ORIGIN on page 2474.
LOCAL_PREF	Used only within an AS to select the best route to a location (like MED)

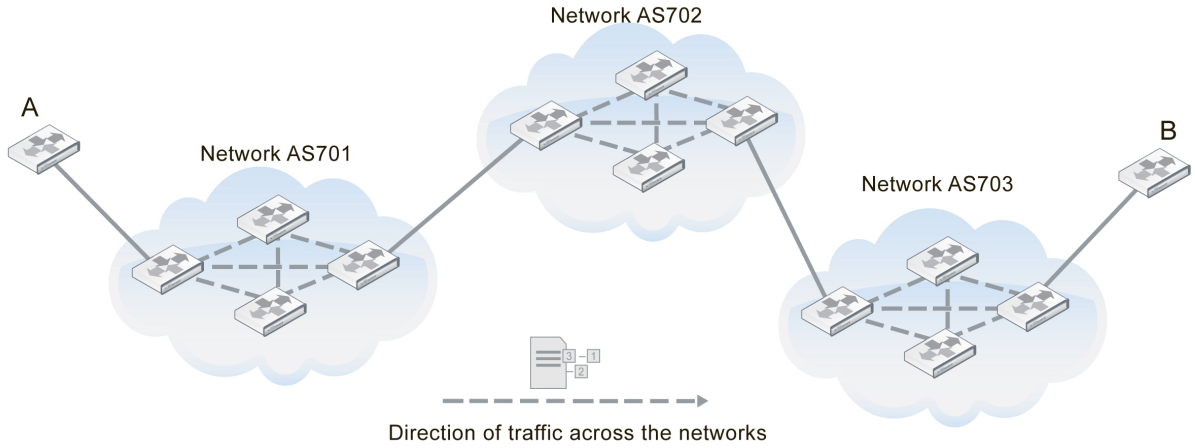
Inbound policies on FortiGate units can change the NEXT-HOP,LOCAL-PREF, MED and AS-PATH attributes of an internal BGP (iBGP) route for its local route selection purposes. However, outbound policies on the unit cannot affect these attributes.

AS_PATH

AS_PATH is the BGP attribute that keeps track of each AS a route advertisement has passed through. AS_PATH is used by confederations and by exterior BGP (EBGP) to help prevent routing loops. A router knows there is a loop if it receives an AS_PATH with that routers AS in it. The figure below shows the route between router A and router B. The AS_PATH from A to B would read 701,702,703 for each AS the route passes through.

As of the start of 2010, the industry upgraded from 2-byte to 4-byte AS_PATHs. This upgrade was due to the imminent exhaustion of 2-byte AS_PATH numbers. FortiOS supports 4-byte AS_PATHs in its BGP implementation.

AS_PATH of 701,702, 703 between routers A and B



The BGP commands related to AS_PATH include:

```
config router bgp
   set bestpath-as-path-ignore {enable | disable}
end
```

MULTI_EXIT_DESC (MED)

BGP AS systems can have one or more routers that connect them to other ASes. For ASes with more than one connecting router, the Multi-Exit Discriminator (MED) lists which router is best to use when leaving the AS. The MED is based on attributes such as delay. It is a recommendation only, as some networks may have different priorities.

BGP updates advertise the best path to a destination network. When the FortiGate unit receives a BGP update, the FortiGate unit examines the Multi-Exit Discriminator (MED) attribute of potential routes to determine the best path to a destination network before recording the path in the local FortiGate unit routing table.

FortiGate units have the option to treat any routes without an MED attribute as the worst possible routing choice. This can be useful because a lack of MED information is a lack of routing information which can be suspicious — possibly a hacking attempt or an attack on the network. At best it signifies an unreliable route to select.

The BGP commands related to MED include:

```
config router bgp
   set always-compare-med {enable | disable}
   set bestpath-med-confed {enable | disable}
   set bestpath-med-missing-as-worst {enable | disable}
   set deterministic-med {enable | disable}
   config neighbor
      set attribute-unchanged [as-path] [med] [next-hop]
   end
end
```

COMMUNITY

A community is a group of routes that have the same routing policies applied to them. This saves time and resources. A community is defined by the COMMUNITY attribute of a BGP route.

The FortiGate unit can set the COMMUNITY attribute of a route to assign the route to predefined paths (see RFC 1997). The FortiGate unit can examine the COMMUNITY attribute of learned routes to perform local filtering and/or redistribution.

The BGP commands related to COMMUNITY include:

```
config router bgp
   set send-community {both | disable | extended | standard}
end
```

NEXT_HOP

The NEXT_HOP attribute says what IP address the packets should be forwarded to next. Each time the route is advertised, this value is updated. The NEXT_HOP attribute is much like a gateway in static routing.

FortiGate units allow you to to change the advertising of the FortiGate unit's IP address (instead of the neighbor's IP address) in the NEXT_HOP information that is sent to IBGP peers. This is changed with the config neighbor, set next-hop-self command.

The BGP commands related to NEXT_HOP include:

```
config router bgp
   config neighbor
      set attribute-unchanged [as-path] [med] [next-hop]
      set next-hop-self {enable | disable}
   end
end
```

ATOMIC_AGGREGATE

The ATOMIC_AGGREGATE attribute is used when routes have been summarized. It indicates which AS and which router summarize the routes. It also tells downstream routers not to de-aggregate the route. Summarized routes are routes with similar information that have been combined, or aggregated, into one route that is easier to send in updates. When it reaches its destination, the summarized routes are split back up into the individual routes.

Your FortiGate unit doesn't specifically set this attribute in the BGP router command, but it is used in the route map command.

The commands related to ATOMIC_AGGREGATE include:

```
config router route-map
   edit <route_map_name>
      config rule
      edit <route_map_rule_id>
         set set-aggregator-as <id_integer>
         set set-aggregator-ip <address_ipv4>
         set set-atomic-aggregate {enable | disable}
      end
   end
end
```

ORIGIN

The ORIGIN attribute records where the route came from. The options can be IBGP, EBGP, or incomplete. This information is important because internal routes (IBGP) are by default higher priority than external routes (EBGP). However incomplete ORIGINs are the lowest priority of the three.

The commands related to ORIGIN include:

```
config router route-map
   edit <route_map_name>
      set comments <string>
      config rule
      edit <route_map_rule_id>
         set match-origin {egp | igp | incomplete | none}
      end
   end
end
```

How BGP works

BGP is a link-state routing protocol and keeps link-state information about the status of each network link it has connected. A BGP router receives information from its peer routers that have been defined as neighbors. BGP routers listen for updates from these configured neighboring routers on TCP port 179.

A BGP router is a finite state machine with six various states for each connection. As two BGP routers discover each other, and establish a connection they go from the idle state, through the various states until they reach the established state. An error can cause the connection to be dropped and the state of the router to be reset to either active or idle. These errors can be caused by: TCP port 179 not being open, a random TCP port above port 1023 not being open, the peer address being incorrect, or the AS number being incorrect.

When BGP routers start a connection, they negotiate which (if any) optional features will be used such as multiprotocol extensions that can include IPv6 and VPNs.

IBGP versus EBGP

When you read about BGP, often you see EBGP or IBGP mentioned. These are both BGP routing, but BGP used in different roles. Exterior BGP (EBGP) involves packets crossing multiple autonomous systems (ASes) where interior BGP (IBGP) involves packets that stay within a single AS. For example the AS_PATH attribute is only useful for EBGP where routes pass through multiple ASes.

These two modes are important because some features of BGP are only used for one of EBGP or IBGP. For example confederations are used in EBGP, and route reflectors are only used in IBGP. Also routes learned from IBGP have priority over EBGP learned routes.

FortiGate units have some commands specific to EBGP. These include:

- automatically resetting the session information to external peers if the connection goes down — `set fast-external-failover {enable | disable}`
- setting an administrative distance for all routes learned from external peers (must also configure local and internal distances if this is set) — `set distance-external <distance_integer>`
- enforcing EBGP multihops and their TTL (number of hops) — `set ebgp-enforce-multihop {enable | disable}` and `set ebgp-multihop-ttl <seconds_integer>`

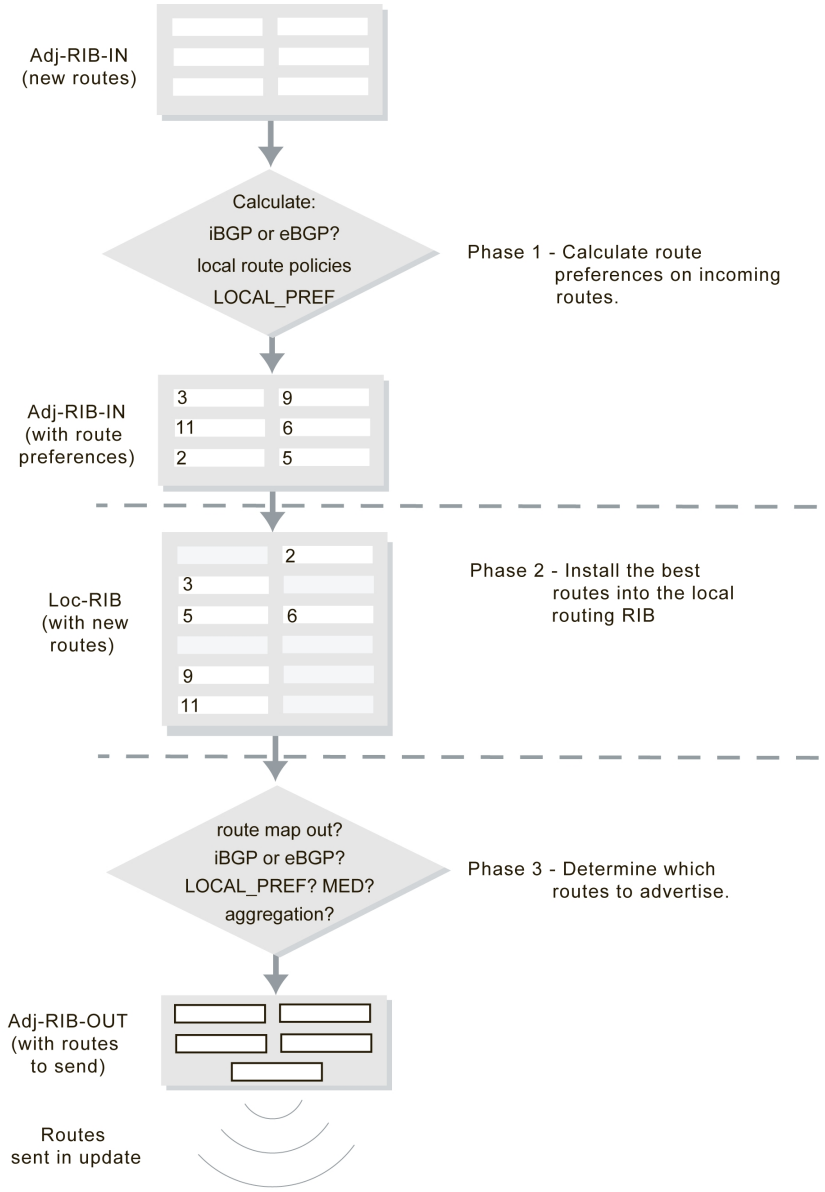
BGP path determination — which route to use

Firstly, recall that the number of available or supported routes is not set by the configuration but depends on your FortiGate's available memory. All learned routes and their attributes come into the BGP router in raw form. Before routes are installed in the routing table or are advertised to other routers, three levels of decisions must be made.

The three phases of BGP best path determination do not change. However, some manufacturers have added more information to the process, such as Cisco's WEIGHT attribute to enable an administrator to force one route's selection over another.

There is one Adj-RIB-IN and Adj-RIB-OUT for each configured neighbor. They are updated when the FortiGate unit receives BGP updates, or when the FortiGate unit sends out BGP updates.

Three phases of BGP routing decision



Decision phase 1

At this phase, the decision is to calculate how preferred each route and its NRLI are the Adjacent Routing Information Base Incoming (Adj-RIBs-In) compared to the other routes. For internal routes (IBGP), policy information or LOCAL_PREF is used. For external peer learned routes, it is based strictly on policy. These rules set up a list of which routes are most preferred going into Phase 2.

Decision phase 2

Phase 2 involves installing the best route to each destination into the local Routing Information Base (Loc-RIB). Effectively, the Loc-RIB is the master routing table. Each route from Phase 1 has their NEXT_HOP checked to ensure the destination is reachable. If it is reachable, the AS_PATH is checked for loops. After that, routes are installed based on the following decision process:

- If there is only one route to a location, it is installed.
- If multiple routes to the same location, use the most preferred route from Level 1.
- If there is a tie, break the tie based on the following in descending order of importance: shortest AS_PATH, smallest ORIGIN number, smallest MED, EBGP over IBGP, smallest metric or cost for reaching the NEXT_HOP, BGP identifier, and lowest IP address.

Note that the new routes that are installed into the Loc-RIB are in addition to any existing routes in the table. Once Phase 2 is completed the Loc-RIB will consist of the best of both the new and older routes.

Decision phase 3

Phase 3 is route distribution or dissemination. This is the process of deciding which routes the router will advertise. If there is any route aggregation or summarizing, it happens here. Also any route filtering from route maps happens here.

Once Phase 3 is complete, an update can be sent out to update the neighbor of new routes.

Aggregate routes and addresses

BGP4 allows classless routing, which uses netmasks as well as IP addresses. This classless routing enables the configuration of aggregate routes by stating the address bits the aggregated addresses have in common. For more information, see Dynamic Routing Overview on page 2371.

The ATOMIC_AGGREGATE attribute informs routers that the route has been aggregated, and should not be de-aggregated. An associated AGGREGATOR attribute include the information about the router that did the aggregating including its AS.

The BGP commands associated with aggregate routes and addresses are:

```
config router bgp
   config aggregate-address
      edit <aggr_addr_id>
      set as-set {enable | disable}
      set prefix <address_ipv4mask>
      set summary-only {enable | disable}
   end
   config aggregate-address6
      edit <aggr_addr_id>
      set as-set {enable | disable}
      set prefix6 <address_ipv6mask>
      set summary-only {enable | disable}
   end
```

Troubleshooting BGP

There are some features in BGP that are used to deal with problems that may arise. Typically the problems with a BGP network that has been configured, involve routes going offline frequently. This is called route flap and causes problems for the routers using that route.

Clearing routing table entries

To see if a new route is being properly added to the routing table, you can clear all or some BGP neighbor connections (sessions) using the `execute router clear bgp` command.

For example, if you have 10 routes in the BGP routing table and you want to clear the specific route to IP address 10.10.10.1, enter the command:

```
execute router clear bgp ip 10.10.10.1
```

To remove all routes for AS number 650001, enter the command:

```
execute router clear bgp as 650001
```

Route flap

When routers or hardware along a route go offline and back online that is called a route flap. Flapping is the term if these outages continue, especially if they occur frequently.

Route flap is a problem in BGP because each time a peer or a route goes down, all the peer routers that are connected to that out-of-service router advertise the change in their routing tables which creates a lot of administration traffic on the network. And the same traffic happens again when that router comes back online. If the problem is something like a faulty network cable that wobbles on and offline every 10 seconds, there could easily be overwhelming amounts of routing updates sent out unnecessarily.

Another possible reason for route flap occurs with multiple FortiGate units in HA mode. When an HA cluster fails over to the secondary unit, other routers on the network may see the HA cluster as being offline resulting in route flap. While this doesn't occur often, or more than once at a time, it can still result in an interruption in traffic which is unpleasant for network users. The easy solution for this problem is to increase the timers on the HA cluster, such as TTL timers, so they do not expire during the failover process. Also configuring graceful restart on the HA cluster will help with a smooth failover.

The first method of dealing with route flap should be to check your hardware. If a cable is loose or bad, it can easily be replaced and eliminate the problem. If an interface on the router is bad, either avoid using that interface or swap in a functioning router. If the power source is bad on a router, either replace the power supply or use a power conditioning backup power supply. These quick and easy fixes can save you from configuring more complex BGP options. However if the route flap is from another source, configuring BGP to deal with the outages will ensure your network users uninterrupted service.

Some methods of dealing with route flap in BGP include:

- Holddown timer
- Dampening
- Graceful restart
- Bi-directional forwarding detection (BFD)

Holddown timer

The first line of defence to a flapping route is the hold down timer. This timer reduces how frequently a route going down will cause a routing update to be broadcast.

Once activated, the holddown timer won't allow the FortiGate unit to accept any changes to that route for the duration of the timer. If the route flaps five times during the timer period, only the first outage will be recognized by the FortiGate unit — for the duration of the other outages there will be no changes because the Fortigate unit is essentially treating this router as down. After the timer expires, if the route is still flapping it will happen all over again.

Even if the route isn't flapping — if it goes down, comes up, and stays back up — the timer still counts down and the route is ignored for the duration of the timer. In this situation the route will be seen as down longer than it really is, but there will be only the one set of route updates. This is not a problem in normal operation because updates are not frequent.

Also the potential for a route to be treated as down when it is really up can be viewed as a robustness feature. Typically you do not want most of your traffic being routed over an unreliable route. So if there is route flap going on, it is best to avoid that route if you can. This is enforced by the holddown timer.

How to configure the holddown timer

There are three different route flapping situations that can occur: the route goes up and down frequently, the route goes down and back up once over a long period of time, or the route goes down and stays down for a long period of time. These can all be handled using the holddown timer.

For example, your network has two routes that you want to set the holddown timer for. One is your main route (to 10.12.101.4) that all your Internet traffic goes through, and it can't be down for long if its down. The second is a low speed connection to a custom network that is used infrequently (to 10.13.101.4). The holddown timer for the main route should be fairly short, lets say 60 seconds instead of the default 180 seconds. The second route timer can be left at the default or even longer since it is rarely used. In your BGP configuration this looks like:

```
config router bgp
   config neighbor
   edit 10.12.101.4
      set holddown-timer 60
   next
   edit 10.13.101.4
      set holddown-timer 180
   next
   end
end
```

Dampening

Dampening is a method used to limit the amount of network problems due to flapping routes. With dampening the flapping still occurs, but the peer routers pay less and less attention to that route as it flaps more often. One flap doesn't start dampening, but the second starts a timer where the router will not use that route — it is considered unstable. If the route flaps again before the timer expires, the timer continues to increase. There is a period of time called the reachability half-life after which a route flap will only be suppressed for half the time. This half-life comes into effect when a route has been stable for a while but not long enough to clear all the dampening completely. For the flapping route to be included in the routing table again, the suppression time must expire.

If the route flapping was temporary, you can clear the flapping or dampening from the FortiGate units cache by using one of the `execute router clear bgp` commands:

```
execute router clear bgp dampening {<ip_address> | <ip/netmask>}
```
or
```
execute router clear bgp flap-statistics {<ip> | <ip/netmask>}
```

For example, to remove route flap dampening information for the 10.10.0.0/16 subnet, enter the command:

```
execute router clear bgp dampening 10.10.0.0/16
```

The BGP commands related to route dampening are:

```
config router bgp
   set dampening {enable | disable}
```

```
    set dampening-max-suppress-time <minutes_integer>
    set dampening-reachability-half-life <minutes_integer>
    set dampening-reuse <reuse_integer>
    set dampening-route-map <routemap-name_str>
    set dampening-suppress <limit_integer>
    set dampening-unreachability-half-life <minutes_integer>
end
```

Graceful restart

BGP4 has the capability to gracefully restart.

In some situations, route flap is caused by routers that appear to be offline but the hardware portion of the router (control plane) can continue to function normally. One example of this is when some software is restarting or being upgraded, but the hardware can still function normally.

Graceful restart is best used for these situations where routing will not be interrupted, but the router is unresponsive to routing update advertisements. Graceful restart does not have to be supported by all routers in a network, but the network will benefit when more routers support it.

FortiGate HA clusters can benefit from graceful restart. When a failover takes place, the HA cluster will advertise it is going offline, and will not appear as a route flap. It will also enable the new HA main unit to come online with an updated and usable routing table — if there is a flap the HA cluster routing table will be out of date.

For example, your FortiGate unit is one of four BGP routers that send updates to each other. Any of those routers may support graceful starting—when a router plans to go offline, it will send out a message to its neighbors how long it expects to be before being back online. That way its neighbor routers don't remove it from their routing tables. However if that router isn't back online when expected, the routers will mark it offline. This prevents routing flap and its associated problems.

Scheduled time offline

Graceful restart is a means for a router to advertise it is going to have a scheduled shutdown for a very short period of time. When neighboring routers receive this notice, they will not remove that router from their routing table until after a set time elapses. During that time if the router comes back online, everything continues to function as normal. If that router remains offline longer than expected, then the neighboring routers will update their routing tables as they assume that router will be offline for a long time.

FortiGate units support both graceful restart of their own BGP routing software, and also neighboring BGP routers.

For example, if a neighbor of your FortiGate unit, with an IP address of 172.20.120.120, supports graceful restart, enter the command:

```
config router bgp
   config neighbor
   edit 172.20.120.120
      set capability-graceful-restart enable
   end
end
```

If you want to configure graceful restart on your FortiGate unit where you expect the Fortigate unit to be offline for no more than 2 minutes, and after 3 minutes the BGP network should consider the FortiGate unit offline, enter the command:

```
config router bgp
   set graceful-restart enable
   set graceful-restart-time 120
   set graceful-stalepath-time 180
end
```

The BGP commands related to BGP graceful restart are:

```
config router bgp
   set graceful-restart { disable| enable}
   set graceful-restart-time <seconds_integer>
   set graceful-stalepath-time <seconds_integer>
   set graceful-update-delay <seconds_integer>
   config neighbor
      set capability-graceful-restart {enable | disable}
   end
end

execute router restart
```

Before the restart, the router sends its peers a message to say it is restarting. The peers mark all the restarting router's routes as stale, but they continue to use the routes. The peers assume the router will restart and check its routes and take care of them if needed after the restart is complete. The peers also know what services the restarting router can maintain during its restart. After the router completes the restart, the router sends its peers a message to say it is done restarting.

Bi-directional forwarding detection (BFD)

Bi-directional Forwarding Detection (BFD) is a protocol used to quickly locate hardware failures in the network. Routers running BFD communicate with each other, and if a timer runs out on a connection then that router is declared down. BFD then communicates this information to the routing protocol and the routing information is updated.

While BGP can detect route failures, BFD can be configured to detect these failures more quickly allowing faster responses and improved convergence. This can be balanced with the bandwidth BFD uses in its frequent route checking.

Configurable granularity

BFD can run on the entire FortiGate unit, selected interfaces, or on BGP for all configured interfaces. The hierarchy allows each lower level to override the upper level's BFD setting. For example, if BFD was enabled for the FortiGate unit, it could be disabled only for a single interface or for BGP. For information about FortiGate-wide BFD options, see config system settings in the FortiGate CLI Reference.

BFD can only be configured through the CLI.

The BGP commands related to BFD are:

```
config system {setting | interface}
   set bfd {enable | disable | global}
   set bfd-desired-mix-tx <milliseconds>
   set bfd-detect-mult <multiplier>
   set bfd-required-mix-rx <milliseconds>
   set bfd-dont-enforce-src-port {enable | disable}

config router bgp
   config neighbor
      edit <neighbor_address_ipv4>
      set bfd {enable | disable}
```

```
    end
end

get router info bfd neighbor
execute router clear bfd session <src_ipv4> <dst_ipv4> <interface>
```

The `config system` commands allow you to configure whether BFD is enabled in a particular unit/vdom or individual interface, and how often the interface requires sending and receiving of BFD information.

The `config router bgp` commands allow you to set the addresses of the neighbor units that are also running BFD. Both units must be configured with BFD in order to make use of it.

Dual-homed BGP example

This is an example of a small network that uses BGP routing connections to two ISPs. This is a common configuration for companies that need redundant connections to the Internet for their business.

This configuration is for a small company connected to two ISPs. The company has one main office, the Head Office, and uses static routing for internal routing on that network.

Both ISPs use BGP routing, and connect to the Internet directly. They want the company to connect to the ISP networks using BGP. They also use graceful restart to prevent unneeded updates, and use smaller timer values to detect network failures faster.

As can be expected, the company wants to keep their BGP configuration relatively simple and easy to manage. The current configuration has only 3 routers to worry about — the 2 ISP border routers, and the FortiGate unit. This means the FortiGate unit will only have two neighbor routers to configure.

This configuration has the added benefit of being easy to expand if the Company wants to add a remote office in the future.

To keep the configuration simple, the Company is allowing only HTTP, HTTPS, FTP, and DNS traffic out of the local network. This will allow employees access to the Internet and their web-mail.

This section includes the following topics:

- Network layout and assumptions
- Configuring the FortiGate unit
- Configuring other networking devices
- Testing this configuration

Why dual home?

Dual homing means having two separate independent connections to the Internet. Servers in this configuration have also been called bastion hosts and can include DNS servers which require multiple connections.

Benefits of dual homing can include:

- Redundant Internet connection that essentially never fails
- Faster connections through one ISP or the other for some destinations, such as other clients of those ISPs
- Load balancing traffic to your Company network
- Easier to enable more traffic through two connections than upgrading one connection to bigger bandwidth
- Easier to create protection policies for different traffic through a specific ISP

Some companies require reliable Internet access at all times as part of their business. Consider a doctor operating remotely who has their Internet connection fail — the consequences could easily be life or death.

Dual homing is extra expense for the second ISP connection, and more work to configure and maintain the more complex network topology.

Potential dual homing issues

BGP comes with load balancing issues, and dual homing is the same category. BGP does not inherently deal well with load balancing, or getting default routes through BGP. Ideally one connect may be best for certain destinations, but it may not have that traffic routed to it making the load balancing less than perfect. This kind of fine tuning can be very time consuming, and usually results in a best effort situation.

When dual homing is not configured properly, your network may become a link between your ISPs and result in very high traffic between the ISPs that does not originate from your network. The problems with this situation are that your traffic may not have the bandwidth it needs, and you will be paying for a large volume of traffic that is not yours. This problem can be solved by not broadcasting or redistributing BGP routes between the ISPs.

If you learn your default routes from the ISPs in this example, you may run into an asymmetric routing problem where your traffic loops out one ISP and back to you through the other ISP. If you think this may be happening you can turn on asymmetric routing on the FortiGate unit (config system settings, set asymmetric enable) to verify that really is the problem. Turn this feature off once this is established since it disables many features on the FortiGate by disabling stateful inspection. Solutions for this problem can include using static routes for default routes instead of learning them through BGP, or configuring VDOMs on your FortiGate unit to provide a slightly different path back that is not a true loop.

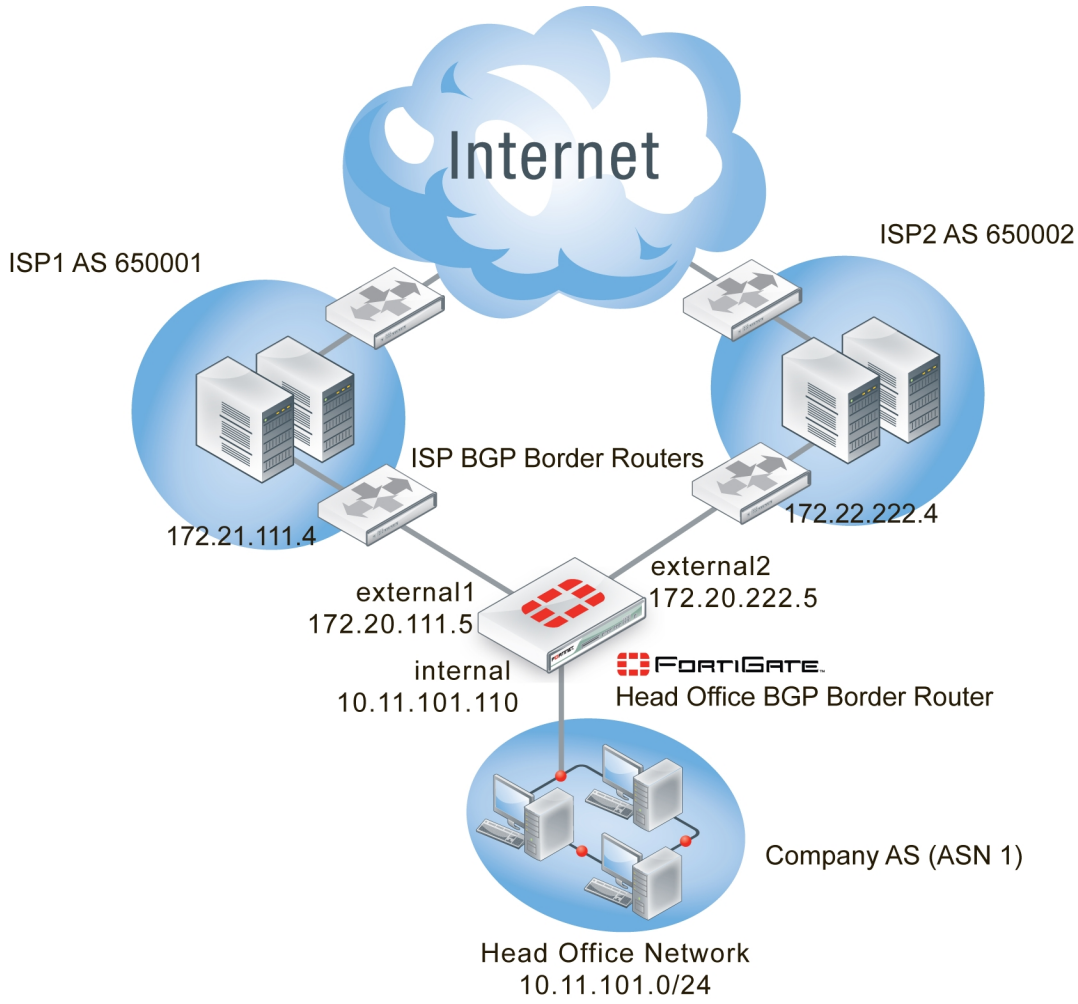
Network layout and assumptions

The network layout for the basic BGP example involves the company network being connected to both ISPs as shown below. In this configuration the FortiGate unit is the BGP border router between the Company AS, ISP1's AS, and ISP2's AS.

The components of the layout include:

- The Company AS (AS number 1) is connected to ISP1 and ISP2 through the FortiGate unit.
- The Company has one internal network — the Head Office network at 10.11.101.0/24.
- The FortiGate unit internal interface is on the the Company internal network with an IP address of 10.11.101.110.
- The FortiGate unit external1 interface is connected to ISP1's network with an IP address of 172.20.111.5, an address supplied by the ISP.
- The FortiGate unit external2 interface is connected to IPS2's network with an IP address of 172.20.222.5, an address supplied by the ISP.
- ISP1 AS has an AS number of 650001, and ISP2 has an AS number of 650002.
- Both ISPs are connected to the Internet.
- The ISP1 border router is a neighbor (peer) of the FortiGate unit. It has an address of 172.21.111.4.
- The ISP2 border router is a neighbor (peer) of the FortiGate unit. It has an address of 172.22.222.4.
- Apart from graceful restart, and shorter timers (holdtimer, and keepalive) default settings are to be used whenever possible.

Basic BGP network topology



Assumptions

The basic BGP configuration procedure follows these assumptions:

- ISP1 is the preferred route, and ISP2 is the secondary route
- All basic configuration can be completed in both GUI and CLI
- Only one AS is used for the Company

For these reasons this example configuration does not include:

- Bi-directional forwarding detection (BFD)
- Route maps
- Access lists
- Changing redistribution defaults — make link when example is set up
- IPv6

For more information on these features, see the corresponding section.

Configuring the FortiGate unit

In this topology, the FortiGate unit is the link between the Company Network and the ISP network. The FortiGate unit is the only BGP router on the Company Network, but there is at least one other BGP router on the ISP Network — there may be more but we don't have that information.

As mentioned in the general configuration steps, the ISP must be notified of the Company's BGP router configuration when complete as it will need to add the FortiGate BGP router as a neighbor router on its domain. This step is required for the FortiGate unit to receive BGP routing updates from the ISP network and outside networks.

If the ISP has any special BGP features enabled such as graceful restart, or route dampening that should be determined up front so those features can be enabled on the FortiGate unit.

To configure the FortiGate unit as a BGP router

1. Configure interfaces and default routes
2. Configure firewall services, addresses, and policies
3. Set the FortiGate BGP information
4. Add the internal network to the AS
5. Additional FortiGate BGP configuration

Configure interfaces and default routes

The FortiGate unit is connected to three networks — Company Network on the internal interface, ISP1 Network on external1interface, and ISP2 on external2 interface.

This example uses basic interface settings. Check with your ISP to determine if additional settings are required such as setting the maximum MTU size, or if gateway detection is supported.

High end FortiGate units do not have interfaces labeled Internal, or External. Instead, for clarity's sake, we are using the alias feature to name interfaces for these roles.

Default routes to both external interfaces are configured here as well. Both are needed in case one goes offline. ISP1 is the primary connection and has a smaller administrative distance so it will be preferred over ISP2. Both distances are set low so they will be preferred over any learned routes.

To configure the FortiGate interfaces - web-based manager

1. Go to **System > Network > Interface**.
2. Edit port 1 (internal) interface.
3. Set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.11.101.110/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Company internal network
Administrative Status	Up

4. Edit port 2 (external1) interface.
5. Set the following information, and select **OK**.

Alias	external1
IP/Network Mask	172.21.111.5/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	ISP1 External BGP network
Administrative Status	Up

6. Edit port 3 (external2) interface.
7. Set the following information, and select **OK**.

Alias	external2
IP/Network Mask	172.22.222.5/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	ISP2 External BGP network
Administrative Status	Up

To configure the FortiGate interfaces - CLI

```
config system interface
   edit port1
      set alias internal
      set ip 10.11.101.110 255.255.255.0
      set allowaccess http https ssh
      set description "Company internal network"
      set status up
   next
   edit port2
      set alias external1
      set ip 172.21.111.5 255.255.255.0
      set allowaccess https ssh
      set description "ISP1 External BGP network"
      set status up
   next
   edit port3
      set alias external2
      set ip 172.22.222.5 255.255.255.0
      set allowaccess https ssh
      set description "ISP2 External BGP network"
      set status up
   next
end
```

To configure default routes for both ISPs - web-based manager

1. Go to **Router > Static > Static Routes**.
2. Delete any existing routes with a IP/Mask of address of 0.0.0.0/0.0.0.0
3. Select **Create New**, and set the following information.

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port2
Gateway	172.21.111.5
Distance	10

4. Select **OK**.
5. Select **Create New**, and set the following information.

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port3
Gateway	172.22.222.5
Distance	15

6. Select **OK**.

To configure default routes for both ISPs - CLI

```
config router static
   edit 1
      set device "port2"
      set distance 10
      set gateway 172.21.111.5
   next
   edit 2
      set device "port3"
      set distance 15
      set gateway 172.22.222.5
   next
end
```

Configure firewall services, addresses, and policies

To create the security policies, first you must create the firewall services group that will include all the services that will be allowed, then you must define the addresses that will be used in the security policies, and lastly you configure the security policies themselves.

To keep the configuration simple, the Company is allowing only HTTP traffic out of the local network. This will allow employees access to the Internet and their web-mail. DNS services will also be allowed through the firewall.

The security policies will allow HTTP traffic (port 80 and port 8080), HTTPS traffic (port 443), FTP traffic (port 21), and DNS traffic (port 53 and port 953) in both directions. Also BGP (port 179) may need access through the firewall.

For added security, you may want to define a smaller range of addresses for the internal network. For example if only 20 addresses are used, only allow those addresses in the range.

In the interest of keeping things simple, a zone will be used to group the two ISP interfaces together. This will allow using one security policy to apply to both ISPs at the same time. Remember to block intra-zone traffic as this will help prevent one ISP sending traffic to the other ISP through your FortiGate unit using your bandwidth. The zone keeps configuration simple, and in the future if there is a need for separate policies for each ISP, they can be created and the zone can be deleted.

The addresses that will be used are the addresses of the FortiGate unit internal and external ports, and the internal network.

More policies or services can be added in the future as applications are added to the network. For more information on security policies, see the firewall chapter of the FortiGate Administration Guide.

When configuring security policies always enable logging to help you track and debug your traffic flow.

To create a firewall services group - web-based manager

1. Go to **Policy & Objects > Services**, select the dropdown arrow next to **Create New** and select **Service Group**.
2. For **Group Name**, enter “Basic_Services”.
3. From the **Members** dropdown, choose the following six services — BGP, FTP, FTP_GET, FTP_PUT, DNS, HTTP, and HTTPS.
4. Select **OK**.

To create a firewall services group - CLI

```
config firewall service group
   edit "Basic_Services"
      set member "BGP" "DNS" "FTP" "FTP_GET" "FTP_PUT" "HTTP" "HTTPS"
   next
end
```

To create a zone for the ISP interfaces - web-based manager

1. Go to **Network > Interfaces.**
2. Select the caret to the right of **Create New** and then select **Zone**.
3. Enter the following information.

Zone Name	ISPs
Block Intra-zone traffic	enable
interface members	port2 port3

4. Select **OK**.

To create a zone for the ISP interfaces - CLI

```
config system zone
   edit "ISPs"
      set interface "port2" "port3"
      set intrazone block
   next
end
```

To add the firewall addresses - web-based manager

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**, and set the following information.

Category	Address
Name	Internal_network
Type	Subnet / IP Range
Subnet / IP Range	10.11.101.0 255.255.255.0
Interface	port1

3. Select **OK**.

To add the firewall addresses - CLI

```
config firewall address
   edit "Internal_network"
      set associated-interface "port1"
      set subnet 10.11.101.0 255.255.255.0
   next
end
```

To add the HTTP and DNS security policies - web-based manager

1. Go to **Policy & Objects > IPv4 Policy**, and select **Create New**.
2. Set the following information.

Incoming Interface	port1(internal)
Source Address	Internal_network
Outgoing Interface	ISPs
Destination Address	All
Schedule	Always
Service	Basic_services
Action	ACCEPT

Log Allowed Traffic	Enable
Firewall / Network Options	Enable NAT
Comments	ISP1 basic services out policy

3. Select **OK**.
4. Select **Create New**, and set the following information.

Incoming Interface	ISPs
Source Address	All
Outgoing Interface	port1(internal)
Destination Address	Internal_network
Schedule	Always
Service	Basic_services
Action	ACCEPT
Log Allowed Traffic	Enable
Firewall / Network Options	Enable NAT
Comments	ISP1 basic services in policy

To add the security policies - CLI

```
config firewall policy
   edit 1
      set srcintf "port1"
      set srcaddr "Internal_network"
      set dstintf "ISPs"
      set dstaddr "all"
      set schedule "always"
      set service "Basic_services"
      set action accept
      set nat enable
      set profile-status enable
      set logtraffic enable
      set comments "ISP1 basic services out policy"
   next
   edit 2
      set srcintf "ISPs"
      set srcaddr "all"
      set dstintf "port1"
      set dstaddr "Internal_network"
      set schedule "always"
      set service "Basic_services"
      set action accept
      set nat enable
      set profile-status enable
      set logtraffic enable
```

```
      set comments "ISP1 basic services in policy"
   next
end
```

Set the FortiGate BGP information

When using the default information, there are only two fields to set to configure the FortiGate unit as a BGP router.

For this configuration the FortiGate unit will be in a stub area with one route out — the ISP BGP router. Until you configure the ISP router as a neighbor, even that route out is not available. So while after this part of the configuration is complete your FortiGate unit will be running BGP, it won't know about any other routers running BGP until the next part of the configuration is complete.

To set the BGP router information - web-based mananger

1. Go to **Network > BGP**.
2. Set the following information, and select **OK**.

Local As	1
Router ID	10.11.101.110

To set the BGP router information - CLI

```
config router BGP
   set as 1
   set router-id 10.11.101.110
end
```

Add the internal network to the AS

The Company is one AS with the FortiGate unit configured as the BGP border router connecting that AS to the two ISPs ASes. The internal network in the Company's AS must be defined. If there were other networks in the company such as regional offices, they would be added here as well.

To set the networks in the AS - web-based manager

1. Go to **Network > BGP**.
2. In **Networks**, next to **IP/Netmask**, set the following information and select **Add**.

IP/Netmask	10.11.101.0/255.255.255.0

To set the networks in the AS - CLI

```
config router bgp
   config network
   edit 1
      set prefix 10.11.101.0 255.255.255.0
   next
   end
end
```

Add BGP neighbor information

The configuration will not work unless you set **Remote AS** neighbors. This can be done in either the web-based manager or the CLI.

To configure the BGP neighbors - web-based manager

1. Go to **Network > BGP**.
2. Add a **Neighbors IP** of 172.21.111.4 with the **Remote AS** set to 650001, then click **Add/Edit**.
3. Add another **Neighbors IP** of 172.22.222.4 with the **Remote AS** set to 650002, then click **Add/Edit**.

To configure the BGP neighbors - CLI

```
config router BGP
   set as 1
      config neighbor
         edit "172.21.111.4"
            set remote-as 650001
         next
         edit "172.22.222.4"
            set remote-as 650002
         next
      end
   end
```

Additional FortiGate BGP configuration

At this point that is all the settings that can be done in both the web-based manger and the CLI. The remaining configuration must be completed in the CLI.

These additional settings are mainly determined by your ISP requirements. They will determine your timers such as keep alive timers, if extended features like BFD and graceful restart are being used, and so on. For this example, some common simply features are being used to promote faster detections of network failures which will result in better service for the Company's internal network users.

The ISPs do not require authentication between peer routers.

These commands will enable or modify the following features on the FortiGate unit, and where possible on neighboring routers as well:

- `bestpath-med-missing-as-worst` — treats a route without an MED as the worst possible available route due to expected unreliability
- `fast-external-failover` — immediately reset the session information associated with BGP external peers if the link used to reach them goes down
- `graceful-restart*` — advertise reboots to neighbors so they do not see the router as offline, wait before declaring them offline, and how long to wait when they reboot before advertising updates. These commands applies to neighbors and are part of the BGP capabilities. This prevents unneeded routing updates.
- `holdtime-timer` — how long the router will wait for a keepalive message before declaring a router offline. A shorter time will find an offline router faster.
- `keepalive-timer` — how often the router sends out keepalive messages to neighbor routers to maintain those sessions.
- `log-neighbor-changes` — log changes to neighbor routers' status. This can be useful for troubleshooting from both internal and external networks.

- `connect-timer` — how long in seconds the FortiGate unit will try to reach this neighbor before declaring it offline.
- `weight` — used to prefer routes from one neighbor over the other. In this example ISP1 is the primary connection so it is weighted higher than ISP2

To configure additional BGP options - CLI

```
config router bgp
   set bestpath-med-missing-as-worst enable
   set fast-external-failover enable
   set graceful-restart enable
   set graceful-restart-time 120
   set graceful-stalepath-time 180
   set graceful-update-delay 180
   set holdtime-timer 120
   set keepalive-timer 45
   set log-neighbor-changes enable
   config neighbor
      edit 172.21.111.4
         set connect-timer 60
         set description "ISP1"
         set holdtime-timer 120
         set keepalive-timer 45
         set weight 250
      next
      edit 172.22.222.4
         set connect-timer 60
         set description "ISP2"
         set holdtime-timer 120
         set keepalive-timer 45
         set weight 100
      next
   end
end
```

Configuring other networking devices

There are two other networking devices that need to be configured: both ISPs' BGP routers.

The ISPs' routers must add the FortiGate unit as a neighbor so route updates can be sent in both directions. Note that ISP1 is not directly connected to ISP2 that we are aware of.

Inform both of your ISPs of your FortiGate unit's BGP information. Once they have configured their router, you can test your BGP connection to the Internet.

They will require your FortiGate unit's:

- IP address of the connected interface
- The router ID
- Your Company's AS number

Testing this configuration

With the dual-homed BGP configuration in place, you should be able to send and receive traffic, send and receive routes, and not have any routing loops. Testing the networks will confirm things are working as expected.

In general for routing you need to look at the routing table on different routers to see what routes are being installed. You also need to sniff packets to see how traffic is being routed in real time. These two sources of information will normally tell you what you need to know.

Testing of this example's network configuration should be completed in two parts:

- Testing network connectivity
- Verifying the FortiGate unit's routing tables
- Verifying traffic routing
- Verifying the dual-homed side of the configuration

Testing network connectivity

A common first step in testing a new network topology is to test if you can reach the Internet and other locations as you expect you should. If not, you may be prevented be cabling issues, software or other issues.

The easiest way to test connections is to use ping, once you ensure that all the FortiGate unit's interfaces and ISP routers have ping support enabled. Also ensure that the security policies allow ping through the firewall.

Connections to test in this example are the internal network to ISP1's router or the Internet, and the same for ISP2. If you can connect on the external side of the Fortinet unit, try to ping the internal network. Those three tests should prove your basic network connections are working.

Once you have completed testing the network connectivity, turn off ping support on the external interfaces for additional security.

Verifying the FortiGate unit's routing tables

The FortiGate routing table contains the routes stored for future use. If you are expecting certain routes to be there and they are not, that is a good indicator that your configuration is not what you expected.

The CLI command `get router info routing-table details` will provide you with every route's routing protocol, destination address, gateway address, interface, weighting, and if the address is directly connected or not.

If you want to limit the display to BGP routes only, use the CLI command `get router info routing-table bgp`. If there are no BGP routes in the routing table, nothing will be displayed. In the CLI command you can replace BGP with static, or other routing protocols to only display those routes.

If you want to see the contents of the routing information database (RIB), use the CLI command `get router info routing-table database`. This will display the incoming routes that may or may not make it into the routing table.

Verifying traffic routing

Traffic may be reaching the internal network, but it may be using a different route than you think to get there.

Use a browser to try and access the Internet.

If needed, allow traceroute and other diag ports to be opened until things are working properly. Then remove access for them again.

Look for slow hops on the traceroute, or pings to a location, as they may indicate network loops that need to be fixed.

Any locations that have an unresolved traceroute or ping must be examined and fixed.

Use network packet sniffing to ensure traffic is being routed as you expect.

Verifying the dual-homed side of the configuration

Since there are two connections to the Internet in this example, theoretically you can pull the plug on one of the ISP connections, and all traffic will go through the other connection. Alternately, you may choose to remove a default route to one ISP, remove that ISP's neighbor settings, or change the weightings to prefer other other ISP. These alternate ways to test dual-homing do not change physical cabling, which may be preferred in some situations.

If this does not work as expected, things to check include:

- Default static routes — If these are wrong or don't exist, the traffic can't get out.
- BGP neighbor information — If the ISP router information is incorrect, the FortiGate unit won't be able to talk to it.

Redistributing and blocking routes in BGP

During normal BGP operation, peer routers redistribute routes from each other. However, in some specific situations it may be best to not advertise routes from one peer, such as if the peer is redundant with another peer (they share the same routes exactly), if it might be unreliable in some way, or some other reason. The FortiGate can also take routes it learns from other protocols and advertise them in BGP, for example OSPF or RIP. If your Company hosts its own web or email servers, external locations will require routes to your networks to reach those services.

In this example the Company has an internal network in an OSPF area, and is connected to a BGP AS and two BGP peers. Company goes through these two peers to reach the Internet. However, Peer 1 routes will not be advertised to Peer 2. The Company internal user and server networks are running OSPF, and will redistribute those routes to BGP so external locations can reach the web and email servers.

This section includes the following topics:

- Network layout and assumptions
- Configuring the FortiGate unit
- Testing network configuration

Network layout and assumptions

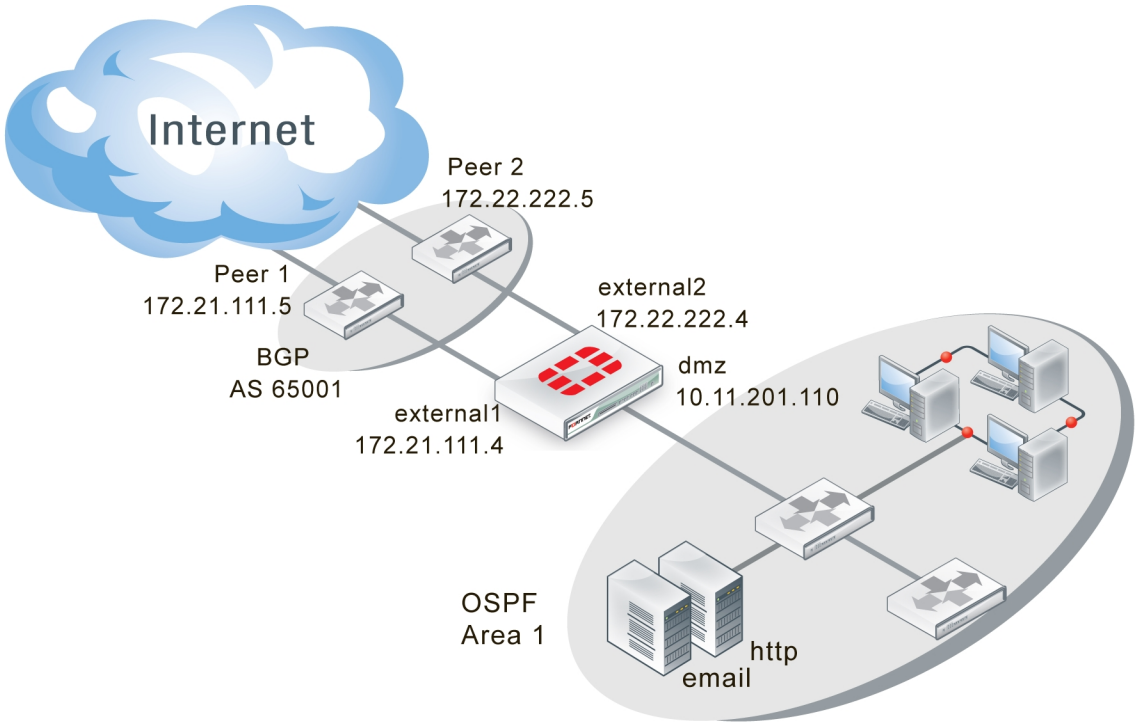
The network layout for the BGP redistributing routes example involves the company network being connected to two BGP peers as shown below. In this configuration the FortiGate unit is the BGP border router between the Company AS, and the peer routers.

The components of the layout include:

- There is only one BGP AS in this example — AS 65001, shared by the FortiGate unit and both peers.
- The Company's FortiGate unit connects to the Internet through two BGP peers.
- The Company internal networks on the dmz interface of the FortiGate unit with an IP of 10.11.201.0/24.
- The FortiGate units' interfaces are connected as follows:

  - port1 (dmz) has IP 10.11.201.110 and is the internal user and server network
  - port2 (external1) has IP 172.21.111.4 and is connected to Peer 1's network
  - port3 (external2) has IP 172.22.222.4 and is connected to Peer 2's network
- Peer 1 has IP 172.21.111.5, and Peer 2 has IP 172.22.222.5.
- OSPF Area 1 is configured on the dmz interface of the FortiGate unit, and is the routing protocol used by the internal users and servers.

BGP network topology



Assumptions

The the BGP redistributing routes configuration procedure follows these assumptions:

- The FortiGate unit has been configured following the Install Guide
- Interfaces port1, port2, and port 3 exist on the FortiGate unit
- We don't know the router manufacturers of Peer 1 and Peer 2
- We don't know what other devices are on the BGP AS or OSPF Area
- All basic configuration can be completed in both GUI and CLI
- Access lists and route maps will only be configured in CLI
- VDOMs are not enabled on the FortiGate unit

Configuring the FortiGate unit

1. Configuring the FortiGate unit — networks and firewalls
2. Configuring the FortiGate unit - BGP
3. Configuring the FortiGate unit - OSPF

4. Configuring other networking devices
5. Configuring ECMP support for BGP

Configuring the FortiGate unit — networks and firewalls

The FortiGate unit has three interfaces connected to networks — two external and one dmz.

Security policies must be in place to allow traffic to flow between these networks.

Firewall services will change depending on which routing protocol is being used on that network — either BGP or OSPF. Beyond that, all services that are allowed will be allowed in both directions due to the internal servers. The services allowed are web-server services (DNS, HTTP, HTTPS, SSH, NTP, FTP*, SYSLOG, and MYSQL), email services (POP3, IMAP, and SMTP), and general troubleshooting services (PING, TRACEROUTE). Those last two can be removed once the network is up and working properly to increase security. Other services can be added later as needed.

To configure the interfaces - GUI

1. Go to **Network > Interfaces**.
2. Edit port1 (dmz) interface.
3. Set the following information, and select **OK**.

Alias	dmz
IP/Network Mask	10.11.201.110/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	OSPF internal networks
Administrative Status	Up

4. Edit port2 (external1) interface.
5. Set the following information, and select **OK**.

Alias	external1
IP/Network Mask	172.21.111.4/255.255.255.0
Administrative Access	HTTPS SSH
Description	BGP external Peer 1
Administrative Status	Up

6. Edit port3 (external2) interface.
7. Set the following information, and select **OK**.

Alias	external2
IP/Network Mask	172.22.222.4/255.255.255.0

Administrative Access	HTTPS SSH
Description	BGP external2 Peer2
Administrative Status	Up

To configure the FortiGate interfaces (CLI)

```
config system interface
   edit port1
      set alias dmz
      set ip 10.11.201.110 255.255.255.0
      set allowaccess https ssh ping
      set description "OSPF internal networks"
      set status up
   next
   edit port2
      set alias external1
      set ip 172.21.111.5 255.255.255.0
      set allowaccess https ssh
      set description "external1 Peer 1"
      set status up
   next
   edit port3
      set alias external2
      set ip 172.22.222.5 255.255.255.0
      set allowaccess https ssh
      set description "external2 Peer 2"
      set status up
   next
end
```

To configure the firewall addresses - GUI

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**, and set the following information.

Category	Address
Name	BGP_services
Type	Subnet / IP Range
Subnet / IP Range	10.11.201.0 255.255.255.0
Interface	port1

3. Select **OK**.

To configure the firewall addresses - CLI

```
config firewall address
   edit "BGP_services"
      set associated-interface "port1"
      set subnet 10.11.201.0 255.255.255.0
```

```
    next
end
```

To configure firewall service groups - GUI

1. Go to **Policy & Objects > Services.** Under the **Create New** dropdown menu, select **Service Group**.
2. Name the group BGP_Services.
3. Add the following services to the **Members** list: BGP, DNS, FTP, FTP_GET, FTP_PUT, HTTP, HTTPS, IMAP, MYSQL, NTP, PING, POP3, SMTP, SSH, SYSLOG, and TRACEROUTE.
4. Select **OK**.
5. Create another new **Service Group**.
6. Name the group OSPF_Services.
7. Add the following services to the *Members* list: DNS, FTP, FTP_GET, FTP_PUT, HTTP, HTTPS, IMAP, MYSQL, NTP, OSPF, PING, POP3, SMTP, SSH, SYSLOG, and TRACEROUTE.
8. Select **OK**.

To configure firewall service groups - CLI

```
config firewall service group
   edit "BGP_services"
      set member "BGP", "DHCP" "DNS" "FTP" "FTP_GET" "FTP_PUT" "HTTP" "HTTPS" "IMAP"
          "MYSQL" "NTP" "PING" "POP3" "SMTP" "SSH" "TRACEROUTE" "SYSLOG"
   next
   edit "OSPF_services"
      set member "DHCP" "DNS" "FTP" "FTP_GET" "FTP_PUT" "HTTP" "HTTPS" "IMAP" "MYSQL"
          "NTP" "PING" "POP3" "SMTP" "SSH" "TRACEROUTE" "SYSLOG" "OSPF"
   next
end
```

Configuring the FortiGate unit - BGP

The only change from the standard BGP configuration for this example is configuring the blocking Peer 1's routes from being advertised to Peer 2. From the network topology you can guess that both of these peers likely share many routes in common and it makes no sense to advertise unneeded routes.

Blocking Peer 1's routes to Peer 2 is done with distribute-list-out keyword. They allow you to select which routes you will advertise to a neighbor using an access list. In this case we will block all incoming routes from Peer 1 when we send updates to Peer 2. Otherwise Peer 1 and Peer 2 are regular neighbors.

The FortiGate unit will redistribute routes learned from OSPF into BGP.

This is advanced configuration and the commands are only available in the CLI.

To create access list to block Peer 1 - CLI

```
config access-list
   edit "block_peer1"
      config rule
      edit 1
         set prefix 172.21.111.0 255.255.255.0
         set action deny
         set exact-match enable
      end
   end
```

```
end
```

To configure BGP on the FortiGate unit - CLI

```
config router bgp
   set as 65001
      set router-id 10.11.201.110
      config redistribute ospf
         set status enable
      end
      config neighbor
      edit 172.22.222.5
         set remote-as 65001
         set distribute-list-out "block_peer1"
      next
      edit 172.21.111.5
         set remote-as 65001
      end
   end
```

Configuring the FortiGate unit - OSPF

This configuration involves only one OSPF Area, so all traffic will be intra-area. If there were two or more areas with traffic going between them it would be inter-area traffic. These two types are comparable to BGP's traffic within one AS (iBGP) or between multiple ASes (eBPG). Redistributing routes from OSPF to BGP is considered external because either the start or end point is a different routing protocol.

The OSPF configuration is basic apart from redistributing BGP routes learned.

To configure OSPF on the FortiGate unit - web-based manager

1. Go to **Network > OSPF**.
2. For Router ID enter `10.11.201.110` and then select **Apply**.
3. Under **Advanced Options** > **Redistribute**, select **BGP** and set the BGP **Metric** to 1.
4. For **Areas**, select **Create New,** enter the following information and then select **OK**.

Area (IP)	`0.0.0.0`
Type	Regular
Authentication	None

5. For **Networks**, select **Create New**.
6. Enter 10.11.201.0/255.255.255.0 for **IP/Netmask**, and select **OK**.
7. For **Interfaces**, select **Create New**.
8. Enter `OSPF_dmz_network` for **Name**.
9. Select `port1(dmz)` for **Interface**, and then select **OK**.

To configure OSPF on the FortiGate unit - CLI

```
config router ospf
   set router-id 10.11.201.110
   config area
```

```
      edit 0.0.0.0
         set type regular
         set authentication none
      end
   config network
      edit 1
         set area 0.0.0.0
         set prefix 10.11.201.0 255.255.255.0
      end
   config interface
      edit "OSPF_dmz_network"
         set interface port1(dmz)
         set status enable
      end
   config redistribute bgp
      set status enable
      set metric 1
   end
end
```

Configuring other networking devices

As with all BGP configurations, the peer routers will need to be updated with the FortiGate unit's BGP information including IP address, AS number, and what capabilities are being used such as IPv6, graceful restart, BFD, and so on.

Configuring ECMP support for BGP

"ECMP" stands for "Equal Cost Multiple Path". ECMP is a mechanism that allows multiple routes to the same destination with different next-hops and load-balances routed traffic over those multiple next-hops.

- ECMP only works for routes that are sourced by the same routing protocol (that is: Static Routes, OSPF, or BGP).
- ECMP is enabled by default with 10 paths.
- ECMP with static routes is effective if the routes are configured with the same distance and same priority.

To configure ECMP support - CLI

```
config router bgp
   set ebgp-multipath disable[|enable]
   set ibgp-multipath disable[|enable]
   ...
end
```

Testing network configuration

Testing this configuration involves the standard connectivity checks, but also ensuring that routes are being passed between protocols as expected.

Check the routing table on the FortiGate unit to ensure that routes from both OSPF and BGP are present.

Check the routing table on devices on the OSPF network for routes redistributed from BGP. Also check those devices for connectivity to the Internet.

Check the routing table on Peer 2 to ensure no routes from Peer 1 are present, but routes from the internal OSPF network are present.

For help with troubleshooting, see Redistributing and blocking routes in BGP on page 2495.

Intermediate System to Intermediate System Protocol (IS-IS)

This section describes the Intermediate System to Intermediate System Protocol (IS-IS).

The following topics are included in this section:

IS-IS background and concepts

Intermediate System to Intermediate System Protocol (IS-IS) allows routing of ISO's OSI protocol stack Connectionless Network Service (CLNS). IS-IS is an Interior Gateway Protocol (IGP) not intended to be used between Autonomous Systems (ASes).

Background

IS-IS was developed by Digital Equipment Corporation and later standardized by ISO in 1992 as ISO 19589 (see RFC 1142—note this RFC is different from the ISO version). At roughly the same time, the Internet Engineering Task Force developed OSPF (see Open Shortest Path First (OSPF) on page 2424). After the initial version, IP support was added to IS-IS and this version was called Integrated IS-IS (see RFC 1195). Its widespread use started when an early version of IS-IS was included with BSD v4.3 Linux as the routed daemon. The routing algorithm used by IS-IS, the Bellman–Ford algorithm, first saw widespread use as the initial routing algorithm of the ARPANET.

IS-IS is a link state protocol well-suited to smaller networks that is in widespread use and has near universal support on routing hardware. It is quick to configure, and works well if there are no redundant paths. However, IS-IS updates are sent out node-by-node, so it can be slow to find a path around network outages. IS-IS also lacks good authentication, can not choose routes based on different quality of service methods, and can create network loops if you are not careful. IS-IS uses Djikstra's algorithm to find the best path, like OSPF.

While OSPF is more widely known, IS-IS is a viable alternative to OSPF in enterprise networks and ISP infrastructures, largely due to its native support for IPv6 and its non-disruptive methods for splitting, merging, migrating, and renumbering network areas.

The FortiGate implementation supports IS-IS for IPv4 (see RFCs 1142 and 1162), but does not support IS-IS for IPv6 (although this technically can be achieved using the ZebOS routing module).

How IS-IS works

As one of the original modern dynamic routing protocols, IS-IS is straightforward. Its routing algorithm is not complex, there are some options to allow fine tuning, and it is straightforward to configure IS-IS on FortiGate units.

From RFC 1142:

> *The routing algorithm used by the Decision Process is a shortest path first (SPF) algorithm. Instances of the algorithm are run independently and concurrently by all intermediate systems in a routing domain. IntraDomain routing of a PDU occurs on a hop-by-hop basis: that is, the algorithm determines only the next hop, not the complete path, that a data PDU will take to reach its destination.*

IS-IS versus static routing

IS-IS was one of the earliest dynamic routing protocols to work with IP addresses. As such, it is not as complex as more recent protocols. However, IS-IS is a big step forward from simple static routing.

While IS-IS may be slow in response to network outages, static routing has zero response. The same is true for convergence—static routing has zero convergence. Both IS-IS and static routing have the limited hop count, so it is neither a strength nor a weakness.

TLV

IS-IS uses *type-length-variable (TLV)* parameters to carry information in Link-State PDUs (LSPs). Each IS-IS LSP consists of a variable-length header to which TLVs are appended in order to extend IS-IS for IP routing. The TLV field consists of one octet of type (T), one octet of length (L), and "L" octets of Value (V). They are included in all of the IS-IS Packet types. For a complete breakdown of the LSP, see LSP structure on page 2503.

In IS-IS, TLVs are used to determine route-leaking and authentication, and are also used for IPv4 and IPv6 awareness and reachability.

- To determine which TLVs are responsible for route-leaking, see Default routing on page 2506.
- To determine which TLVs are responsible for authentication, see Authentication on page 2507.

For a complete list of reserved TLV codepoints, refer to RFC 3359.

LSP structure

It is difficult to fully understand a routing protocol without knowing what information is carried in its packets. Knowing how routers exchange each type of information will help you better understand the IS-IS protocol and will allow you to configure your network more appropriatey.

This section provides information on the contents of the IS-IS LSP. LSPs describe the network topology and can include IP routes and checksums.

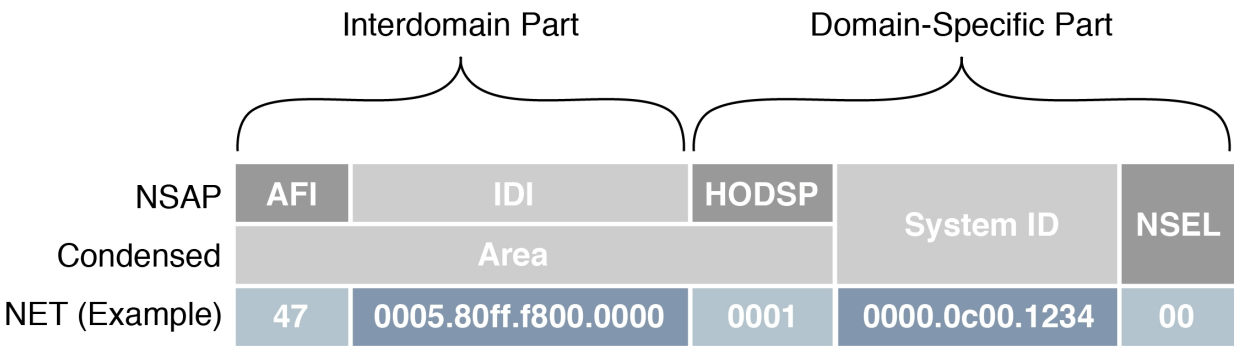
NSAP and NET

IS-IS routing protocol utilizes ISO network addressing to identify network interfaces. The addresses are known as Network Service Access Points (NSAPs). In general, IS-IS routers consist of only one NSAP, whereas IP addressing requires one IP address per interface.

In IS-IS, the NSAP address is translated into a Network Entity Title (NET), which is the same as the NSAP but can differentiate end systems by way of a byte called the *n-selector* (NSEL). In order for adjacencies to form in IS-IS, the NSEL must necessarily be set to zero, to indicate "this system". The total NET can be anywhere between 8 and 20 bytes long due to the support for variable length area addressing.

The following diagram identifies the individual parts of the NSAP, with explanations below.

NSAP and NET example



AFI — The *Authority and Format Identifier (AFI)* specifies the format of the addressing family used. IS-IS is designed to carry routing information for several different protocols. Each entry has an address family identifier that identifies the globally unique Interdomain Part (IDP). For example, 49 is the AFI for private addresses, whereas 47 is the AFI for international organizations.

IDI — The *Initial Domain Identifier (IDI)* identifies the routing domain within an interconnected network. The length of the IDI is typically determined by the AFI. If you are using an AFI of 49, you do not need to specify an IDI, since the network is private.

HODSP — The *High Order Domain-Specific Part (HODSP)* identifies the unique address within a specific routing domain. Together, the AFI, IDI, and HODSP define the area address. All of the nodes within an area must have the same area address.

System ID — The *System ID* represents the 6-8 byte router identifier. The ID could be Media Access Control (MAC) format, as in the example above, or a static length IP address expressed in binary-coded decimal (BCD) format.

NSEL — The *n-selector (NSEL)*, as previously described, identifies the network layer transport service and must always be set to zero for IS-IS NETs.

Parts and terminology of IS-IS

Before you can understand how IS-IS functions, you need to understand some of the main concepts and parts of IS-IS.

This section includes:

- DIS election and pseudonode LSP
- Packet types
- Default routing
- Timer options
- Authentication

DIS election and pseudonode LSP

In IS-IS routing protocol, a single router is chosen to be the designated intermediate system (DIS). The election of the DIS is determined automatically and dynamically on the LAN depending on highest interface priority and the subnetwork point of attachment (SNPA). The FortiGate is typically the DIS, and each router in its LAN is an intermediate system (IS).

Unlike OSPF, which elects a designated router (DR) and backup designated router (BDR), the DIS has no backup and determines the election of a new DIS whenever a router is added to the LAN or whenever the current DIS drops. A backup DIS is irrelevant since all of the routers on an IS-IS system are synchronized, and the short Hello interval used by the DIS quickly detects failures and the subsequent replacement of the DIS.

Synchronization of all the nodes in an IS-IS area could prove troublesome when updating the network infrastructure, and would demand ever-increasing resources each time a new router is added (at an exponential scale). For this purpose the DIS creates a pseudonode, which is essentially a virtual, logical node representing the LAN. The pseudonode requests adjacency status from all the routers in a multi-access network by sending IS-IS Hello (IIH) PDUs to Level 1 and Level 2 routers (where Level 1 routers share the same address as the DIS and Level 2 routers do not). Using a pseudonode to alter the representation of the LAN in the link-state database (LSD) greatly reduces the amount of adjacencies that area routers have to report. In essence, a pseudonode *collapses* a LAN topology, which allows a more linear scale to link-state advertising.

In order to maintain the database synchronization, the DIS periodically sends complete sequence number packets (CSNPs) to all participating routers.

Packet types

Four general packet types (PDUs) are communicated through IS-IS, appearing at both Level 1 and Level 2. They are described below.

Intermediate System-to-Intermediate System Hello (IIH) PDU — As mentioned previously, the IIH PDU, or Hello packet, detects neighboring routers and indicates to the pseudonode the area's adjacency mesh. The Hello packet, flooded to the multicast address, contains the system ID of the sending router, the holding time, the circuit type of the interface on which the PDU was sent, the PDU length, the DIS identifier, and the interface priority (used in DIS election). The Hello packet also informs its area routers that it is the DIS.

Hello packets are padded to the maximum IS-IS PDU size of 1492 bytes (the full MTU size) to assist in the detection of transmission errors with large frames or with MTU mismatches between adjacencies.

The DIS typically floods Hello packets to the entire LAN every three seconds.

Link-state PDU (LSP) — The LSP contains information about each router in an area and its connected interfaces. LSPs are refreshed periodically and acknowledged on the network by way of sequence number PDUs. If new LSP information is found, based on the most recent complete sequence number PDU (CSNP), then out-of-date entries in the link-state database (LSDB) are removed and the LSDB is updated.

For a more detailed breakdown of the LSP, see LSP structure on page 2503.

Complete sequence number PDU (CSNP) — CSNPs contain a list of all LSPs in the current LSDB. The CSNP informs other area routers of missing or outdated links in the adjacency mesh. The receiving routers then use this information to update their own database to ensure that all area routers converge.

In contrast to Hello packets, CSNPs are sent every ten seconds and only between neighbors. In other words, they are never flooded.

Partial sequence number PDU (PSNP) — PSNPs are used to request and acknowledge LSP information from an adjacency. When a router compares a CSNP with its local database and determines a discrepancy, the router requests an updated LSP using a PSNP. Once received, the router stores the LSP in its local database and responds to the DIS with acknowledgement.

Default routing

The default route is used if either there are no other routes in the routing table or if none of the other routes apply to a destination. Including the gateway in the default route gives all traffic a next-hop address to use when leaving the local network. The gateway address is normally another router on the edge of the local network.

FortiGate units come with a default static route with an IPv4 address of 0.0.0.0, an administration distance of 10, and a gateway IPv4 address. Beginner administrators can use the default route settings until a more advanced configuration is warranted.

By default, all routes are displayed in the Routing Monitor list. To display the routes in the routing table, go to **Monitor > Routing Monitor**.

Route leaking

Route leaking is the term used to describe the bi-directional flow of information between internal and external routing interfaces. By default, IS-IS leaks routing information from a Level 1 area into a Level 2 area. In order to leak Level 2 routing information into a Level 1 area, you must configure an export policy. Whether or not a route is leaked is determined by the ATT bit, using TLV 128 (for internal IP reachability) and TLV 130 (for external IP address information). For more information on TLVs, see Troubleshooting IS-IS on page 2508.

To configure IS-IS route leaking, use the following CLI commands.

1. On a Level 1-2 router:

```
config router isis
   set redistribute-l2 enable
end
```

2. You can use the following commands to show the results

```
get router info routing-table isis
get router info isis route
```

Default information originate option

Enabling default-information-originate generates and advertises a default route into the FortiGate unit's IS-IS-enabled networks. The generated route may be based on routes learned through a dynamic routing protocol, routes in the routing table, or both. IS-IS does not create the default route unless you use the `always` option.

Select **Disable** if you experience any issues or if you wish to advertise your own static routes into IS-IS updates.

The CLI commands associated with default information originate include:

```
config router isis
   set default-originate
end
```

Timer options

IS-IS uses various timers to regulate its performance including a garbage timer, update timer, and timeout timer. The FortiGate unit default timer settings (30, 180, and 120 seconds respectively) are effective in most configurations—if you change these settings, ensure that the new settings are compatible with local routers and access servers.

You can configure the three IS-IS timers in the CLI, using the following commands:

```
config router isis
   set garbage-timer
```

```
    set update-timer
    set timeout-timer
end
```

You will find more information on each timer below.

Update timer

The update timer determines the interval between routing updates. Generally, this value is set to 30 seconds. There is some randomness added to help prevent network traffic congestion, which could result from all routers simultaneously attempting to update their neighbors. The update timer should be at least three times smaller than the timeout timer, otherwise you will experience an error.

If you are experiencing significant traffic on your network, you can increase this interval to send fewer updates per minute. However, ensure you increase the interval for all the routers on your network or you will experience timeouts that will degrade your network speed.

Timeout timer

The timeout timer is the maximum amount of time (in seconds) that a route is considered reachable while no updates are received for the route. This is the maximum time the DIS will keep a reachable route in the routing table while no updates for that route are received. If the DIS receives an update for the route before the timeout period expires, the timer is restarted. The timeout period should be at least three times longer than the update period, otherwise you will experience an error.

If you are experiencing problems with routers not responding in time to updates, increase this timer. However, remember that longer timeout intervals result in longer overall update periods — it may be considerable time before the DIS is done waiting for all the timers to expire on unresponsive routes.

Garbage timer

The garbage timer is the amount of time (in seconds) that the DIS will advertise a route as being unreachable before deleting the route from the routing table. If this timer is shorter, it will keep more up-to-date routes in the routing table and remove old ones faster. This results in a smaller routing table which is useful if you have a very large network, or if your network changes frequently.

Authentication

In routing protocols, it is typically desireable to establish authentication rules that prevent malicious and otherwise unwanted information from being injected into the routing table. IS-IS routing protocol utilizes TLV 10 to establish authentication. For more information on TLVs, see TLV on page 2503.

Initially, IS-IS used plain Clear Text to navigate the authentication rules, but this was found to be insecure since the Clear Text packets were unencrypted and could be exposed to packet sniffers. As per RFC 3567, HMAC-MD5 and Enhanced Clear Text authentication features were introduced to IS-IS, both of which encrypt authentication data, making them considerably more secure than using plain Clear Text authentication.

HMAC-MD5 authentication

Hashed Message Authentication Codes - Message Digest 5 (HMAC-MD5) is a mechanism for applying a cryptographic hash function to the message authentication process. It is applied at both Level 1 and Level 2 routing. In IS-IS, an HMAC-MD5 can be applied to each type of LSP, on different interfaces, and with different passwords.

Authentication data is hashed using an AH (Authentication Header) key. From RFC 2085:

> *The "AH Key" is used as a shared secret between two communicating parties. The Key is not a "cryptographic key" as used in a traditional sense. Instead, the AH key (shared secret) is hashed with the transmitted data and thus, assures that an intervening party cannot duplicate the authentication data. [...] Implementation should, and as frequently as possible, change the AH key. Keys need to be chosen at random, or generated using a cryptographically strong pseudo-random generator seeded with a random seed."*

Clear Text authentication uses the configuration commands `area-password` and `domain-password` for authentication, but when migrating from Clear Text authentication to HMAC-MD5, these command settings are automatically overwritten.

By the year 2005, the MD5 hash function had been identified as vulnerable to collision search attacks and various weaknesses. While such vulnerabilities do not compromise the use of MD5 within HMAC, administrators need to be aware of potential developments in cryptanalysis and cryptographic hash functions in the likely event that the underlying hash function needs to be replaced.

Enhanced Clear Text authentication

Enhanced Clear Text authentication is an extension to Clear Text authentication that allows the encryption of passwords as they are displayed in the configuration. It includes a series of authentication mode commands and an authentican key chain, and allows for more simple password modification and password management. Enhanced Clear Text authentication also provides for smoother migration to and from changing authentication types. Intermediate systems continue to use the original authentication method until all the area routers are updated to use the new method.

Authentication key chain

A key chain is a list of one or more authentication keys including the send and receive lifetimes for each key. Keys are used for authenticating routing packets only during the specified lifetimes. A router migrates from one key to the next according to the scheduled send and receive lifetimes. If an active key is unavailable, then the PDU is automatically discarded.

From RFC 5310:

> *It should be noted that the cryptographic strength of the HMAC depends upon the cryptographic strength of the underlying hash function and on the size and quality of the key.*

Troubleshooting IS-IS

This section includes:

- Routing loops
- Split horizon and Poison reverse updates

Routing loops

Normally in routing, a path between two addresses is chosen and traffic is routed along that path from one address to the other. When there is a routing loop, that normal path doubles back on itself creating a loop. When there are loops, the network has problems.

A routing loop happens when a normally functioning network has an outage, and one or more routers are offline. When packets encounter this, an alternate route is attempted to maneuver around the outage. During this phase

it is possible for a route to be attempted that involves going back a hop, and trying a different hop forward. If that hop forward is blocked by the outage as well, a hop back and possibly the original hop forward may be selected. You can see if this continues, how it can consume not only network bandwidth but also many resources on those routers affected. The worst part is this situation will continue until the network administrator changes the router settings, or the downed routers come back online.

Routing loop effect on the network

In addition to this “traffic jam” of routed packets, every time the routing table for a router changes that router sends an update out to all of the IS-IS routers connected to it. In a network loop, its possible for a router to change its routes very quickly as it tries and fails along these new routes. This can quickly result in a flood of updates being sent out, which can effectively grind the network to a halt until the problem is fixed.

How can you spot a routing loop

Any time network traffic slows down, you will be asking yourself if it is a network loop or not. Often slowdowns are normal, they are not a full stoppage, and normal traffic resumes in a short period of time.

If the slow down is a full halt of traffic or a major slowdown does not return to normal quickly, you need to do serious troubleshooting quickly.

Some methods to troubleshoot your outage include:

- Checking your logs
- Using SNMP network monitoring
- Using Link Health Monitor and e-mail alerts
- Looking at the packet flow

If you aren’t running SNMP, dead gateway detection, or you have non-Fortinet routers in your network, you can use networking tools such as ping and traceroute to define the outage on your network and begin to fix it.

Checking your logs

If your routers log events to a central location, it can be easy to check the logs for your network for any outages.

On your FortiGate unit, go to **Log & Report > Log & Archive Access**. You will want to look at both event logs and traffic logs. Events to look for will generally fall under CPU and memory usage, interfaces going offline (due to dead gateway detection), and other similar system events.

Once you have found and fixed your network problem, you can go back to the logs and create a report to better see how things developed during the problem. This type of forensics analysis can better help you prepare for next time.

Using SNMP network monitoring

If your network had no problems one minute and slows to a halt the next, chances are something changed to cause that problem. Most of the time an offline router is the cause, and once you find that router and bring it back online, things will return to normal.

If you can enable a hardware monitoring system such as SNMP or sFlow on your routers, you can be notified of the outage and where it is exactly as soon as it happens.

Ideally you can configure SNMP on all your FortiGate routers and be alerted to all outages as they occur.

To use SNMP to detect potential routing loops

1. Go to **System > SNMP**.
2. Enable **SNMP Agent**.
3. Optionally enter the **Description**, **Location**, and **Contact** information for this device for easier location of the problem report.
4. In either **SNMP v1/v2c** section or **SNMP v3** section, as appropriate, select **Create New**.
5. Enter the **Community Name** that you want to use.
6. In **Hosts**, select Add to add an IP address where you will be monitoring the FortiGate unit. You can add up to 8 different addresses.
7. Ensure that ports 161 and 162 (SNMP queries and traps) are allowed through your security policies.
8. In **SNMP Event**, select the events you want to be notified of. For routing loops this should include **CPU Overusage**, **Memory Low**, and possibly **Log disk space low**. If there are problems, the log will be filling up quickly, and the FortiGate unit's resources will be overused.
9. Select **OK**.
10. Configure SNMP host (manager) software on your administration computer. This will monitor the SNMP information sent out by the FortiGate unit. Typically you can configure this software to alert you to outages or CPU spikes that may indicate a routing loop.

Using Link Health Monitor and e-mail alerts

Another tool available to you on FortiGate units is the Link Health Monitor, useful for dead gateway detection. This feature allows the FortiGate unit to ping a gateway at regular intervals to ensure it is online and working. When the gateway is not accessible, that interface is marked as down.

To detect possible routing loops with Link Health Monitor

Use the following command to configure dead gateway detection:

```
config system link-monitor
   edit "test"
      set srcintf "internal4"
      set server "8.8.8.8"
      set interval 5
      set failtime 1
   end
```

Set the `Interval` (how often to send a ping) and `failtime` (how many lost pings is considered a failure). A smaller interval and smaller number of lost pings will result in faster detection, but will create more traffic on your network.

You may also want to log CPU and Memory usage as a network outage will cause your CPU activity to spike.

If you have VDOMs configured, you will have to enter the basic SMTP server information in the Global section, and the rest of the configuration within the VDOM that includes this interface.

After this configuration, when this interface on the FortiGate unit cannot connect to the next router, the FortiGate unit will bring down the interface and alert you with an email to the outage.

Looking at the packet flow

If you want to see what is happening on your network, look at the packets travelling on the network. In this situation, you are looking for routes that have metrics higher than 15 as that indicates they are unreachable. Ideally if you debug the flow of the packets, and record the routes that are unreachable, you can create an accurate picture of the network outage.

Action to take on discovering a routing loop

Once you have mapped the problem on your network, and determined it is in fact a routing loop there are a number of steps to take in correcting it.

1. Get any offline routers back online. This may be a simple reboot, or you may have to replace hardware. Often this first step will restore your network to its normal operation, once the routing tables finish being updated.
2. Change your routing configuration on the edges of the outage. Even if step 1 brought your network back online, you should consider making changes to improve your network before the next outage occurs. These changes can include configuring features like holddowns and triggers for updates, split horizon, and poison reverse updates.

Split horizon and Poison reverse updates

Split horizon is best explained with an example. You have three routers linked serially, let's call them A, B, and C. A is only linked to B, C is only linked to B, and B is linked to both A and C. To get to C, A must go through B. If the link to C goes down, it is possible that B will try to use A's route to get to C. This route is A-B-C, so it will not work. However, if B tries to use it this begins an endless loop.

This situation is called a split horizon because from B's point of view the horizon stretches out in each direction, but in reality it only is on one side.

Poison reverse is the method used to prevent routes from running into split horizon problems. Poison reverse "poisons" routes away from the destination that use the current router in their route to the destination. This "poisoned" route is marked as unreachable for routers that cannot use it. In IS-IS this means that route is marked with a distance of 16.

Simple IS-IS example

This is an example of a typical medium-sized network configuration using IS-IS routing.

Imagine a company with four FortiGate devices connected to one another. A FortiGate at one end of the network connects to two routers, each with its own local subnet; one of these routers uses OSPF and the other uses RIP.

Your task is to configure the four FortiGates to route traffic and process network updates using IS-IS, such that the farthest FortiGate (see 'FGT4' in Network layout and assumptions on page 2512) receives route updates for the two routers at the opposite end of the network. Furthermore, FGT4 has been given a loopback subnet that must be identified by the router running RIP.

Since the internal networks use OSPF and RIP, those protocols will need to be redistributed through the IS-IS network. To keep the example simple, there will be no authentication of router traffic.

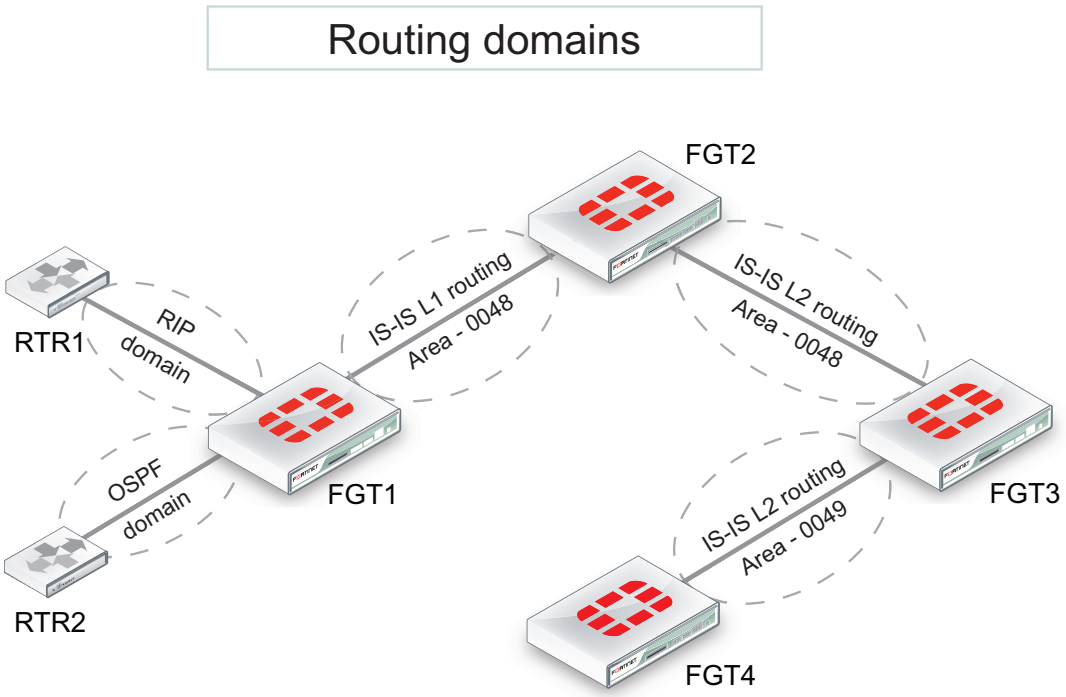
With IS-IS properly configured in this example, if a router fails or temporarily goes offline, the route change will propagate throughout the system.

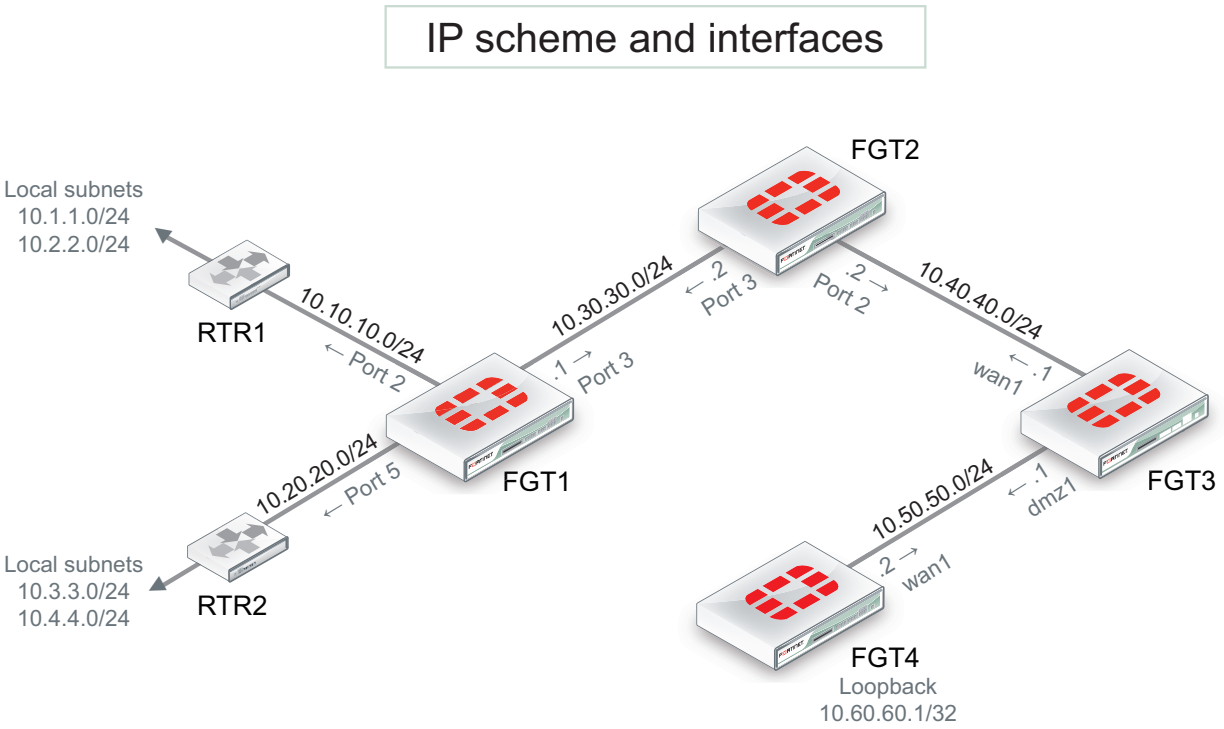
This section includes the following topics:

- Network layout and assumptions
- Expectations

- CLI configuration
- Verification
- Troubleshooting

Network layout and assumptions





- It is assumed that each FortiGate is operating in NAT mode, running FortiOS 4.0MR2+.
- All interfaces have been previously assigned and no static routes are required.
- The AFI (Authority and Format Identifier) used is 49 : Locally administered (private).
- The Area identifiers are 0048 and 0049.

Expectations

- FGT4 must get the IS-IS route updates for RTR1 and RTR2 local subnets (10.1.1.0, 10.2.2.0, 10.3.3.0, 10.4.4.0).
- RTR1 must receive (via RIP2) the loopback subnet of FGT4 (10.60.60.1/32).

CLI configuration

The following CLI configuration occurs on each FortiGate (as identified), including only the relevant parts.

FGT1

```
config router isis
   config isis-interface
      edit "port3"
         set circuit-type level-1
         set network-type broadcast
         set status enable
      next
   end
   config isis-net
      edit 1
         set net 49.0048.1921.6818.2136.00
      next
   end
```

```
      config redistribute "connected"
      end
      config redistribute "rip"
         set status enable
         set level level-1
      end
      config redistribute "ospf"
         set status enable
         set level level-1
      end
   end
   config router rip
      config interface
         edit "port2"
            set receive-version 2
            set send-version 2
         next
      end
      config network
         edit 1
            set prefix 10.10.10.0 255.255.255.0
         next
      end
      config redistribute "isis"
         set status enable
      end
   end
```

FGT2

```
   config router isis
      config isis-interface
         edit "port3"
            set circuit-type level-1
            set network-type broadcast
            set status enable
         next
         edit "port2"
            set network-type broadcast
            set status enable
         next
      end
      config isis-net
         edit 1
            set net 49.0048.1221.6818.2110.00
         next
      end
      set redistribute-l1 enable
      set redistribute-l2 enable
   end
```

FGT3

```
   config router isis
      set is-type level-2-only
```

```
      config isis-interface
         edit "wan1"
            set network-type broadcast
            set status enable
         next
         edit "dmz1"
            set network-type broadcast
            set status enable
         next
      end
      config isis-net
         edit 1
            set net 49.0048.1921.6818.2108.00
         next
         edit 2
            set net 49.0049.1921.6818.2108.00
         next
      end
end
```

FGT4

```
config router isis
   set is-type level-2-only
      config isis-interface
         edit "wan1"
            set network-type broadcast
            set status enable
         next
      end
      config isis-net
         edit 1
            set net 49.0049.1721.0160.1004.00
         next
      end
      config redistribute "connected"
         set status enable
      end
end
```

Verification

Once the network has been configured, you need to test that it works as expected. Use the following CLI commands on the devices indicated.

Verifying if RTR1 receives loopback subnet of FGT4

```
(RTR1) # get router info routing-table all
```

Result:

```
C    10.1.1.0/24 is directly connected, vlan1
C    10.2.2.0/24 is directly connected, vlan2
C    10.10.10.0/24 is directly connected, dmz1
R    10.40.40.0/24 [120/2] via 10.10.10.1, dmz1, 00:04:07
```

```
R    10.50.50.0/24 [120/2] via 10.10.10.1, dmz1, 00:04:07
R    10.60.60.1/32 [120/2] via 10.10.10.1, dmz1, 00:04:07
```

(*) If required, filtering out 10.50.50.0 and 10.40.40.0 from the routing table could be done with a route-map.

Verification on FGT2, which is the border between L1 and L2 routing levels; looking at IS-IS information

```
FGT2 # get router info isis interface
```

Result:

```
port2 is up, line protocol is up
Routing Protocol: IS-IS ((null))
Network Type: Broadcast

```

Troubleshooting

The following diagnose commands are available for further IS-IS troubleshooting and will display all IS-IS activity (sent and received packets):

```
FGT # diagnose ip router isis level info
FGT # diagnose ip router isis all enable
FGT # diagnose debug enable
```

…to stop the debug type output:

```
FGT # diagnose ip router isis level none
```

Output and interpretation depends on the issue faced. You can provide this information to TAC if you open a support ticket.

Multicast forwarding

Multicasting (also called IP multicasting) consists of using a single multicast source to send data to many receivers. Multicasting can be used to send data to many receivers simultaneously while conserving bandwidth and reducing network traffic. Multicasting can be used for one-way delivery of media streams to multiple receivers and for one-way data transmission for news feeds, financial information, and so on.

Also RIPv2 uses multicasting to share routing table information, OSPF uses multicasting to send hello packets and routing updates, Enhanced Interior Gateway Routing Protocol (EIGRP) uses multicasting to send routing information to all EIGRP routers on a network segment and the Bonjour network service uses multicasting for DNS.

A FortiGate unit can operate as a Protocol Independent Multicast (PIM) version 2 router. FortiGate units support PIM sparse mode (RFC 4601) and PIM dense mode (RFC 3973) and can service multicast servers or receivers on the network segment to which a FortiGate unit interface is connected. Multicast routing is not supported in transparent mode (TP mode).

To support PIM communications, the sending/receiving applications and all connecting PIM routers in between must be enabled with PIM version 2. PIM can use static routes, RIP, OSPF, or BGP to forward multicast packets to their destinations. To enable source-to-destination packet delivery, either sparse mode or dense mode must be enabled on the PIM-router interfaces. Sparse mode routers cannot send multicast messages to dense mode routers. In addition, if a FortiGate unit is located between a source and a PIM router, two PIM routers, or is connected directly to a receiver, you must create a security policy manually to pass encapsulated (multicast) packets or decapsulated data (IP traffic) between the source and destination.

A PIM domain is a logical area comprising a number of contiguous networks. The domain contains at least one Boot Strap Router (BSR), and if sparse mode is enabled, a number of Rendezvous Points (RPs) and Designated Routers (DRs). When PIM is enabled on a FortiGate unit, the FortiGate unit can perform any of these functions at any time as configured.

Sparse mode

Initially, all candidate BSRs in a PIM domain exchange bootstrap messages to select one BSR to which each RP sends the multicast address or addresses of the multicast group(s) that it can service. The selected BSR chooses one RP per multicast group and makes this information available to all of the PIM routers in the domain through bootstrap messages. PIM routers use the information to build packet distribution trees, which map each multicast group to a specific RP. Packet distribution trees may also contain information about the sources and receivers associated with particular multicast groups.

When a FortiGate unit interface is configured as a multicast interface, sparse mode is enabled on it by default to ensure that distribution trees are not built unless at least one downstream receiver requests multicast traffic from a specific source. If the sources of multicast traffic and their receivers are close to each other and the PIM domain contains a dense population of active receivers, you may choose to enable dense mode throughout the PIM domain instead.

An RP represents the root of a non-source-specific distribution tree to a multicast group. By joining and pruning the information contained in distribution trees, a single stream of multicast packets (for example, a video feed) originating from the source can be forwarded to a certain RP to reach a multicast destination.

Each PIM router maintains a Multicast Routing Information Base (MRIB) that determines to which neighboring PIM router join and prune messages are sent. An MRIB contains reverse-path information that reveals the path of a multicast packet from its source to the PIM router that maintains the MRIB.

To send multicast traffic, a server application sends IP traffic to a multicast group address. The locally elected DR registers the sender with the RP that is associated with the target multicast group. The RP uses its MRIB to forward a single stream of IP packets from the source to the members of the multicast group. The IP packets are replicated only when necessary to distribute the data to branches of the RP's distribution tree.

To receive multicast traffic, a client application can use Internet Group Management Protocol (IGMP) version 1 (RFC 1112), 2 (RFC 2236), or 3 (RFC 3376) control messages to request the traffic for a particular multicast group. The locally elected DR receives the request and adds the host to the multicast group that is associated with the connected network segment by sending a join message towards the RP for the group. Afterward, the DR queries the hosts on the connected network segment continually to determine whether the hosts are active. When the DR no longer receives confirmation that at least one member of the multicast group is still active, the DR sends a prune message towards the RP for the group.

FortiOS supports PIM sparse mode multicast routing for IPv6 multicast (multicast6) traffic and is compliant with RFC 4601: Protocol Independent Multicast - Sparse Mode (PIM-SM). You can use the following command to configure IPv6 PIM sparse multicast routing.

```
config router multicast6
   set multicast-routing {enable | disable}
      config interface
         edit <interface-name>
            set hello-interval <1-65535 seconds>
            set hello-holdtime <1-65535 seconds>
         end
      config pim-sm-global
         config rp-address
            edit <index>
               set ipv6-address <ipv6-address>
            end
```

The following diagnose commands for IPv6 PIM sparse mode are also available:

```
diagnose ipv6 multicast status
diagnose ipv6 multicast vif
diagnose ipv6 multicast mroute
```

Dense mode

The packet organization used in sparse mode is also used in dense mode. When a multicast source begins to send IP traffic and dense mode is enabled, the closest PIM router registers the IP traffic from the multicast source (S) and forwards multicast packets to the multicast group address (G). All PIM routers initially broadcast the multicast packets throughout the PIM domain to ensure that all receivers that have requested traffic for multicast group address G can access the information if needed.

To forward multicast packets to specific destinations afterward, the PIM routers build distribution trees based on the information in multicast packets. Upstream PIM routers depend on prune/graft messages from downstream PIM routers to determine if receivers are actually present on directly connected network segments. The PIM

routers exchange state refresh messages to update their distribution trees. FortiGate units store this state information in a Tree Information Base (TIB), which is used to build a multicast forwarding table. The information in the multicast forwarding table determines whether packets are forwarded downstream. The forwarding table is updated whenever the TIB is modified.

PIM routers receive data streams every few minutes and update their forwarding tables using the source (S) and multicast group (G) information in the data stream. Superfluous multicast traffic is stopped by PIM routers that do not have downstream receivers—PIM routers that do not manage multicast groups send prune messages to the upstream PIM routers. When a receiver requests traffic for multicast address G, the closest PIM router sends a graft message upstream to begin receiving multicast packets.

FortiGate units operating in NAT mode can also be configured as multicast routers. You can configure a FortiGate unit to be a Protocol Independent Multicast (PIM) router operating in Sparse Mode (SM) or Dense Mode (DM).

PIM Support

A FortiGate unit can be configured to support PIM by going to **Network > Multicast** and enabling multicast routing. You can also enable multicast routing using the `config router multicast` CLI command. When PIM is enabled, the FortiGate unit allocates memory to manage mapping information. The FortiGate unit communicates with neighboring PIM routers to acquire mapping information and if required, processes the multicast traffic associated with specific multicast groups.

The end-user multicast client-server applications must be installed and configured to initiate Internet connections and handle broadband content such as audio/video information.

Client applications send multicast data by registering IP traffic with a PIM-enabled router. An end-user could type in a class D multicast group address, an alias for the multicast group address, or a call-conference number to initiate the session.

Rather than sending multiple copies of generated IP traffic to more than one specific IP destination address, PIM-enabled routers encapsulate the data and use the one multicast group address to forward multicast packets to multiple destinations. Because one destination address is used, a single stream of data can be sent. Client applications receive multicast data by requesting that the traffic destined for a certain multicast group address be delivered to them — end-users may use phone books, a menu of ongoing or future sessions, or some other method through a user interface to select the address of interest.

A class D address in the 224.0.0.0 to 239.255.255.255 range may be used as a multicast group address, subject to the rules assigned by the Internet Assigned Numbers Authority (IANA). All class D addresses must be assigned in advance. Because there is no way to determine in advance if a certain multicast group address is in use, collisions may occur (to resolve this problem, end-users may switch to a different multicast address).

To configure a PIM domain

1. If you will be using sparse mode, determine appropriate paths for multicast packets.
2. Make a note of the interfaces that will be PIM-enabled. These interfaces may run a unicast routing protocol.
3. If you will be using sparse mode and want multicast packets to be handled by specific (static) RPs, record the IP addresses of the PIM-enabled interfaces on those RPs.
4. Enable PIM version 2 on all participating routers between the source and receivers. On FortiGate units, use the `config router multicast` command to set global operating parameters.

5. Configure the PIM routers that have good connections throughout the PIM domain to be candidate BSRs.
6. If sparse mode is enabled, configure one or more of the PIM routers to be candidate RPs.
7. If required, adjust the default settings of PIM-enabled interface(s).

Multicast forwarding and FortiGate units

In both transparent mode and NAT mode you can configure FortiGate units to forward multicast traffic.

For a FortiGate unit to forward multicast traffic you must add FortiGate multicast security policies. Basic multicast security policies accept any multicast packets at one FortiGate interface and forward the packets out another FortiGate interface. You can also use multicast security policies to be selective about the multicast traffic that is accepted based on source and destination address, and to perform NAT on multicast packets.

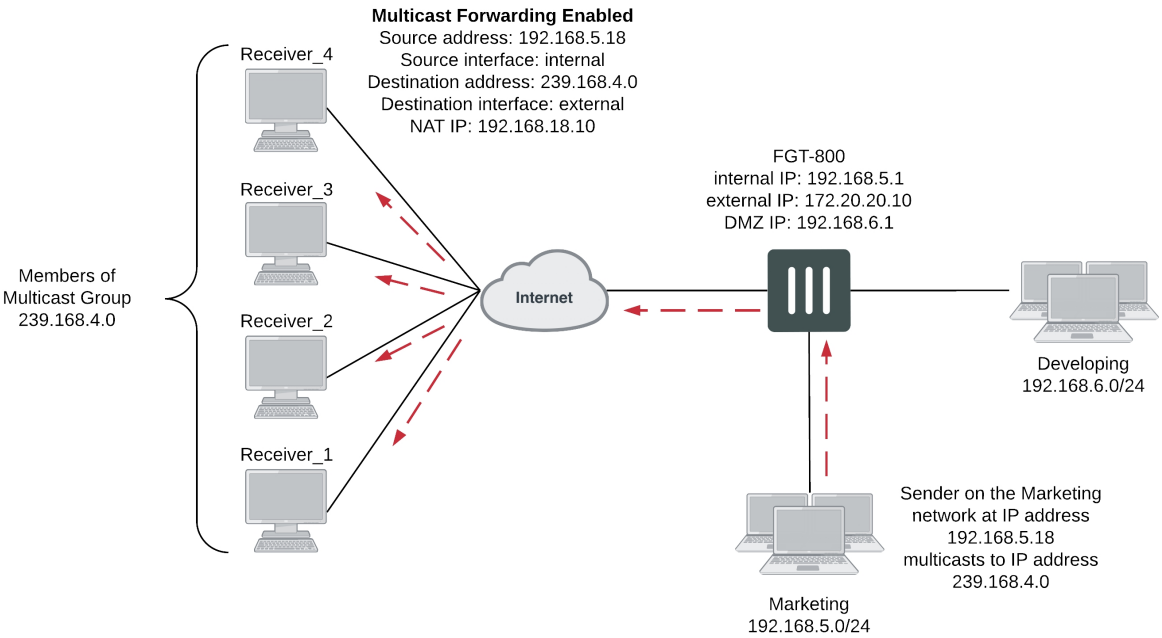
In the example shown below, a multicast source on the Marketing network with IP address 192.168.5.18 sends multicast packets to the members of network 239.168.4.0. At the FortiGate unit, the source IP address for multicast packets originating from workstation 192.168.5.18 is translated to 192.168.18.10. In this example, the FortiGate unit is not acting as a multicast router.

Multicast forwarding and RIPv2

RIPv2 uses multicast to share routing table information. If your FortiGate unit is installed on a network that includes RIPv2 routers, you must configure the FortiGate unit to forward multicast packets so that RIPv2 devices can share routing data through the FortiGate unit. No special FortiGate configuration is required to share RIPv2 data, you can simply use the information in the following sections to configure the FortiGate unit to forward multicast packets.

RIPv1 uses broadcasting to share routing table information. To allow RIPv1 packets through a FortiGate unit you can add standard security policies. Security policies to accept RIPv1 packets can use the ANY predefined firewall service or the RIP predefined firewall service.

Example multicast network including a FortiGate unit that forwards multicast packets



Configuring FortiGate multicast forwarding

You configure FortiGate multicast forwarding from the Command Line Interface (CLI). Two steps are required:

- Adding multicast security policies
- Enabling multicast forwarding
  This second step is only required if your FortiGate unit is operating in NAT mode. If your FortiGate unit is operating in transparent mode, adding a multicast policy enables multicast forwarding.

There is sometimes a confusion between the terms “forwarding” and “routing”. These two functions should not be taking place at the same time.

It is mentioned that multicast-forward should be enabled when the FortiGate unit is in NAT mode and that this will forward any multicast packet to all interfaces. However, this parameter should **NOT** be enabled when the FortiGate unit operates as a multicast router (i.e. with a routing protocol enabled. It should only be enabled when there is no routing protocols activated.

Adding multicast security policies

You need to add security policies to allow packets to pass from one interface to another. Multicast packets require multicast security policies. You add multicast security policies from the CLI using the `config firewall multicast-policy` command. As with unicast security policies, you specify the source and destination interfaces and optionally the allowed address ranges for the source and destination addresses of the packets.

You can also use multicast security policies to configure source NAT and destination NAT for multicast packets.

Keep the following in mind when configuring multicast security policies:

- The matched forwarded (outgoing) IP multicast source IP address is changed to the configured IP address.
- Source and Destination interfaces are optional. If left blank, then the multicast will be forwarded to ALL interfaces.
- Source and Destination addresses are optional. If left un set, then it will mean ALL addresses.
- The `nat` keyword is optional. Use it when source address translation is needed.

Enabling multicast forwarding

Multicast forwarding is enabled by default. In NAT mode you must use the `multicast-forward` keyword of the `system settings` CLI command to enable or disable multicast forwarding. When `multicast-forward` is enabled, the FortiGate unit forwards any multicast IP packets in which the TTL is 2 or higher to all interfaces and VLAN interfaces except the receiving interface. The TTL in the IP header will be reduced by 1. Even though the multicast packets are forwarded to all interfaces, you must add security policies to actually allow multicast packets through the FortiGate. In our example, the security policy allows multicast packets received by the internal interface to exit to the external interface.

Enabling multicast forwarding is only required if your FortiGate unit is operating in NAT mode. If your FortiGate unit is operating in transparent mode, adding a multicast policy enables multicast forwarding.

Enter the following CLI command to enable multicast forwarding:

```
config system settings
   set multicast-forward enable
end
```

If multicast forwarding is disabled and the FortiGate unit drops packets that have multicast source or destination addresses.

You can also use the `multicast-ttl-notchange` keyword of the `system settings` command so that the FortiGate unit does not increase the TTL value for forwarded multicast packets. You should use this option only if packets are expiring before reaching the multicast router.

```
config system settings
   set multicast-ttl-notchange enable
end
```

In transparent mode, the FortiGate unit does not forward frames with multicast destination addresses. Multicast traffic such as the one used by routing protocols or streaming media may need to traverse the FortiGate unit, and should not be interfere with the communication. To avoid any issues during transmission, you can set up multicast security policies. These types of security policies can only be enabled using the CLI.

The CLI parameter multicast-skip-policy must be disabled when using multicast security policies. To disable enter the command

```
config system settings
     set multicast-skip-policy disable
end
```

In this simple example, no check is performed on the source or destination interfaces. A multicast packet received on an interface is flooded unconditionally to all interfaces on the forwarding domain, except the incoming interface.

To enable the multicast policy

```
config firewall multicast-policy
   edit 1
      set action accept
   end
```

In this example, the multicast policy only applies to the source port of WAN1 and the destination port of Internal.

To enable the restrictive multicast policy

```
config firewall multicast-policy
   edit 1
      set srcintf wan1
      set dstinf internal
      set action accept
   end
```

In this example, packets are allowed to flow from WAN1 to Internal, and sourced by the address 172.20.120.129, which is represented by the address object "example_addr-1".

To enable the restrictive multicast policy

```
config firewall multicast-policy
   edit 1
      set srcintf wan1
      set srcaddr example_addr-1
      set dstinf internal
      set action accept
   end
```

This example shows how to configure the multicast security policy required for the configuration shown. This policy accepts multicast packets that are sent from a PC with IP address 192.168.5.18 to destination address range 239.168.4.0. The policy allows the multicast packets to enter the internal interface and then exit the external interface. When the packets leave the external interface their source address is translated to 192.168.18.10

```
config firewall multicast-policy
   edit 5
      set srcaddr 192.168.5.18 255.255.255.255
      set srcintf internal
      set destaddr 239.168.4.0 255.255.255.0
      set dstintf external
      set nat 192.168.18.10
   end
```

This example shows how to configure a multicast security policy so that the FortiGate unit forwards multicast packets from a multicast Server with an IP 10.10.10.10 is broadcasting to address 225.1.1.1. This Server is on the network connected to the FortiGate DMZ interface.

```
config firewall multicast-policy
   edit 1
      set srcintf DMZ
      set srcaddr 10.10.10.10 255.255.255.255
      set dstintf Internal
      set dstaddr 225.1.1.1 255.255.255.255
      set action accept
   edit 2
      set action deny
   end
```

Multicast routing examples

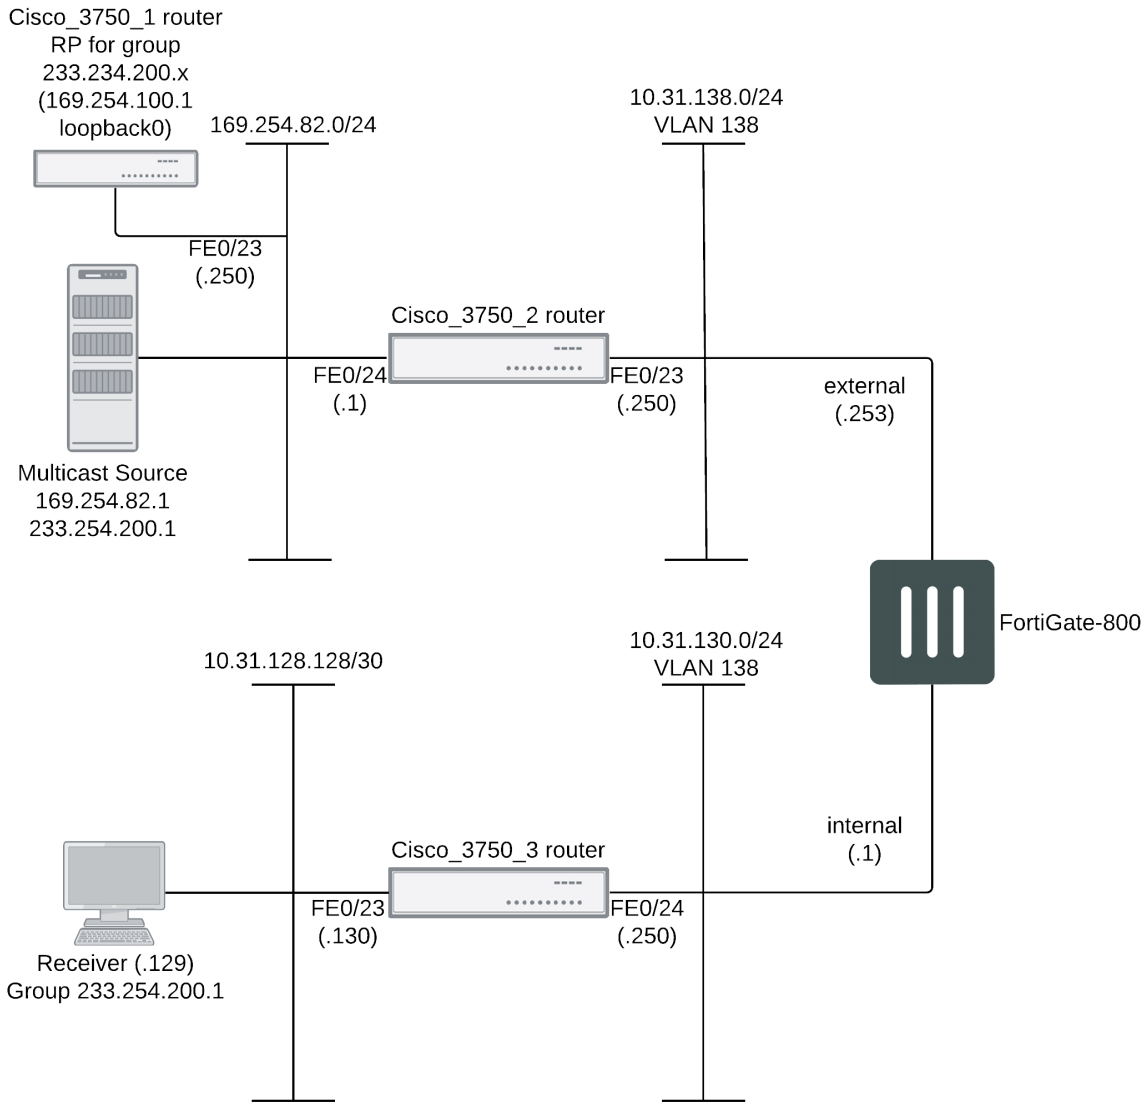
This section contains the following multicast routing configuration examples and information:

- Example FortiGate PIM-SM configuration using a static RP
- FortiGate PIM-SM debugging examples
- Example multicast destination NAT (DNAT) configuration
- Example PIM configuration that uses BSR to find the RP

Example FortiGate PIM-SM configuration using a static RP

The example Protocol Independent Multicast Sparse Mode (PIM-SM) configuration shown below has been tested for multicast interoperability using PIM-SM between Cisco 3750 switches running 12.2 and a FortiGate-800 running FortiOS v3.0 MR5 patch 1. In this configuration, the receiver receives the multicast stream when it joins the group 233.254.200.1.

Example FortiGate PIM-SM topology



The configuration uses a statically configured rendezvous point (RP) which resides on the Cisco_3750_1. Using a bootstrap router (BSR) was not tested in this example. See “Example PIM configuration that uses BSR to find the RP” for an example that uses a BSR.

Configuration steps

The following procedures show how to configure the multicast configuration settings for the devices in the example configuration.

- Cisco_3750_1 router configuration
- Cisco_3750_2 router configuration
- To configure the FortiGate-800 unit
- Cisco_3750_3 router configuration

Cisco_3750_1 router configuration

```
version 12.2
!

```

To configure the FortiGate-800 unit

1. Configure the internal and external interfaces.

- **Internal**

  Go to **Network > Interfaces**.

  Select the internal interface.

  Verify the following settings:

Type:	Physical Interface
Addressing mode:	Manual
IP/Network Mask:	10.31.138.253 255.255.255.0
Administrative Access:	PING

  Select **OK**.

- **External**

Go to **System > Network > Interfaces**.

Select the external interface.

Verify the following settings:

Type:	Physical Interface
Addressing mode:	Manual
IP/Network Mask:	10.31.130.253 255.255.255.0
Administrative Access:	HTTPS and PING

Select **OK**.

2. Add a firewall addresses.

Go to **Policy & Objects > Addresses.**

- RP

Select **Create New**.

Use the following settings:

Category:	Address
Name:	RP
Type:	Subnet
Subnet/IP Range:	169.254.100.1/32
Interface:	Any
Visibility:	<enabled>

Select **OK**.

- Multicast source subnet

Select **Create New**.

Use the following settings:

Category:	Address
Name:	multicast_source_subnet
Type:	Subnet
Subnet/IP Range:	169.254.82.0/24

Interface:	Any
Visibility:	<enabled>

Select **OK**.

3. Add destination multicast address
   Go to **Policy & Objects > Addresses.**

   Select **Create New**.

   Use the following settings:

Category:	Multicast Address
Name:	Multicast_stream
Type:	Broadcast Subnet
Broadcast Subnet:	233.254.200.0/24
Interface:	Any
Visibility:	<enabled>

   Select **OK**.

4. Add standard security policies to allow traffic to reach the RP.

   Go to **Policy & Objects > IPv4 Policy**.

   - 1st policy

   Select **Create New**

   Use the following settings:

Incoming Interface:	internal
Source Address:	all
Outgoing Interface:	external
Destination Address:	RP
Schedule:	always
Service:	ALL
Action:	ACCEPT

   Select **OK**.

   - 2nd policy

   Select **Create New**

   Use the following settings:

Incoming Interface:	external
Source Address:	RP
Outgoing Interface:	internal
Destination Address:	all
Schedule:	always
Service:	ALL
Action:	ACCEPT

Select **OK**.

5. Add the multicast security policy.

   Go to **Policy & Objects > Multicast Policy**.

   Select **Create New**.

   Use the following settings:

Incoming Interface:	external
Source Address:	multicast_source_subnet
Outgoing Interface:	internal
Destination Address:	multicast_stream
Protocol:	Any
Action:	ACCEPT

   Select **OK**.

6. Add an access list. (CLI only)

```
config router access-list
   edit Source-RP
      config rule
         edit 1
            set prefix 233.254.200.0 255.255.255.0
            set exact-match disable
         next
      end
```

7. Add some static routes.

   Go to **Network > Static Routes**.

   - Route 1

   Select **Create New**.

   Use the following settings:

Destination IP/Mask:	0.0.0.0/0.0.0.0
Device:	internal
Gateway:	10.31.130.250
Distance:	<default>
Priority:	<default>

Select **OK**.

- Route 2

Select **Create New**.

Use the following settings:

Destination IP/Mask:	169.254.0.0/16
Device:	external
Gateway:	10.31.138.250
Distance:	<default>
Priority:	<default>

Select **OK**.

8. Configure multicast routing.

   Go to **Network > Multicast**.

   Add the following Static Rendezvous Point(s):
   - 169.254.100.1

   - Route 1

   Select **Create New**.

   Use the following settings:

Interface:	internal
PIM Mode:	Sparse Mode
DR Priority:	<not needed in this scenario>
RP Candidate:	<not needed in this scenario>
RP Candidate Priority:	<not needed in this scenario>

   Select **OK.**

   - Route 2

Select **Create New**.

Use the following settings:

Interface:	external
PIM Mode:	Sparse Mode
DR Priority:	
RP Candidate:	
RP Candidate Priority:	

Select **OK.**

Cisco_3750_3 router configuration

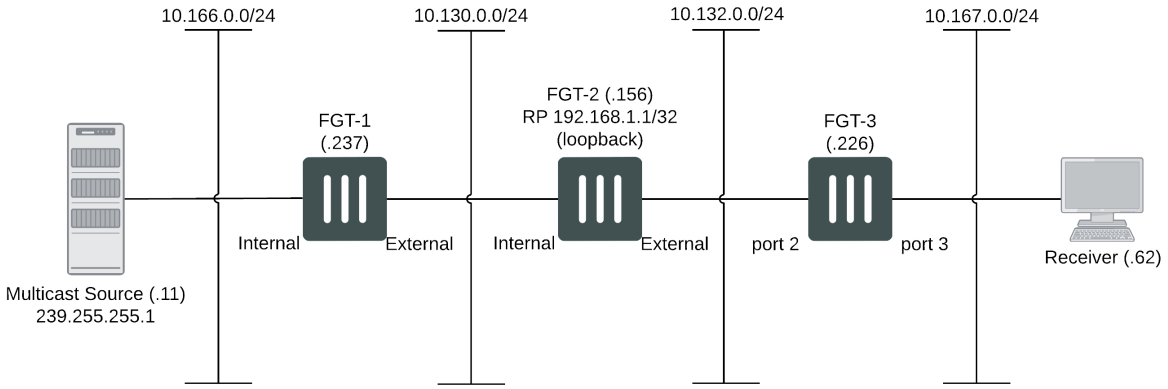
```
version 12.2
!
hostname Cisco-3750-3
!
switch 1 provision ws-c3750-24ts
ip subnet-zero
ip routing
!
ip multicast-routing distributed
!
spanning-tree mode pvst
no spanning-tree optimize bpdu transmission
spanning-tree extend system-id
!
interface FastEthernet1/0/23
   switchport access vlan 128
   switchport mode access
!
interface FastEthernet1/0/24
   switchport access vlan 130
   switchport mode access
!
interface Vlan128
   ip address 10.31.128.130 255.255.255.252
   ip pim sparse-mode
   ip mroute-cache distributed
!
interface Vlan130
   ip address 10.31.130.250 255.255.255.0
   ip pim sparse-mode
   ip mroute-cache distributed
!
ip classless
ip route 0.0.0.0 0.0.0.0 10.31.130.1
ip http server
ip pim rp-address 169.254.100.1 Source-RP
!
!
ip access-list standard Source-RP
```

```
permit 233.254.200.0 0.0.0.255
```

FortiGate PIM-SM debugging examples

Using the example topology shown below, you can trace the multicast streams and states within the three FortiGate units (FGT-1, FGT-2, and FGT-3) using the debug commands described in this section. The command output in this section is taken from FortiGate unit when the multicast stream is flowing correctly from source to receiver.

PIM-SM debugging topology



Checking that the receiver has joined the required group

From the last hop router, FGT-3, you can use the following command to check that the receiver has correctly joined the required group.

```
FGT-3 # get router info multicast igmp groups
IGMP Connected Group Membership
Group Address Interface Uptime Expires Last Reporter
239.255.255.1 port3 00:31:15 00:04:02 10.167.0.62
```

Only 1 receiver is displayed for a particular group, this is the device that responded to the IGMP query request from the FGT-3. If a receiver is active the expire time should drop to approximately 2 minutes before being refreshed.

Checking the PIM-SM neighbors

Next the PIM-SM neighbors should be checked. A PIM router becomes a neighbor when the PIM router receives a PIM hello. Use the following command to display the PIM-SM neighbors of FGT-3.

```
FGT-3 # get router info multicast pim sparse-mode neighbour
Neighbor Interface Uptime/Expires Ver DR
Address Priority/Mode
10.132.0.156 port2 01:57:12/00:01:33 v2 1 /
```

Checking that the PIM router can reach the RP

The rendezvous point (RP) must be reachable for the PIM router (FGT-3) to be able to send the `*,G` join to request the stream. This can be checked for FGT-3 using the following command:

```
FGT-3 # get router info multicast pim sparse-mode rp-mapping
```

```
PIM Group-to-RP Mappings
Group(s): 224.0.0.0/4, Static
RP: 192.168.1.1
Uptime: 07:23:00
```

Viewing the multicast routing table (FGT-3)

The FGT-3 unicast routing table can be used to determine the path taken to reach the RP at 192.168.1.1. You can then check the stream state entries using the following commands:

```
FGT-3 # get router info multicast pim sparse-mode table
IP Multicast Routing Table

(*,*,RP) Entries: 0
(*,G) Entries: 1
(S,G) Entries: 1
(S,G,rpt) Entries: 1
FCR Entries: 0
```

(*,*,RP) Entries	This state may be reached by general joins for all groups served by a specified RP.
(*,G) Entries	State that maintains the RP tree for a given group.
(S,G) Entries	State that maintains a source-specific tree for source `S` and group `G`.
(S,G,rpt) Entries	State that maintains source-specific information about source s on the RP tree for `G`. For example, if a source is being received on the source-specific tree, it will normally have been pruned off the RP tree.
FCR	The FCR state entries are for tracking the sources in the <*, G> when <S, G> is not available for any reason, the stream would typically be flowing when this state exists.

Breaking down each entry in detail:

```
(*, 239.255.255.1)
RP: 192.168.1.1
RPF nbr: 10.132.0.156
RPF idx: port2
Upstream State: JOINED
Local:
port3
Joined:
Asserted:
FCR:
```

The RP will always be listed in a `*,G` entry, the RPF neighbor and interface index will also be shown. In this topology these are the same in all downstream PIM routers. The state is active so the upstream state is joined.

In this case FGT-3 is the last hop router so the IGMP join is received locally on port3. There is no PIM outgoing interface listed for this entry as it is used for the upstream PIM join.

```
(10.166.0.11, 239.255.255.1)
RPF nbr: 10.132.0.156
RPF idx: port2
SPT bit: 1
Upstream State: JOINED
```

```
Local:
Joined:
Asserted:
Outgoing:
port3
```

This is the entry for the SPT, no RP IS listed. The `S,G` stream will be forwarded out of the stated outgoing interface.

```
(10.166.0.11, 239.255.255.1, rpt)
RP: 192.168.1.1
RPF nbr: 10.132.0.156
RPF idx: port2
Upstream State: NOT PRUNED
Local:
Pruned:
Outgoing:
```

The above `S,G,RPT` state is created for all streams that have both a `S,G` and a `*,G` entry on the router. This is not pruned in this case because of the topology, the RP and source are reachable over the same interface.

Although not seen in this scenario, assert states may be seen when multiple PIM routers exist on the same LAN which can lead to more than one upstream router having a valid forwarding state. Assert messages are used to elect a single forwarder from the upstream devices.

Viewing the PIM next-hop table

The PIM next-hop table is also very useful for checking the various states, it can be used to quickly identify the states of multiple multicast streams

```
FGT-3 # get router info multicast pim sparse-mode next-hop
Flags: N = New, R = RP, S = Source, U = Unreachable
Destination Type Nexthop Nexthop Nexthop Metric Pref Refcnt
Num Addr Ifindex
_____________________________________________________________
10.166.0.11 ..S. 1 10.132.0.156 9 21 110 3
192.168.1.1 .R.. 1 10.132.0.156 9 111 110 2
```

Viewing the PIM multicast forwarding table

Also you can check the multicast forwarding table showing the ingress and egress ports of the multicast stream.

```
FGT-3 # get router info multicast table

IP Multicast Routing Table
Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed
Timers: Uptime/Stat Expiry
Interface State: Interface (TTL threshold)

(10.166.0.11, 239.255.255.1), uptime 04:02:55, stat expires 00:02:25
Owner PIM-SM, Flags: TF
Incoming interface: port2
Outgoing interface list:
port3 (TTL threshold 1)
```

Viewing the kernel forwarding table

Also the kernel forwarding table can be verified, however this should give similar information to the above command:

```
FGT-3 # diag ip multicast mroute
grp=239.255.255.1 src=10.166.0.11 intf=9 flags=(0x10000000)[ ] status=resolved
last_assert=2615136 bytes=1192116 pkt=14538 wrong_if=0 num_ifs=1
index(ttl)=[6(1),]
```

Viewing the multicast routing table (FGT-2)

If you check the output on FGT-2 there are some small differences:

```
FGT-2 # get router info multicast pim sparse-mode table
IP Multicast Routing Table

(*,*,RP) Entries: 0
(*,G) Entries: 1
(S,G) Entries: 1
(S,G,rpt) Entries: 1
FCR Entries: 0

(*, 239.255.255.1)
RP: 192.168.1.1
RPF nbr: 0.0.0.0
RPF idx: None
Upstream State: JOINED
Local:
Joined:
external
Asserted:
FCR:
```

The `*,G` entry now has a joined interface rather than local because it has received a PIM join from FGT-3 rather than a local IGMP join.

```
(10.166.0.11, 239.255.255.1)
RPF nbr: 10.130.0.237
RPF idx: internal
SPT bit: 1
Upstream State: JOINED
Local:
Joined:
external
Asserted:
Outgoing:
external
```

The `S,G` entry shows that we have received a join on the external interface and the stream is being forwarded out of this interface.

```
(10.166.0.11, 239.255.255.1, rpt)
RP: 192.168.1.1
RPF nbr: 0.0.0.0
RPF idx: None
Upstream State: PRUNED
Local:
Pruned:
Outgoing:
```

```
External
```

The S,G,RPT is different from FGT-3 because FGT-2 is the RP, it has pruned back the SPT for the RP to the first hop router.

Viewing the multicast routing table (FGT-1)

FGT-1 again has some differences with regard to the PIM-SM states, there is no *,G entry because it is not in the path of a receiver and the RP.

```
FGT-1_master # get router info multicast pim sparse-mode table
IP Multicast Routing Table

(*,*,RP) Entries: 0
(*,G) Entries: 0
(S,G) Entries: 1
(S,G,rpt) Entries: 1
FCR Entries: 0
```

Below the S,G is the SPT termination because this FortiGate unit is the first hop router, the RPF neighbor always shows as 0.0.0.0 because the source is local to this device. Both the joined and outgoing fields show as external because the PIM join and the stream is egressing on this interface.

```
(10.166.0.11, 239.255.255.1)
RPF nbr: 0.0.0.0
RPF idx: None
SPT bit: 1
Upstream State: JOINED
Local:
Joined:
external
Asserted:
Outgoing:
external
```

The stream has been pruned back from the RP because the end-to-end SPT is flowing, there is no requirement for the stream to be sent to the RP in this case.

```
(10.166.0.11, 239.255.255.1, rpt)
RP: 0.0.0.0
RPF nbr: 10.130.0.156
RPF idx: external
Upstream State: RPT NOT JOINED
Local:
Pruned:
Outgoing:
```

Example multicast destination NAT (DNAT) configuration

The example topology shown and described below shows how to configure destination NAT (DNAT) for two multicast streams. Both of these streams originate from the same source IP address, which is 10.166.0.11. The example configuration keeps the streams separate by creating 2 multicast NAT policies.

In this example the FortiGate units have the following roles:

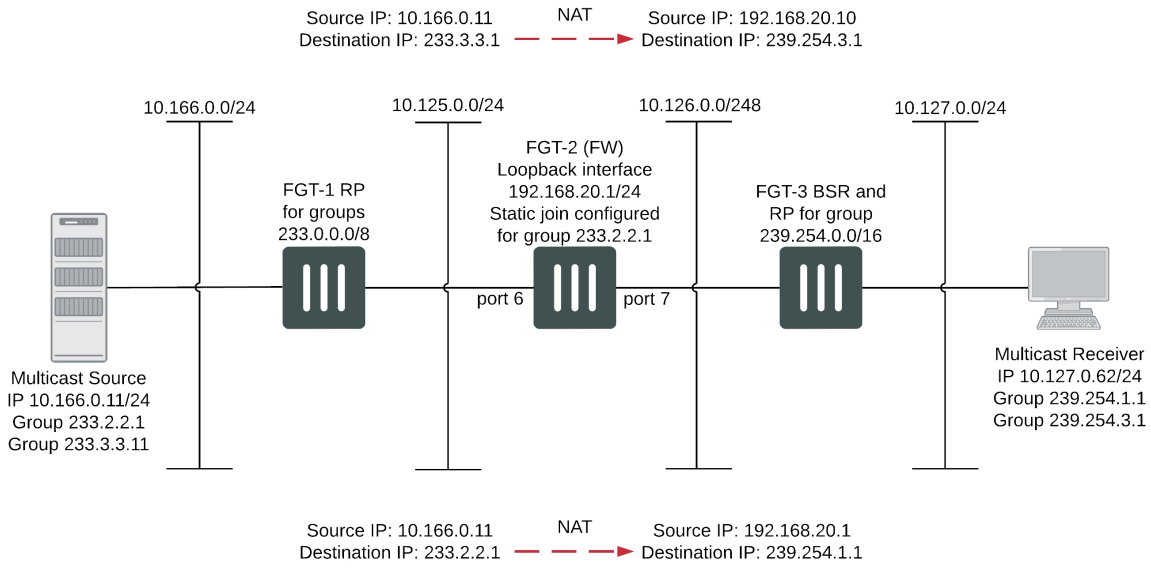
- FGT-1 is the RP for dirty networks, 233.0.0.0/8.
- FGT-2 performs all firewall and DNAT translations.
- FGT-3 is the RP for the clean networks, 239.254.0.0/16.
- FGT-1 and FGT-3 are functioning as PM enabled routers and could be replaced can be any PIM enabled router.

This example only describes the configuration of FGT-2.

FGT-2 performs NAT so that the receivers connected to FGT-3 receive the following translated multicast streams.

- If the multicast source sends multicast packets with a source and destination IP of 10.166.0.11 and 233.2.2.1; FGT-3 translates the source and destination IPs to 192.168.20.1 and 239.254.1.1
- If the multicast source sends multicast packets with a source and destination IP of 10.166.0.11 and 233.3.3.1; FGT-3 translates the source and destination IPs to 192.168.20.10 and 239.254.3.1

Example multicast DNAT topology



To configure FGT-2 for DNAT multicast

1. Add a loopback interface. In the example, the loopback interface is named `loopback`.

```
config system interface
   edit loopback
      set vdom root
      set ip 192.168.20.1 255.255.255.0
      set type loopback
   next
end
```

2. Add PIM and add a unicast routing protocol to the loopback interface as if it was a normal routed interface. Also add static joins to the loopback interface for any groups to be translated.

```
config router multicast
   config interface
      edit loopback
         set pim-mode sparse-mode
            config join-group
               edit 233.2.2.1
               next
               edit 233.3.3.1
               next
```

```
            end
        next
```

3. In this example, to add firewall multicast policies, different source IP addresses are required so you must first add an IP pool:

```
config firewall ippool
   edit Multicast_source
      set endip 192.168.20.20
      set interface port6
      set startip 192.168.20.10
   next
end
```

4. Add the translation security policies.

   Policy 2, which is the source NAT policy, uses the actual IP address of port6. Policy 1, the DNAT policy, uses an address from the IP pool. The source and destination addresses will need to be previously created address objects. For this example, 233.3.3.1 255.255.255.255 will be represented by "example-addr_1" and 10.166.0.11 255.255.255.255 will be represented by "example-addr_2". You will likely want to use something more intuitive from your own network.

```
config firewall multicast-policy
   edit 1
      set dnat 239.254.3.1
      set dstaddr example-addr_1
      set dstintf loopback
      set nat 192.168.20.10
      set srcaddr example-addr_2
      set srcintf port6
   next
   edit 2
      set dnat 239.254.1.1
      set dstaddr 233.2.2.1 255.255.255.255
      set dstintf loopback
      set nat 192.168.20.1
      set srcaddr 10.166.0.11 255.255.255.255
      set srcintf port6
   next
end
```

5. Add a firewall multicast policy to forward the stream from the loopback interface to the physical outbound interface.

   This example is an any/any policy that makes sure traffic accepted by the other multicast policies can exit the FortiGate unit.

```
config firewall multicast-policy
   edit 3
      set dstintf port7
      set srcintf loopback
   next
end
```

Example PIM configuration that uses BSR to find the RP

This example shows how to configure a multicast routing network for a network consisting of four FortiGate-500A units (FortiGate-500A_1 to FortiGate-550A_4). A multicast sender is connected to FortiGate-500A_2. FortiGate-

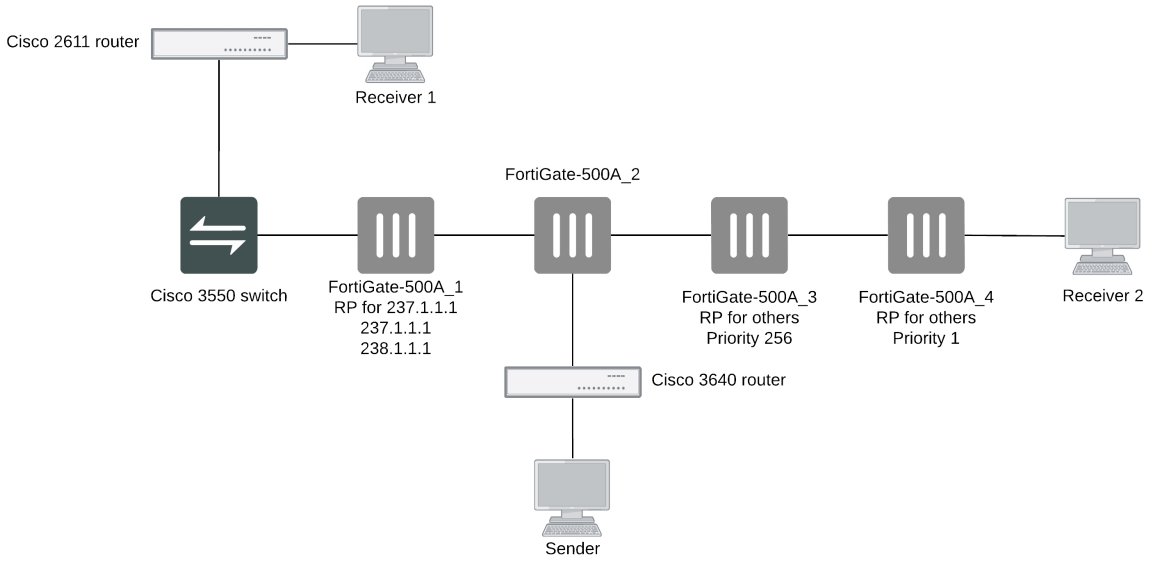
500A_2 forwards multicast packets in two directions to reach Receiver 1 and Receiver 2.

The configuration uses a Boot Start Router (BSR) to find the Rendezvous Points (RPs) instead of using static RPs. Under interface configuration, the loopback interface `lo0` must join the 236.1.1.1 group (source).

This example describes:

- Commands used in this example
- Configuration steps
- Example debug commands

PIM network topology using BSR to find the RP



Commands used in this example

This example uses CLI commands for the following configuration settings:

- Adding a loopback interface (lo0)
- Defining the multicast routing
- Adding the NAT multicast policy

Adding a loopback interface (lo0)

Where required, the following command is used to define a loopback interface named `lo0`.

```
config system interface
   edit lo0
      set vdom root
      set ip 1.4.50.4 255.255.255.255
      set allowaccess ping https ssh snmp http telnet
      set type loopback
   next
end
```

Defining the multicast routing

In this example, the following command syntax is used to define multicast routing.

The example uses a Boot Start Router (BSR) to find the Rendezvous Points (RPs) instead of using static RPs. Under interface configuration, the loopback interface `lo0` must join the 236.1.1.1 group (source).

```
config router multicast
   config interface
      edit port6
         set pim-mode sparse-mode
      next
      edit port1
         set pim-mode sparse-mode
      next
      edit lo0
         set pim-mode sparse-mode
         set rp-candidate enable
            config join-group
               edit 236.1.1.1
               next
            end
         set rp-candidate-priority 1
      next
   end
set multicast-routing enable
   config pim-sm-global
      set bsr-allow-quick-refresh enable
      set bsr-candidate enable
      set bsr-interface lo0
      set bsr-priority 200
   end
end
```

Adding the NAT multicast policy

In this example, the incoming multicast policy does the address translation.

The NAT address should be the same as the IP address of the of loopback interface. The DNAT address is the translated address, which should be a new group.

```
config firewall multicast-policy
   edit 1
      set dstintf port6
      set srcintf lo0
   next
   edit 2
      set dnat 238.1.1.1
      set dstintf lo0
      set nat 1.4.50.4
      set srcintf port1
   next
```

Configuration steps

In this sample, FortiGate-500A_1 is the RP for the group 228.1.1.1, 237.1.1.1, 238.1.1.1, and FortiGate-500A_4 is the RP for the other group which has a priority of1. OSPF is used in this example to distribute routes including

the loopback interface. All firewalls have full mesh security policies to allow any to any.

- In the FortiGate-500A_1 configuration, the NAT policy translates source address 236.1.1.1 to 237.1.1.1
- In the FortiGate-500A_4, configuration, the NAT policy translates source 236.1.1.1 to 238.1.1.1
- Source 236.1.1.1 is injected into network as well.

The following procedures include the CLI commands for configuring each of the FortiGate units in the example configuration.

To configure FortiGate-500A_1

1. Configure multicast routing.

```
config router multicast
   config interface
      edit port5
         set pim-mode sparse-mode
      next
      edit port4
         set pim-mode sparse-mode
      next
      edit lan
         set pim-mode sparse-mode
      next
      edit port1
         set pim-mode sparse-mode
      next
      edit lo999
         set pim-mode sparse-mode
      next
      edit lo0
         set pim-mode sparse-mode
         set rp-candidate enable
         set rp-candidate-group 1
      next
   end
set multicast-routing enable
   config pim-sm-global
      set bsr-candidate enable
      set bsr-interface lo0
   end
end
```

2. Add multicast security policies.

```
config firewall multicast-policy
   edit 1
      set dstintf port5
      set srcintf port4
   next
   edit 2
      set dstintf port4
      set srcintf port5
   next
   edit 3
   next
end
```

3. Add router access lists.

```
config router access-list
   edit 1
      config rule
         edit 1
            set prefix 228.1.1.1 255.255.255.255
            set exact-match enable
         next
         edit 2
            set prefix 237.1.1.1 255.255.255.255
            set exact-match enable
         next
         edit 3
            set prefix 238.1.1.1 255.255.255.255
            set exact-match enable
         next
      end
   next
end
```

To configure FortiGate-500A_2

1. Configure multicast routing.

```
config router multicast
   config interface
      edit "lan"
         set pim-mode sparse-mode
next
edit "port5"
  set pim-mode sparse-mode
      next
      edit "port2"
         set pim-mode sparse-mode
      next
      edit "port4"
         set pim-mode sparse-mode
      next
      edit "lo_5"
         set pim-mode sparse-mode
            config join-group
               edit 236.1.1.1
               next
            end
         next
      end
   set multicast-routing enable
end
```

2. Add multicast security policies.

```
config firewall multicast-policy
   edit 1
      set dstintf lan
      set srcintf port5
   next
   edit 2
      set dstintf port5
```

```
      set srcintf lan
    next
    edit 4
      set dstintf lan
      set srcintf port2
    next
    edit 5
      set dstintf port2
      set srcintf lan
    next
    edit 7
      set dstintf port1
      set srcintf port2
    next
    edit 8
      set dstintf port2
      set srcintf port1
    next
    edit 9
      set dstintf port5
      set srcintf port2
    next
    edit 10
      set dstintf port2
      set srcintf port5
    next
    edit 11
      set dnat 237.1.1.1
      set dstintf lo_5
      set nat 5.5.5.5
      set srcintf port2
    next
    edit 12
      set dstintf lan
      set srcintf lo_5
    next
    edit 13
      set dstintf port1
      set srcintf lo_5
    next
    edit 14
      set dstintf port5
      set srcintf lo_5
    next
    edit 15
      set dstintf port2
      set srcintf lo_5
    next
    edit 16
    next
  end
```

To configure FortiGate-500A_3

1. Configure multicast routing.

```
config router multicast
  config interface
```

```
      edit port5
         set pim-mode sparse-mode
      next
      edit port6
         set pim-mode sparse-mode
      next
      edit lo0
         set pim-mode sparse-mode
         set rp-candidate enable
         set rp-candidate-priority 255
      next
      edit lan
         set pim-mode sparse-mode
      next
   end
set multicast-routing enable
   config pim-sm-global
      set bsr-candidate enable
      set bsr-interface lo0
   end
end
```

2. Add multicast security policies.

```
config firewall multicast-policy
   edit 1
      set dstintf port5
      set srcintf port6
   next
   edit 2
      set dstintf port6
      set srcintf port5
   next
   edit 3
      set dstintf port6
      set srcintf lan
   next
   edit 4
      set dstintf lan
      set srcintf port6
   next
   edit 5
      set dstintf port5
      set srcintf lan
   next
   edit 6
      set dstintf lan
      set srcintf port5
   next
end
```

To configure FortiGate-500A_4

1. Configure multicast routing.

```
config router multicast
   config interface
      edit port6
         set pim-mode sparse-mode
```

```
            next
            edit lan
               set pim-mode sparse-mode
            next
            edit port1
               set pim-mode sparse-mode
            next
            edit lo0
               set pim-mode sparse-mode
               set rp-candidate enable
                  config join-group
                     edit 236.1.1.1
                     next
                  end
               set rp-candidate-priority 1
            next
         end
      set multicast-routing enable
         config pim-sm-global
set bsr-allow-quick-refresh enable
            set bsr-candidate enable
            set bsr-interface lo0
            set bsr-priority 1
         end
      end
```

2. Add multicast security policies.

```
      config firewall policy
         edit 1
            set srcintf lan
            set dstintf port6
            set srcaddr all
            set dstaddr all
            set action accept
            set schedule always
            set service ANY
         next
         edit 2
            set srcintf port6
            set dstintf lan
            set srcaddr all
            set dstaddr all
            set action accept
            set schedule always
            set service ANY
         next
         edit 3
            set srcintf port1
            set dstintf port6
            set srcaddr all
            set dstaddr all
            set action accept
            set schedule always
            set service ANY
         next
         edit 4
            set srcintf port6
```

```
      set dstintf port1
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
      set service ANY
   next
   edit 5
      set srcintf port1
      set dstintf lan
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
      set service ANY
   next
   edit 6
      set srcintf lan
      set dstintf port1
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
      set service ANY
   next
   edit 7
      set srcintf port1
      set dstintf port1
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
      set service ANY
   next
   edit 8
      set srcintf port6
      set dstintf lo0
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
      set service ANY
   next
   edit 9
      set srcintf port1
      set dstintf lo0
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
      set service ANY
   next
   edit 10
      set srcintf lan
      set dstintf lo0
      set srcaddr all
      set dstaddr all
```

```
        set action accept
        set schedule always
        set service ANY
      next
    end
```

Chapter 23 - Parallel Path Processing - Life of a Packet

Life of a Packet

This FortiOS Handbook chapter contains the following sections:

Parallel Path Processing introduces the concept of Parallel Path Processing.

Packet flow ingress and egress: FortiGates without network processor offloading describes the overall packet flow through a FortiGate with no network offloading (NP) hardware.

Packet flow: FortiGates with NP6 processors first packet of a new session similar to the previous section, the first packet in a new session that can be offloaded is processed in much the same way as on a FortiGate with no network processors.

Packet flow: FortiGates with NP6 processors - packets in an offloaded session describes the much simpler packet flow for a packet from an offloaded session.

UTM/NGFW packet flow: flow-based inspection describes how single pass UTM/NGFW processing occurs in a flow-based FortiGate or VDOM.

UTM/NGFW packet flow: proxy-based inspection describes how UTM/NGFW processing occurs in a proxy-based FortiGate or VDOM.

Comparison of inspection types shows how different security functions map to different inspection types.

Parallel Path Processing

Parallel Path Processing (PPP) uses the firewall policy configuration to choose from a group of parallel options to determine the optimal path for processing a packet. Most FortiOS features are applied through Firewall policies and the features applied determine the path a packet takes. Using firewall policies you can impose UTM/NGFW processing on content traffic that may contain security threats (such as HTTP, email and so on). Many UTM/NGFW processes are offloaded and accelerated by CP8 or CP9 processors. Using the policy configuration you can apply a range of protection from basic IPS attack protection that looks for network-based attacks to full scale advanced threat management (ATM), application control, antivirus, DLP and so on.

You can also create policies for traffic that does not pose security threats and bypass UTM/NGFW checking. This control allows you to improve network performance without compromising security. On FortiGates with network processors (for example the NP6) much of the traffic that does not require UTM/NGFW processing can be offloaded to the NP6 processors freeing up FortiGate processing resources for other higher risk traffic.

In addition, many FortiGate models support NTurbo to offload flow-based UTM/NGFW sessions to network processors. Flow-based sessions can also be accelerated using IPSA technology to enhance offloading of pattern matching to CP8 and CP9 content processors.

This chapter begins with an overview of packet flow ingress and egress and includes a section that shows how NP6 offloading optimizes packet flow for packets that don't require UTM/NGFW processing and for packets that use NTurbo to offload flow-based UTM/NGFW processing.

Next this chapter breaks down how packets pass through UTM/NGFW processing both for a single-pass flow-based UTM/NGFW processing and a proxy-based UTM/NGFW processing.

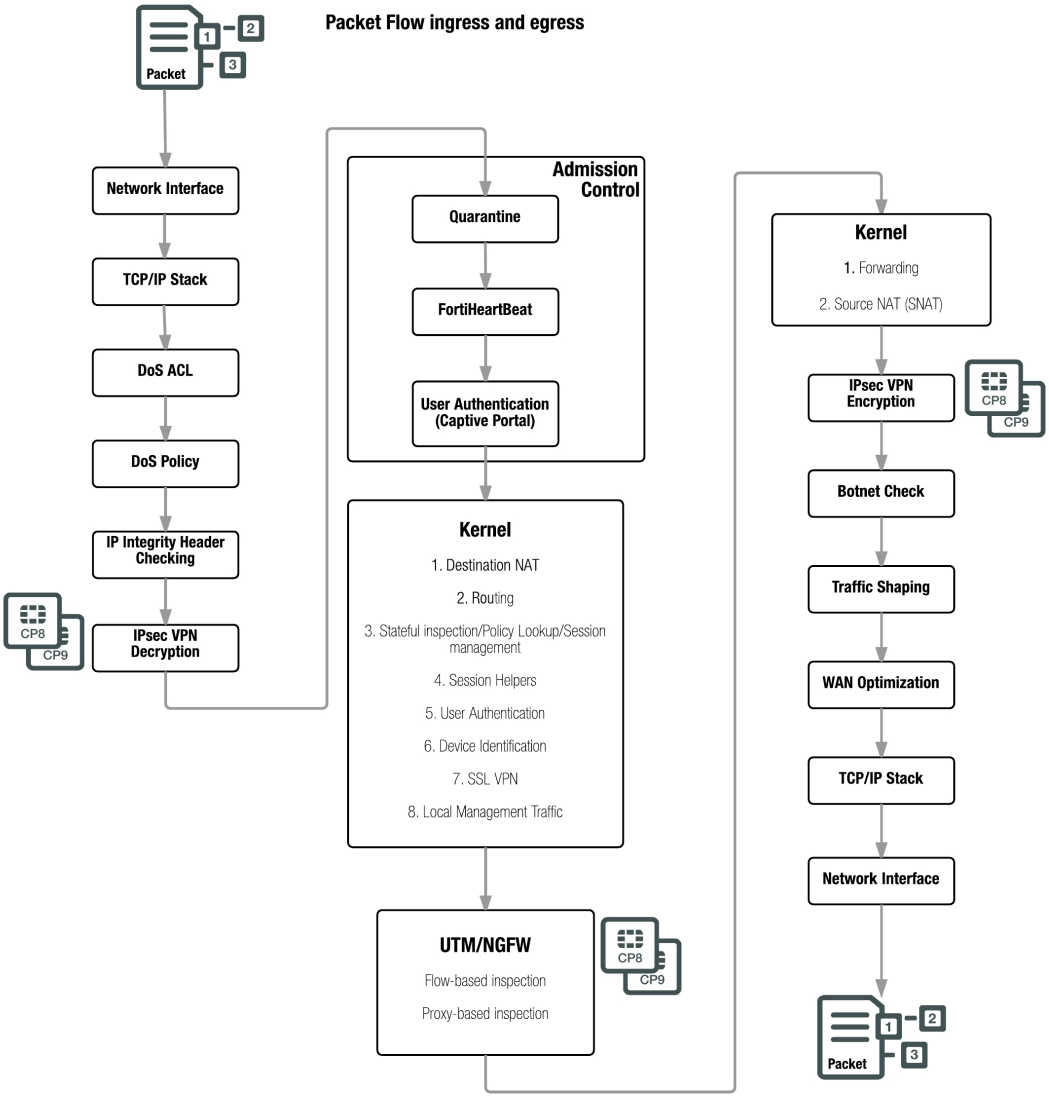
High-level list of processes that affect packets

In general packets passing through a FortiGate unit can be affected by the following processes. This is a complete high-level list of all of the processes. Not all packets see all of these processes. The processes a packet encounters depends on the type of packet and on the FortiGate software and hardware configuration.

- **Ingress packet flow**
  - Network Interface
  - TCP/IP stack
  - DoS ACL
  - DoS Policy
  - IP integrity header checking
  - IPsec VPN decryption
- **Admission Control**
  - Quarantine
  - FortiTelemetry
  - User Authentication
- **Kernel**
  - Destination NAT
  - Routing
  - Stateful inspection/Policy Lookup/Session management
  - Session Helpers
  - User Authentication
  - Device Identification
  - SSL VPN
  - Local Management Traffic
- **UTM/NGFW**
  - Flow-based inspection
    - NTurbo
    - IPSA
  - Proxy-based inspection
- **Kernel**
  - Forwarding
  - Source NAT (SNAT)
- **Egress packet flow**
  - IPsec VPN Encryption
  - Botnet check
  - Traffic shaping
  - WAN Optimization
  - TCP/IP stack
  - Network Interface

Packet flow ingress and egress: FortiGates without network processor offloading

This section describes the steps a packet goes through as it enters, passes through and exits from a FortiGate unit. This scenario shows all of the steps a packet goes through if a FortiGate does not contain network processors (such as the NP6).



Ingress

All packets accepted by a FortiGate pass through a network interface and are processed by the TCP/IP stack. Then if **DoS policies** or **Access Control List (ACL) policies** have been configured the packet must pass through these as well as automatic **IP integrity header checking**.

DoS scans are handled very early in the life of the packet to determine whether the traffic is valid or is part of a DoS attack. The DoS module inspects all traffic flows but only tracks packets that can be used for DoS attacks (for example, TCP SYN packets), to ensure they are within the permitted parameters. Suspected DoS attacks are blocked, other packets are allowed.

IP integrity header checking reads the packet headers to verify if the packet is a valid TCP, UDP, ICMP, SCTP or GRE packet. The only verification that is done at this step to ensure that the protocol header is the correct length. If it is, the packet is allowed to carry on to the next step. If not, the packet is dropped.

Incoming **IPsec packets** that match configured IPsec tunnels on the FortiGate are decrypted after header checking is done.

If the packet is an IPsec packet, the IPsec engine attempts to decrypt it. If the IPsec engine can apply the correct encryption keys and decrypt the packet, the unencrypted packet is sent to the next step. Non-IPsec traffic and IPsec traffic that cannot be decrypted passes on to the next step without being affected. IPSec VPN decryption is offloaded to and accelerated by CP8 or CP9 processors.

Admission Control

Admission control checks to make sure the packet is not from a source or headed to a destination on the quarantine list. If configured admission control then imposes FortiTelemetry protection that requires a device to have FortiClient installed before allowing packets from it. Admission control can also impose captive portal authentication on ingress traffic.

Kernel

Once a packet makes it through all of the ingress steps, the FortiOS kernel performs the following checks to determine what happens to the packet next.

Destination NAT

Destination NAT checks the NAT table and determines if the destination IP address for incoming traffic must be changed using DNAT. DNAT is typically applied to traffic from the Internet that is going to be directed to a server on a network behind the FortiGate. DNAT means the actual address of the internal network is hidden from the Internet. This step determines whether a route to the destination address actually exists. DNAT must take place before routing so that the FortiGate unit can route packets to the correct destination.

Routing

Routing uses the routing table to determine the interface to be used by the packet as it leaves the FortiGate unit. Routing also distinguishes between local traffic and forwarded traffic. Firewall policies are matched with packets depending on the source and destination interface used by the packet. The source interface is known when the packet is received and the destination interface is determined by routing.

Stateful inspection/Policy lookup/Session management

Stateful inspection looks at the first packet of a session and looks in the policy table to make a security decision about the entire session. Stateful inspection looks at packet TCP SYN and FIN flags to identity the start and end of a session, the source/destination IP, source/destination port and protocol. Other checks are also performed on the packet payload and sequence numbers to verify it as a valid session and that the data is not corrupted or poorly formed.

When the first packet of a session is matched in the policy table, stateful inspection adds information about the session to its session table. So when subsequent packets are received for the same session, stateful inspection can determine how to handle them by looking them up in the session table (which is more efficient than looking them up in the policy table).

Stateful inspection makes the decision to drop or allow a session and apply security features to it based on what is found in the first packet of the session. Then all subsequent packets in the same session are processed in the same way.

When the final packet in the session is processed, the session is removed from the session table. Stateful inspection also has a session idle timeout that removes sessions from the session table that have been idle for the length of the timeout.

See the Stateful Firewall Wikipedia article (https://en.wikipedia.org/wiki/Stateful_firewall) for an excellent description of stateful inspection.

Session helpers

Some protocols include information in the packet body (or payload) that must be analyzed to successfully process sessions for this protocol. For example, the SIP VoIP protocol uses TCP control packets with a standard destination port to set up SIP calls. To successfully process SIP VoIP calls, FortiOS must be able to extract information from the body of the SIP packet and use this information to allow the voice-carrying packets through the firewall.

FortiOS uses session helpers to analyze the data in the packet bodies of some protocols and adjust the firewall to allow those protocols to send packets through the firewall. FortiOS includes the following session helpers:

- PPTP
- H323
- RAS
- TNS
- TFTP
- RTSP
- FTP
- MMS
- PMAP
- SIP
- DNS-UDP
- RSH
- DCERPC
- MGCP

User authentication

User authentication added to security policies is handled by the stateful inspection, which is why Firewall authentication is based on IP address. Authentication takes place after policy lookup selects a policy that includes authentication.

Device identification

Device identification is applied if required by the matching policy.

SSL VPN

Local SSL VPN traffic is treated like special management traffic as determined by the SSL VPN destination port. Packets are decrypted and are routed to an SSL VPN interface. Policy lookup is then used to control how packets are forwarded to their destination outside the FortiGate. SSL encryption and decryption is offloaded to and accelerated by CP8 or CP9 processors.

Local management traffic

Local management traffic terminates at a FortiGate interface. This can be any FortiGate interface including dedicated management interfaces. In multiple VDOM mode local management traffic terminates at the management interface. In Transparent mode, local management traffic terminates at the management IP address.

Local management traffic includes administrative access, some routing protocol communication, central management from FortiManager, communication with the FortiGuard network and so on. Management traffic is allowed or blocked according to the Local In Policy list which lists all management protocols and their access control settings. You configure local management access indirectly by configuring administrative access and so on.

Management traffic is processed by applications such as the web server which displays the FortiOS web-based manager, the SSH server for the CLI or the FortiGuard server to handle local FortiGuard database updates or FortiGuard Web Filtering URL lookups.

Local management traffic is not involved in subsequent stateful inspection steps.

SSL VPN traffic terminates at a FortiGate interface similar to local management traffic. However, SSL VPN traffic uses a different destination port number than administrative HTTPS traffic and can thus be detected and handled differently.

UTM/NGFW

If the policy matching the packet includes security profiles, then the packet is subject to Unified Threat Management (UTM)/Next Generation Firewall (NGFW) processing. UTM/NGFW processing depends on the inspection mode of the FortiGate: Flow-based (single pass architecture) or proxy-based. Many UTM/NGFW processes are offloaded and accelerated by CP8 or CP9 processors.

Single pass flow-based UTM/NGFW inspection identifies and blocks security threats in real time as they are identified using single-pass Direct Filter Approach (DFA) pattern matching to identify possible attacks or threats.

Proxy-based UTM/NGFW inspection can apply both flow-based and proxy-based inspection. Packets initially encounter the IPS engine, which can apply single-pass flow-based IPS, Application Control and CASI (as configured). The packets are then sent to the proxy for proxy-based inspection. Proxy-based inspection can apply VoIP inspection, DLP, AntiSpam, Web Filtering, Antivirus, and ICAP.

Content processors (CP8 and CP9)

Most FortiGate models contain FortiASIC Content Processors (CPs) that accelerate IPsec and SSL VPN encryption/decryption and key exchance and flow-based content processing pattern matching. CPs work at the system level with tasks being offloaded to them as determined by the main CPU. Capabilities of the CPs vary by model. Newer FortiGate units include CP8 and new CP9 processors.

CP9 capabilities

The CP9 content processor provides the following services:

- Flow-based inspection pattern matching acceleration with over 10Gbps throughput
- High performance VPN bulk data engine
- Key Exchange Processor that supports high performance IKE and RSA computation
- DLP fingerprint support

CP8 capabilities

The CP8 content processor provides the following services:

- Flow-based inspection pattern matching acceleration
- High performance VPN bulk data engine
- Key Exchange Processor that supports high performance IKE and RSA computation

Kernel

Traffic is now in the process of exiting the FortiGate unit. The kernel uses the routing table to forward the packet out the correct exit interface.

The kernel also checks the NAT table and determines if the source IP address for outgoing traffic must be changed using SNAT. SNAT is typically applied to traffic from an internal network heading out to the Internet. SNAT means the actual address of the internal network is hidden from the Internet.

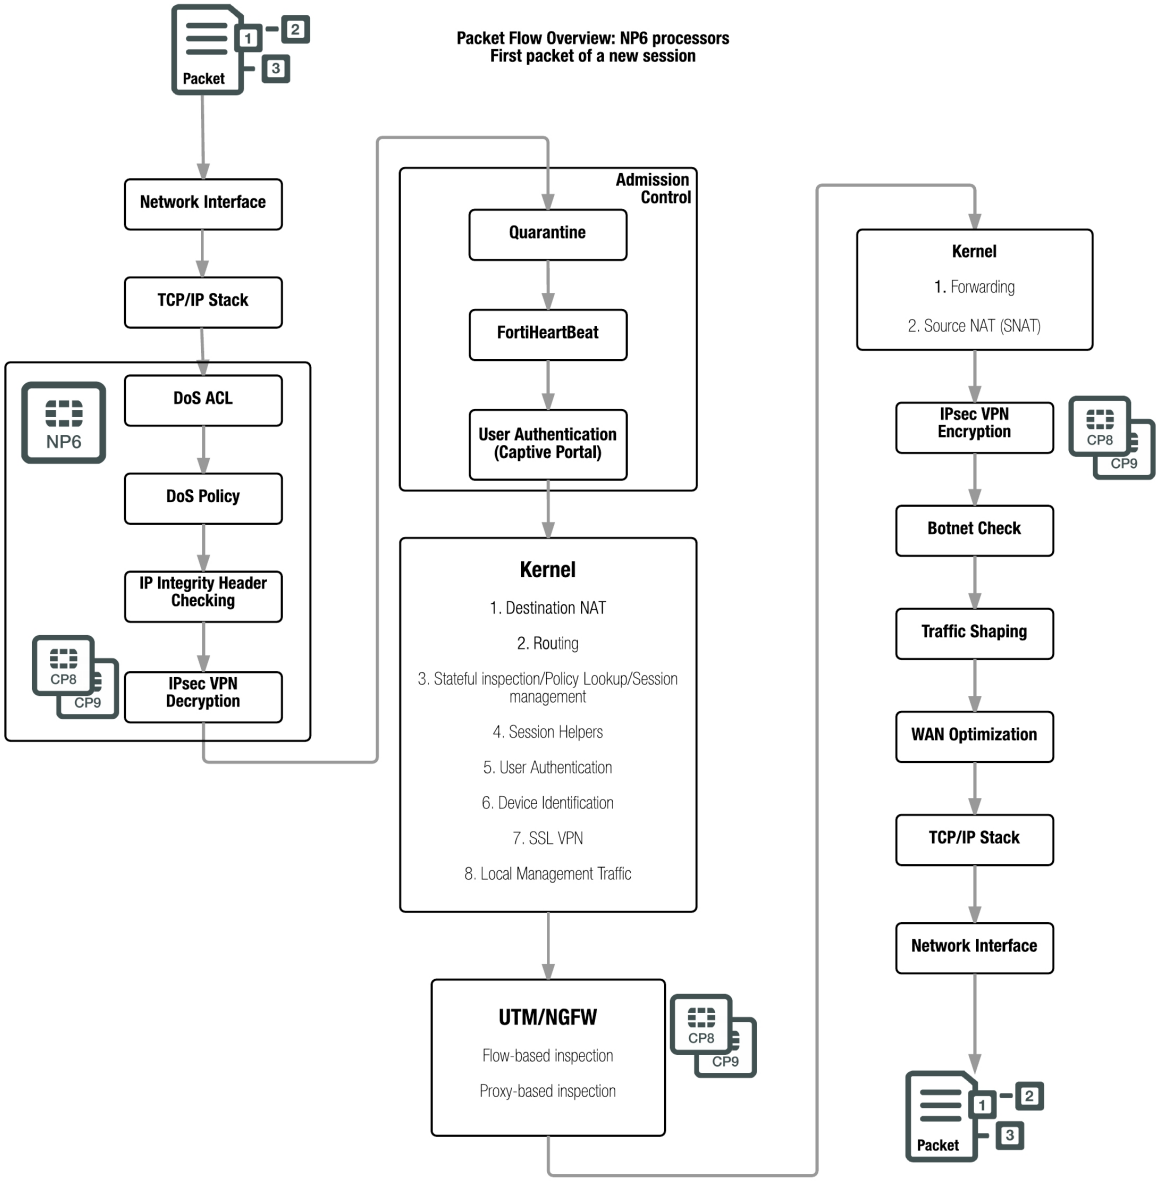
Egress

Before exiting the FortiGate outgong packets that are entering an IPsec VPN tunnel are encrypted and encapsulated. IPSec VPN encryption is offloaded to and accelerated by CP8 or CP9 processors. Packets are then subject to botnet checking to make sure they are not destined for known botnet addresses.

Traffic shaping is then imposed, if configured, followed by WAN Optimization. The packet is then processed by the TCP/IP stack and exits out the egress interface.

Packet flow: FortiGates with NP6 processors first packet of a new session

On a FortiGate with NP6 processors the first packet in a new session is handled the same way as on a FortiGate with no NP6 processors. Except that some processes, such as DoS, ACL, IP integrity checking, and IPsec VPN decryption are accelerated by the NP6 processor.



Network processors (NP6)

FortiASIC network processors work at the interface level to accelerate traffic by offloading sessions from the main CPU. Current FortiGate models contain NP6 network processors. Older FortiGate models include NP4 and older network processors.

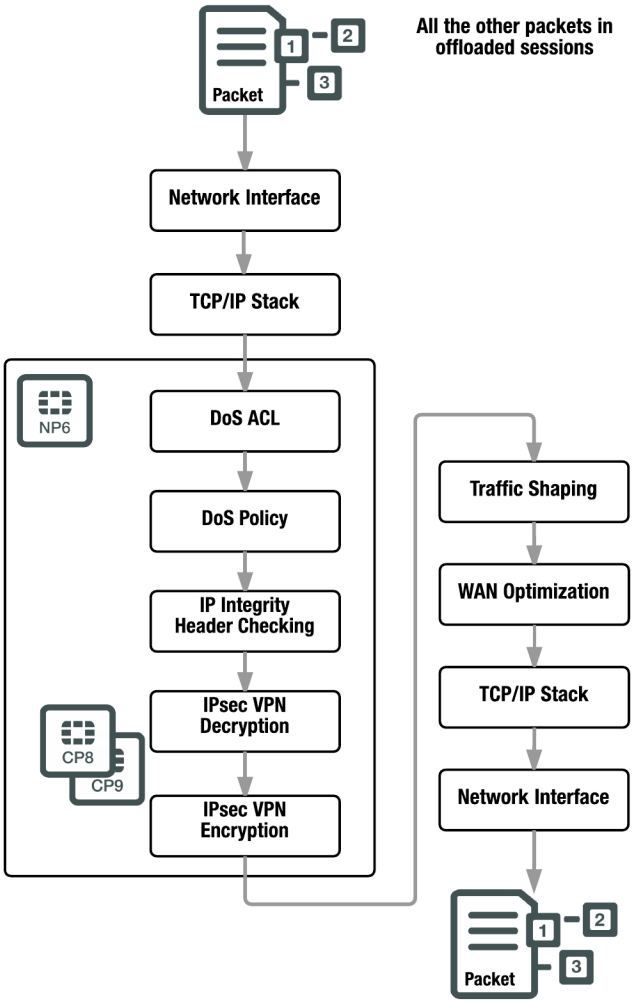
NP6 processors can offload most IPv4 and IPv6 traffic, IPsec VPN encryption, CAPWAP traffic, and multicast traffic. The NP6 has a capacity of 40 Gbps through 4 x 10 Gbps interfaces or 3 x 10 Gbps and 16 x 1 Gbps interfaces.

Sessions that require proxy-based UTM/NGFW (including proxy-based virus scanning, web filtering, and so on) are not fast pathed and must be processed by the CPU.

Sessions that require flow-based UTM/NGFW (including IPS, application control, flow-based virus scanning and so on) can be offloaded to NP4 or NP6 network processors if the FortiGate supports NTurbo.

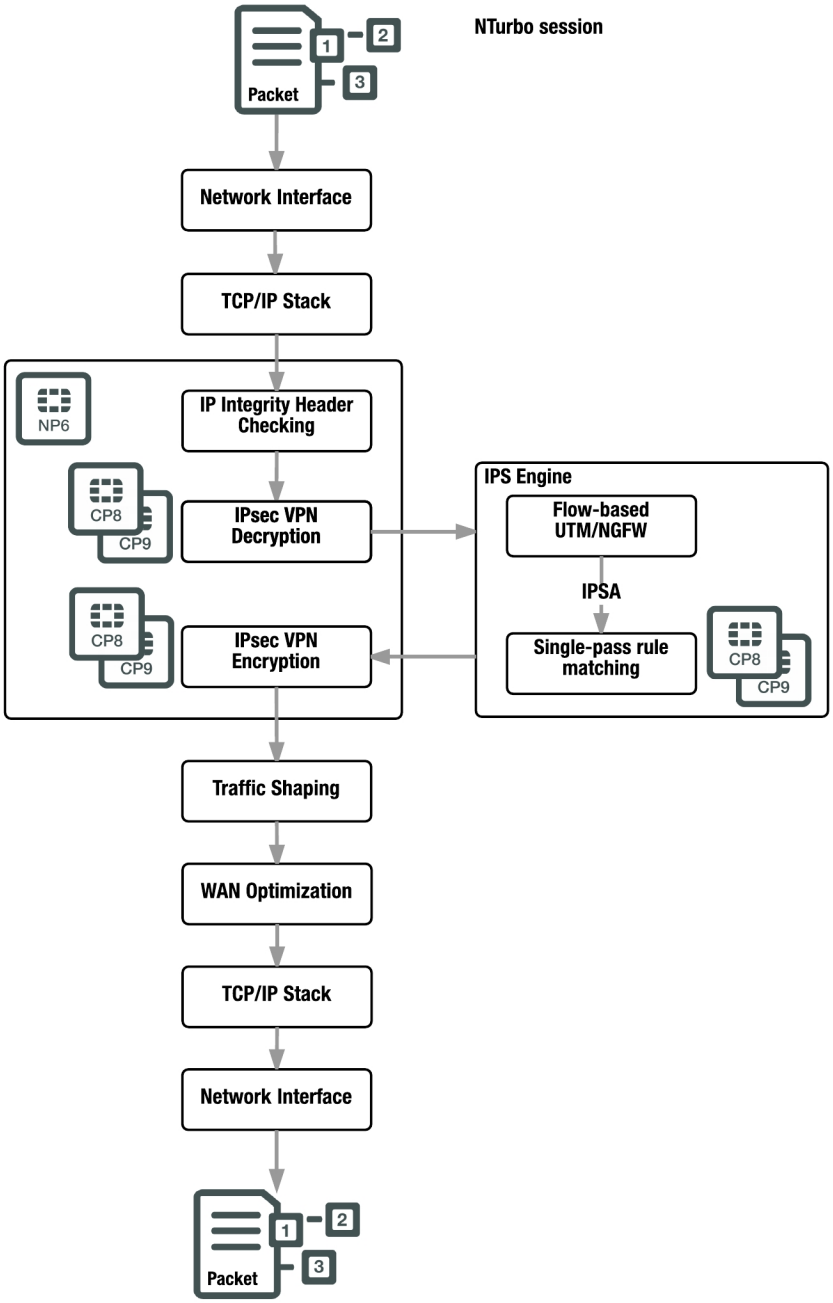
Packet flow: FortiGates with NP6 processors - packets in an offloaded session

The first packet of a session determines if the session can be offloaded. As long as there is no proxy-based UTM/NGFW, if your FortiGate includes NP6 processors, most sessions can be offloaded to them. After the first packet, subsequent packets in an offloaded session skip routing, UTM/NGFW, and kernel processors and are just forwarded out the egress interface by the NP6 processor. As well, security measures such as DoS policies, ACL, and so on are accelerated by the NP6 processor.



Packet flow: FortiGates with NP6 processors - packets in an NTurbo session

If your FortiGate supports NTurbo, many flow-based UTM/NGFW sessions can be offloaded to NP6 processors.



After the first packet, subsequent packets in an offloaded flow-based UTM/NGFW session skip routing, and kernel processors. Flow-based UTM/NGFW operations are still handled by the CPU with IPSA offloading pattern matching to CP8 or CP9 processors.

If a security threat is found the session is dropped. Otherwise, packets that are not blocked by UTM/NGFW are forwarded out of the egress interfaces by the NP6 processor.

NTurbo is not compatible with DoS polices, session helpers, or and most types of tunneling. If any of these features are present, flow-based UTM/NGFW sessions are not offloaded by NTurbo.

UTM/NGFW packet flow: flow-based inspection

Flow-based UTM/NGFW inspection identifies and blocks security threats in real time as they are identified using single-pass architecture that involves Direct Filter Approach (DFA) pattern matching to identify possible attacks or threats.

If a FortiGate or a VDOM is configured for flow-based inspection, depending on the options selected in the firewall policy that accepted the session, flow-based inspection can apply **IPS**, **Application Control**, **Cloud Access Security Inspection (CASI)**, **Web Filtering**, **DLP**, and **Antivirus**. Flow-based inspection is all done by the IPS engine and as you would expect, no proxying is involved.

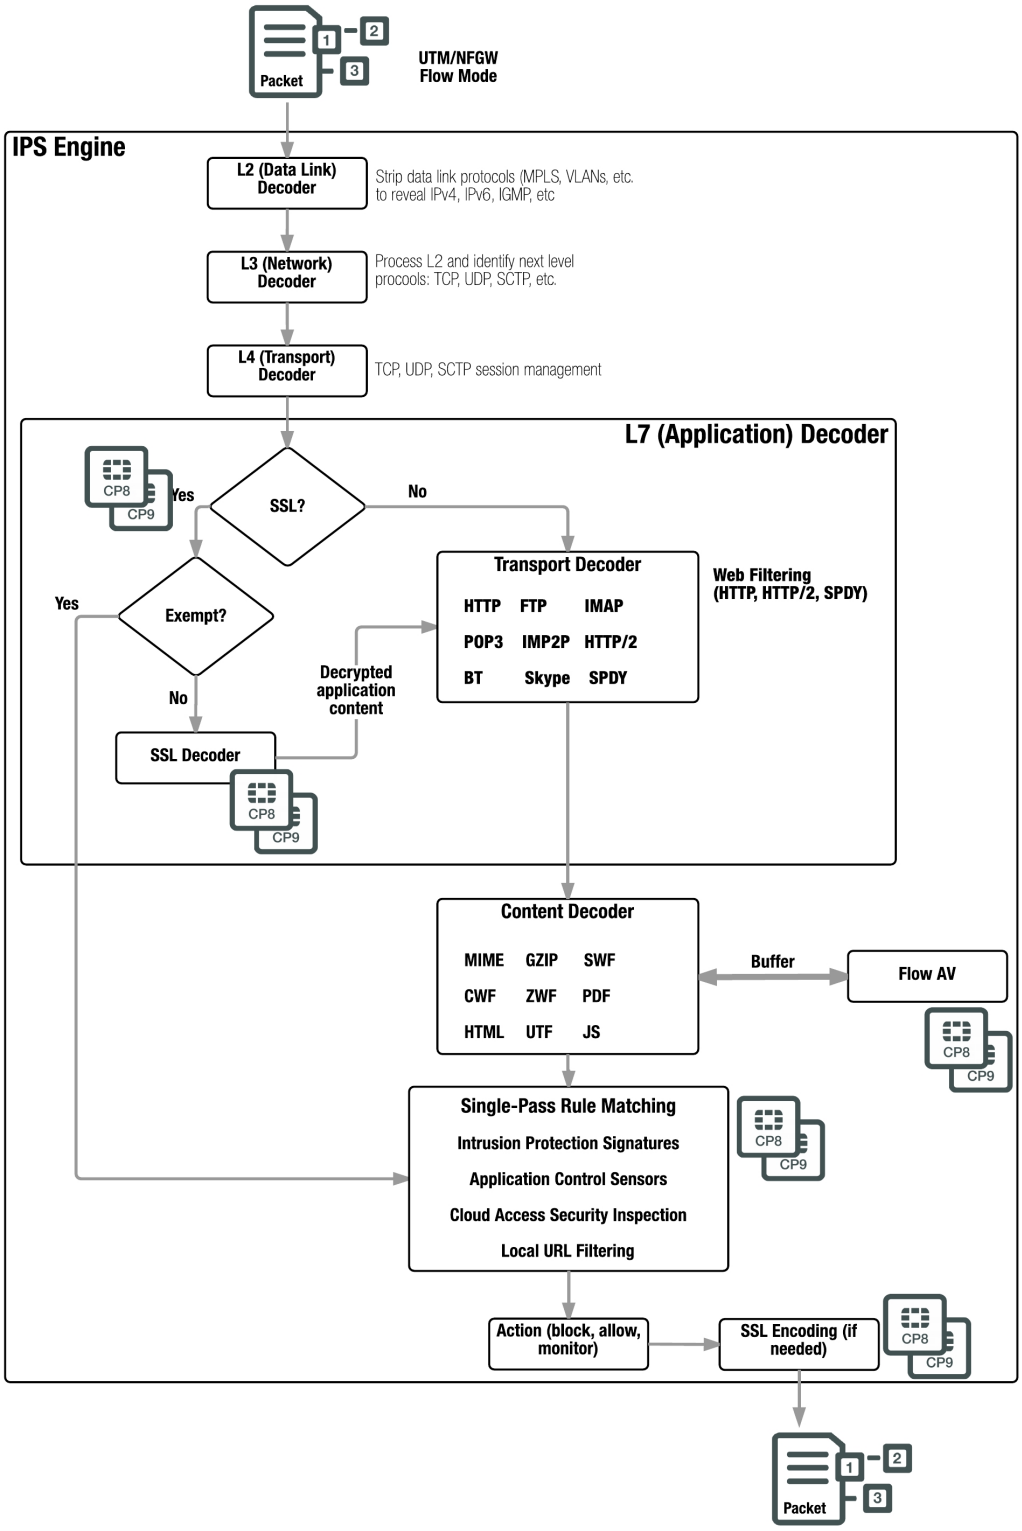
Flow-based DLP is supported but not recommended. Flow-based DLP is not available from the GUI, but can be configured from the CLI.

Before flow-based inspection can be applied the IPS engine uses a series of decoders to determine the appropriate security modules to be applied depending on the protocol of the packet and on policy settings. In addition, if SSL inspection is configured, the IPS engine also decrypts SSL packets. SSL decryption is offloaded and accelerated by CP8 or CP9 processors

All of the applicable flow-based security modules are applied simultaneously in one single pass, and pattern matching is offloaded and accelerated by CP8 or CP9 processors. IPS, Application Control and CASI, flow-based Web Filtering and flow-based DLP filtering happen together. CASI signatures are applied as part of application control. Flow-based antivirus caches files during protocol decoding and submits cached files for virus scanning while the other matching is carried out.

Flow-based inspection typically requires less processing resources than proxy-based inspection and since its not a proxy, flow-based inspection does not change packets (unless a threat is found and packets are blocked). Flow-based inspection cannot apply as many features as proxy inspection (for example, flow-based inspection does not support client comforting and some aspects of replacement messages).

IPS, Application Control, and CASI are only applied using flow-based inspection. Web Filtering, DLP and Antivirus can also be applied using proxy-based inspection.



Packet

Packet

UTM/NGFW packet flow: proxy-based inspection

If a FortiGate or VDOM is configured for proxy-based inspection then a mixture of flow-based and proxy-based inspection occurs. Packets initially encounter the IPS engine, which uses the same steps described in UTM/NGFW packet flow: flow-based inspection on page 2562 to apply single-pass IPS, Application Control and CASI if configured in the firewall policy accepting the traffic.

The packets are then sent to the FortiOS UTM/NGFW proxy for proxy-based inspection. The proxy first determines if the traffic is SSL traffic that should be decrypted for SSL inspection. SSL traffic to be inspected is decrypted by the proxy. SSL decryption is offloaded to and accelerated by CP8 or CP9 processors.

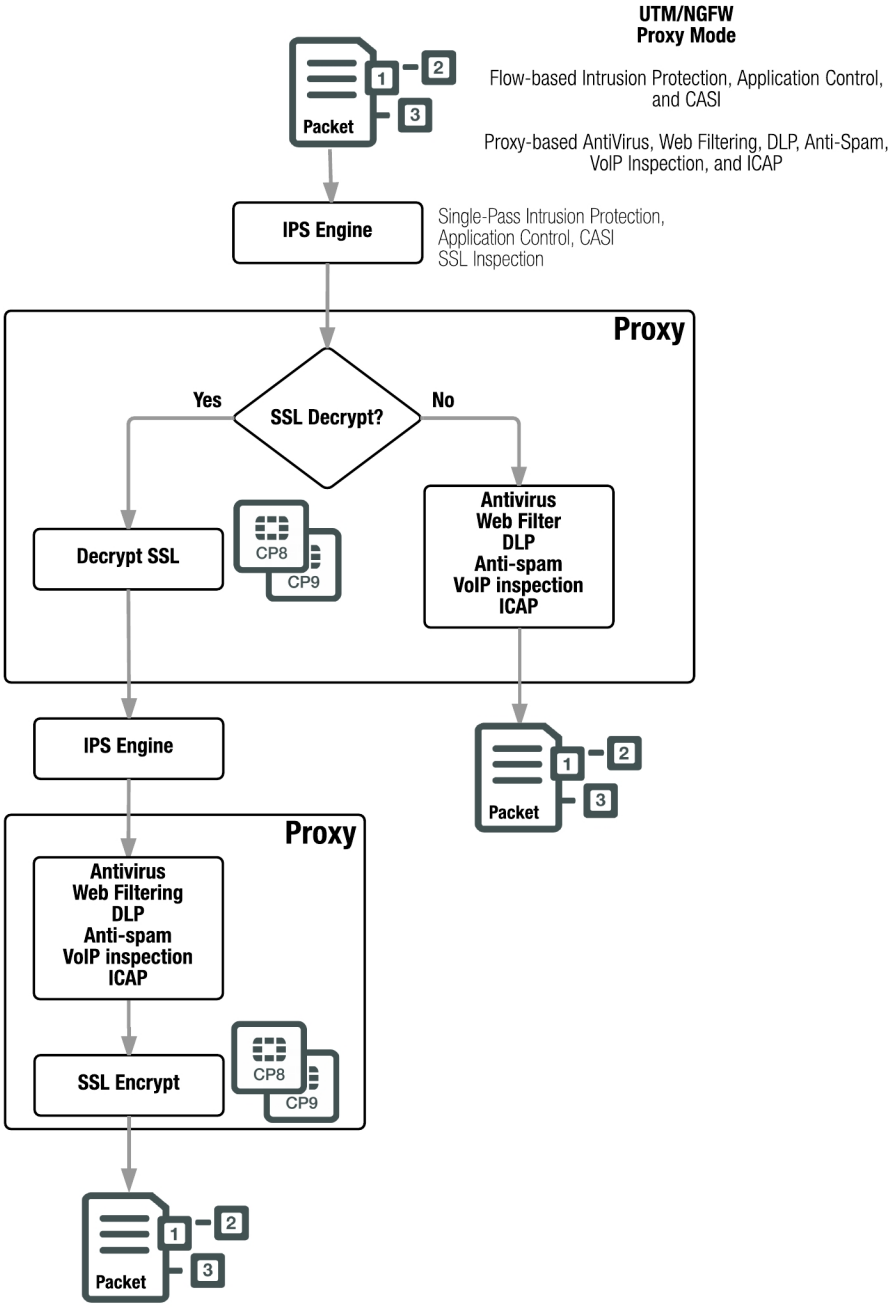
Proxy-based inspection extracts and caches content, such as files and web pages, from a content session and inspects the cached content for threats. Content inspection happens in the following order: **VoIP inspection**, **DLP**, **AntiSpam**, **Web Filtering**, **Antivirus**, and **ICAP**.

If no threat is found the proxy relays the content to its destination. If a threat is found the proxy can block the threat and replace it with a replacement message.

Decrypted SSL traffic is sent to the IPS engine (where IPS, Application Control, and CASI can be applied) before re-entering the proxy where actual proxy-based inspection is applied to the decrypted SSL traffic. Once decrypted SSL traffic has been inspected it is re-encrypted and forwarded to its destination. SSL encryption is offloaded to and accelerated by CP8 or CP9 processors. If a threat is found the proxy can block the threat and replace it with a replacement message.

The proxy can also block VoIP traffic that contains threats. VoIP inspection can also look inside VoIP packets and extract port and address information and open pinholes in the firewall to allow VoIP traffic through.

ICAP intercepts HTTP and HTTPS traffic and forwards it to an ICAP server. The FortiGate is the surrogate, or “middle-man”, and carries the ICAP responses from the ICAP server to the ICAP client; the ICAP client then responds back, and the FortiGate unit determines the action that should be taken with these ICAP responses and requests.



Comparison of inspection types

The tables in this section show how different security functions map to different inspection types.

Mapping security functions to inspection types

The table below lists FortiOS security functions and shows whether they are applied by the kernel, flow-based inspection or proxy-based inspection. This table does not indicate which inspection types are available depending

on the inspection mode. When the inspection mode is set to proxy all inspection types are available. When the inspection mode is set to flow-based then proxy-only inspection types are not available.

FortiOS security functions and inspection types

Security Function	Kernel (Stateful inspection)	Flow-based inspection	Proxy-based inspection
Firewall	yes		
IPsec VPN	yes		
Traffic Shaping	yes		
User Authentication	yes		
Management Traffic	yes		
SSL VPN	yes		
IPS		yes	
Antivirus		yes	yes
Application Control		yes	
CASI		yes	
Web filtering		yes	yes
DLP		yes	yes
Anti-Spam			yes
VoIP inspection			yes
ICAP			yes

More information about inspection methods

The three inspection methods each have their own strengths and weaknesses. The following table looks at all three methods side-by-side.

Inspection methods comparison

Feature	Stateful	Flow	Proxy
Inspection unit per session	first packet	selected packets, single pass architecture, simultaneous application of configured inspection methods	complete content, configured inspection methods applied in order
Memory, CPU required	low	medium	high
Level of threat protection	good	better	best
Authentication	yes		
IPsec and SSL VPN	yes		
Antivirus protection		yes	yes
Web Filtering		yes	yes
Data Leak Protection (DLP)		yes	yes
Application control		yes	
IPS		yes	
Delay in traffic	minor	no	small
Reconstruct entire content		no	yes

Chapter 24 - Sandbox Inspection

Sandbox Inspection

This guide explains how to set up sandbox inspection using FortiSandbox with a FortiGate. It contains the following sections:

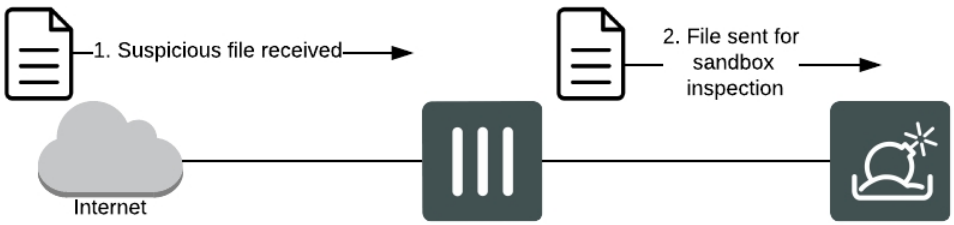
- An Overview of Sandbox Inspection: General information about how sandbox inspection works.
- Using FortiSandbox with a FortiGate: How to set up sandbox inspection on a FortiGate.
- Sandbox Integration: Integrating sandbox inspection with FortiGate, FortiSandbox, and FortiClient.
- Sandbox Inspection FAQ: Frequently asked questions to help troubleshoot sandbox inspection.

An Overview of Sandbox Inspection

This section contains information about how Fortinet sandbox inspection works.

- What is Sandbox Inspection?
- Sending Files for Sandbox Inspection
- FortiSandbox Appliance vs FortiCloud

What is Sandbox Inspection?



Sandbox inspection is a network process that allows files to be sent to a separate device, such as FortiSandbox, to be inspected without risking network security. This allows the detection of threats which may bypass other security measures, including zero-day threats.

When a FortiGate uses sandbox inspection, files are sent to the FortiSandbox. Then the FortiSandbox uses virtual machines (VMs) running different operating systems to test the file, to determine if it is malicious. If the file exhibits risky behavior, or is found to contain a virus, a new signature can be added to the FortiGuard AntiVirus signature database.

Sending Files for Sandbox Inspection

Sending files to the FortiSandbox appliance or to FortiCloud does not block files immediately. Instead, the files assist in the discovery of new threats and the creation of new signatures to be added to the global FortiGuard AntiVirus database. Files deemed malicious are also immediately added to a custom Malware Package which is sent to the FortiGate every two minutes for live remediation.

Options for sending files for Sandbox Inspection differ between FortiOS 5.4 and FortiOS 5.4.1. Go to **Security Profiles > AntiVirus** to set those options.

FortiOS 5.4

There are three options concerning what type of files can be sent for sandbox inspection: **All Files**, **Suspicious Files**, or **Executable Files**.

All Files is the recommended selection to increase the likelihood of detecting unknown malware.

If **Suspicious Files** is selected, then the FortiGate will examine each file and determine if it should be considered suspicious. A file is deemed suspicious when it does not contain a known threat but has characteristics that suggest it may be malware. The characteristics that determine if a file is suspicious are updated by Fortinet to reflect the current threat climate.

If **Executable Files** is chosen, all executable files will be sent to FortiSandbox while other file types are not inspected.

FortiOS 5.4.1

There are two options for sending files for sandbox inspection: **None** or **All Supported Files**. If **All Supported Files** is selected, users can withhold files from being submitted for inspection by type or name pattern.

FortiSandbox Appliance vs FortiCloud

FortiSandbox is available as a physical or virtual appliance (FortiSandbox Appliance), or as a cloud advanced threat protection service integrated with FortiGate (FortiCloud). The table below highlights the supported features of both types of FortiSandbox:

Feature	FortiSandbox Appliance (including VM)	FortiCloud
Sandbox inspection for FortiGate	Yes (FortiOS 5.0.4+)	Yes (FortiOS 5.2.3+)
Sandbox inspection for FortiMail	Yes (FortiMail OS 5.1+)	Yes (FortiMail OS 5.3+)
Sandbox inspection for FortiWeb	Yes (FortiWeb OS 5.4+)	No
Sandbox inspection for FortiClient	Yes (FortiClient 5.4 for Windows only)	No
Manual File upload for analysis	Yes	No
Sniffer mode	Yes	No
File Status Feedback and Report	Yes	Yes
Dynamic Threat Database updates for FortiGate	Yes (FortiOS 5.4+)	Yes (FortiOS 5.4+)
Dynamic Threat Database updates for FortiMail	Yes (FortiMail OS 5.3+)	Yes (FortiMail OS 5.3+)
Dynamic Threat Database updates for FortiClient	Yes (FortiClient 5.4 for Windows only)	No

For more information, see the FortiSandbox documentation.

Using FortiSandbox with a FortiGate

This section contains information about how to use sandbox inspection with FortiSandbox and FortiGate. It includes the following sections:

- Connecting a FortiGate to FortiSandbox
- The FortiSandbox Dashboard

Connecting a FortiGate to FortiSandbox

The procedures for connecting a FortiGate to FortiSandbox differ depending whether you are using FortiSandbox Appliance or FortiSandbox Cloud.

Connecting to FortiSandbox Appliance

1. Connect the FortiSandbox Appliance to your FortiGate so that port 1 and port 3 on the FortiSandbox are on different subnets.

FortiSandbox port 3 is used for outgoing communication triggered by the execution of the files under analysis. It is recommended to connect this port to a dedicated interface on your FortiGate to protect the rest of the network from threats currently being investigated by the FortiSandbox.

2. FortiSandbox port 3 must be able to connect to the Internet. On the FortiGate, go to **Policy & Objects > IPv4 Policy** and create a policy allowing connections from the FortiSandbox to the Internet (using the isolated interface on the FortiGate mentioned above).
3. On the FortiSandbox, go to **Network > System Routing** and add static routes for port 1 and port 3.
4. On the FortiSandbox, go to **Dashboard** and locate the **System Information** widget. Now that the FortiSandbox has Internet access, it can activate its VM licenses. Wait until a green arrow shows up beside **Windows VM** before continuing to the next step.
5. On the FortiGate, go to **System > Cooperative Security Fabric**. Select **Enable Sandbox Inspection** and select **FortiSandbox Appliance.** Set the **IP Address** and enter a **Notifier Email.** If you select **Test Connectivity**, the **Status** shows as **Service is not configured** because the FortiGate has not been authorized to connect to the FortiSandbox.
6. On the FortiSandbox, go to **File Detection >Summary Report** and select the **Device** from the drop-down list. Edit the entry for the FortiGate. Under **Permissions,** enable **Authorized**.
7. On the FortiGate, go to **System > Cooperative Security Fabric** and for FortiSandbox select **Test Connectivity**. The **Status** now shows that **Service is online**.

Once the FortiGate is connected to FortiSandbox, an AntiVirus profile can be configured to send suspicious files for inspection. Sandbox integration can also be configured, for more information see "Sandbox Integration" on page 2573.

Connecting to FortiSandbox Cloud

Before you can connect a FortiGate to FortiSandbox Cloud, you need an active FortiCloud account. For more information, see the FortiCloud documentation.

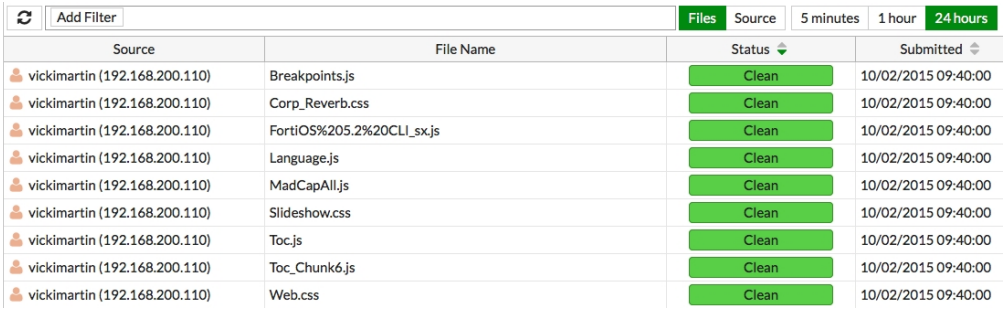
Once you have created a FortiCloud account, sandbox inspection should be enabled by default. To verify this, go to **System > Cooperative Security Fabric**and make sure **Enable Sandbox Inspection** is selected and set to **FortiSandbox Cloud**.

To see the results from FortiSandbox Cloud in the FortiGate logs, go to **Log & Report > Log Settings** and make sure **Send Logs to FortiCloud** is enabled and **GUI Preferences** is set to **Display Logs from FortiCloud**.

Now that the FortiGate is connected to FortiSandbox, an AntiVirus profile can be configured to send suspicious files for inspection. Sandbox integration can also be configured, for more information see "Sandbox Integration" on page 2573.

The FortiSandbox Dashboard

The FortiSandbox dashboard is available from **FortiView > FortiSandbox**. The dashboard shows all samples submitted for inspection. Information on the dashboard can be filtered by checksum, file name, result, source, status, and user name.



Source	File Name	Status	Submitted
vickimartin (192.168.200.110)	Breakpoints.js	Clean	10/02/2015 09:40:00

If you right-click on an entry, you can choose to **Drill Down to Details**, **Quarantine Source Address**, or **Quarantine FortiClient Device**.

Information about the FortiSandbox database and sandboxing statistics are also available at **System > Cooperative Security Fabric** once sandbox inspection is enabled. The Advanced Threat Protection dashboard widget shows you the number of files that your FortiGate unit has uploaded or submitted to FortiSandbox.

Information can also be found by accessing FortiSandbox. For more information, please refer to the FortiSandbox documentation.

Sandbox Integration

Sandbox integration adds another level to sandbox inspection, allowing you allows you to set up automatic actions to protect your network from files FortiSandbox determines are malicious. These actions include: receiving AntiVirus signature updates from FortiSandbox, adding the originating URL of any malicious file to a blocked URL list, and extending sandbox scanning to FortiClient devices.

This section contains the following topics:

- Overview
- Example Configuration

See the What's New chapter on FortiSandbox Integration for changes made in FortiOS releases 5.4.1 and later.

Overview

FortiSandbox integration involves three different FortiGate security profiles: AntiVirus, Web Filtering, and FortiClient Profiles.

FortiGate can retrieve scan results and details from FortiSandbox, and also receive antivirus and web filtering signatures to supplement the current signature database. When FortiGate learns from FortiSandbox that an endpoint is infected, the administrator can push instruction for self-quarantine on a registered FortiClient host.

When integrated with FortiGate, the following protocols are supported by FortiSandbox: HTTP, HTTPS, FTP, FTPS, POP3, POP3S, IMAP, IMAPS, SMTPS, MAPI, MAPIS, SMB, and supported IM protocols.

AntiVirus

When FortiSandbox discovers a malicious file, it can create an AntiVirus signature for that file and add that signature to both the local FortiGate malware database and the FortiGuard AntiVirus signature database. Through FortiSandbox integration, this signature can be sent to a FortiGate to block the file from re-entering the network and to prevent the future retransmission of that file to FortiSandbox.

Use of the FortiSandbox AntiVirus database is enabled in an AntiVirus profile, found at **Security Profiles > AntiVirus**. It can also be configured using the following CLI commands:

```
config antivirus profile
   edit <profile>
      set analytics-db enable
   end
```

Web Filtering

FortiSandbox integration can also be used to allow FortiSandbox to add a URL filter blocking the source of a discovered malicious file to the FortiGate's blocked URL list.

Blocking malicious URLs discovered by FortiSandbox is enabled in a Web Filter profile, found at **Security Profiles > Web Filter**. It can also be configured using the following CLI commands:

```
config webfilter profile
   edit <profile>
      config web
         set blacklist enable
      end
```

FortiClient Profiles

Extended FortiSandbox scanning is currently only supported by FortiClient 5.4 for Windows. It can also only be used with FortiSandbox Appliance.

When extended FortiSandbox scanning is enabled for FortiClient, files downloaded by FortiClient can be sent to the FortiSandbox for inspection. Also, if a suspicious file is discovered, FortiClient can be configured to wait until sandbox inspection is complete before allowing that file to be accessed.

AntiVirus signatures can also be pushed by the FortiGate to FortiClient.

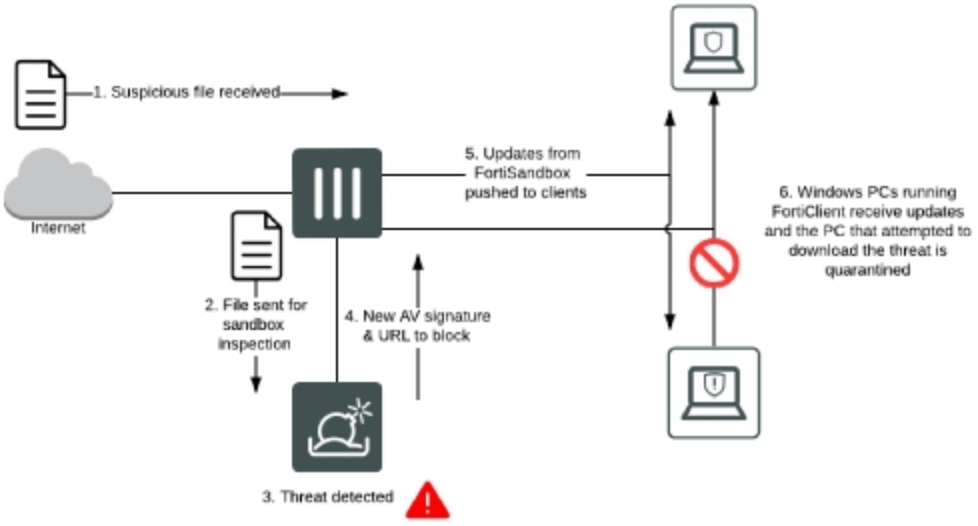
If a FortiClient device attempts to download a file that FortiSandbox discovers is malicious, the FortiSandbox notifies the FortiGate. The administrator can take action to quarantine the device. When a quarantine is in effect, FortiClient cuts off other network traffic from the device directly, preventing it from infecting or scanning the local network. When a device is under quarantine, FortiClient cannot be shutdown or uninstalled. A user is also unable to unregister from the FortiGate that quarantined them, or register to another FortiGate unit. A quarantine can only be lifted by the administrator of the FortiGate where the FortiClient device is registered.

Extending FortiSandbox scanning can by configured in the **Security** settings of a FortiClient Profile, found at **Security Profiles > FortiClient Profiles**. It can also be configured using the following CLI commands:

```
config endpoint-control profile
   edit <profile>
      config forticlient-winmac-settings
         set scan-download-file enable
         set sandbox-analysis enable
         set sandbox-address <address>
         set wait-sandbox-result {enable | disable}
         set use-sandbox-signature {enable | disable}
      end
```

Extending FortiSandbox scanning can also be configured directly in the FortiClient **AntiVirus** settings.

Example Configuration



The following example configuration sets up FortiSandbox integration using AntiVirus, Web Filtering, and a FortiClient profile. This configuration assumes that a connection has already been established between the FortiSandbox Appliance and the FortiGate.

1. Go to **Security Profiles > AntiVirus** and edit the default profile. Under **Inspection Options**, enable both **Send Files to FortiSandbox Appliance for Inspection** and **Use FortiSandbox Database**. Select **Apply**.
2. Go to **Security Profiles > Web Filter** and edit the default profile. Under **Static URL Filter**, enable **Block malicious URLS discovered by FortiSandbox**. Select **Apply**.
3. Go to **Security Profiles > FortiClient Profiles** and edit the default profile. Under **AntiVirus**, enable **Realtime Protection**, then enable **Scan Downloads**, followed by **Scan with FortiSandbox**. Enter the IP of the FortiSandbox, then enable **Use FortiSandbox signatures**. Select **Apply**.
4. Go to **Policy & Objects > IPv4 Policy** and view the policy list. If a policy has AntiVirus and Web Filtering scanning applied, the profiles will be listed in the **Security Profiles** column. If scanning needs to be added to any security policy (excluding the **Implicit Deny** policy) select the **+** button in the **Security Profiles** column for that policy, then select the default **AntiVirus Profile**, the default **Web Filter Profile**, the appropriate **Proxy Options**, and the **deep-inspection** profile for **SSL Inspection Options** (to ensure that encrypted traffic is inspected).
5. Select **OK**.

Results

If your FortiGate discovers a suspicious file, it will now be sent to the FortiSandbox. To view information about the files that have been sent on the FortiGate, go to **FortiView > FortiSandbox** to see a list of file names and current status.

To view results on the FortiSandbox, go to the **Dashboard**and view the **Scanning Statistics** widget. There may be a delay before results appear on the FortiSandbox.

Open FortiClient using a Windows PC on the internal network. Make sure it is registered to your FortiGate. Go to **AntiVirus > Realtime Protection Enabled** and edit the settings. You will see that the **Realtime Protection** settings match the FortiClient Profile configured on the FortiGate. These settings cannot be changed using FortiClient.

If a PC running FortiClient downloads a suspicious file that the FortiSandbox determined was malicious, a quarantine would be applied automatically. While the quarantine is in effect, FortiClient cannot be shutdown on the PC. It can not be uninstalled or unregistered from the FortiGate. The quarantine can only be released from the FortiClient Monitor on the FortiGate.

Sandbox Inspection FAQ

The following are some frequently asked questions about using sandbox inspection with FortiSandbox and FortiGate.

Why is the FortiSandbox Cloud option not available when sandbox inspection is enabled?

This option is only available if you have already created a FortiCloud account. For more information, see the FortiCloud documentation.

Why don't results from FortiSandbox Cloud appear in the FortiGate GUI?

Go to **Log & Report > Log Settings** and make sure **Send Logs to FortiCloud** is enabled and **GUI Preferences** is set to **Display Logs from FortiCloud**.

Why are the FortiSandbox Appliance VMs inactive?

Make sure that port 3 on the FortiSandbox has an active Internet connection. This is required in order to active the FortiSandbox VMs.

Why aren't files are being scanned by FortiSandbox?

Make sure an AntiVirus profile that sends files to FortiSandbox is enabled for all policies that require sandbox inspection.

Chapter 25 - Fortinet Security Fabric

FortiGate Security Fabric

This guide explains how to configure your network as a Security Fabric. It contains the following sections:

- Overview
- Example Network
- Core Devices
- Extended Devices

Because Security Fabric is a new feature in FortiOS and other Fortinet products, it will be developing and expanding as new firmware is released. Please refer back to this document for information about these changes when new firmware is available.

Overview

This section provides an overview of what a Security Fabric is and how the devices in the fabric work together as a whole. It contains the following topics:

- What is a Security Fabric?
- FortiView
- Communication Between Devices
- Firmware Versions

What is a Security Fabric?

A Security Fabric uses FortiTelemetry to link different security sensors and tools together to collect, coordinate, and respond to malicious behavior anywhere it occurs on your network in real time.

The core of a security fabric is an upstream FortiGate located at the edge of the network, with several internal FortiGates functioning as Internet Segmentation Firewalls (ISFWs). A security fabric can be used to coordinate the behavior of other Fortinet products in your network, including FortiAnalyzer, FortiManager, FortiClient, FortiClient EMS, FortiWeb, FortiSwitch, and FortiAP.

A security fabric ties your network together data to provide visibility and control. The Fortinet Security fabric covers:

- Endpoint client security
- Secure wired, wireless, and VPN access
- Network security
- Data center security (physical and virtual)
- Application (OTS and custom) security
- Cloud security
- Content (email and web) security
- Infrastructure (switching and routing) security

Multiple VDOM support is disabled when security fabric is enabled.

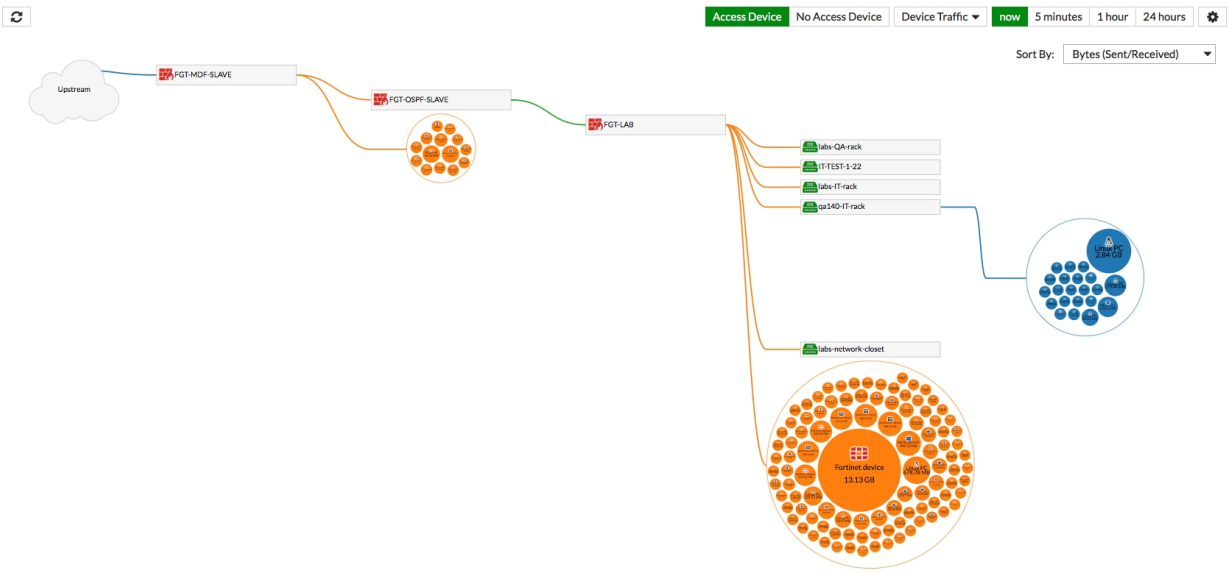
FortiView

FortiView can be used to view a security fabric's topology. Two different visualizations are available: Physical Topology and Logical Topology.

Both visualizations can be filtered to show four main views: device traffic, device count, device type, or no devices. Finally, like other FortiView pages, the topology can be filtered by time.

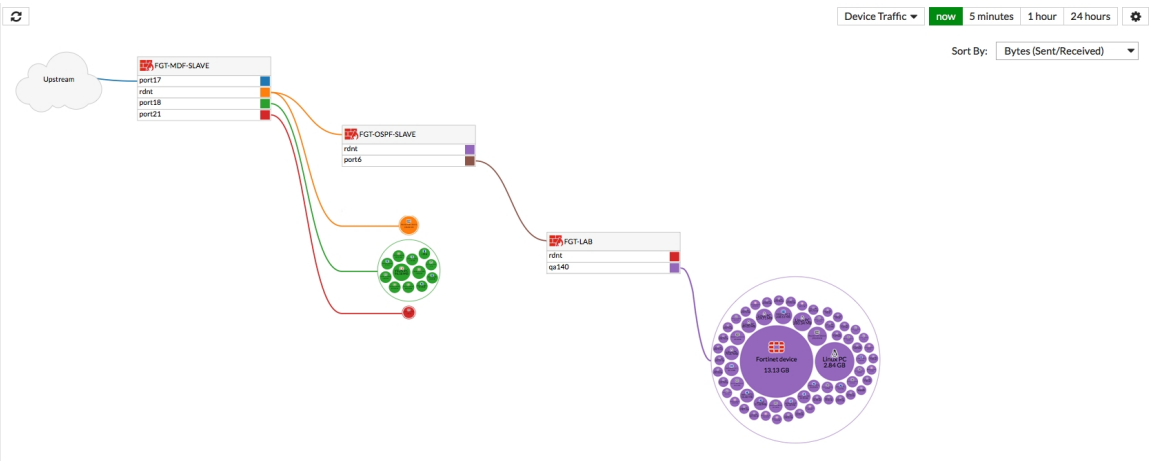
Physical Topology

Physical Topology shows the devices in the security fabric and which devices are connected. You can select whether or not to view access layer devices in this topology.



Logical Topology

Logical Topology displays information about network interface (logical or physical) and which interfaces are used to connect devices in the fabric.



Communication Between Devices

There are two main ways that devices within a security fabric communicate with each other: FortiTelemetry and Routing using OSPF.

FortiTelemetry

FortiTelemetry is a protocol, similar to the FGCP HA heartbeat, used for communication between the Fortinet products in the security fabric. FortiTelemetry connects devices in a security fabric allowing dynamic status updates between these devices. FortiTelemetry also supports FortiClient On-Net functionality, and monitors and enforces FortiClient protection on user endpoints devices on the network.

FortiTelemetry must be enabled on interfaces that connect Fortinet devices in the security fabric.

Routing using OSPF

Dynamic routing, most often using OSPF, is recommended for allowing communication among all of the devices in a security fabric. OSPF can be set up relatively easily on all of the FortiGate units in the security fabric from the FortiGate GUI. Since FortiOS fully supports OSPF, no additional routers are required.

For an example OSPF setup for an example security fabric, see Installing internal FortiGates and enabling a security fabric.

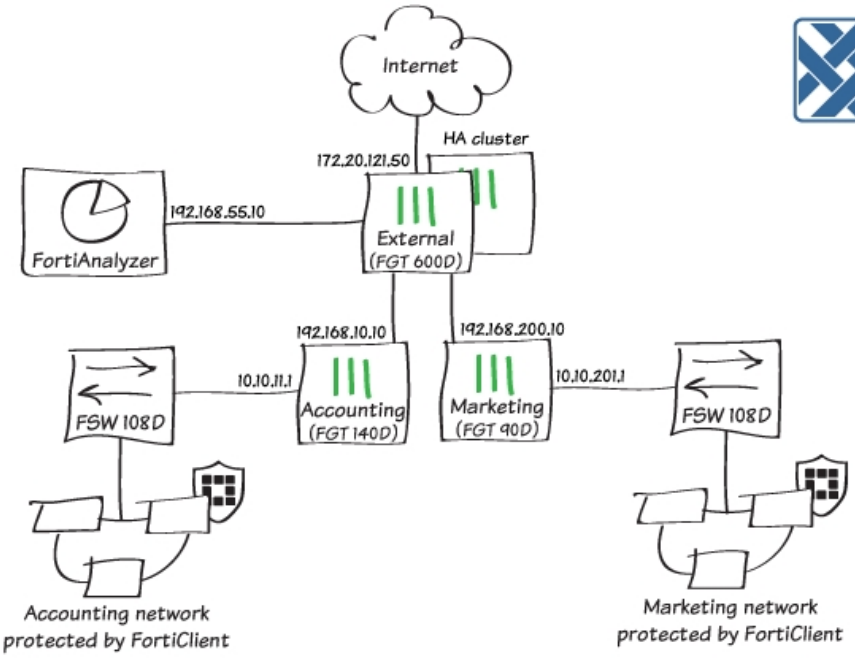
Firmware Versions

Some features of the Security Fabric are only available in certain firmware versions. The chart below shows the products that have required firmware versions.

Product	Required Firmware
FortiGate	5.4.1
FortiAnalyzer	5.4.1
FortiManager	5.4.1
FortiClient	5.4.1
FortiSwitch	3.4.2 and later
FortiAP	5.4.1
FortiSandbox	2.1.0 and later 1.4.0 and later

For any additional compatibility information, please refer to the Release Notes.

Example Network



To demonstrate how to configure a security fabric, the Security Fabric collection is available on Fortinet Cookbook website. Currently the Security Fabric collection includes the following recipes:

- Installing a FortiGate in NAT/Route Mode
- Installing internal FortiGates and enabling a security fabric
- Adding FortiAnalyzer to a security fabric
- High Availability with two FortiGates
- Setting up an internal network with a managed FortiSwitch
- Adding endpoint control to a security fabric

This collection will expand over time, so check back to see if anything new has been added.

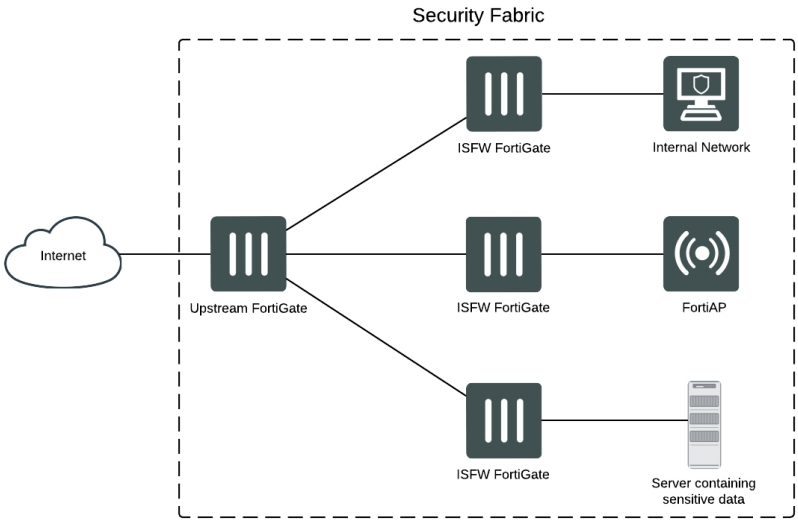
Core Devices

The following Fortinet products are the key components of a Security Fabric:

- FortiGate
- FortiAnalyzer
- FortiManager
- FortiClient
- FortiClient EMS

FortiGate

There are two roles a FortiGate can have in a security fabric: Upstream or Internal Segmentation Firewall (ISFW). Both FortiGates work together to provide Distributing security functions.



Upstream

The upstream FortiGate is the heart of the security fabric. It is located on the edge of the network, connecting the internal devices and networks to the Internet through your ISP.

From the upstream FortiGate, you can view information about the entire security fabric using FortiView.

Internal Segmentation Firewall (ISFW)

Once an upstream FortiGate has been installed, all other FortiGates in the security fabric act as Internal Segmentation Firewalls (ISFWs).

An ISFW is a firewall that sits at strategic internal points of the internal network, rather than on the network edge. This allows extra security measures to be taken around key network components, such a servers that contain valuable intellectual property.

ISFW FortiGates in a security fabric send traffic and information about their devices to the upstream FortiGate, allowing network visibility.

Distributing security functions

Security Fabric configurations allow you to distribute security functions to different FortiGates in the security fabric. For example, you may want to implement virus scanning on the External FortiGate but add application control and web filtering to the ISFW FortiGates.

This results in distributed processing between the FortiGates in the Security Fabric; reducing the load on each one. It also allows you to customize the web filtering and application control for the specific needs of the Accounting network as other internal networks may have different application control and web filtering

requirements. This configuration may result in threats getting through the External FortiGate which means you should very closely limit access to the network connections between the FortiGates in the Security Fabric.

Another strategy you could choose is to have flow-based inspection on the External FortiGate and proxy-based inspection used by the ISFW FortiGates.

FortiAnalyzer

Using a FortiAnalyzer in a security fabric allows you to simplify network logging by storing and displaying all log information in one place.

Currently, FortiAnalyzer does not have any security fabric specific features. However, you can configure all of the FortiGates in the security fabric to send log messages to your FortiAnalyzer and use its analysis tools on this data.

To add FortiAnalyzer to a fabric, all FortiGates in the fabric must be able to send logs to the FortiAnalyzer. To do this, go to **Log & Report > Log Settings** and configure **Remote Logging and Archiving** to send logs to the FortiAnalyzer.

FortiManager

Using a FortiManager in a security fabric allows you to simplify network management by centralizing management access in a single device.

Currently, FortiManager does not have any security fabric specific features.

To add FortiManager to a fabric, all FortiGates in the fabric must be able to send logs to the FortiAnalyzer. To do this, go to **Log & Report > Log Settings** and configure **Remote Logging and Archiving** to send logs to the FortiManager.

FortiClient

FortiClient is used to add endpoint control to devices located within a security fabric. This is done by creating a FortiClient Profile that only allows traffic from compliant devices to flow through the FortiGate.

In a security fabric, FortiClient profiles are applied by the first FortiGate that a device's traffic flows through, which is often an ISFW FortiGate, rather than the Upstream FortiGate. Information about the FortiClient device's registration and on-net status will appear only on the FortiGate that applies the FortiClient profile.

For more information about FortiClient profiles, see the Security Profiles handbook.

FortiClient EMS

FortiClient Enterprise Management Server (FortiClient EMS) is a security management solution that enables scalable and centralized management of multiple endpoint devices. It can be used in a security fabric to provide visibility across the network, to securely share information and assign security profiles to endpoints.

For more information, refer to the FortiClient EMS documentation.

Extended Devices

The following Fortinet products can be used to extend the use and range of a Security Fabric:

- FortiSwitch
- FortiAP
- FortiSandbox
- FortiMail, FortiWeb, and FortiCache

FortiSwitch

A FortiSwitch can be added to a security fabric when it is managed by a FortiGate within the fabric, connecting to an interface that uses FortiTelemetry. Devices connected to the FortiSwitch will appear in the Security Fabric FortiView dashboard and security features, such as FortiClient profiles, will be applied to them.

For more information, see Managing FortiSwitches using FortiGate.

FortiAP

FortiAPs can be added to extend a security fabric to your wireless devices. Devices connected to the FortiAP will appear in the Security Fabric FortiView dashboard. Ideally FortiClient should be installed on them to truly extend the security fabric to all of your devices. This also allows you to apply features, such as FortiClient profiles to them.

FortiSandbox

Add FortiSandbox to your Security Fabric to improve security with sandbox inspection. The sandbox integration added in FortioS 5.4 allows FortiGates in the fabric to automatically receive signature updates from FortiSandbox and add the originating URL of any malicious file to a blocked URL list. FortiSandbox also integrates with FortiClient, allowed extended scanning to used by FortiClient devices.

For more information, see the Sandbox Inspection handbook.

FortiMail, FortiWeb, and FortiCache

External Security Devices can be added to a Security Fabric to offload processes to other devices, such as a FortiWeb, FortiCache, or FortiMail. Example processes could include HTTP inspection, web caching, and anti-spam.

Offloading HTTP traffic to FortiWeb

Use the following steps to offload HTTP traffic to FortiWeb to apply Web Application Firewall features to the traffic. Using these steps you can select the HTTP traffic to offload by adding a web application firewall profile configured for external inspection to selected firewall policies. Only the HTTP traffic accepted by those firewall policies is offloaded.

If you offload HTTP traffic to FortiWeb you can also apply other HTTP inspection to it from your FortiGate including virus scanning and web filtering.

A single FortiGate cannot offload HTTP traffic to both FortiCache and FortiWeb.

To offload HTTP traffic to FortiWeb:

1. Go to the **System Information** dashboard widget and make sure **Inspection Mode** is set to **Proxy-based**.
2. Go to **System > Feature Select** and turn on **Web Application Firewall**.
3. Go to **System > Cooperative Security Fabric**, enable **HTTP Service**, select **FortiWeb** and add the IP addresses of your FortiWeb devices. You can also select **Authentication** add a **password** if required.
4. Go to **Security Profiles > Web Application Firewall** and add or edit a Web Application Firewall profile and set **Inspection Device** to **External**.
5. Go to **Policy & Objects > IPv4 Policy**, add or edit a firewall policy, select **Web Application Firewall**, and select the profile that you set to use the external inspection device.

These steps add the following configuration to the CLI:

```
config system wccp
   set service-id 51
   set router-id 5.5.5.5 (the IP address of the FortiGate interface that communicates with
       the FortiWeb)
   set group address 0.0.0.0
   set server-list 5.5.5.25 255.255.255.255 (the IP address of the FortiWeb)
   set authentication enable
   set forward-method GRE
   set return-method GRE
   set assignment-method HASH
   set password *
end
```

Offloading HTTP traffic to FortiCache

To offload Web Caching to FortiCache a FortiGate must support WAN Optimization and WAN Optimization must be enabled. For some FortiGate models you need to turn off disk logging to support WAN Optimization. See "WAN Optimization" on page 218 in What's New for details.

Use the following steps to offload web caching to FortiCache. Using these steps you can select the web traffic to offload by selecting web caching in firewall policies. Only the web traffic accepted by those firewall policies will be offloaded.

A single FortiGate cannot offload HTTP traffic to both FortiCache and FortiWeb.

1. Go to the **System Information** dashboard widget and make sure **Inspection Mode** is set to **Proxy-based**.
2. Go to **System > Advanced > Disk Settings** and assign at least one disk to **WAN Optimization**.
3. Go to **System > Feature Select** and turn on **WAN Opt. & Cache**.
4. Go to **System > Cooperative Security Fabric**, enable **HTTP Service**, select **FortiCache** and add the IP addresses of your FortiCache devices. You can also select **Authentication** add a **password** if required.
5. Go to **Policy & Objects > IPv4 Policy**, add or edit a firewall policy and select **Web Cache**.

These steps add the following configuration to the CLI:

```
config system wccp
   set service-id 51
   set router-id 5.5.5.5 (the IP address of the FortiGate interface that communicates with
       the FortiCache)
   set group address 0.0.0.0
   set server-list 5.5.5.45 255.255.255.255 (the IP address of the FortiCache)
   set authentication enable
   set forward-method GRE
   set return-method GRE
   set assignment-method HASH
   set password *
end
```

Offloading SMTP traffic to FortiMail

Use the following steps to offload SMTP traffic to FortiMail to apply FortiMail features to the traffic. Using these steps you can select the SMTP traffic to offload by adding an AntiSpam profile configured for external inspection to selected firewall policies. Only the SMTP traffic accepted by those firewall policies is offloaded.

If you offload HTTP traffic to FortiWeb you can also apply other HTTP inspection to it from your FortiGate including virus scanning and web filtering.

To be able to offload Anti-Spam processing to a FortiMail device you should:

1. Go to the **System Information** dashboard widget and make sure **Inspection Mode** is set to **Proxy-based**.
2. Go to **System > Feature Select** and turn on **Anti-Spam Filter**.
3. Go to **System > Cooperative Security Fabric**, enable **SMTP Service - FortiMail** and add the IP address of your FortiMail devices. You can also select **Authentication** add a **password** if required.
4. Go to **Security Profiles > Anti-Spam** and edit an Anti-Spam profile and set **Inspection Device** to **External**.
5. Go to **Policy & Objects > IPv4 Policy**, add or edit a Firewall policy, enable **Anti-Spam** and select the profile for which you set Inspection Device to External.

These steps add the following configuration to the CLI:

```
config system wccp
   set service-id 52
   set router-id 5.5.5.5 (the IP address of the FortiGate interface that communicates with
       the FortiMail)
   set group address 0.0.0.0
   set server-list 5.5.5.65 255.255.255.255 (the IP address of the FortiMail)
   set authentication enable
   set forward-method GRE
   set return-method GRE
   set assignment-method HASH
   set password *
end
```

Chapter 26 - Security Profiles

This FortiOS Handbook chapter contains the following sections:

What's new in FortiOS 5.4 lists and describes the new security profile features in FortiOS 5.4 and 5.4.1.

Inside FortiOS highlights the features and benefits of key FortiOS 5.4 components. The technical documentation team maintains these documents as part of the Handbook and as standalone documents which are available at Fortinet's Online Help for FortiOS 5.4. Inside FortiOS covers the following security profiles topics:

- AntiVirus
- Application Control
- Intrusion Prevention System
- Web Filtering

Security Profiles overview describes Security Profiles components and their relation to firewall policies, as well as SSL content scanning and inspection.

AntiVirus explains how the FortiGate unit scans files for viruses and describes how to configure the antivirus options.

Web filter describes basic web filtering concepts, FortiGuard Web Filtering, the order in which the FortiGate unit performs web filtering, and configuration.

Application Control describes how your FortiGate unit can detect and take action against network traffic based on the application generating the traffic.

FortiClient Profiles addresses the FortiClient Profiles endpoint protection features and configuration, including changes that first appeared in FortiOS 5.4.1.

Intrusion protection explains basic Intrusion Protection System (IPS) concepts and how to configure IPS options; includes guidance and a detailed table for creating custom signatures as well as several examples.

Custom Application & IPS Signatures describes how to create custom Application Control and IPS signatures.

Anti-Spam filter explains how the FortiGate unit filters email and describes how to configure the filtering options and the action to take with email detected as spam.

Data leak prevention describes the DLP features that allow you to prevent sensitive data from leaving your network and explains how to configure the DLP rules, compound rules, and sensors.

ICAP support describes how to offload traffic to a separate server specifically set up for the specialized processing of the traffic.

Other Security Profiles considerations addresses topics like Security Profiles VDOMs, conserve mode, SSL content scanning and inspection, using wildcards and Perl regular expressions, adding External Security Devices, CPU allocation and tuning commands to survive reboot and so on.

What's New in FortiOS 5.4

This chapter describes new security profile features added to FortiOS 5.4.0 andFortiOS 5.4.1.

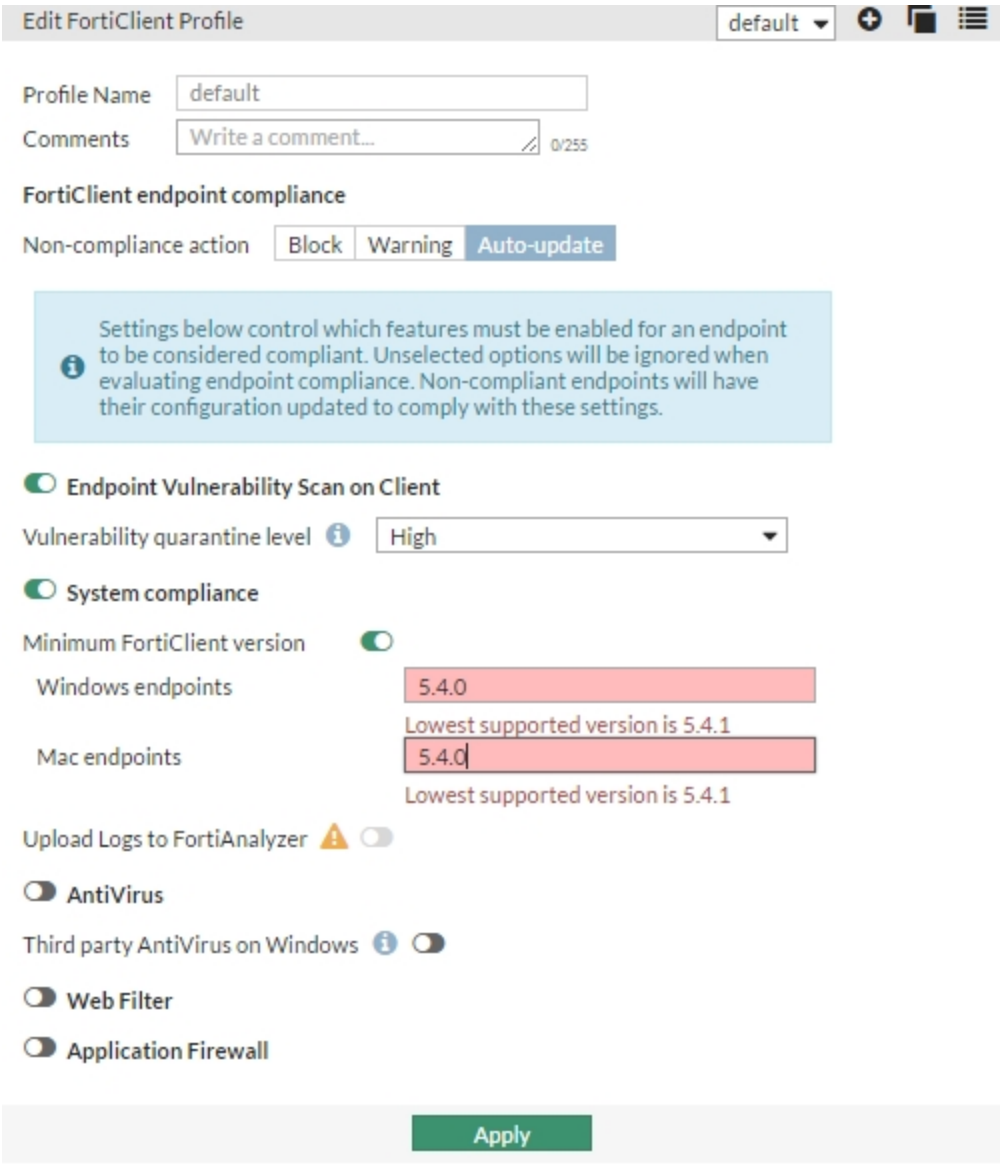
FortiOS 5.4.1

These features first appeared in FortiOS 5.4.1.

FortiClient Profile changes (356205)

Features involving general settings have been removed from the FortiClient profile GUI in 5.4.1. Features emphasizing compliance of the endpoint devices have been added. These enhancements facilitate integration with the Cooperative Security Fabric.

When FortiClient endpoint compliance is enabled and FortiClient endpoints are registered to FortiGate, you must upgrade registered FortiClient endpoints. Be sure to upgrade registered endpoints to FortiClient 5.4.1 before upgrading your FortiGate to FortiOS 5.4.1.



FortiClient endpoint compliance enforcement has three actions. When the action is set to **Block** or **Warning**, it is up to you to provision endpoints either via the Enterprise Management Server (EMS) or manually. When the action is set to **Auto-update**, the FortiGate will provision the endpoint.

Action	Meaning
Block	If the endpoint does not match compliance rules in the FortiClient Security Profile, then it will be blocked.
Warning	If the endpoint does not match compliance rules in the FortiClient Security Profile, then it will show on the Monitor > FortiClient Monitor as not-compliant. Traffic will not be blocked.
Auto-update	If the endpoint is not-compliant, the FortiGate will push a limited profile to the endpoint and attempt to get it to be compliant.

CLI syntax

A third value called **compliant** and new attributes have been added to existing CLI.

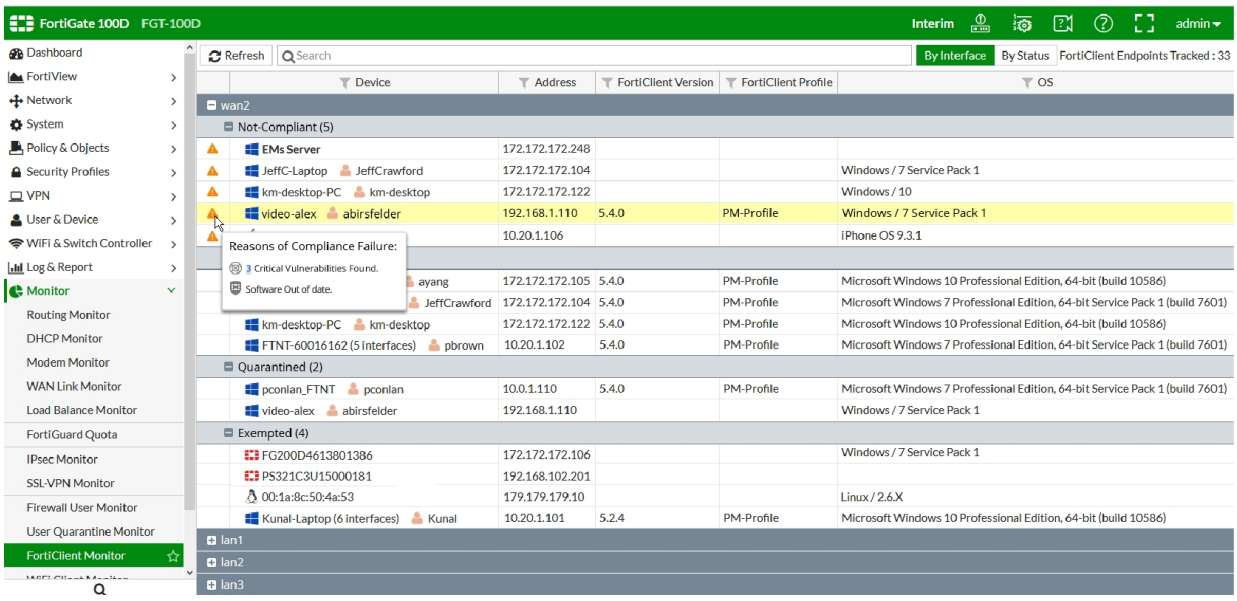
```
config endpoint-control profile
   edit <profile name>
      config forticlient-winmac-settings
         set compliance-action {block | warning | auto-update}
         set os-av-software-installed {enable | disable}
         set forticlient-log-upload-level {traffic | vulnerability | event}
         set forticlient-system-compliance {enable | disable}
         set forticlient-minimum-software-version {enable | disable}
         set forticlient-vuln-scan-enforce {enable | disable}
         set forticlient-vuln-scan-enforce-grace {0 - 30 days, default = 1}
         set sandbox-analysis {enable | disable}
      end
   end
```

FortiClient Monitor page updates (304254)

Updates to the **Monitor** page allow the user to view FortiClient endpoint devices grouped by interface and then sub-grouped by compliance status. Compliance status can be compliant, non-compliant, exempt, or quarantined.

	FortiClient Enforcement	
Status	**Enabled**	**Disabled**
Compliant	List only active FortiClientEndpoints.	No devices listed
Not-compliant	List devices not-compliant with FortiClient profile, so long as they are not exempt.	No devices listed
Exempt	List FortiClient endpoints exempt from FortiClient compliance.	List of all user devices except those quarantined by the administrator.
Quarantined	List devices quarantined by the administrator.	List devices quarantined by the administrator.

You can see the reasons for non-compliance by right-clicking on an endpoint in the list.



FortiClient Endpoint Control Profile Attributes (306833)

Certain attributes have been removed from, added to, or changed in the FortiClient endpoint control profile configuration.

Attributes Removed

You can no longer configure these attributes in the FortiClient endpoint control profile:

```
view-profile-details
scan-download-file
wait-sandbox-result
use-sandbox-signature
block-malicious-website
block-attack-channel
av-scheduled-scan
av-scan-type
av-scan-schedule
av-scan-time
av-scan-exclusions
monitor-unknown-application
install-ca-certificate
disable-wf-when-protected
forticlient-vuln-scan-schedule
forticlient-vuln-scan-on-registration
forticlient-vpn-provisioning
forticlient-advanced-vpn
forticlient-advanced-vpn-buffer
disable-unregister-option
forticlient-log-ssl-upload
forticlient-log-upload-schedule
forticlient-update-from-fmg
forticlient-update-server
forticlient-update-failover-to-fdn
forticlient-settings-lock
forticlient-settings-lock-passwd
```

```
   auto-vpn-when-off-net
   auto-vpn-name
   client-log-when-on-net
   forticlient-ad
   fsso-ma
   fsso-ma-server
   fsso-ma-psk
   allow-personal-vpn
   disable-user-disconnect
   vpn-before-logon
   vpn-captive-portal
   forticlient-ui-options
   forticlient-advanced-cfg
   forticlient-advanced-cfg-buffer
```

Attributes Added

The following attributes have been added to the FortiClient endpoint control profile configuration.

```
config endpoint-control profile
   edit <profile_name>
   config forticlient-winmac-settings
      set sandbox-analysis {enable | disable}
      set compliance-action {block | warning | auto-update}
      set os-av-software-installed {enable | disable}
      set forticlient-minimum-software-version {enable | disable}
      set forticlient av {enable | disable}
      set forticlient-system-compliance {enable | disable}
      set forticlient-log-upload
      set forticlient-log-upload-level {traffic |vulnerability | event}
      set forticlient-vuln-scan-enforce {enable | disable}
      set forticlient-vuln-scan-enforce-grace {number}
   end
end
```

Attributes Changed

There is a change to the CLI commands to enable or disable the sending of files to FortiSandbox for analysis.

The CLI command:

```
config endpoint-control profile
   edit <name_str>
   config forticlient-winmac-settings
      edit <name_str>
         set sandbox-scan {enable | disable}
      end
   end
```

has been replaced by:

```
config endpoint-control profile
   edit <name_str>
   config forticlient-winmac-settings
      edit <name_str>
         set sandbox-analysis {enable | disable}
```

```
        end
    end
```

Optionally include FortiGuard spam responses in email log messages (284055)

The field **FortiGuard Spam Response** has been added as an option to the anti-spam log to aid in identifying misclassified email.

Virus scanning of MS Outlook email (308797)

FortiOS 5.4.1 allows users to enable or disable inspection of MAPI-over-HTTP (MAPI/HTTP) protocol. This protocol was first delivered with Outlook 2013 SP1 and Exchange 2013 SP1. Enabling inspection ensures that the FortiGate can scan Outlook email for viruses.

CLI commands

```
config firewall ssl-ssh-profile
   edit deep-inspection
   set mapi-over-https {enable|disable}
```

Improved Visibility of Botnet and Command & Control (C&C) protection (308104)

Mobile & Botnet C&C license information is now displayed in the License Information widget in the Dashboard. Additionally, you can view the list of Botnet C&C packages in the IP Reputation Database (IRDB) and the Botnet Domain Database (BDDB) from the License Information widget.

A button has been added to the GUI on the DNS filter page allowing you to block DNS requests known to FortiGuard. When you enable this feature, you can open a definitions window by clicking on "botnet package."

Access to the IRDB is available to users through FortiCare support contracts purchased or renewed before October 1, 2016. After that date, users will have to subscribe to the IRDB either through the FortiGuard Mobility Security Service (FMSS) or the FortiGuard Enterprise Bundle.

What's New in FortiOS 5.4.0

These features first appeared in FortiOS 5.4.0.

Proxy and flow-based inspection per VDOM

You can select Flow or Proxy Inspection Mode from the System Information dashboard widget to control your FortiGate's security profile inspection mode. Having control over flow and proxy mode is helpful if you want to be sure that only flow inspection mode is used (and that proxy inspection mode is not used).

Switching to Flow Inspection Mode also turns off WAN Optimization, Web Caching, the Explicit Web Proxy, and the Explicit FTP Proxy making sure that no proxying can occur.

In most cases proxy mode is preferred because more security profile features are available and more configuration options for these individual features are available. Some implementations; however, may require all security profile scanning to only use flow mode. In this case, you can set your FortiGate to flow mode knowing that proxy mode inspection will not be used.

If you select flow-based to use external servers for FortiWeb and FortiMail you must use the CLI to set a Web Application Firewall profile or Anti-Spam profile to external mode and add the Web Application Firewall profile or Anti-Spam profile to a firewall policy.

Changing between proxy and flow mode

Proxy mode is enabled by default and you change to flow mode by changing the **Inspection Mode** on the System Information dashboard widget.

When you select **Flow-based** you are reminded that all proxy mode profiles are converted to flow mode, removing any proxy settings. As well proxy-mode only features (for example, Web Application Profile) are removed from the GUI.

In addition, selecting **Flow-based** inspection will cause the **Explicit Web Proxy** and **Explicit FTP Proxy** features to be removed from the GUI and the CLI. This includes Explicit Proxy firewall policies.

When you select **Flow-based** you can only configure Virtual Servers (under **Policy & Objects > Virtual Servers**) with Type set to HTTP, TCP, UDP, or IP.

If required, you can change back to proxy mode through the System Information dashboard widget.

If your FortiGate has multiple VDOMs, you can set the inspection mode independently for each VDOM. Use the top left dropdown menu to go to **Global > System > VDOM**. Click **Edit** for the VDOM you wish to change and select the **Inspection Mode**.

Security profile features mapped to inspection mode

The table below lists FortiOS security profile features and shows whether they are available in flow-based or proxy-based inspection modes.

The DNS Filter security profile feature is only available for proxy-based inspection in FortiOS versions 5.4.0 and 5.4.1. It is available for both proxy-based and flow-based inspection in FortiOS versions 5.4.2 and above.

Security Profile Feature	Flow-based inspection	Proxy-based inspection
AntiVirus	x	x
Web Filter	x	x
DNS Filter	x	x
Application Control	x	x
Cloud Access Security Inspection	x	x
Intrusion Protection	x	x
Anti-Spam		x
Data Leak Protection		x
VoIP		x

Security Profile Feature	Flow-based inspection	Proxy-based inspection
ICAP		x
Web Application Firewall		x
FortiClient Profiles	x	x
Proxy Options		x
SSL/SSH Inspection	x	x
Web Rating Overrides	x	x
Web Profile Overrides		x

From the GUI, you can only configure antivirus and web filter security profiles in proxy mode. From the CLI you can configure flow-based antivirus profiles, web filter profiles and DLP profiles and they will appear on the GUI and include their inspection mode setting. Also, flow-based profiles created when in flow mode are still available when you switch to proxy mode.

In flow mode, antivirus and web filter profiles only include flow-mode features. Web filtering and virus scanning is still done with the same engines and to the same accuracy, but some inspection options are limited or not available in flow mode. Application control, intrusion protection, and FortiClient profiles are not affected when switching between flow and proxy mode.

CASI does not work when using proxy-based profiles for AV or Web filtering. Make sure to only use flow-based profiles in combination with CASI on a specific policy.

Even though VoIP profiles are not available from the GUI in flow mode, the FortiGate can process VoIP traffic. In this case the appropriate session helper is used (for example, the SIP session helper).

Setting flow or proxy mode doesn't change the settings available from the CLI. However, when in flow mode you can't save security profiles that are set to proxy mode.

You can also add proxy-only security profiles to firewall policies from the CLI. So, for example, you can add a VoIP profile to a security policy that accepts VoIP traffic. This practice isn't recommended because the setting will not be visible from the GUI.

Proxy mode and flow mode antivirus and web filter profile options

The following tables list the antivirus and web filter profile options available in proxy and flow modes.

Antivirus features in proxy and flow mode

Feature	Proxy	Flow
Scan Mode (Quick or Full)	no	yes

Feature	Proxy	Flow
Detect viruses (Block or Monitor)	yes	yes
Inspected protocols	yes	no (all relevant protocols are inspected)
Inspection Options	yes	yes (not available for quick scan mode)
Treat Windows Executables in Email Attachments as Viruses	yes	yes
Send Files to FortiSandbox Appliance for Inspection	yes	yes
Use FortiSandbox Database	yes	yes
Include Mobile Malware Protection	yes	yes

Web Filter features in proxy and flow mode

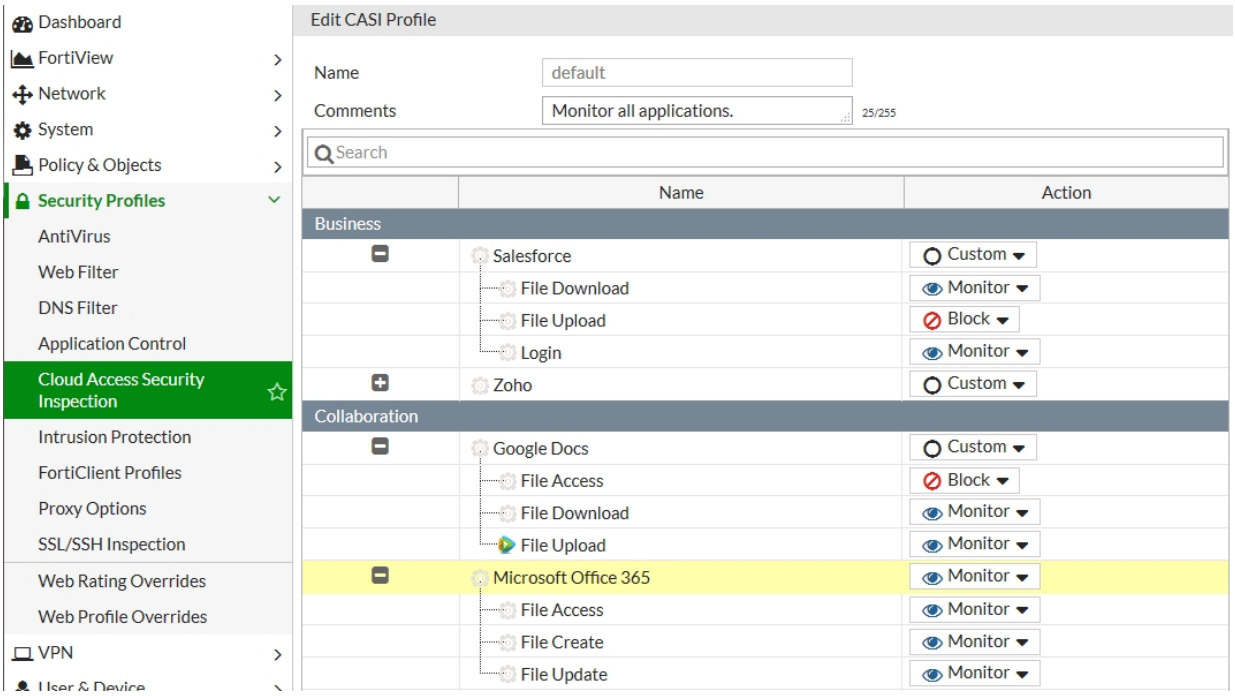
Feature		Proxy	Flow
FortiGuard category based filter		yes	yes (show, allow, monitor, block)
Category Usage Quota		yes	no
Allow users to override blocked categories (on some models)		yes	no
Search Engines		yes	no
	Enforce 'Safe Search' on Google, Yahoo!, Bing, Yandex	yes	no
	Restrict YouTube Access	yes	no
	Log all search keywords	yes	no
Static URL Filter		yes	yes
	Block invalid URLs	yes	no
	URL Filter	yes	yes
	Block malicious URLs discovered by FortiSandbox	yes	yes
	Web Content Filter	yes	yes
Rating Options		yes	yes

Feature		Proxy	Flow
	Allow websites when a rating error occurs	yes	yes
	Rate URLs by domain and IP Address	yes	yes
	Block HTTP redirects by rating	yes	no
	Rate images by URL	yes	no
Proxy Options		yes	no
	Restrict Google account usage to specific domains	yes	no
	Provide details for blocked HTTP 4xx and 5xx errors	yes	no
	HTTP POST Action	yes	no
	Remove Java Applets	yes	no
	Remove ActiveX	yes	no
	Remove Cookies	yes	no
	Filter Per-User Black/White List	yes	no

Cloud Access Security Inspection (CASI)

This feature introduces a new security profile called Cloud Access Security Inspection (CASI) that provides support for fine-grained control on popular cloud applications, such as YouTube, Dropbox, Baidu, and Amazon. The CASI profile is applied to a policy much like any other security profile.

Unfortunately CASI does not work when using Proxy-based profiles for AV or Web filtering for example.
Make sure to only use Flow-based profiles in combination with CASI on a specific policy.



For this feature, **Deep Inspection of Cloud Applications** (`set deep-app-inspection [enable|disable]`) has been moved out of the **Application Control** security profile options.

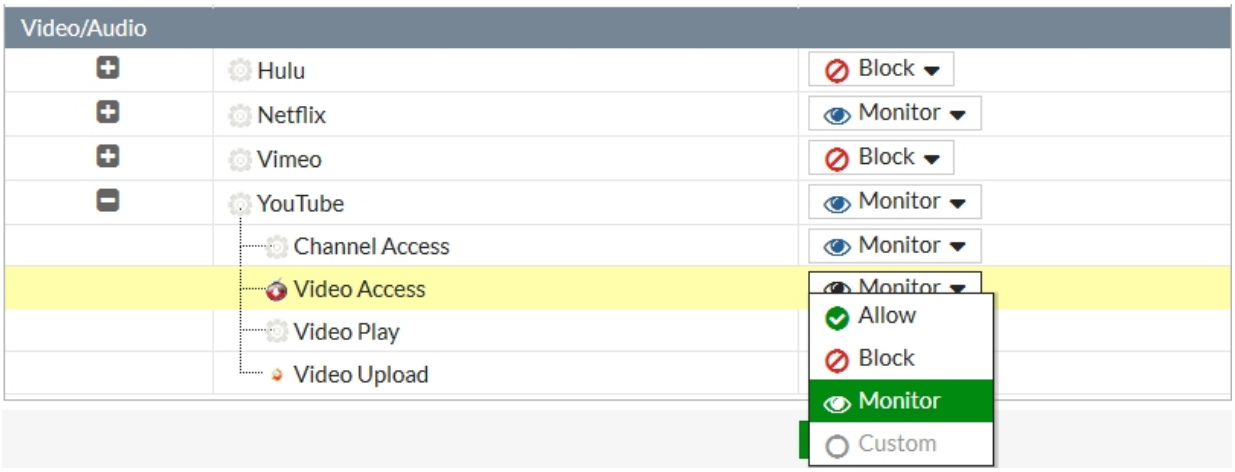
You will find the Cloud Access Security Inspection feature under **Security Profiles > Cloud Access Security Inspection**, but you must first enable it in the Feature store under **System > Feature Select > CASI**.

Editing CASI profiles

The CASI profile application list consists of the **Name**, **Category**, and **Action**. A default CASI profile exists, with the option to create custom profiles.

There is an **improvement to the CASI GUI (303760)** under release 5.4.1. When you search for a profile application to edit, you can hit enter after typing your search terms to see the results. Under release 5.4.0, hitting enter causes the screen to refresh and the profile to be applied.

For each CASI profile application, the user has the option to **Allow**, **Block**, or **Monitor** the selected cloud application. The following image demonstrates the ability to **Allow**, **Block**, or **Monitor** YouTube using CASI:



When the user drills down into a selected cloud application, the following options are available (depending on the type of service):

- **For business services, such as Salesforce and Zoho:** Option to allow, block, or monitor file download/upload and login.
- **For collaboration services, such as Google.Docs and Webex:** Option to allow, block, or monitor file access/download/upload and login.
- **For web email services, such as Gmail and Outlook:** Option to allow, block, or monitor attachment download/upload, chat, read/send message.
- **For general interest services, such as Amazon, Google, and Bing:** Option to allow, block, or monitor login, search phase, and file download/upload.
- **For social media services, such as Facebook, Twitter, and Instagram:** Option to allow, block, or monitor chat, file download/upload, post, login.
- **For storage backup services, such as Dropbox, iCloud, and Amazon Cloud Drive:** Option to allow, block, or monitor file access/download/upload and login.
- **For video/audio services, such as YouTube, Netflix, and Hulu**:
  Option to allow, block, or monitor channel access, video access/play/upload, and login.

CLI Syntax

```
configure application casi profile
   edit "profile name"
      set comment "comment"
      set replacemsg-group "xxxx"
      set app-replacemsg [enable|disable]
      configure entries
         edit
            set application "app name"
            set action [block|pass]
            set log [enable|disable]
         next
         edit 2
   next
end

configure firewall policy
   edit "1"
      set casi-profile "profile name"
   next
end

config firewall sniffer
   edit 1
      set casi-profile-status [enable|disable]
      set casi-profile "sniffer-profile"
   next
end

config firewall interface-policy
   edit 1
      set casi-profile-status [enable|disable]
      set casi-profile "2"
   next
end
```

External Security Devices

External Security Devices can be configured as means to offload processes to other devices, such as a FortiWeb, FortiCache, or FortiMail. Example processes could include HTTP inspection, web caching, and anti- spam.

Offloading HTTP traffic to FortiWeb

Use the following steps to offload HTTP traffic to FortiWeb to apply Web Application Firewall features to the traffic. Using these steps you can select the HTTP traffic to offload by adding a web application firewall profile configured for external inspection to selected firewall policies. Only the HTTP traffic accepted by those firewall policies is offloaded.

If you offload HTTP traffic to FortiWeb you can also apply other HTTP inspection to it from your FortiGate including virus scanning and web filtering.

A single FortiGate cannot offload HTTP traffic to both FortiCache and FortiWeb.

To offload HTTP traffic to FortiWeb:

1. Go to the **System Information** dashboard widget and make sure **Inspection Mode** is set to **Proxy-based**.
2. Go to **System > Feature Select** and turn on **Web Application Firewall**.
3. Go to **System > Cooperative Security Fabric**, enable **HTTP Service**, select **FortiWeb** and add the IP addresses of your FortiWeb devices. You can also select **Authentication** add a **password** if required.
4. Go to **Security Profiles > Web Application Firewall** and add or edit a Web Application Firewall profile and set **Inspection Device** to **External**.
5. Go to **Policy & Objects > IPv4 Policy**, add or edit a firewall policy, select **Web Application Firewall**, and select the profile that you set to use the external inspection device.

These steps add the following configuration to the CLI:

```
config system wccp
   set service-id 51
   set router-id 5.5.5.5 (the IP address of the FortiGate interface that communicates with
       the FortiWeb)
   set group address 0.0.0.0
   set server-list 5.5.5.25 255.255.255.255 (the IP address of the FortiWeb)
   set authentication enable
   set forward-method GRE
   set return-method GRE
   set assignment-method HASH
   set password *
end
```

Offloading HTTP traffic to FortiCache

To offload Web Caching to FortiCache a FortiGate must support WAN Optimization and WAN Optimization must be enabled. For some FortiGate models you need to turn off disk logging to support WAN Optimization. See "WAN Optimization" on page 218 in What's New for details.

Use the following steps to offload web caching to FortiCache. Using these steps you can select the web traffic to offload by selecting web caching in firewall policies. Only the web traffic accepted by those firewall policies will be offloaded.

A single FortiGate cannot offload HTTP traffic to both FortiCache and FortiWeb.

1. Go to the **System Information** dashboard widget and make sure **Inspection Mode** is set to **Proxy-based**.
2. Go to **System > Advanced > Disk Settings** and assign at least one disk to **WAN Optimization**.
3. Go to **System > Feature Select** and turn on **WAN Opt. & Cache**.
4. Go to **System > Cooperative Security Fabric**, enable **HTTP Service**, select **FortiCache** and add the IP addresses of your FortiCache devices. You can also select **Authentication** add a **password** if required.
5. Go to **Policy & Objects > IPv4 Policy**, add or edit a firewall policy and select **Web Cache**.

These steps add the following configuration to the CLI:

```
config system wccp
   set service-id 51
   set router-id 5.5.5.5 (the IP address of the FortiGate interface that communicates with
       the FortiCache)
   set group address 0.0.0.0
   set server-list 5.5.5.45 255.255.255.255 (the IP address of the FortiCache)
   set authentication enable
   set forward-method GRE
   set return-method GRE
   set assignment-method HASH
   set password *
end
```

Offloading SMTP traffic to FortiMail

Use the following steps to offload SMTP traffic to FortiMail to apply FortiMail features to the traffic. Using these steps you can select the SMTP traffic to offload by adding an AntiSpam profile configured for external inspection to selected firewall policies. Only the SMTP traffic accepted by those firewall policies is offloaded.

If you offload HTTP traffic to FortiWeb you can also apply other HTTP inspection to it from your FortiGate including virus scanning and web filtering.

To be able to offload Anti-Spam processing to a FortiMail device you should:

1. Go to the **System Information** dashboard widget and make sure **Inspection Mode** is set to **Proxy-based**.
2. Go to **System > Feature Select** and turn on **Anti-Spam Filter**.
3. Go to **System > Cooperative Security Fabric**, enable **SMTP Service - FortiMail** and add the IP address of your FortiMail devices. You can also select **Authentication** add a **password** if required.
4. Go to **Security Profiles > Anti-Spam** and edit an Anti-Spam profile and set **Inspection Device** to **External**.
5. Go to **Policy & Objects > IPv4 Policy**, add or edit a Firewall policy, enable **Anti-Spam** and select the profile for which you set Inspection Device to External.

These steps add the following configuration to the CLI:

```
config system wccp
   set service-id 52
   set router-id 5.5.5.5 (the IP address of the FortiGate interface that communicates with
       the FortiMail)
   set group address 0.0.0.0
   set server-list 5.5.5.65 255.255.255.255 (the IP address of the FortiMail)
   set authentication enable
   set forward-method GRE
   set return-method GRE
   set assignment-method HASH
   set password *
end
```

Blocking DNS requests to known Botnet C&C addresses

A new FortiGuard database contains a list of known Botnet C&C addresses. This database is updated dynamically and stored on the FortiGate. This database is covered by FortiGuard web filter licensing, so you must have a FortiGuard web filtering license to use this feature.

When you block DNS requests to known Botnet C&C addresses, using IPS, DNS lookups are checked against the Botnet C&C database. All matching DNS lookups are blocked. Matching uses a reverse prefix match, so all sub-domains are also blocked.

To enable blocking of DNS requests to known Botnet C&C addresses, go to **Security Profiles > DNS Filter**, and enable **Block DNS requests to known botnet C&C**.

Static URL filter

The DNS inspection profile static URL filter allows you to block, exempt, or monitor DNS requests by using IPS to look inside DNS packets and match the domain being looked up with the domains on the static URL filter list. If there is a match the DNS request can be blocked, exempted, monitored, or allowed.

If blocked, the DNS request is blocked and so the user cannot look up the address and connect to the site.

If exempted, access to the site is allowed even if another method is used to block it.

DNS-based web filtering

This feature is similar to the FortiGuard DNS web filtering available in FortiOS 5.2. You can configure DNS web filtering to allow, block, or monitor access to web content according to FortiGuard categories. When DNS web filtering is enabled, your FortiGate must use the FortiGuard DNS service for DNS lookups. DNS lookup requests sent to the FortiGuard DNS service return with an IP address and a domain rating that includes the FortiGuard category of the web page.

If that FortiGuard category is set to block, the result of the DNS lookup is not returned to the requester. If the category is set to redirect, then the address returned to the requester points at a FortiGuard redirect page.

You can also allow access or monitor access based on FortiGuard category.

CLI commands

Rename webfilter-sdns-server-ip and webfilter-sdns-server-port:

```
config system fortiguard
   set sdns-server-ip x.x.x.x
   set sdns-server-port 53
end
```

Configure DNS URL filter:

```
config dnsfilter urlfilter
   edit 1
      set name "url1"
      set comment ''
         config entries
            edit 1
               set url "www.google.com"
               set type simple
               set action block
               set status enable
            next
```

```
            edit 2
               set url "www.yahoo.com"
               set type simple
               set action monitor
               set status enable
            next
            edit 3
               set url "www.foritnet.com"
               set type simple
               set action allow
               set status enable
            next
         end
   next
end
```

Configure DNS filter profile:

```
config dnsfilter profile
   edit "dns_profile1"
      set comment ''
         config urlfilter
            set urlfilter-table 1
         end
         config ftgd-dns
               config filters
                  edit 1
                     set category 49
                     set action block
                     set log enable
                  next
                  edit 2
                     set category 71
                     set action monitor
                     set log enable
                  next
               end
         end
      set log-all-url disable
      set block-action redirect
      set redirect-portal 0.0.0.0
      set block-botnet enable
   next
end
```

Configure DNS profile in a firewall policy:

```
config firewall policy
   edit 1
      set srcintf "any"
      set dstintf "any"
      set srcaddr "all"
      set dstaddr "all"
      set action accept
      set schedule "always"
      set service "FTP"
      set utm-status enable
      set dnsfilter-profile "dns_profile1"
```

```
      set profile-protocol-options "default"
      set nat enable
   next
end
```

Configure DNS profile in profile group:

```
config firewall profile-group
   edit "pgrp1"
      set dnsfilter-profile "dns_profile1"
      set profile-protocol-options "default"
   next
end
```

Other new Security Profile features

DLP changes (297960)

Some DLP features removed. DLP fingerprinting removed from the GUI.

FortiClient Endpoint Profile improvements and new features (285443 275781 287137)

- **275781:** New options available in **FortiClient Profiles**.
- **285446:** VPN can be configured on the GUI either on **IPsec VPN** or **SSL-VPN** and changes can be preserved.
- **287137:** In the **Mobile** tab, .mobileconfig files can be configured and **Client VPN Provisioning** can be enabled.

Features involving general settings have been removed from the FortiClient profile GUI in 5.4.1. Features emphasizing compliance of the endpoint devices have been added. Read FortiClient Profile changes for more information.

FortiClient Enforcement added to Interfaces (253933)

FortiClient enforcement has been moved from the Policy page to **Network > Interfaces** to enforce FortiClient registration on a desired LAN interface rather than a policy.

To enforce FortiClient endpoint registration - GUI:

1. Go to **System > Feature Select** and enable **Endpoint Control**.
2. Go to **Network > Interfaces** and select the internal interface.
3. Under **Restrict Access**, enable **FortiTelemetry**.
4. Under **Admission Control**, enable **Enforce FortiTelemetry for all FortiClients**.

FortiClient exempt list improvements (268357 293191)

- **268357:** Before you could only configure captive portal policy addresses in the CLI, but it can now be performed in the GUI.
- **293191: Exempt List** has been replaced with **Exempt Sources**, and **Exempt Destinations/Services** has been added (once an interface has been set to captive portal). Before it was only possible to configure the FortiGate interface port to captive portal through the CLI, but it can now also be performed in the GUI.

FortiClient endpoint profile page updates (283968)

The **Security Profiles > FortiClient Profiles** page has been redesigned to better present the information available, and so the user can easily locate particular settings of interest.

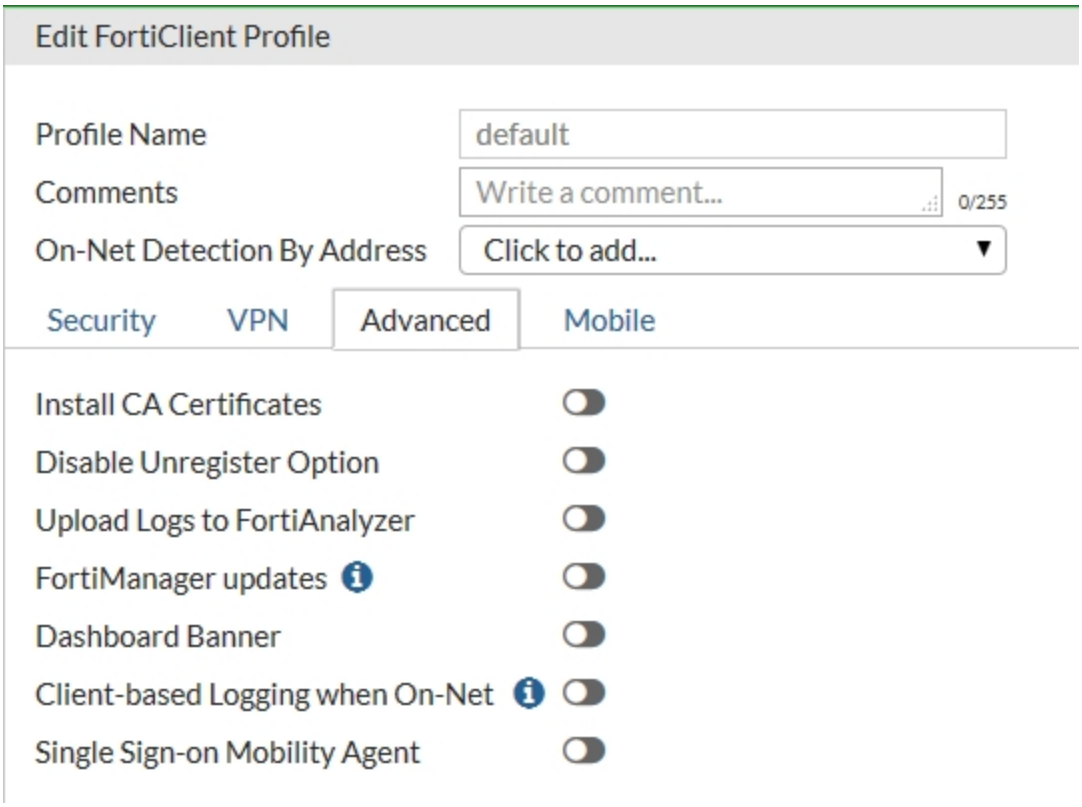
Pre-existing GUI options under **User & Device > FortiClient Profiles** have been moved to the **Security Profiles** menu, and have been reorganized into separate tabs: **Security**, **VPN**, **Advanced**, and **Mobile**. Profiles can be created and options can be enabled within these tabs.

The **VPN**, **Advanced**, and **Mobile** tabs do not appear in the GUI in FortiOS5.4.1. See FortiClient Profile changes (356205).

Note that **Client-based Logging when On-Net** has been renamed to **Allow Access to Logs from FortiClient Console**.

In addition, the following features were added:

- Support for FortiSandbox integration
- Option for C&C destination scanning and blocking
- Certificate deployment as part of endpoint profile
- FortiClientRTP Option updates
- Option to monitor all unknown applications



Configure the ability to store FortiClient configuration files (171380)

1. Enable the advanced FortiClient configuration option in the endpoint profile:

```
config endpoint-control profile
   edit "default"
      set forticlient-config-deployment enable
      set fct-advanced-cfg enable
      set fct-advanced-cfg-buffer "hello"
      set forticlient-license-timeout 1
      set netscan-discover-hosts enable
   next
end
```

2. Export the configuration from FortiClient (xml format).
3. Copy the contents of the configuration file and try to paste in the advanced FortiClient configuration box.

If the configuration file is greater than 32k, you need to use the following CLI:

```
config endpoint-control profile
   edit <profile>
      config forticlient-winmac-settings
         config extra-buffer-entries
            edit <entry_id>
               set buffer xxxxxx
            next
         end
      end
   end
```

FortiOS 5.4 no longer supports FortiClient 5.0 or earlier (289455)

FortiOS 5.2 would support FortiClient 5.0 (only if the FortiGate upgraded to FortiOS 5.2), however FortiOS 5.4 will no longer support FortiClient 5.0. Customers need to purchase a FortiClient 5.4 subscription-based FortiClient license.

Session timers for IPS sessions (174696 163930)

The standard FortiOS session time-to-live (session TTL) timer for IPS sessions has been introduced to reduce synchronization problems between the FortiOS Kernel and IPS. This has been added so that FortiGate hard-coded timeout values can be customized, and IPS was using too much overall memory.

Botnet protection with DNS Filter (293259)

The new botnet list from FortiGuard can be used to block DNS requests to known botnet C&C IP addresses within a new DNS filter profile.

You can view the botnet list by going to **System > FortiGuard > Botnet Definitions**.

Secure white list database (288365)

Secure white list exemption for SSL deep inspection. To enable, go to **Security Profiles > SSL/SSH Inspection** and enable **Exempt from SSL Inspection** and enable **Reputable Websites**.

Mobile Malware protection update (288022)

Mobile Malware protection requires a separate license and can be downloaded as a separate object. The mobile malware signatures are no longer part of the AntiVirus Database but these signatures can be enabled by going to **Security Profiles > AntiVirus** and enabling **Include Mobile Malware Protection**.

Options not supported by the new quick mode flow-based virus scanning (288317)

Files cannot be sent to FortiSandbox for inspection while in quick mode flow-based virus scanning, and so the GUI option for it has been removed. No option to switch between quick mode and full mode, as choice between **Proxy** and **Flow** based inspection has been removed.

Add mobile malware to FortiGuard licenses page and include more version information (290049)

An entry and version information for **Mobile Malware Definitions** has been added in the **License Information** table under **System > FortiGuard**. Also, main items have been bolded and sub-items have been indented for clarification.

Secure white-list DB for flow based UTM features (287343)

A new feature that gathers a list of reputable domain names that can be excluded from SSL deep inspection. This list is periodically updated and downloaded to FortiGate units through FortiGuard.

Syntax:

```
config firewall ssl-ssh-profile
   edit deep-inspection
      set whitelist enable
end
```

New customizable replacement message that appears when an IPS sensor blocks traffic (240081)

A new replacement message will appear specifically for IPS sensor blocked Internet access, to differentiate between IPS sensor blocking and application control blocking.

Low-end models don't support flow AV quick mode and don't support the IPS block-malicious-url option (288318)

AV quick mode and the IPS block-malicious-url option have been disabled on low-end FortiGate models, however these features can be enabled if the FortiGate unit has a hard disk. Low-end models will only support**Full**scan mode (the option is left in the GUI to show which mode is active for the user).

New quick mode flow-based virus scanning (281291)

When configuring flow-based virus scanning you can now choose between quick and full mode. Full mode is the same as flow-based scanning in FortiOS 5.2. Quick mode uses a compact antivirus database and advanced techniques to improve performance. Use the following command to enable quick mode in an antivirus profile:

```
config antivirus profile
   edit <profile-name>
      set scan-mode {quick | full}
   end
```

CVE-IDs now appear in the FortiOS IPS signature list (272251)

The signature list can be found at **Security Profiles > Intrusion Protection > View IPS Signatures**.

Botnet protection added (254959)

The latest Botnet database is available from FortiGuard. You can see the version of the database and display its contents from the **System > FortiGuard** GUI page. You can also block, monitor or allow outgoing connections to Botnet sites for each FortiGate interface.

FortiSandbox URL database added

You can see the version of the database and display its contents from the **System > FortiSandbox** GUI page.

New Web Filter profile whitelist setting and changes to blacklist setting (283855, 285216)

Domain reputation can now be determined by "common sense", for sites such as Google, Apple, and even sites that may contain sensitive material that would otherwise be trusted (i.e. there is no risk of receiving botnets or malicious attacks). You can tag URL groups with flags that exempt them from further sandboxing or AV analyzing.

You can identify reputable sites and enable certain bypasses under **Security Profiles > Web Filter**.

Similarly, you can exempt the identified reputable sites from SSL inspection.

CLI Syntax

```
config firewall ssl-ssh-profile
   edit <profile-name>
      set whitelist [enable | disable]
end

config webfilter profile
   edit <profile-name>
      config web
      set whitelist exempt-av exempt-webcontent exempt-activex-java-cookie exempt-dlp
          exempt-rangeblock extended-log-others
      end
end
```

Support security profile scanning of RPC over HTTP traffic (287508)

This protocol is used by Microsoft Exchange Server so this feature supports security profile features such as virus scanning of Microsoft Exchange Server email that uses RPC over HTTP.

Users now allowed to override blocked categories using simple, wildcard, and regex expressions to identify the URLs that are blocked (270165)

This feature is also called per-user BWL. To be able to configure this feature from the GUI enter the following command:

```
config system global
   set per-user-bwl enable
end
```

Then go to **Security Profiles > Web Filtering**, edit a web filtering profile and select **Allow users to override blocked categories**.

Use the following command to configure this feature from the CLI:

```
config webfilter profile
   edit <profile-name>
      set options per-user-bwl
   end
```

Set flow or proxy mode for your FortiGate (or per VDOM) (266028)

You can configure your FortiGate or a VDOM to apply security profile features in proxy or flow mode. Change between modes from the System Information dashboard widget. Proxy mode offers the most accurate results and the greatest depth of functionality. Flow mode provides enhanced performance. IPS and application control always operates in flow mode and so is not affected by changing this mode.

Security Profiles > Web Application Firewall

Signatures can now be filtered based on risk level.

The options to reset action and apply traffic shaping is now only available in the CLI.

The *All Other Known Applications* option has been removed, while the option for *All Other Unknown Applications* has been renamed *Unknown Applications*.

Block all Windows executable files (.exe) in email attachments (269781)

A new option has been added to AntiVirus profiles to block all Windows executable files (.exe) in email attachments.

CLI Syntax

```
config antivirus profile
   edit "default"
      config imap
         set executables {default | virus}
      end
      config pop3
         set executables {default | virus}
      end
      config smtp
         set executables {default | virus}
      end
      config mapi
         set executables {default | virus}
      end
   end
```

Cookies can now be used to authenticate users when a web filter override is used (275273)

Cookies can be used to authenticate users when a web filter override is used. This feature is available in CLI only.

CLI Syntax

```
config webfilter cookie-ovrd
```

```
   set redir-host <name or IP>
   set redir-port <port>
end

config webfilter profile
   edit <name>
      config override
         set ovrd-cookie {allow | deny}
         set ovrd-scope {user | user-group | ip | ask}
         set profile-type {list | radius}
         set ovrd-dur-mode {constant | ask}
         set ovrd-dur <duration>
         set ovrd-user-group <name>
         set profile <name>
      end
   end
```

Blocking malicious URLs (277363)

A local malicious URL database dowloaded from FortiGuard has been added to assist IPS detection for live exploits, such as drive-by attacks. You enable blocking malicious URLs in an IPS profile from the CLI using the following command:

CLI Syntax

```
config ips sensor
   edit default
      set block-malicious-url {enable | disable}
   next
end
```

The FortiGuard IPS/AV update schedule can be set by time intervals (278772)

This feature allows updates to occur more frequently (syntax below shown for updates randomly every 2-3 hours).

CLI Syntax

```
config system autoupdate schedule
   set frequency every
   set time 02:60
end
```

Application Control signatures belonging to industrial category/group are excluded by default (277668)

Use the following command to be able to add industrial signatures to an application control sensor:

```
config ips global
   set exclude-signatures {none | industrial}
end
```

The Industrial category now appears on the Application Control sensor GUI.

An SSL server table can now be used for SSL offloading (275273)

CLI Syntax

```
config firewall ssl-ssh-profile
   edit <name>
      set use-ssl-server {enable | disable}
   next
end
```

MAPI RPC over HTTP/HTTPS traffic is now supported for security scanning (278012)

CLI Syntax

```
config firewall profile-protocol-options
   edit "default"
      set comment "All default services."
         config http
            set ports 80 3128
            set options rpc-over-http
         end
      end
```

New Dynamic DNS FortiGuard web filtering sub-category (276495)

A new FortiGuard web filtering sub-category, Dynamic DNS, has been added and can be found in the Security Risk Category. Also, the sub-category *Shopping and Auction* has been separated into two sub-categories: *Auction* and *Shopping*.

New Filter Overrides in the Application Sensor GUI (260901)

The overrides allow you to select groups of applications and override the application signature settings for them.

FortiGate CA certificates installed on managed FortiClients (260902)

This feature allows you to enable or disable CA certificate installation on managed FortiClients in a FortiClient Profile.

Syntax

```
config endpoint-control profile
   edit <profile>
      config forticlient-winmac-settings
         set install-ca-certificate [enable | disable]
      end
   next
end
```

More exemptions to SSL deep inspection (267241)

Some common sense exemptions have been added to the default SSL deep inspection profile, such as Fortinet, Android, Apple, Skype, and many more.

Exempting URLs for flow-based web filtering (252010)

You can once again exempt URLs for flow-based web filtering.

Filter overrides in Application Sensors (246546)

In the Application Sensor page, a new section named **Filter Overrides** has been introduced. From this section, clicking **Add Filter/Edit Filter** will launch a dialog to pick/edit the advanced filter and save it back to the list.

New keyword byte_extract for custom IPS and Application Control signatures (179116)

The new `byte_extract` custom IPS signature key has been added that supports snort-like byte extraction actions. It is used for writing rules against length-encoded protocols. The keyword reads some of the bytes from the packet payload and saves it to a variable. You can use the `-quiet` option to suppress the reporting of signatures.

IPS logging changes (254954)

IPS operations severely affected by disk logging are moved out of the quick scanning path, including logging, SNMP trap generation, quarantine, etc.

Scanning processes are dedicated to nothing but scanning, which results in more evenly distributed CPU usage. Slow (IPS) operations are taken care of in a dedicated process, which usually stays idle.

New FortiGuard web filtering category: Dynamic DNS (265680)

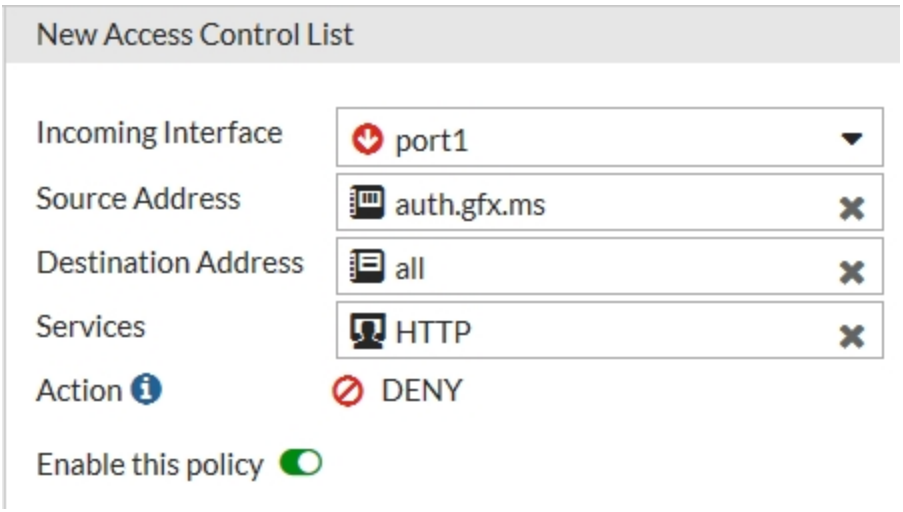
A new FortiGuard web filtering category has been added for **Dynamic DNS** under the **Security Risk** heading, to account for nearly half a million URLs of "Information Technology" rated by BlueCoat as "Dynamic DNS Host".

Syntax

```
config webfilter profile
   edit <profile>
      config ftgd-wf
         config filters
            edit <id>
               set category 88<--- New category, Dynamic DNS; number 88
         end
   end
end
```

Access Control Lists in DoS Policies (293399)

You can go to **Policy & Objects > IPv4 Access Control List** or **Policy & Objects > IPv6 Access Control List** and select an incoming interface and add a list of Firewall source and destination addresses and services and drop traffic that matches.



You can use the following CLI command to add an ACL:

```
config firewall acl
   edit 1
      set interface "port1"
      set srcaddr "google-drive"
      set dstaddr "all"
      set service "ALL"
   next
end
```

Websense web filtering through WISP (287757)

WISP is a Websense protocol that is similar in functionality to ICAP, it allows for URLs to be extracted by a firewall and submitted to Websense systems for rating and approval checking.

This feature provides a solution for customers who have large, existing, deployed implementations of Websense security products to replace their legacy firewalls with a Fortigate family, such that they are not forced to make a change to their web filtering infrastructure at the same time.

In order to use Websense's web filtering service, a WISP server per VDOM needs to be defined and enabled first. A Web filtering profile is then defined that enables WISP, which in turn is applied to a firewall policy.

When WISP is enabled, the FortiGate will maintain a pool of TCP connections to the WISP server. The TCP connections will be used to forward HTTP request information and log information to the WISP server and receive policy decisions.

Syntax

```
config web-proxy wisp
   set status enable
   set server-ip 72.214.27.138
   set max-connection 128
end

config webfilter profile
   edit "wisp_only"
      set wisp enable
   next
end
```

Other new Security Profiles features:

- CPU allocation & tuning commands now remain after a system reboot (276190)
- The GUI notifies an administrator when the FortiGate is in conserve mode (266937)
- A new custom IPS signature option, "--ip_dscp" has been added to be compatible with engine 1.x. (269063)
- The RTP/RTSP decoder can now detect slave sessions (273910)
- ISNIFF can now dump all HTML files if the dump-all-html CLI command is used (277793)
- Sender and recipient fields have been added to flow-based SMTP spam logs (269063)
- Browser Signature Detection added to Application Control profiles (279934)

Inside FortiOS: AntiVirus

AntiVirus uses a suite of integrated security technologies to provide against a variety of threats, including both known and unknown malicious codes (Malware), plus Advanced Targeted Attacks (ATA), also known as Advanced Persistent Threats (APT).

Advanced Protection against Malware and APTs

Malware and Advanced Persistent Threats can cause significant damages to today's organizations. These malicious codes are commonly designed to steal valuable data, gain unauthorized access, or cause products to degrade. FortiOS's AntiVirus is an industry-proven anti-malware security solution with robust features and deployment options

FortiOS offers the unique ability to implement both Flow- and Proxy-based AV concurrently, depending on traffic type, users, and locations. Flow-based AV offers higher throughput performance while proxy-based solutions are useful in mitigating stealthy malicious codes. The AV detection capabilities are further enhanced with complementary security features and external sandbox integration.

By utilizing the unique Content Pattern Recognition Language (CPRL) built into the FortiASIC Content Processor, FortiOS is able to deliver high performance and low latency anti-malware capabilities. This real-time protection is backed by a team of worldwide researchers.

Highlights

- Certification from multiple industries for best-in-class security and capacity with proven coverage and high performance.
- Multi-layered protection with extended AV components and external file analysis integration.
- Comprehensive remediation actions such as file quarantine and knowledge tools.

Key Features & Benefits

Robust feature set	Allows the flexibility to deploy appropriate protection according to security needs and infrastructure designs.
High performance utilizing FortiASIC and patented CPRL AV signatures	Low latency and high capacity ensures that business applications are not affected while security is enforced.

Backed by FortiGuard Labs that deliver real-time protection	Critical digital assets are covered by continuous protection against latest threats.

Features

Industry's Validated Protection

FortiOS anti-malware components and FortiGuard AV signatures periodically undergo numerous authoritative certifications. These independent certifications demonstrate that the solution offered is of the highest standard in performance and accuracy, ensuring organizations are truly protected.

Fortinet has been consistently ranked among the top vendors for Virus Bulletin's RAP (Reactive And Proactive) bimonthly tests. This test measures a product's detection rates over the freshest samples available, as well as samples not seen until after product databases are frozen, thus reflecting both the vendor's ability to handle the huge quantity of newly emerging malware and accurately detect previously unknown malware.

Real Time Protection

The FortiGuard AntiVirus Service provides fully automated updates to ensure protection against the latest content-level threats via the experienced FortiGuard global network is backed by over 200 researchers.

FortiGuard AV service quick facts

- 95,000 malware programs neutralized per minute
- 1.8 Million new and updated AV definitions per week
- 190 TB of threat samples till date

Organizations can also engage the FortiGuard Premier Signature Service, which provides enhanced virus detection and threat analysis support. This service offers submissions for custom AntiVirus signatures on a daily basis, offering prioritized support with guaranteed response times.

Unique Proxy and Flow Based AV

FortiOS offers organizations the flexibility to select the most appropriate inspection method for different network sessions. This can be implemented by defining policies that match specific source objects (IP, IP ranges, users, and devices), destination objects, applications, and schedules with different AV profiles.

Flow-based AV relies on IPS technology where packets are inspected in real-time and matched against the AV signature database. It offers lower latency and higher throughput than Proxybased AV. Flow-based AV is recommended for inspecting traffic that requires spontaneous user experience or when serving as an additional AV protection layer.

FortiOS's Proxy-based AV offers the most secure AV protection as it's able to inspect more protocols and provides replacement messages on wider range of applications.

AV Acceleration with Content Processor

The FortiASICS Content Processor (CP) accelerates content processing traditionally performed completely by the CPU. The CP reduces the resources required by the CPU when matching an incoming file against the signature database, thus improving system performance and stability.

Proactive Protection using Patented CPRL

Compact Pattern Recognition Language (CPRL) is a patented and proprietary programming language that allows for further inspection of common patterns to not only protect against threats and their variants but also to predict tomorrow's zero-day malware. It allows FortiGuard analysts to describe entire families of malware with a single program, instead of the traditional signature- based "one signature, one variant" model used by other vendors. With fewer signatures to match, throughput performance and latency naturally improve.

Intelligent Behavioral Evaluation

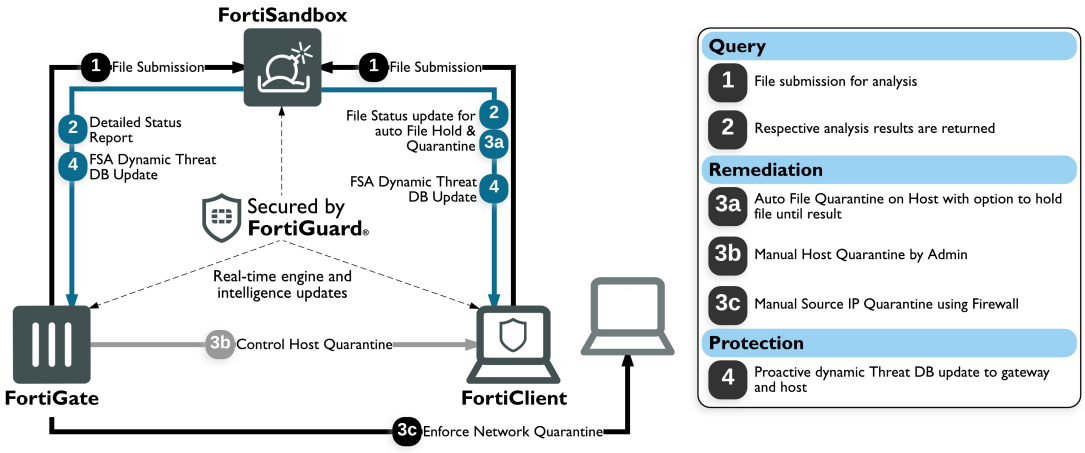
Signature-based security alone is no longer sufficient; it is now critical to understand how devices on your network are behaving. Threat Weight scoring provides a cumulative security ranking of each client device on your network based on a range of behaviors. It provides specific, actionable information that helps identify compromised systems and potential zero-day attacks in real-time.

This unique system attaches predefined scores to various malicious network activities discovered by IPS, application control, URL filtering, etc., to determine the top suspicious users. Administrator can then further inspect these users to undercover unknown threats or APTs via FortiView.

External File Analysis Integration

FortiOS offers organizations the ability to adopt robust ATP (Advanced Threat Protection) framework that reaches mobile users and branch offices, detecting and preventing advanced attacks that may bypass traditional defenses by examining files from various vectors, including encrypted files. To detect unknown threats, zero-day, and targeted attacks, the FortiGate can engage external resources to perform additional file analysis. Files can be submitted to an on- premise appliance (FortiSandbox) or cloud-based service (FortiSandbox Cloud) after both proxy-based and flow- based AV processing.

It is also possible to configure the FortiGate to automatically receive dynamic signature updates from FortiSandbox and add the originating URL of any malicious file to a blocked URL list. In addition, if the organization deploys integrated endpoint control with FortiClient, an administrator can instruct an infected terminal to self-quarantine.



File Filtering

File filtering using data leak prevention (DLP) on the FortiGate offers an effective ways to stop unwanted file transmission instantly. Administrators may implement granular file controls by defining protection profiles using filenames or nearly 50 different file types over mail, web, and file download protocols.

File Quarantine

FortiOS offers sophisticated file quarantine capabilities that allow organizations to archive suspicious or blocked files for further examination or to release false positives.

Anti-bot

Organizations may prevent, uncover, and block botnet activities using FortiOS Anti-Bot traffic pattern detection and domain and IP reputation services supplied in real-time by FortiGuard threat experts.

User Notification

User notifications are helpful in reducing administration and support burdens, as well as providing user education. FortiOS is able to automatically replace blocked attachments and downloads with detailed information sent to E-mail, FTP, or web users.

Monitoring, Logging, and Reporting

FortiOS empowers organizations to implement security best practices that require continuous examination of their threat status and adaptation to new requirements. The FortiView widgets provide useful analysis data with detailed and contextual session information, which can be filtered, ranked, and –further inspected. System events can also be archived via logs, which in turn can generate useful trending and overview reports.

FortiOS also offers robust in-built E-mail and SMS alert systems, as well as integration with external threat management systems using SNMP and standard-based Syslogs.

Recipes

Visit cookbook.fortinet.com for these and other recipes:

- Enforcing network security using a FortiClient Profile
- Inspecting traffic content using flow-based inspection
- Sandboxing with FortiSandbox and FortiClient
- FortiOS AntiVirus inspection modes

Inside FortiOS: Application Control

Application control technologies detect and take action against network traffic based on the application that generated the traffic. Application control uses protocol decoders with signatures that analyze network traffic to detect application traffic, even if the traffic uses nonstandard ports or protocols.

Enhance Control and Network Visibility

Controlling and monitoring applications on a network can seem like a daunting task due to the wide range of available applications. It is no longer an option to simply block or allow TCP and/or UDP ports since most applications do not map to individual ports. For example, controlling traffic on an HTTP or HTTPS port is futile against complex social networking sites and cloud applications.

FortiOS leverages its massive application database to identify applications and their activities while still providing a suitable and sufficient user experience, thanks to FortiASIC Content Processors (CPs), which boost CPU performance. Organizations can adopt more granular control, such as allowing logins but not chatting over selected sites. Traffic shaping may also be applied to the application traffic that is allowed. After applying control measures, continuous monitoring ensures that the measures are effective and allow for changes in application traffic patterns to be managed.

Highlights

- Superior performance using the unique FortiASIC Content Processor that offloads heavy computation from the CPU.
- Flexible implementation with robust deployment modes and granular controls.
- Excellent visibility and management tools that help administrators improve security.
- Supports detection for traffic using HTTP protocol (versions 1.0, 1.1, and 2.0).

Key Features & Benefits

Identifies and controls application traffic	Allows organization to strengthen security policies by controlling evasive application communications.
Leverages FortiGate's hardware acceleration and software optimization	Offers more security without compromising performance.
Granular control and integration with other FortiOS capabilities	Provides administrators the ability to implement the most appropriate configuration for any given organization.

Features

NSS Labs “Recommend” Rating for Next Generation Firewall

Fortinet’s entry into the NSS Labs Next Generation Firewall Group Test in 2013, 2014 and 2016 received the “Recommend” rating, placing it as one of the top performing systems. NSS Labs uses respectable real-world testing methodologies to measure Next Generation Firewall protection and performance, including application control.

Superior performance with Unique Hardware Architecture

Unlike a traditional security gateway, which relies heavily on CPUs for packet inspection, the FortiGate’s unique hardware architecture allows FortiOS to automatically utilize appropriate hardware components to achieve optimal performance. This prevents the CPU from becoming a bottleneck as it performs various functions concurrently.

In support of application control, the Content Processor (CP) is a specialized ASIC chip that handles demanding cryptographic computation for SSL inspection and intensive signature matching. By offloading these processes from the CPU, the FortiGate is able to minimize performance degradation when administrators opt for greater security.

Robust Deployment Modes

FortiOS supports a wide array of network protocols and operating modes, allowing administrators to deploy the most appropriate security for their unique IT infrastructure. FortiOS also supports a variety of routing and switching protocols.

The FortiGate is able to operate in inline route and transparent mode. It can also operate in offline sniffer mode for passive monitoring of user activities. These different operating modes run concurrently by using virtual systems.

Protection at the Edge

With today’s BYOD and mobile workforce environment, it is no longer wise to deploy control just at the Internet gateway. Through Fortinet Security Fabric, FortiOS unique wireless and switch controller feature allows organizations to implement better visibility and protection closer to internal devices. Moreover, with FortiClient, administrators can also apply similar policies when mobile users are outside of the protected networks.

Advanced Application Detection and Control

By relying on the FortiOS 3rd Generation IPS engine, the FortiGate is able to inspect many of today’s encrypted and evasive traffic, as well as traffic running on new technologies, such as SPDY protocol. The inspection can be applied to both network and IPsec/SSL VPN traffic.

An application and its specific activity are identified using FortiGuard's Application Control database of over 2,500 distinct signatures. These signatures are crafted by researchers across the globe to include applications that may be unique to platforms, regions, and/or languages. It also offers specific application activity identification, such as a Facebook posting or Dropbox file sync. The database is kept up to date via scheduled or manual downloads.

The application database is classified into 20 intuitive categories for ease of use. Administrators may also create specific application overrides that differ from the category settings. These specific applications can be filtered and selected by type of behavior, risk levels, technology type, application vendor and popularity.

Administrators may also apply advanced controls, such as setting up session TTLs for specific applications using CLI commands.

Traffic Shaping

Organizations may better utilize bandwidth and protect critical applications by enforcing granular application usage with traffic shaping. Administrators can create various traffic shaping profiles by defining traffic priority and maximum or guaranteed bandwidth. These profiles can then be assigned to targeted applications.

User Notification

User education is central to an effective security implementation. In response to this, FortiOS lets you provide user notification when blocking an unauthorized application. The notification appears as an HTML block page for web-based applications.

Advanced notification is possible by implementing Fortinet's browser-embedded frame. And when "off-net" users are denied access, notifications appear via FortiClient's notification pop-ups.

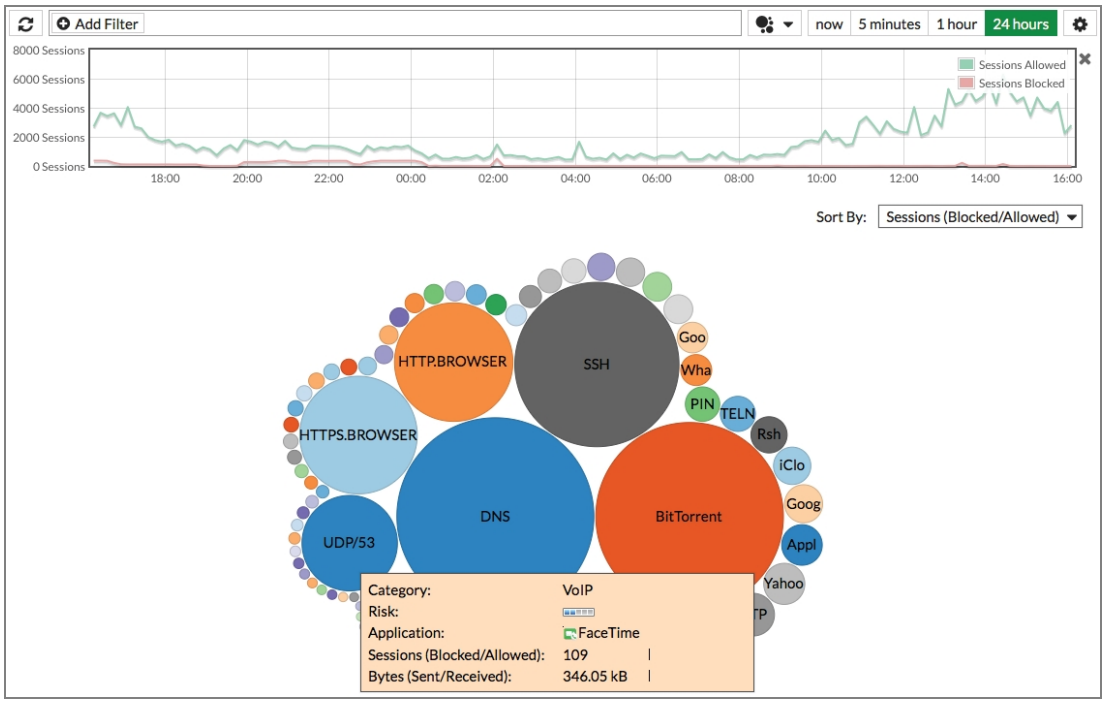
Deep Inspection for Cloud Applications

The prevalence of cloud applications like Dropbox poses a security challenge to today's organizations. Using FortiOS's deep inspection for popular cloud applications, administrators gain deep and useful insights, via FortiView and logs, into activities associated with these applications, such as user IDs, cloud actions, file names, and file sizes. For popular video sites, FortiOS will also be able to track video files viewed.

SSL Inspection for Encrypted Traffic

SSL (Secure Sockets Layer) is a popular encryption standard used to protect Internet traffic but may also be used to evade traditional inspection. FortiOS enables organizations to adopt effective application control even when traffic is encrypted.

Unique hardware components and software optimizations can decrypt traffic with minimal performance impact. The inspection can easily omit sensitive communications, such as financial transaction (thereby complying with privacy policies), or bypass applications that forbid SSL inspection by using granular policy settings.



Monitoring, Logging, and Reporting

FortiOS empowers organization to implement security best practices that require continuous examination of threat statuses and the ability to adapt to new requirements.

The FortiView widgets provide useful analyses with detailed and contextual session information that can be filtered, ranked, and further inspected. For example, an administrator can instantly query the top applications that are currently consuming bandwidth and drill down to identify their users and help decide if such activities should be blocked.

Network, threat, and system events activities can be archived via syslogs. In turn, these logs can generate useful trending and overview reports.

Lastly, the FortiOS offers robust in-built email and SMS alert systems. Meanwhile, integration with external threat management systems can be achieved with SNMP and standard-based syslogs.

- Monitoring and blocking P2P traffic

Inside FortiOS: Intrusion Prevention System (IPS)

Intrusion Prevention System (IPS) technology protects your network from cybercriminal attacks by actively seeking and blocking external threats before they can reach potentially vulnerable network devices.

World Class Next Generation IPS Capabilities

Today, sophisticated and high volume attacks are the challenges that every organization must recognize. These attacks are evolving, infiltrating ever-increasing vectors and complex network environments. The result is an urgent need for network protection while maintaining the ability to efficiently provide demanding services and applications.

FortiOS's IPS functionality is an industry-proven network security solution that scales up to over 200 Gbps of in-line protection. Powered by purpose-built hardware and FortiASICs, FortiOS is able to achieve attractive TCO while meeting performance requirements. IPS is easy to set up, yet offers feature-rich capabilities, with contextual visibility and coverage. It is kept up-to-date by research teams that work 24 hours a day worldwide, in order to detect and deter the latest known threats as well as zero-day attacks.

Highlights

- Validated best-in-class security and capacity with proven coverage and high performance.
- Comprehensive protection provided by a signatures-based IPS engine, protocol anomaly scanning, and DDOS mitigation.
- Flexible deployment options and actionable implementations for a wide array of network integration and operation requirements.

Key Features & Benefits

High Performance IPS, powered by FortiASIC	Low latency and high capacity ensure business applications are not affected while security is enforced.
Best-in-class security with superior coverage	Protects critical digital resources from both internal exploits and external cybercriminals, even if sophisticated attacks are crafted.
Backed by FortiGuard Labs that deliver real-time protection	Maintains up-to-date and proactive protection against latest known threats and newly discovered hacking techniques while allowing time for organizations to patch vulnerable systems.

Features

Tested and Proven Protection

Not only have FortiGates been deployed in some of the largest enterprises in the world since 2002, FortiOS IPS components and FortiGuard IPS signatures are periodically tested and certified by well-known external labs. For example, Fortinet's FortiGate 3000D earned the highest ratings for Security Effectiveness, blocking 99.9 percent of exploits in the recent NSS Labs DCIPS test. These independent certifications ensure that solutions delivered to customers are of the highest standards in performance, coverage, and accuracy.

Real-Time & Zero-day Protection

The FortiGuard Intrusion Prevention Service (IPS) provides customers with the latest defenses against stealthy network-level threats through a constantly updated database of known threats and behavior-based signatures.

FortiGuard IPS service quick facts

- Over 10,000 signatures consisting of 18,000 rules
- Approximately 470,000 network intrusion attempts resisted per minute
- About 1,000 rules are updated or added per week
- Over 300 Zero-day vulnerabilities discovered to date

This update service is backed by a team of threat experts and a close relationship with major application vendors. The best-in-class team also uncovers significant zero-day vulnerabilities continuously, providing FortiGate units with advanced protection ahead of vendor patches.

Uncompromised Performance

The FortiASICS Content Processor (CP) accelerates content processing, which is traditionally done completely by the CPU. The CP reduces the resources required by the CPU when matching an incoming file against the signature database, thus improving system performance and stability.

Protocol Decoders and Anomaly Detection

Protocol decoders are required to assemble the packets and detect suspicious, nonconforming sessions that resemble known attacks or are non-compliant to RFC or standard implementation.

FortiOS offers one of the most comprehensive arrays of protocol decoders in the industry, providing customers with significantly wide coverage in all kinds of environments.

Pattern & Rate-Based Signatures

The pattern signature matching technique is essential in IPS implementation due to its high level of precision and accuracy. FortiOS offers administrators robust pattern signature selection using filters based on severity, target, operating system, application, and protocol. Each of the 10,000+ signatures has a direct link to its detailed entry on the threat encyclopedia and CVE-ID references. After selection, administrators are able to assign associated actions such as monitoring, blocking, or resetting the session.

Rate-based IPS signatures protect networks against applicationbased DoS and brute force attacks. Administrators can configure nearly 30 rate-based IPS signatures and tune them to their needs. Threshold (incidents per minute) and an action to take when the threshold is reached can be assigned to each signature. If the action is set to block, then a timeout period can be set so that the block is removed after a specified duration.

DoS and DDoS Mitigation

DoS policies can help protect against DDoS attacks that aim to overwhelm server resources. In FortiOS, the DoS scans precede the policy engine at the incoming interfaces, thus eliminating unnecessary sessions from the firewall process and state table entry during a surge of attack traffic. This helps to safeguard the firewall from overloading and allows it to perform optimally.

FortiOS DoS policies can be configured to detect and block floodings, port scans, and sweeps. Administrators can set baselines for the amount of concurrent sessions from sources or to destinations. The settings utilize thresholds and can be applied to UDP, TCP, ICMP, IP, and SCTP.

Network interfaces associated with a port attached to a Network Processor (NP) can be configured to offload anomaly checking, further offloading the CPU for greater performance. Some of the anomaly traffic dropped includes LAND attacks, IP protocol with malformed options, and WinNukes.

Quarantine Attacks

FortiOS offers sophisticated automatic attack quarantine capabilities which allow organizations to proactively prevent further attacks from known attackers over a predefined duration. Quarantining by duration can be used to protect potentially vulnerable servers until more permanent defense.

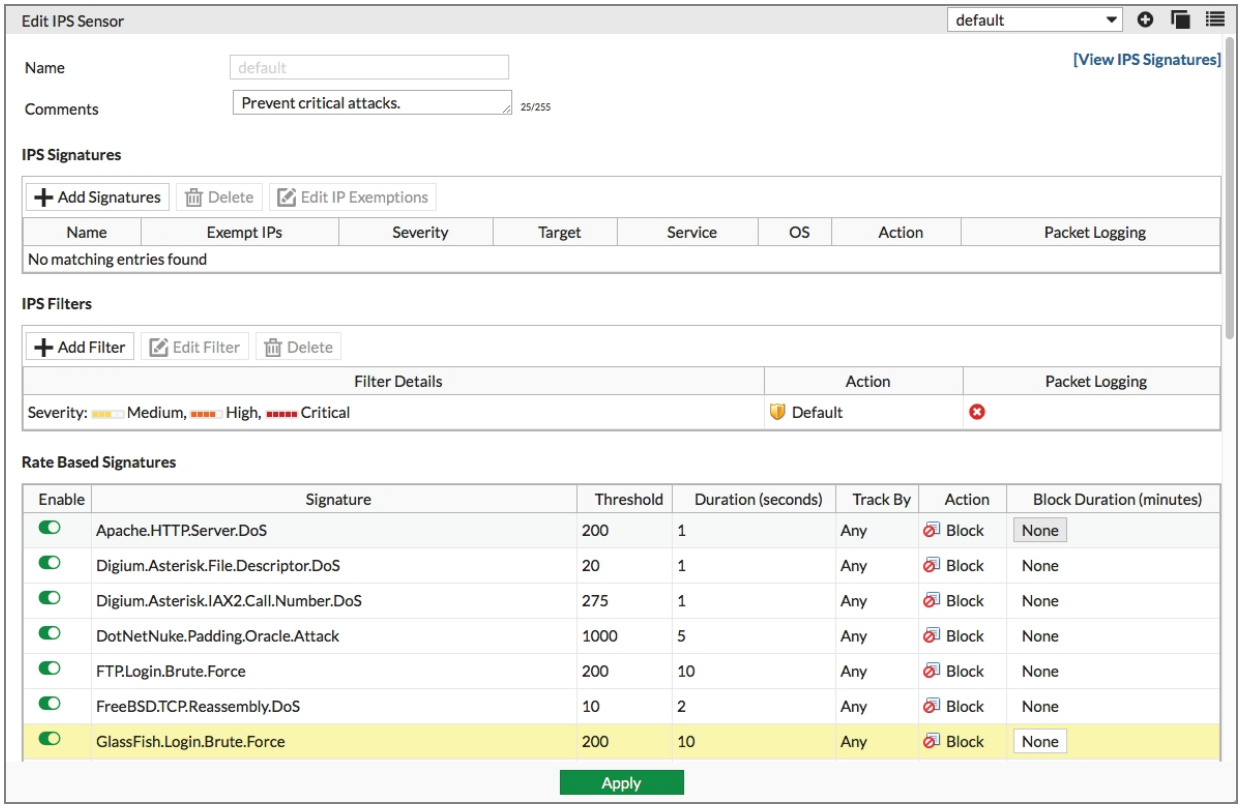
Packet Logging

Administrators may choose to automatically perform IPS packet logging, which saves packets for detailed analysis when an IPS signature is matched. Saved packets can be viewed and analyzed on the FortiGate unit or by using third-party analysis tools. Packet logging is also useful in determining false positives.

Custom Signatures

Custom IPS signatures can be created to further extend protection. For example, you can use custom IPS signatures to protect unusual or specialized applications, or even custom platforms from known and unknown attacks.

Organizations may use FortiConverter to easily convert Snort signatures for FortiOS use.



Resistant Against Evasions

Evasion techniques attempt to fool the protocol decoders in IPS products by crafting exotic network streams that would not be handled or reconstructed by the decoders, yet still be valid enough for the target recipient to process. Robust IPS engine is capable of handling both common evasions and sophisticated AETs (Advanced Evasion Techniques) deployed by hackers such as IP Packet Fragmentation, TCP Stream Segmentation, RPC Fragmentation, URL & HTML Obfuscation, and other protocolspecific evasion techniques.

Intrusion Detection Mode

In out-of-band sniffer mode (or one-arm IPS mode), IPS operates as an Intrusion Detection System (IDS), detecting attacks and reporting them but not taking any action against them. In sniffer mode, the FortiGate unit does not process network traffic and instead is connected to a spanning or mirrored switch port, or a network tap. If an attack is detected, log messages can be recorded and alerts sent to system administrators.

Traffic Bypass

Since most IPS deployments are in transparent inline mode, active traffic bypass is often desired until normal operation of the device resumes. Some FortiGates offer inbuilt active bypass interfaces while others may use external bypass devices such as the FortiBridge. Administrators are also offered with software fail-open option to tackle instances where the IPS engine fails.

Monitoring, Logging, and Reporting

FortiOS empowers organizations to implement security best practices that require continuous examination of their threat status and adaptation to new requirements. The FortiView query widgets provide useful analysis data with detailed and contextual session information, which can be filtered, ranked, and further inspected. System events can also be archived via logs, which in turn can generate useful trending and overview reports.

Inside FortiOS: Web Filtering

A Web Filtering solution is designed to restrict or control the content a reader is authorized to access, delivered over the Internet via the Web browser. It may be used to improve security, prevent objectionable activities, and increase productive within an organization.

Intelligent and Effective Content Control

Web-based threats such as Phishing, drive-by Malware sites, and Botnets are more sophisticated and scrutinized than ever, and as well as increasingly difficult to control due to the rise of mobility in the workplace, even more difficult for you to control. The Web has become the preferred medium of choice for hackers and thieves looking for new ways to disrupt services, steal information, and perform malicious activities for financial gain. In addition, employees who visit websites containing objectionable content can expose your organization to civil or criminal liability.

FortiOS Web Filtering solution utilizes three main components of the web filtering function: the Web Content Filter, the URL Filter, and the FortiGuard Web Filtering Service. These functions integrate with each other to provide maximum control over what the Internet user can view as well as protection to the network from many Internet content threats. Web Content Filtering blocks web pages containing words or patterns that you specify. URL filtering uses URLs and URL patterns to block or exempt web pages from specific sources. FortiGuard Web Filtering provides many additional categories you can use to filter web traffic by independent real-world tests.

Highlights

- Comprehensive and advanced Web Filtering features Safe Search and user override options.
- FortiGuard Web Filtering Services with superior coverage of over 250 million rated websites.
- Integration with other FortiOS components, such as User Identification for flexible and secured implementation.
- Supports detection for traffic using HTTP protocol (versions 1.0, 1.1, and 2.0).

Key Features & Benefits

Cloud-based Rating Database	Real-time website category rating provides accurate content control.
Wide choice of web filtering technologies	Various web filtering technology options are available to provide each organization the most suitable implementation.
Integrated with other security and networking functions	Allows organizations to simplified networks and reduce TCO.

Features

Cloud-based Rating System

Fortinet is a pioneer in cloud-based rating systems for web filtering. FortiOS provides an innovative approach to HTTP and HTTPS web filtering technology by combining the advantages of a cloud-based service offering with layered response caching. The multiple FortiGuard data centers around the world hold the entire categorized URL database and receive rating requests from FortiGate units triggered by browser-based URL requests. FortiGuard responds to these rating requests with the categories stored for specific URLs, the requesting FortiGate unit then uses its own local profile configuration to determine what action is appropriate to the category, such as: blocking, monitoring, allowing the page, displaying a warning, or requiring authentication to view the page.

Rating responses are also cached directly in FortiGate unit memory so that ratings for frequently used sites can be retrieved directly from the cache, reducing the number of requests to the FortiGuard network. Caching URLs in memory makes URL lookups almost instantaneous while only using a very small amount of system memory.

An appropriately licensed FortiManager appliance can be synchronized to the FortiGuard network and as such can be used in the same way to as the FortiGuard network for managed FortiGate devices. This can further reduce any latency associated with the round trip time for individual rating requests while at the same time ensuring complete database coverage. Consider the combination of a LAN attached FortiGate cluster and FortiManager combination with the potential to handle tens of thousands of requests per second.

Superior Coverage

FortiGuard Web Filter ratings are performed by a combination of proprietary methods including text analysis, exploitation of the web structure, and human raters. This service currently rates more than 250 million sites covering billions of URLs with each site able to be rated in multiple categories. The FortiGuard database provides a truly international service with support for 70 languages.

Extensive and Flexible Categorization

Rated URLs are assigned into one of the 98 categories (including 20 user defined ones) which administrators can then easily manage and control. Administrators can configure and populate local categories or place specific URLs in existing categories should the FortiGuard rating not be in agreement with an organization's policies and practices.

Rating Override

At times, administrators may have to allow approved people to access what they need during periods when an exception to the normal rules is required, while still having enough control that the organization's web usage policies are not compromised. FortiOS can provide such setup by using alternate profiles.

Protection against Malicious URLs

The malicious URL database contains all malicious URLs active in the last month and is organized as one of the categories. With Fortinet Security Fabric, customers can further their protection by having the FortiSandbox add newly discovered URLs to a dynamic URL filter, thus blocking files from being downloaded again from that URL.

Inspection Modes

FortiOS web filtering can operate in three modes. Each mode has strengths and weaknesses and all three can be active at the same time on different traffic streams.

Proxy-based web filtering uses a proxy to assemble and analyze web content as it passes through the FortiGate unit. If a page is blocked the proxy can replace the blocked page with a customizable web page informing users that the page is blocked. Proxy-based web filtering is the most feature-rich mode, supporting many advanced filters including web content filtering that analyzes web page content according to your custom requirements, Java applet filtering, and blocking invalid URLs.

Flow-based web filtering uses the FortiOS IPS engine to filter web content packets as they pass through the FortiGate unit without any buffering. Flow-based inspection does not use a proxy, so inspected packets are not proxied and altered by the FortiGate unit. Flow-based inspection does not support as many advanced features as proxy-based web filtering.

DNS web filtering employs DNS lookups to the FortiGuard DNS service to get web page ratings. Filtering is done as part of the DNS lookup and web pages can be blocked or redirected to a web filter block page before the HTTP session starts. As a result, it is lightweight in terms of resource usage although it only supports a limited number of advanced features.

Usage Quota

Administrators can set a daily timed access quota by category or category group. Quotas allow access for a specified length of time or traffic volume, calculated separately for each user.

Safe Search

SafeSearch is a feature of popular search sites that prevents explicit web sites and images from appearing in search results. Although SafeSearch is a useful tool, especially in educational environments, the resourceful user may be able to simply turn it off. Enabling SafeSearch on the FortiGate for the supported search sites can better enforce its use by rewriting the search URL to include the code to indicate the use of the SafeSearch feature. In addition, FortiOS also provide implementation of YouTube Education Filter.

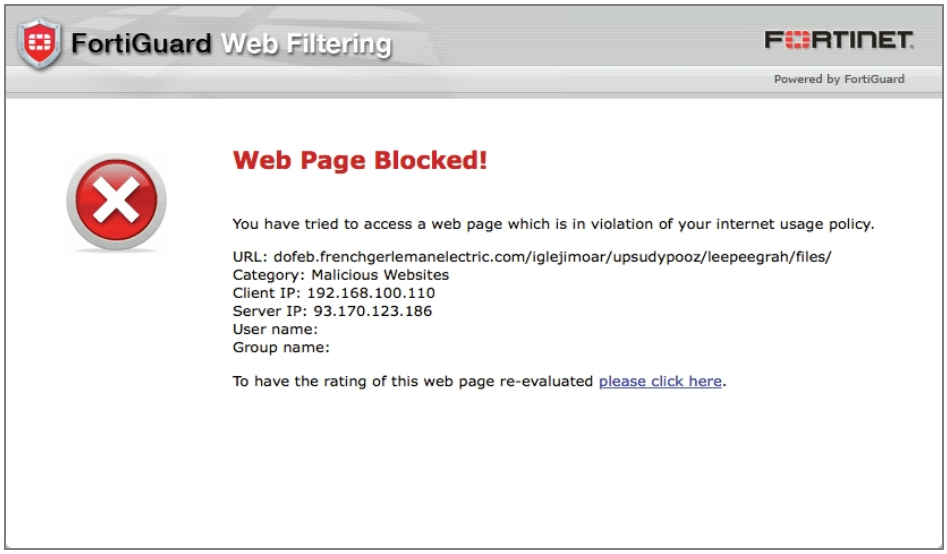
Manual URL and Content Filter

FortiOS web filtering offers specific URL filtering by standard, wildcard, and regular expression definition, as well as content filtering by pattern type and language.

Advanced web filter configurations

FortiOS rich feature set includes ability to implement a number of enterprise features such as:

- Block HTTP redirects by rating, invalid URLs, HTTP POST actions, and Web resume download
- Cookie, Java applet, and ActiveX filter
- Rate Images by URL and URLs by domain and IP address
- Restrict Google account usage to specific domains



Proxy Avoidance Preventions

FortiGate is able to improve the effectiveness of the web filtering by preventing users from evading the security implementation. Organizations can use its multiple integrated technologies including proxy site URL, proxy application control, and IPS proxy behavior blocking.

User and Device Awareness

Most networks in today's organizations are connected with both corporate and personal mobile devices. User and device awareness provides the option to configure intelligent policies that can effectively enforce security.

To tackle the prevalence of BYOD environments, administrators are able to configure web content access policies with sources defined by IPs, users, and devices, either combined or selectively.

External URL Filtering support

In instances where customers have large, existing, deployed implementations of a specific URL filtering solution but replace their legacy firewalls with a FortiGate family, they can still retain their web filtering infrastructure since FortiOS supports both ICAP and WISP.

Monitoring, Logging, and Reporting

FortiOS empowers an organization to implement security best practices that require continuous monitoring of threats, allowing the organization to adapt to new requirements.

The FortiView dashboards display useful analysis data with detailed and contextual session information, which can be filtered and ranked, with drilldown options also available. This information, including system events activities and administration audit trails, can also be archived via logs.

FortiOS logs all the types of traffic that can connect to or terminate at the FortiGate unit. In turn, these logs can generate useful trending and overview reports.

Recipes

Visit cookbook.fortinet.com for these and other recipes:

- Blocking Facebook with Web Filtering
- Blocking social media websites using FortiGuard categories
- Web rating overrides

Security Profiles overview

The FortiGate line combines a number of security features to protect your network from threats. As a whole, these features, when included in a single Fortinet security appliance, are referred to as Security Profiles.

This overview addresses the following topics:

- Traffic inspection
- Content inspection and filtering
- Security Profiles components
- Security Profiles/lists/sensors

Firewall policies limit access, and while this and similar features are a vital part of securing your network, they are not covered in this discussion of Security Profiles.

FortiOS 5.4 no longer supports FortiClient 5.0.

FortiOS 5.4.1 supports only FortiClient 5.4.1. Be sure to upgrade managed FortiClients before upgrading the FortiGate to 5.4.1.

FortiOS 5.2 can support FortiClient 5.0, but only if the FortiGate upgraded to FortiOS 5.2. Customers need to purchase a FortiClient 5.4 subscription-based FortiClient license.

Traffic inspection

When the FortiGate unit examines network traffic one packet at a time for IPS signatures, it is performing traffic analysis. This is unlike content analysis where the traffic is buffered until files, email messages, web pages, and other files are assembled and examined as a whole.

DoS policies use traffic analysis by keeping track of the type and quantity of packets, as well as their source and destination addresses.

Application control uses traffic analysis to determine which application generated the packet.

Although traffic inspection doesn't involve taking packets and assembling files they are carrying, the packets themselves can be split into fragments as they pass from network to network. These fragments are reassembled by the FortiGate unit before examination.

No two networks are the same and few recommendations apply to all networks. This topic offers suggestions on how you can use the FortiGate unit to help secure your network against content threats.

IPS signatures

IPS signatures can detect malicious network traffic. For example, the Code Red worm attacked a vulnerability in the Microsoft IIS web server. Your FortiGate's IPS system can detect traffic attempting to exploit this vulnerability. IPS may also detect when infected systems communicate with servers to receive instructions.

IPS recommendations

- Enable IPS scanning at the network edge for all services.
- Use FortiClient endpoint IPS scanning for protection against threats that get into your network.
- Subscribe to FortiGuard IPS Updates and configure your FortiGate unit to receive push updates. This will ensure you receive new IPS signatures as soon as they are available.
- Your FortiGate unit includes IPS signatures written to protect specific software titles from DoS attacks. Enable the signatures for the software you have installed and set the signature action to **Block**.
- You can view these signatures by going to **Security Profiles > Intrusion Protection** and selecting the **[View IPS Signatures]** link in the right-hand corner of the window.
- Because it is critical to guard against attacks on services that you make available to the public, configure IPS signatures to block matching signatures. For example, if you have a web server, configure the action of web server signatures to **Block**.

Suspicious traffic attributes

Network traffic itself can be used as an attack vector or a means to probe a network before an attack. For example, SYN and FIN flags should never appear together in the same TCP packet. The SYN flag is used to initiate a TCP session while the FIN flag indicates the end of data transmission at the end of a TCP session.

The FortiGate unit has IPS signatures that recognize abnormal and suspicious traffic attributes. The SYN/FIN combination is one of the suspicious flag combinations detected in TCP traffic by the `TCP.BAD.FLAGS` signature.

The signatures that are created specifically to examine traffic options and settings, begin with the name of the traffic type they are associated with. For example, signatures created to examine TCP traffic have signature names starting with TCP.

Application control

While applications can often be blocked by the ports they use, application control allows convenient management of all supported applications, including those that do not use set ports.

Application control recommendations

- Some applications behave in an unusual manner in regards to application control. For more information, see Application considerations on page 2725.
- By default, application control allows the applications not specified in the application control list. For high security networks, you may want to change this behavior so that only the explicitly allowed applications are permitted.

SSL/SSH inspection

Regular web filtering can be circumvented by using https:// instead of http://. By enabling this feature, the FortiGate can filter traffic that is using the HTTPS protocol. This sort of analysis is some times referred to as deep scanning.

Deep Inspection works along the following lines: If your FortiGate unit has the correct chipset it will be able to scan SSL encrypted traffic in the same way that regular traffic can be scanned. The FortiGate firewall will essentially receive the traffic on behalf of the client and open up the encrypted traffic. Once it is finished it re-encrypts the traffic and sends it on to its intended recipient. It is very similar to a man-in-the-middle attack. By enabling this feature, it allows the FortiGate firewall to filter on traffic that is using the SSL encrypted protocol.

The encrypted protocols that can be inspected are:

- HTTPS
- SMTPS
- POP3S
- IMAPS
- FTPS

Before the invention of SSL inspection, scanning regular web traffic can be circumvented by using the prefix https:// instead of http:// in the URL. SSL inspection prevents this circumvention. However, because when the encrypted traffic is decrypted it has to be re-encrypted with the FortiGate's certificate rather than the original certificate it can cause errors because the name on the certificate does not match the name on the web site.

At one point deep inspection was something that was either turned on or off. Now individual deep inspection profiles can be created depending on the requirements of the policy. Depending on the Inspection Profile, you can:

- Configure which CA certificate will be used to decrypt the SSL encrypted traffic.
- Configure which SSL protocols will be inspected.
- Configure which ports will be associated with which SSL protocols for the purpose of inspection.
- Configure which websites will be exempt from SSL inspection
- Configure whether or not to allow invalid SSL certificates.
- Configure whether or not SSH traffic will be inspected.

Content inspection and filtering

When the FortiGate unit buffers the packets containing files, email messages, web pages, and other similar files for reassembly before examining them, it is performing content inspection. Traffic inspection, on the other hand, is accomplished by the FortiGate unit examining individual packets of network traffic as they are received.

No two networks are the same and few recommendations apply to all networks. This topic offers suggestions on how you can use the FortiGate unit to help secure your network against threats to content. Be sure to understand the effects of the changes before using the suggestions.

AntiVirus

The FortiGate antivirus scanner can detect viruses and other malicious payloads used to infect machines. The FortiGate unit performs deep content inspection. To prevent attempts to disguise viruses, the antivirus scanner will reassemble fragmented files and uncompress content that has been compressed. Patented Compact Pattern Recognition Language (CPRL) allows further inspection for common patterns, increasing detection rates of virus variations in the future.

AntiVirus recommendations

- Enable antivirus scanning at the network edge for all services.
- Use FortiClient endpoint antivirus scanning for protection against threats that get into your network.
- Subscribe to FortiGuard AntiVirus Updates and configure your FortiGate unit to receive push updates. This will ensure that new antivirus signatures are loaded onto your FortiGate as soon as they are available.
- Enable the Extended Virus Database if your FortiGate unit supports it.
- Examine antivirus logs periodically. Take particular notice of repeated detections. For example, repeated virus detection in SMTP traffic could indicate a system on your network is infected and is attempting to contact other systems to spread the infection using a mass mailer.

- To conserve system resources, avoid scanning email messages twice. Scan messages as they enter and leave your network or when clients send and retrieve them, rather than both.
- Enable **Treat Windows Executables in Email Attachments as Viruses** if you are concerned about incoming '.exe' files.

FortiGuard Web Filtering

The web is the most popular part of the Internet and, as a consequence, virtually every computer connected to the Internet is able to communicate using port 80, HTTP. Botnet communications take advantage of this open port and use it to communicate with infected computers. FortiGuard Web Filtering can help stop infections from malware sites and help prevent communication if an infection occurs.

FortiGuard Web Filtering recommendations

- Enable FortiGuard Web Filtering at the network edge.
- Install the FortiClient application and use FortiGuard Web Filtering on any systems that bypass your FortiGate unit.
- Block categories such as Pornography, Malware, Spyware, and Phishing. These categories are more likely to be dangerous.
- In the Anti-Spam profile, enable **Spam Detection and Filtering** and then enable **IP Address Check**. Many IP addresses used in spam messages lead to malicious sites; checking them will protect your users and your network.

DNS Filter

DNS-based web filtering

This feature is similar to the FortiGuard DNS web filtering available in FortiOS 5.2. You can configure DNS web filtering to allow, block, or monitor access to web content according to FortiGuard categories. When DNS web filtering is enabled, your FortiGate must use the FortiGuard DNS service for DNS lookups. DNS lookup requests sent to the FortiGuard DNS service return with an IP address and a domain rating that includes the FortiGuard category of the web page.

If that FortiGuard category is set to block, the result of the DNS lookup is not returned to the requester. If the category is set to redirect, then the address returned to the requester points at a FortiGuard redirect page.

You can also allow access or monitor access based on FortiGuard category.

The following filtering options can be configured in a DNS Filter security profile:

Blocking DNS requests to known Botnet C&C addresses

A new FortiGuard database contains a list of known Botnet C&C addresses. This database is updated dynamically and stored on the FortiGate. This database is covered by FortiGuard web filter licensing; you must have an active FortiGuard web filtering license to use this feature. You can view the botnet lists by going to **System > FortiGuard > Botnet IPs** and **System > FortiGuard > Botnet Domains**.

When you block DNS requests to known Botnet C&C addresses, using IPS, DNS lookups are checked against the Botnet C&C database. All matching DNS lookups are blocked. Matching uses a reverse prefix match, so all sub-domains are also blocked.

To enable blocking of DNS requests to known Botnet C&C addresses, go to **Security Profiles > DNS Filter**, and enable **Block DNS requests to known botnet C&C**. When you do this in FortiOS 5.4.1, you can open a definitions window by clicking on "botnet package."

Static URL filter

The DNS static URL filter allows you to block, exempt, or monitor DNS requests by using IPS to look inside DNS packets and match the domain being looked up with the domains on the static URL filter list. If there is a match the DNS request can be blocked, exempted, monitored, or allowed.

If blocked, the DNS request is blocked and so the user cannot look up the address and connect to the site.

If exempted, access to the site is allowed even if another method is used to block it.

Anti-Spam

Spam is a common means by which attacks are delivered. Users often open email attachments they should not, and infect their own machine. The FortiGate email filter can detect harmful spam and mark it, alerting the user to the potential danger.

Anti-Spam filter recommendations

- Subscribe to the FortiGuard Anti-Spam Filtering service.
- Enable email filtering at the network edge for all types of email traffic.
- Use FortiClient endpoint scanning for protection against threats that get into your network.

Data Leak Prevention

Most security features on the FortiGate unit are designed to keep unwanted traffic out of your network while Data Leak Prevention (DLP) can help you keep sensitive information from leaving your network. For example, credit card numbers and social security numbers can be detected by DLP sensors.

DLP recommendations

- Rules related to HTTP posts can be created, but if the requirement is to block all HTTP posts, a better solution is to use application control or the **HTTP POST Action** option in the web filter profile.
- While DLP can detect sensitive data, it is more efficient to block unnecessary communication channels than to use DLP to examine it. If you don't use instant messaging or peer-to-peer communication in your organization, for example, use application control to block them entirely.

Security Profiles components

Below is a brief description of the security profiles and their features accessible through the GUI.

AntiVirus

Your FortiGate unit stores a virus signature database that can identify more than 15,000 individual viruses. FortiGate models that support additional virus databases are able to identify hundreds of thousands of viruses. With a FortiGuard AntiVirus subscription, the signature databases are updated whenever a new threat is discovered.

AntiVirus also includes file filtering. When you specify files by type or by file name, the FortiGate unit will block the matching files from reaching your users.

FortiGate units with a hard drive or configured to use a FortiAnalyzer unit can store infected and blocked files for that you can examine later.

Web Filter

Web filtering includes a number of features you can use to protect or limit your users' activity on the web.

FortiGuard Web Filtering is a subscription service that allows you to limit access to web sites. More than 60 million web sites and two billion web pages are rated by category. You can choose to allow or block each of the 77 categories.

URL filtering can block your network users from access to URLs that you specify.

Web content filtering can restrict access to web pages based on words and phrases appearing on the web page itself. You can build lists of words and phrases, each with a score. When a web content list is selected in a web filter profile, you can specify a threshold. If a user attempts to load a web page and the score of the words on the page exceeds the threshold, the web page is blocked.

DNS Filter

The FortiGate will inspect DNS traffic to any DNS server, so long as the policy has DNS inspection enabled. The FortiGate will intercept DNS requests, regardless of the destination IP, and redirect it to the FortiGuard Secure DNS server -- this is separate from the FortiGuard DNS server.

The Secure DNS server will resolve and rate the FQDN and send a DNS response which includes both IP and rating of the FQDN back to the FortiGate, where it will handle the DNS response according to the DNS filter profile.

Application Control

Although you can block the use of some applications by blocking the ports they use for communications, many applications do not use standard ports to communicate. Application control can detect the network traffic of more than 1,000 applications, improving your control over application communication.

Cloud Access Security Inspection (CASI)

This feature introduces a new security profile called Cloud Access Security Inspection (CASI) that provides support for fine-grained control on popular cloud applications, such as YouTube, Dropbox, Baidu, and Amazon. The CASI profile is applied to a policy much like any other security profile.

Unfortunately CASI does not work when using Proxy-based profiles for AV or Web filtering for example.
Make sure to only use Flow-based profiles in combination with CASI on a specific policy.

Intrusion Protection

The FortiGate Intrusion Protection System (IPS) protects your network against hacking and other attempts to exploit vulnerabilities of your systems. More than 3,000 signatures are able to detect exploits against various operating systems, host types, protocols, and applications. These exploits can be stopped before they reach your internal network.

You can also write custom signatures tailored to your network.

Anti-Spam

FortiGuard Anti-Spam is a subscription service that includes an IP address black list, a URL black list, and an email checksum database. These resources are updated whenever new spam messages are received, so you do not need to maintain any lists or databases to ensure accurate spam detection.

You can use your own IP address lists and email address lists to allow or deny addresses, based on your own needs and circumstances.

Data Leak Prevention

Data Leak Prevention (DLP) allows you to define the format of sensitive data. The FortiGate unit can then monitor network traffic and stop sensitive information from leaving your network. Rules for U.S. social security numbers, Canadian social insurance numbers, as well as Visa, Mastercard, and American Express card numbers are included.

VoIP

The Session Initiation Protocol (SIP) is an IETF application layer signaling protocol used for establishing, conducting, and terminating multi-user multimedia sessions over TCP/IP networks using any media. SIP is often used for Voice over IP (VoIP) calls but can be used for establishing streaming communication between end points.

For more information, see VoIP Solutions: SIP.

ICAP

This module allows for the offloading of certain processes to a separate server so that your FortiGate firewall can optimize its resources and maintain the best level of performance possible.

FortiClient Profiles

FortiClient is an all-in-one comprehensive endpoint security solution that extends the power of Fortinet's Advanced Threat Protection (ATP) to end user devices. As the endpoint is the ultimate destination for malware that is seeking credentials, network access, and sensitive information, ensuring that your endpoint security combines strong prevention with detection and mitigation is critical.

The FortiGate provides network security by defining compliance rules for FortiClient endpoints.

For more information, see the FortiClient 5.4.1 Administration Guide.

Proxy Options

Proxy Options includes features you can configure for when your FortiGate is operating in proxy mode, including protocol port mapping, block oversized files/emails, and other web and email options.

SSL/SSH Inspection

SSL/SSH Inspection (otherwise known as Deep Inspection) is used to scan HTTPS traffic in the same way that HTTP traffic can be scanned. This allows the FortiGate to receive and open up the encrypted traffic on behalf of the client, then the traffic is re-encrypted and sent on to its intended destination.

Individual Deep Inspection profiles can be created, depending on the requirements of the policy. Depending on the profile, you can:

- Configure which CA certificate will be used to decrypt the SSL encrypted traffic
- Configure which SSL protocols will be inspected
- Configure which ports will be associated with which SSL protocols for inspection
- Configure whether or not to allow invalid SSL certificates
- Configure whether or not SSH traffic will be inspected

Web Rating Overrides

This feature allows you to override the FortiGuard Web Filtering. This option allows users to change the rating for a website and control access to the site without affecting the rest of the sites in the original category. More information can be found in Overriding FortiGuard website categorization.

Web Profile Overrides

This feature allows administrators to grant temporary access to sites that are otherwise blocked by a web filter profile. The temporary access can be granted to a user, user group, or source IP address. The time limit can be set in days, hours, or minutes. See the section on Web Profile Overrides for more information.

Security Profiles/lists/sensors

A profile is a group of settings that you can apply to one or more firewall policies. Each Security Profile feature is enabled and configured in a profile, list, or sensor. These are then selected in a security policy and the settings apply to all traffic matching the policy. For example, if you create an antivirus profile that enables antivirus scanning of HTTP traffic, and select the antivirus profile in the security policy that allows your users to access the World Wide Web, all of their web browsing traffic will be scanned for viruses.

While you can apply more than one security profile to a firewall policy, it is not recommended that you use flow-based profiles and proxy-based profiles in the same firewall policy.

Because you can use profiles in more than one security policy, you can configure one profile for the traffic types handled by a set of firewall policies requiring identical protection levels and types, rather than repeatedly configuring those same profile settings for each individual security policy.

For example, while traffic between trusted and untrusted networks might need strict protection, traffic between trusted internal addresses might need moderate protection. To provide the different levels of protection, you might configure two separate sets of profiles: one for traffic between trusted networks, and one for traffic between trusted and untrusted networks.

Inspection Modes

You can select one of two inspection modes from the System Information dashboard widget to control the security profile inspection mode for your FortiGate or VDOM.

- Proxy-based inspection, that reconstructs content passing through the FortiGate unit and inspects the content for security threats, or
- Flow-based inspection, that takes a snapshot of content packets and uses pattern matching to identify security threats in the content.

Each inspection component plays a role in the processing of traffic en route to its destination. Having control over flow and proxy mode is helpful if you want to be sure that only flow inspection mode is used (and that proxy inspection mode is not used). In most cases proxy mode is preferred because more security profile features are available and more configuration options for these individual features are available. Yet, some implementations may require all security profile scanning to only use flow mode. In this case, you can set your FortiGate to flow mode knowing that proxy mode inspection will not be used. While both modes offer significant security, proxy-based is more feature-rich and flow-based is designed to optimize performance.

This section addresses the following topics:

Proxy-based inspection

If a FortiGate or VDOM is configured for proxy-based inspection, then a mixture of flow-based and proxy-based inspection occurs. Traffic initially encounters the IPS engine, which applies single-pass IPS, Application Control, and CASI, if configured in the firewall policy accepting the traffic.

The traffic is then sent for proxy-based inspection. Proxy-based inspection extracts and caches content, such as files and web pages, from a content session and inspects the cached content for threats. Content inspection takes place in the following order: **VoIP inspection**, **DLP**, **AntiSpam**, **Web Filtering**, **AntiVirus**, and **ICAP**.

If no threat is found, the proxy relays the content to its destination. If a threat is found, the proxy can block the threat and send a replacement message in its stead. The proxy can also block VoIP traffic that contains threats.

Flow-based inspection

Flow-based inspection identifies and blocks security threats in real time as they are identified using single-pass Direct Filter Approach (DFA) pattern matching to identify possible attacks or threats.

If a FortiGate or a VDOM is configured for flow-based inspection, depending on the options selected in the firewall policy that accepted the session, flow-based inspection can apply **IPS**, **Application Control**, **Cloud Access Security Inspection (CASI)**, **Web Filtering**, and **AntiVirus**. Flow-based inspection is all done by the IPS engine and, as you would expect, no proxying is involved.

All of the applicable flow-based security modules are applied simultaneously in one single pass, and pattern matching is offloaded and accelerated by CP8 or CP9 processors. **IPS**, **Application Control** and **CASI**, and flow-based **Web Filtering** happen together. CASI signatures are applied as part of application control. Flow-based antivirus caches files during protocol decoding and submits cached files for virus scanning while the other matching is carried out.

Flow-based inspection typically requires fewer processing resources than proxy-based inspection and does not change packets, unless a threat is found and packets are blocked. Flow-based inspection cannot apply as many features as proxy inspection. For example, flow-based inspection does not support client comforting and some aspects of replacement messages.

Changing between proxy and flow mode

In **FortiOS 5.4.0 and 5.4.1**, proxy mode is enabled by default and you change to flow mode by changing the **Inspection Mode** on the System Information widget. If required, you can change back to proxy mode through System Information widget.

When you select **Flow-based** you are reminded that all proxy mode profiles are converted to flow mode, removing any proxy settings. As well proxy mode only features (for example, Web Application Profile) are removed from the GUI.

In addition, selecting **Flow-based** inspection will cause the **Explicit Web Proxy** and **Explicit FTP Proxy** features to be removed from the GUI and the CLI. This includes Explicit Proxy firewall policies.

W hen you select **Flow-based** you can only configure Virtual Servers (under **Policy & Objects > Virtual Servers**) with Type set to HTTP, TCP, UDP, or IP.

If required, you can change back to proxy mode through the System Information dashboard widget.

If your FortiGate has multiple VDOMs, you can set the inspection mode independently for each VDOM. Use the top left dropdown menu to go to **Global > System > VDOM**. Click **Edit**for the VDOM you wish to change and select the **Inspection Mode**.

Switching to flow-based inspection also turns off WAN Optimization, Web Caching, the Explicit Web Proxy, and the Explicit FTP Proxy making sure that no proxying can occur.

From the GUI, you can only configure antivirus and web filter security profiles in proxy mode. From the CLI you can configure flow-based antivirus profiles, web filter profiles and DLP profiles and they will appear on the GUI and include their inspection mode setting. Also, flow-based profiles created when in flow mode are still available when you switch to proxy mode.

Comparison of inspection types

The tables in this section show how different security features map to different inspection types and present the strengths and weaknesses of proxy- vs. flow-based inspection.

Security profile features mapped to inspection mode

The table below lists FortiOS security profile features and shows whether they are available in flow-based or proxy-based inspection modes.

The DNS Filter security profile feature is only available for proxy-based inspection in FortiOS versions 5.4.0 and 5.4.1. It is available for both proxy-based and flow-based inspection in FortiOS versions 5.4.2 and above.

Security Profile Feature	Flow-based inspection	Proxy-based inspection
AntiVirus	x	x
Web Filter	x	x
DNS Filter	x	x

Security Profile Feature	Flow-based inspection	Proxy-based inspection
Application Control	x	x
Cloud Access Security Inspection	x	x
Intrusion Protection	x	x
Anti-Spam		x
Data Leak Protection		x
VoIP		x
ICAP		x
Web Application Firewall		x
FortiClient Profiles	x	x
Proxy Options		x
SSL/SSH Inspection	x	x
Web Rating Overrides	x	x
Web Profile Overrides		x

Individual Security Profile considerations

In flow mode, AntiVirus and Web Filter profiles only include flow-mode features. Web filtering and virus scanning are still done with the same engines and to the same accuracy, but some inspection options are limited or not available in flow mode. Application control, intrusion protection, and FortiClient profiles are not affected when switching between flow and proxy mode.

Application control uses flow-based inspection; if you apply an additional security profile to your traffic that is proxy-based, the connection will simply timeout rather than display the warning, or replacement, message. However, Application Control will still function.

CASI does not work when using Proxy-based profiles for AV or Web filtering. Make sure to only use flow-based profiles in combination with CASI on a specific policy.

Even though VoIP profiles are not available from the GUI in flow mode, the FortiGate can process VoIP traffic. In this case the appropriate session helper is used (for example, the SIP session helper).

Setting flow or proxy mode doesn't change the settings available from the CLI. However, when in flow mode you can't save security profiles that are set to proxy mode.

You can also add proxy-only security profiles to firewall policies from the CLI. So, for example, you can add a VoIP profile to a security policy that accepts VoIP traffic. This practice isn't recommended because the setting will not be visible from the GUI.

If you set flow-based to use external servers for FortiWeb and FortiMail you must use the CLI to set a Web Application Firewall profile or Anti-Spam profile to external mode and add the Web Application Firewall profile or AntiSpam profile to a firewall policy.

Proxy mode and flow mode antivirus and web filter profile options

The following tables list the antivirus and web filter profile options available in proxy and flow modes.

Antivirus features in proxy and flow mode

Feature	Proxy	Flow
Scan Mode (Quick or Full)	no	yes
Detect viruses (Block or Monitor)	yes	yes
Inspected protocols	yes	no (all relevant protocols are inspected)
Inspection Options	yes	yes (not available for quick scan mode)
Treat Windows Executables in Email Attachments as Viruses	yes	yes
Send Files to FortiSandbox Appliance for Inspection	yes	yes

	Filter Per-User Black/White List	yes	no

AntiVirus Scanning differences between the FortiOS 5.x versions

If in FortiOS 5.0, 5.2, and 5.4, there are several AntiVirus (AV) scanning inspection modes available. FortiOS 5.0 includes proxy and flow-based virus scanning. FortiOS 5.2 also uses proxy-based and flow-based scanning, but the flow-based mode in FortiOS 5.2 uses a new approach to flow-based scanning (that is sometimes called deepflow or deep flow scanning). FortiOS 5.4 adds another flow-based mode, quick mode, to inspect traffic efficiently.

The databases used for AV scanning does not change from proxy to flow mode unless quick mode is enabled. In flow-based quick mode, a compact antivirus database is used.

AntiVirus scanning examines files in HTTP, HTTPS, email, and FTP traffic for threats as they pass through your FortiGate unit. If the AV scanner finds a threat such as a virus or some other malware, FortiOS protects your network by blocking the file.

FortiOS includes a number of AntiVirus features that make virus scanning more user friendly. One of these features, called replacement messages, sends a customizable message to anyone whose file is blocked by AV scanning, to explain what happened and why. Other features make communication between the client and the server more seamless. The availability of these changes depending on the inspection mode.

Proxy-based AV scanning

Proxy-based AV scanning is the most feature-rich AV scanning mode. This mode uses a proxy to manage the communication between client and server. The proxy extracts content packets from the data stream as they arrive and buffers the content until the complete file is assembled. Once the file is whole, the AV scanner examines the file for threats. If no threats are found, the file is sent to its destination. If a threat is found, the file is blocked.

Because proxy-based scanning is applied to complete files it provides very effective threat detection. Proxy-based scanning also supports a full range of features, including replacement messages and client comforting, making proxy-based scanning the most user friendly inspection mode. In addition the proxy manages the communication between the client and the server, improving the user experience. For example, in flow mode if a virus is found, the last part of the file is not downloaded and the connection just times out and the user cannot tell what is going on. In proxy mode, the users gets a message about the file being blocked.

Proxy-based scanning inspects all files under the oversized threshold. Since the FortiGate unit has a limited amount of memory, files larger than a certain size do not fit within the memory buffer. The default buffer size is 10 MB. You can use the `uncompsizelimit`CLI command to adjust the size of this memory buffer. Files larger than the threshold are passed to the destination without scanning. You can use the **Oversized File/Email** setting in **Security Profiles > Proxy Options** to block files larger than the antivirus buffer if allowing files that are too large to be scanned is an unacceptable security risk.

During the buffering and scanning procedure, the client must wait. With a default configuration, the file is released to the client only after it is scanned. You can enable client comforting in the **Proxy Options** security profile to feed the client a trickle of data to prevent them from possibly thinking the transfer is stalled and consequently canceling the download.

Flow-based AV scanning

Although the name "flow-based scanning" is used in FortiOS 5.0, 5.2, and 5.4, the different versions handle this mode in very different ways.

Flow AV in FortiOS 5.4

In FortiOS 5.4, there are two modes available for flow-based virus scanning: **Quick** and **Full** scan mode. Full mode is the same as flow-based scanning in FortiOS 5.2 (see below). Quick mode uses a compact antivirus database and advanced techniques to improve performance. Use the following command to enable quick or full mode in an antivirus profile:

```
config antivirus profile
   edit <profile>
      set scan-mode {quick | full}
   end
```

Flow AV in FortiOS 5.2 (deepflow or deep flow)

FortiOS 5.2 introduced a new type of flow-based AV scanning, that is sometimes called deepflow or deep flow, and that takes a hybrid approach where content packets are buffered while simultaneously being sent to their destination. When all of the files packets have been collected and buffered, but before the final packet is delivered, the buffered file is scanned. If a threat is found, the last packet is blocked and the client application has to deal with not getting the completed file. If no threat is found the final packet is sent and the user gets their file.

Deepflow AV scanning is as good as proxy-based AV scanning at detecting threats. There may be a small performance advantage over proxy-based AV as files get larger based on the difference between sending the whole file after analysis and just sending the last packet. Deepflow's most notable limitation is that, just like the flow-based AV in 5.0, it does not support many of the user-friendly features provided by proxy-based AV.

Flow AV in FortiOS 5.0

In FortiOS 5.0, flow-based AV scanning examines the content of individual data packets as they pass through the FortiGate. There is no proxy involved so packets are not changed by the proxy and files are not buffered for analysis. Potentially less memory and CPU resources are used, resulting in a potential performance increase compared to using proxy-based mode. FortiOS 5.0 flow-based AV scanning is also not limited by file size.

Flow AV uses the IPS engine and the AV database and is effective at many kinds of threat detection; however, because it can only analyze what is in an individual packet rather than a complete file, flow-based scanning cannot detect some types of malware, including polymorphic code. Malware in documents, compressed files, and some archives are also less likely to be detected.

Flow AV does not actually block files, it stops delivering a file's packets once a threat has been detected. This means that parts of the file may already have been delivered when the threat has been detected and the recipient application is responsible for dealing with the partially complete content.

In addition flow AV can be less user friendly. Replacement messages are not supported and clients may have to wait for sessions to time out without knowing why content has been blocked.

AntiVirus

This section describes how to configure the antivirus options. From an antivirus profile you can configure the FortiGate unit to apply antivirus protection to HTTP, FTP, IMAP, POP3, SMTP, and NNTP sessions. If your FortiGate unit supports SSL/SSH content scanning and inspection, you can also configure antivirus protection for HTTPS, IMAPS, POP3S, SMTPS, and FTPS sessions.

In many cases you can just customize the default antivirus profile and apply it to the security policy that accepts the traffic to be virus scanned. You can also create custom antivirus profiles if want to apply different types of virus protection to different traffic.

This Handbook chapter includes Inside FortiOS: AntiVirus providing readers an overview of the features and benefits of key FortiOS 5.4 components.

For readers needing to delve into greater detail, we provide the following topics:

- Antivirus concepts
- Enabling AntiVirus scanning
- Testing your antivirus configuration
- Example Scenarios

Antivirus concepts

The word “antivirus” refers to a group of features that are designed to prevent unwanted and potentially malicious files from entering your network. These features all work in different ways, which include checking for a file size, name, or type, or for the presence of a virus or grayware signature.

The antivirus scanning routines your FortiGate unit uses are designed to share access to the network traffic. This way, each individual feature does not have to examine the network traffic as a separate operation, and the overhead is reduced significantly. For example, if you enable file filtering and virus scanning, the resources used to complete these tasks are only slightly greater than enabling virus scanning alone. Two features do not require twice the resources.

Antivirus scanning examines files for viruses, worms, trojans, and other malware. The antivirus scan engine has a database of virus signatures it uses to identify infections. If the scanner finds a signature in a file, it determines that the file is infected and takes the appropriate action.

Malware threats

Malware is the general term covering all the different types of threats to your computer safety such as:

- Viruses
- Worms
- Trojan horses
- Ransomware
- Scareware
- Spyware
- Adware
- Botnets

- Phishing
- Grayware

Viruses

Viruses are self-replicating code that install copies of themselves into other programs or data files for boot sectors of storage devices. Viruses can often carry a “payload” which performs some undesirable function. These functions can include but are not limited to:

- Stealing drive space
- Stealing CPU cycles
- Accessing private information
- Corrupting data
- Digital defacement or vandalism
- Spamming contact lists

Worms

A worm is a piece of standalone computer code that replicates itself in order to spread to other computers. It normally uses a computer network to spread itself, using security vulnerabilities on the target computer or network to propagate. Unlike a virus, it does not attach itself to an existing file. Even if there is no payload, worms consume resources such as bandwidth and storage space just through their act of replication.

Trojan horses

A Trojan horse, or Trojan is malware that is defined by its delivery method. Through the use of social engineering, or some other method, the code is installed on a system by a valid user of the system and like the original Trojan horse there is something more than advertised within the software. Trojans, unlike worms or viruses are generally non-self-replicating. The most common payload of a Trojan is the setting up of a “backdoor” control mechanism to the system that it is installed on.

Ransomware

Ransomware is a type of malware that, as the name implies, hold the system ransom until payment of some kind is made. It does this by restricting access to the legitimate owner of the system either by encrypting files or locking the system. Usually, a message of some kind is displayed with the demands. Upon payment a utility or key is sent to the user to unlock the system.

Scareware

Scareware comes in two main flavours; the first tries to convince the user that his computer is infected with some non-existent malware, scaring the user into purchasing the author’s virus removal utility. The utility is nonfunctional or some additional form of malware.

The second form tries to convince the user that the computer has been or is being used for an illegal act, such as being part of a botnet or storing child pornography. Again, the objective is to scare the user into paying to cure something that is not really there.

Spyware

Spyware is used by its authors to collect information about the user and its computer without the user's knowledge. The end result can be as benign as being better able to target ads, to as criminal as key loggers designed to record account ids and passwords of bank accounts and forward them off to the authors.

Adware

Adware is not malware per se. It is merely any software that produces advertisements in order to generate revenue for its author. While a lot of people find this inconvenient or irritating, it is not malware. As such, it is not blocked by the antivirus software for being malware.

Software that has adware built into it will be blocked if it has malware in it.

Botnets

A botnet is a network of Internet connected computers that have been covertly usurped to forward transmissions to other computers on the Internet on behalf of a “master”. These transmissions can be minimally damaging, such as spam, or they can critically impact a target as when used to launch a Distributed Denial of Service attack.

Any such computer is referred to as a zombie - in effect, a computer "robot" or "bot" that serves the wishes of some master spam or virus originator. Most computers compromised in this way are home-based.

According to a report from Russian-based Kaspersky Labs, botnets -- not spam, viruses, or worms -- currently pose the biggest threat to the Internet. A report from Symantec came to a similar conclusion.

See also: Botnet protection.

Phishing

Phishing is a social engineering technique that is used to obtain sensitive and confidential information by masquerading as a communication from a trusted entity such as a well-known institution, company, or website. Usually, the malware is not in the communication itself but in the links within the communication.

Grayware

Grayware programs are unsolicited software programs installed on computers, often without the user’s consent or knowledge. Grayware programs are generally considered an annoyance, but they can also cause system performance problems or be used for malicious purposes.

Scanning Modes

FortiOS has two different modes of scanning for malware. The reasons for the different modes are performance and granularity. In just about everything relating to security there is a constant balancing act going on. As the level of security and comprehensiveness increases, there is by necessity a decrease in either convenience or performance or both. The increase in processing to scan for more threats requires more resources; resources that are a finite supply on the hardware. Granularity can sometimes be used to mitigate performance impact by scanning for a smaller subset of traffic but this is only recommended when that smaller subset of traffic is the only traffic going through the firewall.

If the traffic on the device is slight, then the impact on the performance will hardly be noticeable. But if the unit is working close to capacity in terms of traffic and there are a lot of files coming through, then there might be a noticeable decline in the performance.

While both modes offer significant security, proxy-based is weighted towards being more thorough and easily configurable, while flow-based is designed to optimize performance.

See "What's New in FortiOS 5.4" on page 2599 and Antivirus scanning differences in FortiOS 5.0, 5.2, and 5.4 in the Inspection Modes section for more details on flow vs. proxy inspection modes on your FortiGate.

AntiVirus scanning order

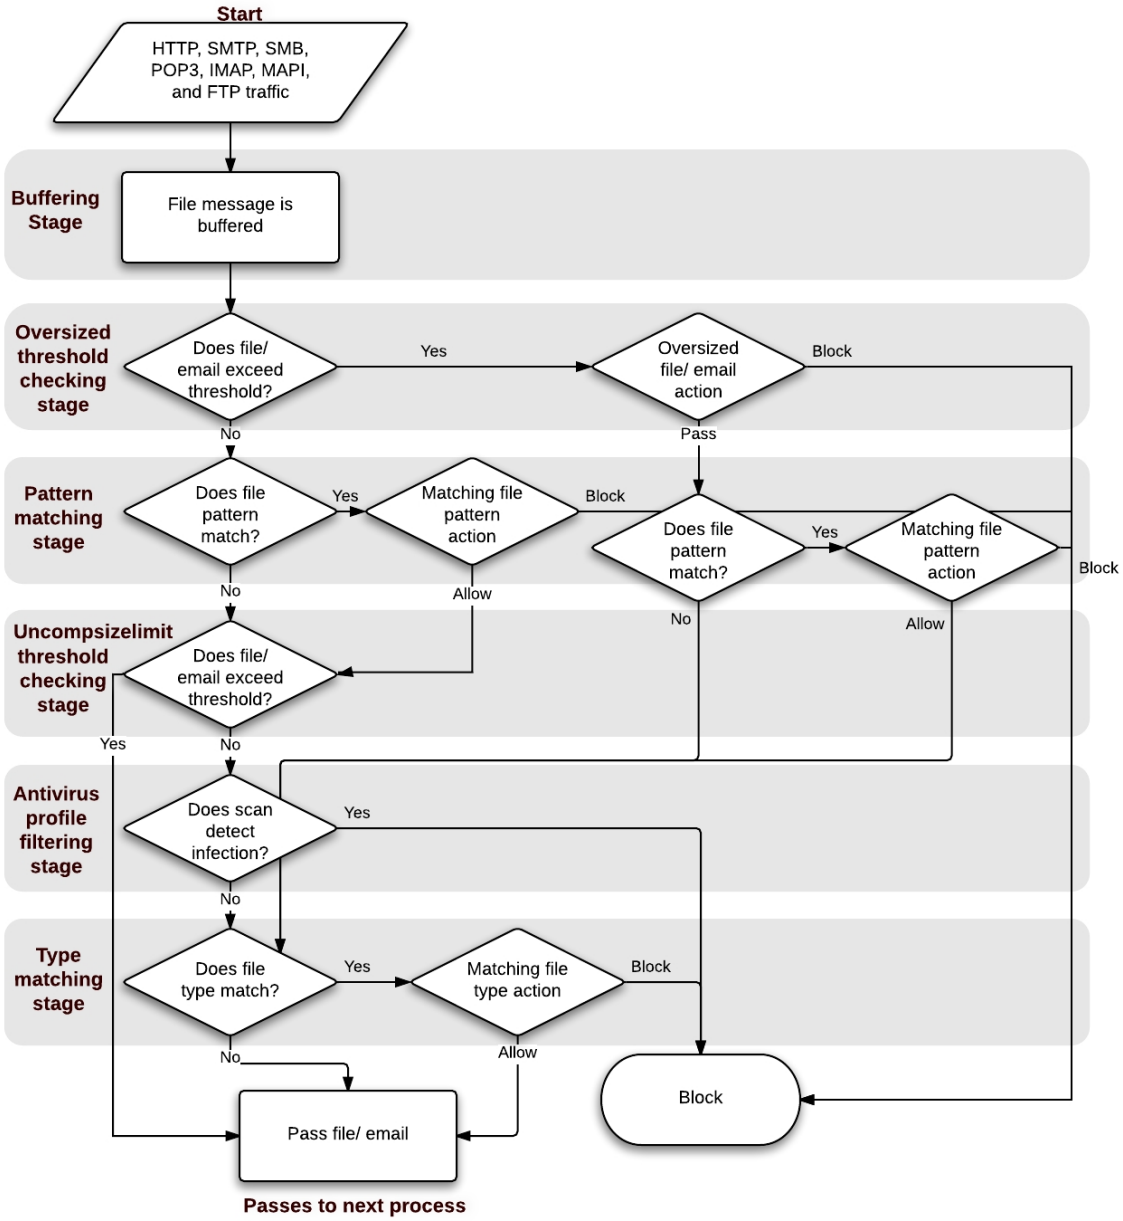
The antivirus scanning function includes various modules and engines that perform separate tasks.

Proxy-based antivirus scanning order

The following figure illustrates the antivirus scanning order when using proxy-based scanning. The first check for oversized files/email is to determine whether the file exceeds the configured size threshold. The `uncompsizelimit` check is to determine if the file can be buffered for file type and antivirus scanning. If the file is too large for the buffer, it is allowed to pass without being scanned. For more information, see the `config antivirus service` command. The antivirus scan includes scanning for viruses, as well as for grayware and heuristics, if enabled.

File filtering includes file pattern and file type scans which are applied at different stages in the antivirus process.

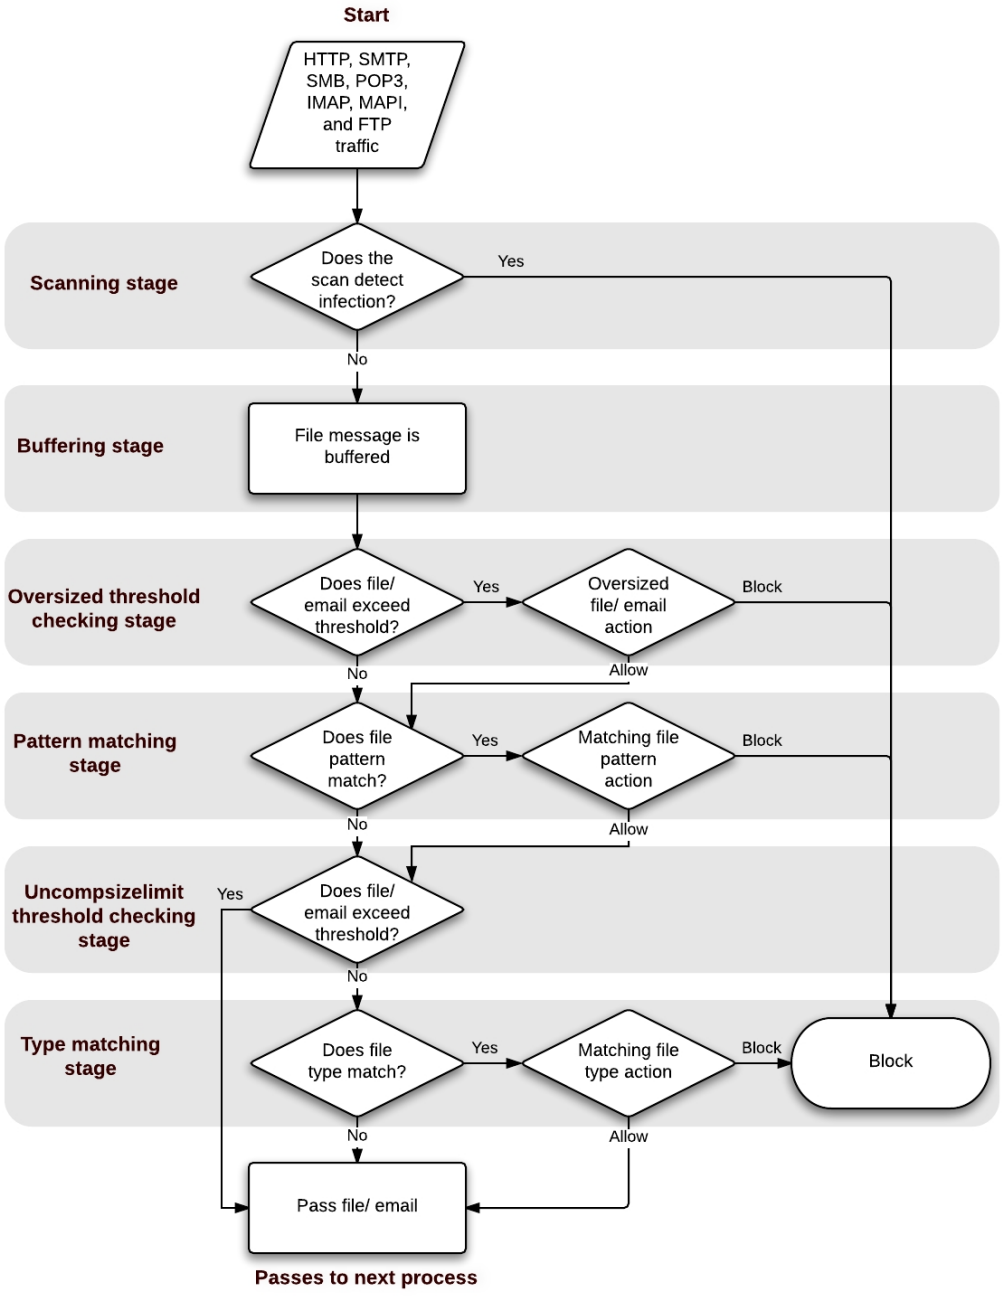
Antivirus scanning order when using the normal, extended, or extreme database



If a file fails any of the tasks of the antivirus scan, no further scans are performed. For example, if the file `fakefile.EXE` is recognized as a blocked file pattern, the FortiGate unit will send the end user a replacement message, and delete or quarantine the file. The unit will not perform virus scan, grayware, heuristics, and file type scans because the previous checks have already determined that the file is a threat and have dealt with it.

Flow-based antivirus scanning order

The following figure illustrates the antivirus scanning order when using flow-based scanning (i.e. the flow-based database). The antivirus scan takes place before any other antivirus-related scan. The antivirus scan includes scanning for viruses, as well as for grayware and heuristics if they are enabled.



AntiVirus databases

The antivirus scanning engine relies on a database of virus signatures to detail the unique attributes of each infection. The antivirus scan searches for these signatures, and when one is discovered, the FortiGate unit determines the file is infected and takes action.

All FortiGate units have the normal antivirus signature database but some models have additional databases you can select for use. Which you choose depends on your network and security needs.

Normal	Includes viruses currently spreading as determined by the FortiGuard Global Security Research Team. These viruses are the greatest threat. The Normal database is the default selection and it is available on every FortiGate unit.
Extended	Includes the normal database in addition to recent viruses that are no-longer active. These viruses may have been spreading within the last year but have since nearly or completely disappeared.
Extreme	Includes the extended database in addition to a large collection of 'zoo' viruses. These are viruses that have not spread in a long time and are largely dormant today. Some zoo viruses may rely on operating systems and hardware that are no longer widely used.

If your FortiGate unit supports extended, extreme, or flow-based virus database definitions, you can select the virus database most suited to your needs.

If you require the most comprehensive antivirus protection, enable the extended virus database. The additional coverage comes at a cost, however, because the extra processing requires additional resources.

To change the antivirus database

Use the CLI to run the following commands:

```
config antivirus settings
   set default-db extended
end
```

AntiVirus techniques

The first three antivirus features in the list below work in sequence to efficiently scan incoming files and offer your network optimal antivirus protection. The first two features have specific functions, the third, heuristics, protects against new or previously unknown virus threats.

- Virus scan
- Grayware protection
- Heuristics
- FortiGuard AntiVirus
- Botnet protection
- Quarantine / Source IP ban

To ensure that your system receives the most protection available, all virus definitions and signatures are updated regularly through the FortiGuard AntiVirus services. To configure this feature, go to **System**

> FortiGuard. Under **AntiVirus & IPS Updates**, enable **Schedule Updates**. From here you can schedule updates to occur on a consistent weekly, daily, or even hourly basis.

Updating antivirus definitions can cause a short disruption of traffic being scanned while the FortiGate unit applies the new signature database. Schedule updates for time periods when traffic is light to minimize disruption.

Virus scan

If the file passes the file pattern scan, the FortiGate unit applies a virus scan to it. The virus definitions are kept up-to-date through the FortiGuard Distribution Network (FDN).

Grayware protection

If the file passes the virus scan, it can be checked for grayware.

Grayware scanning is an optional function and must be enabled in the CLI if it is to be scanned for along with other malware. Grayware cannot be scanned for on its own. While done as a separate step, antivirus scanning must be enabled as well.

To enable grayware detection enter the following in the CLI:

```
config antivirus settings
   set grayware enable
end
```

To disable grayware detection enter the following in the CLI:

```
config antivirus settings
   set grayware disable
end
```

Grayware signatures are kept up to date in the same manner as the antivirus definitions.

Heuristics

After an incoming file has passed the grayware scan, it is subjected to the heuristics scan. The FortiGate heuristic antivirus engine, if enabled, performs tests on the file to detect virus-like behavior or known virus indicators. In this way, heuristic scanning may detect new viruses, but may also produce some false positive results. You configure heuristics from the CLI.

To set heuristics, enter the following in the CLI:

```
config antivirus heuristic
   set mode {pass |block |disable}
end
```

- "`block`" enables heuristics and any files determined to be malware are blocked from entering the network.
- "`pass`" enables heuristics but any files determined to be malware are still allowed to pass through to the recipient.
- "`disable`" turns off heuristics.

FortiGuard Antivirus

The FortiGuard Antivirus services are included in the regular FortiGuard subscription and include automatic updates of antivirus engines and definitions as well as a DNS black list (DNSBL) through the FortiGuard Distribution Network (FDN).

Current information about your subscription and version numbers can be found at **System > FortiGuard.** This page will also allow the configuration of connections to the FortiGuard Center and how often to check for updates to the antivirus files.

Updating antivirus definitions can cause a short disruption of traffic being scanned while the FortiGate unit applies the new signature database. Schedule updates for time periods when traffic is light to minimize disruption.

FortiGuard Botnet protection

Preventing botnets from controlling your system is achieved by detecting and blocking connection attempts to known botnets. This feature also blocks connections to known phishing sites. The FortiGuard database is continually updated with addresses of known Command and Control (C&C) sites that botnet clients attempt to connect to, as well as a addresses of known phishing URLs.

To enable botnet and phishing protection in a DNS Filter profile, enable **Block DNS requests to known botnet C&C**.

The latest botnet database is available from FortiGuard. To see the version of the database and display its contents, go to **System > FortiGuard > Botnet Definitions**. You can also block, monitor, or allow outgoing connections to botnet sites for each FortiGate interface.

Both the DNS Filter security profile and Botnet protection feature are only available for proxy-based inspection in FortiOS versions 5.4.0 and 5.4.1.
These features are available for both proxy-based and flow-based inspection in FortiOS versions 5.4.2 and above.

Improved Visibility of Botnet and Command & Control (C&C) protection in FortiOS 5.4.1

Mobile & Botnet C&C license information is now displayed in the License Information widget in the Dashboard. Additionally, you can view the list of Botnet C&C packages in the IP Reputation Database (IRDB) and the Botnet Domain Database (BDDB) from the License Information widget.

A button has been added to the GUI on the DNS filter page allowing you to block DNS requests known to FortiGuard. When you enable this feature, you can open a definitions window by clicking on "botnet package."

Access to the IRDB is available to users through FortiCare support contracts purchased or renewed before October 1, 2016. After that date, users will have to subscribe to the IRDB either through the FortiGuard Mobility Security Service (FMSS) or the FortiGuard Enterprise Bundle.

Quarantine / Source IP ban

As of FortiOS 5.2, quarantine was a place where traffic content was held in storage where it couldn't interact with the network or system. This was removed, but the term quarantine was kept to describe keeping selected source IPs from interacting with the network and protected systems. This source IP ban is kept in the kernel rather than in any specific application engine and can be queried by APIs. The features that can use the APIs to access and use the banned source IP addresses are antivirus, DLP, DoS and IPS. Both IPv4 and IPv6 version are included in this feature.

GUI Changes

As of FortiOS 5.4.1, you quarantine a source address through the GUI. Go to **FortiView > Sources**. Right-click on the source address you wish to quarantine and select **Quarantine Source Address**. You can set the duration of the quarantine in days, hours, minutes, or seconds. A User Quarantine ban can be removed in **Monitor > User Quarantine Monitor**.

CLI Syntax

To configure the AntiVirus security profile to add the source IP address of an infected file to the quarantine or list of banned source IP addresses in the CLI:

```
config antivirus profile
   edit <name of profile>
      config nac-quar
         set infected quar-src-ip
         set expiry 5m
      end
```

If the `quar-src-ip` action is used, the additional variable of expiry time will become available. This variable determines for how long the source IP adddress will be blocked. In the CLI the option is called `expiry` and the duration is in the format `<###d##h##m>`. The maximum days value is 364. The maximum hour value is 23 and the maximum minute value is 59. The default is 5 minutes.

FortiSandbox

Not every piece of malware has a signature. This is especially true of new malware and variations on existing malware. FortiOS can upload suspicious files to FortiSandbox for sandbox inspection. When a FortiGate uses sandbox inspection, files are sent to the FortiSandbox. Then the FortiSandbox uses virtual machines (VMs) running different operating systems to test the file, to determine if it is malicious. If the file exhibits risky behavior, or is found to contain a virus, a new signature can be added to both the local FortiGate malware database and the FortiGuard AntiVirus signature database.

A file is deemed suspicious when it does not contain a known threat but has characteristics that suggest it may be malware. The characteristics that determine if a file is suspicious are updated by Fortinet to reflect the current threat climate.

FortiSandbox is available as a physical or virtual appliance (FortiSandbox Appliance), or as a cloud advanced threat protection service integrated with FortiGate (FortiCloud).

To configure an AntiVirus profile to send files to FortiSandbox, first verify that your FortiSandbox appliance is configured or that your FortiCloud account is active. Then go to **Security Profiles > AntiVirus** and enter the desired **Inspection Options**.

Sending files to the FortiSandbox appliance or to FortiCloud does not block files immediately. Instead, the files assist in the discovery of new threats and the creation of new signatures to be added to the global FortiGuard AntiVirus database. Files deemed malicious are also immediately added to a custom Malware Package which is sent to the FortiGate every two minutes for live remediation.

The Advanced Threat Protection dashboard widget shows the number of files that your FortiGate unit has uploaded or submitted to FortiSandbox. To see more information regarding the version of the database and display its contents, go to **System > Cooperative Security Fabric**.

Client Comforting

When proxy-based antivirus scanning is enabled, the FortiGate unit buffers files as they are downloaded. Once the entire file is captured, the FortiGate unit scans it. If no infection is found, the file is sent along to the client. The client initiates the file transfer and nothing happens until the FortiGate finds the file clean, and releases it. Users can be impatient, and if the file is large or the download slow, they may cancel the download, not realizing that the transfer is in progress.

The client comforting feature solves this problem by allowing a trickle of data to flow to the client so they can see the file is being transferred. The default client comforting transfer rate sends one byte of data to the client every ten seconds. This slow transfer continues while the FortiGate unit buffers the file and scans it. If the file is infection-free, it is released and the client will receive the remainder of the transfer at full speed. If the file is infected, the FortiGate unit caches the URL and drops the connection. The client does not receive any notification of what happened because the download to the client had already started. Instead, the download stops and the user is left with a partially downloaded file.

If the user tries to download the same file again within a short period of time, the cached URL is matched and the download is blocked. The client receives the Infection cache message replacement message as a notification that the download has been blocked. The number of URLs in the cache is limited by the size of the cache.

Client comforting can send unscanned and therefore potentially infected content to the client. You should only enable client comforting if you are prepared to accept this risk. Keeping the client comforting interval high and the amount low will reduce the amount of potentially infected data that is downloaded.

Client comforting is available for HTTP and FTP traffic. If your FortiGate unit supports SSL content scanning and inspection, you can also configure client comforting for HTTPS and FTPS traffic.

Enable and configure client comforting

1. Go to **Security Profiles > Proxy Options**.
2. Select a Proxy Options profile and choose **Edit**, or select **Create New** to make a new one.
3. Scroll down to the **Common Options** section and check the box next to **Comfort Clients**. This will set the option on all of the applicable protocols. The ability to set this feature on a protocol by protocol basis exists in the CLI
4. Select **OK or Apply** to save the changes.
5. Select this Proxy Options profile in any security policy for it to take effect on all traffic handled by the policy.

The default values for Interval and Amount are 10 and 1, respectively. This means that when client comforting takes effect, 1 byte of the file is sent to the client every 10 seconds. You can change these values to vary the amount and frequency of the data transferred by client comforting.

Oversized files and emails

Downloaded files can range from a few Kilobytes to multiple Gigabytes. A FortiGate doesn't have the memory to allow for a large number of people downloading large files. Imagine the memory required for a team of developers to all download the latest Linux OS distribution at once, in addition to the normal requirements of the firewall. Everything would come to a grinding halt if the FortiGate tried to store each of those Gigabyte+ files in memory. To give you some piece of mind, the chances of malware being in a large file like those is much smaller than in a smaller single Megabyte file, so the threat is somewhat limited, but you will probably want to use your computers antivirus software to scan those large files after they have been downloaded.

A threshold must be set to prevent the resources of the system from becoming overloaded. By default the threshold is 10 MB. Any files larger than the threshold will not be scanned for malware. With a maximum file size threshold in place, it must now be determined what is to be done with the files that are larger than threshold. There are only 2 choices; either the file is passed through without being scanned for malware or the file is blocked. The default action for oversized files is to pass them through.

If you wish to block the downloading of files over the threshold, this can be set within the Proxy Option profile found at **Security Profiles > Proxy Options**, under **Common Options**.

Check **Block Oversized File/Email**.

This will reveal an additional option, **Threshold (MB)**. The threshold of the files is set based upon the protocol being used to transfer the file. In the CLI and configuration file, the threshold variable is found in each of the protocol sections within the profile. Changing the value in this field will change the `oversize-limit` value for all of the protocols.

If you wish to change the oversize-limit value on all of the protocols covered in a Proxy Option profile you have two options.

1. You can go into the CLI and change the value manually within each of the protocol sections.
2. You can use the GUI to temporarily block oversized files, and when configuring it change the threshold to the new value that you want. Apply this setting. Then go back to the profile and turn off the block setting. If you now go into the CLI you will find that the configuration file has retained the new oversize-limit value.

The settings can be found in the CLI by going to:

```
config firewall profile-protocol-options
   edit <the name of the profile>
```

Archive scan depth

The antivirus scanner will open archives and scan the files inside. Archives within other archives, or nested archives, are also scanned to a default depth of twelve nestings. You can adjust the number of nested archives the FortiGate unit will scan with the `uncompressed-nest-limit` CLI command. Further, the limit is configured separately for each traffic type.

Configuring archive scan depth

For example, this CLI command sets the archive scan depth for SMTP traffic to 5. That is, archives within archives will be scanned five levels deep.

config firewall profile-protocol-options

```
edit "default"
   config http
      set uncompressed-nest-limit 5
   end
```

You can set the nesting limit from 2 to 100.

Scan buffer size

When checking files for viruses, there is a maximum file size that can be buffered. Files larger than this size are passed without scanning. The default size for all FortiGate models is 10 megabytes.

Archived files are extracted and email attachments are decoded before the FortiGate unit determines if they can fit in the scan buffer. For example, a 7 megabyte ZIP file containing a 12 megabyte EXE file will be passed without scanning with the default buffer size. Although the archive would fit within the buffer, the uncompressed file size will not.

Configuring the uncompression buffer

In this example, the `uncompressed-oversize-limit` CLI command is used to change the scan buffer size to 20 megabytes for files found in HTTP traffic:

config firewall profile-protocol-options

```
edit "default"
   config http
      set uncompressed-oversize-limit 20
   end
```

The maximum buffer size varies by model. Enter `set uncompressed-oversize-limit ?` to display the buffer size range for your FortiGate unit.

Windows file sharing (CIFS)

FortiOS supports virus scanning of Windows file sharing traffic. This includes CIFS, SMB, and SAMBA traffic. This feature is applied by enabling SMB scanning in an antivirus profile and then adding this profile to a security policy that accepts CIFS traffic. CIFS virus scanning is available only through flow-based antivirus scanning.

FortiOS flow-based virus scanning can detect the same number of viruses in CIFS/SMB/SAMBA traffic as it can for all supported content protocols.

Note the following about CIFS/SMB/SAMBA virus scanning:

- Some newer version of SAMBA clients and SMB2 can spread one file across multiple sessions, preventing some viruses from being detected if this occurs.
- Enabling CIFS/SMB/SAMBA virus scanning can affect FortiGate performance.
- SMB2 is a new version of SMB that was first partially implemented in Windows Vista.
- Currently SMB2 is supported by Windows Vista or later, and partly supported by Samba 3.5 and fully support by Samba 3.6.
- The latest version of SMB2.2 will be introduced with Windows 8.
- Most clients still use SMB as default setting.

Configuring CIFS/SMB/SAMBA virus scanning

Use the following command to enable CIFS/SMB/SAMBA virus scanning in an antivirus profile:

```
config antivirus profile
   edit <smb-profile>
      config smb
         set options scan
      end
```

Then add this antivirus profile to a security policy that accepts the traffic to be virus scanned. In the security policy the service can be set to ANY, SAMBA, or SMB.

```
config firewall policy
   edit 0
      set service ANY
      ...
      set utm-status enable
      set av-profile <smb-profile>
   end
```

Enabling AntiVirus scanning

Antivirus scanning is configured in an AntiVirus profile, but it is enabled in a firewall policy. Once the use of an AntiVirus profile is enabled and selected in one or more firewall policies, all the traffic controlled by those firewall policies will be scanned according to the settings in that profile.

By going to **System > Feature Select,** you can enable or disable 2 aspects of the AntiVirus Profile.

1. Antivirus will determine if the option to use AntiVirus profiles is available.
2. Multiple Security Profiles will determine if you can configure any AntiVirus profiles beyond the default profile.

The **Feature Select** section can sometimes be misunderstood as to its actual effect. The enabling or disabling of a feature in this section refers to its visibility within the GUI, not whether or not the feature's functionality will work. If you were to disable the AntiVirus Profile feature it would disappear from the GUI but not the CLI and configuration file. Since the functionality of the FortiGate unit is based on the contents of the config file any profile referred to by the policy in the configuration will be acted upon. The **Feature Select** section is primarily for keeping the GUI clean and uncluttered by features that are not being used by the administrators.

As the use of antivirus these days is practically a minimum standard for security protection the question left to decide is whether or not you wish to use multiple profiles in your configuration.

AntiVirus profiles

From **Security Profiles > AntiVirus** you can edit existing profiles or create and configure new antivirus profiles that can then be applied to firewall policies. A profile is specific configuration information that defines how the traffic within a firewall policy is examined and what action may be taken based on the examination.

You can create multiple antivirus profiles for different antivirus scanning requirements. For example, you create an antivirus profile that specifies only virus scanning for POP3 which you then apply to the outgoing firewall policy that is designed for users getting their email from the mail server. You can also choose specific protocols, such as HTTP, that will be scanned and if blocked, archived by the unit. This option is available only in the CLI.

Whether the mode of the antivirus detection is proxy-based or flow-based is also set within the profile.

Enabling AntiVirus - GUI

1. Go to **Security Profiles > AntiVirus**.
2. Choose whether you want to edit an existing profile or create a new one.
   - The default profile will be the one displayed by default.
   - If you are going to edit an existing profile, selecting it can be done by either using the drop down menu in the upper right hand corner of the window or by selecting the List icon (the furthest right of the 3 icons in the upper right of the window, if resembles a page with some lines on it), and then selecting the profile you want to edit from the list.

- If you need to create a new profile you can either select the **Create New** icon (a plus sign within a circle) or select the **List icon** and then select the **Create New** link in the upper left of the window that appears.

3. If you are creating a new profile, write a name for it in the **Name** field.
4. For the **Detect Viruses** field, select either **Block** to prevent infected files from passing throughout the FortiGate or **Monitor** to allow infected files to pass through the FortiGate but to record instances of infection.
5. Under **Inspected Protocols**, enable the protocols you wish to be blocked or monitored.
6. Under **Inspection Options**, you may enable the following: **Treat Windows Executables in Email Attachments as Viruses** and **Include Mobile Malware Protection**.

You may also enable the following options if you have a FortiCloud account active on your FortiGate: **Send Files to FortiSandbox Cloud for Inspection** and **Use FortiSandbox Database**.

Furthermore, files can only be sent to FortiSandbox for inspection while in **Full** mode Flow-based virus scanning.

7. Select **OK**.
8. Add the AntiVirus profile to a firewall security policy.

To view Mobile Malware license and version information, go to **System > FortiGuard**. In the **License Information** table, under the **AntiVirus** heading, find **Mobile Malware Definitions**.

Enabling AntiVirus - CLI

You need to configure the scan option for each type of traffic you want scanned.

1. Configure the AntiVirus profile

```
config antivirus profile
   edit "default"
      set comment "scan and delete virus"
      set replacemsg-group ''
      set scan-botnet-connections block
      set ftgd-analytics suspicious
      config http
         set options scan
         end
      config ftp
         set options scan
         end
      config imap
         set options scan
         end
      config pop3
         set options scan
         end
      config smtp
         set options scan
         end
      config nntp
         set options scan
         end
      config smb
```

```
        set options scan
        end
    end
```

2. Add the AntiVirus profile to the Fortigate firewall security policy. When using the CLI, you will need to know the policy ID number.

```
config firewall policy
   edit <policy ID number>
      set av-profile default
      set profile-protocol-options default
      end
```

Testing your antivirus configuration

You have configured your FortiGate unit to stop viruses, but you'd like to confirm your settings are correct. Even if you have a real virus, it would be dangerous to use for this purpose. An incorrect configuration will allow the virus to infect your network.

To solve this problem, the European Institute of Computer Anti-virus Research has developed a test file that allows you to test your antivirus configuration. The EICAR test file is not a virus. It cannot infect computers, nor can it spread or cause any damage. It's a very small file that contains a sequence of characters. Your FortiGate unit recognizes the EICAR test file as a virus so you can safely test your FortiGate unit antivirus configuration.

Go to http://www.fortiguard.com/antivirus/eicartest.html to download the test file (eicar.com) or the test file in a ZIP archive (eicar.zip).

If the antivirus profile applied to the security policy that allows you access to the Web is configured to scan HTTP traffic for viruses, any attempt to download the test file will be blocked. This indicates that you are protected.

Example scenarios

The following examples provide a sample antivirus configuration scenarios.

Configuring simple default AntiVirus profile

The Antivirus function is so straightforward and widely used that many users just create one default profile and use that on all of the applicable firewall policies. If performance is not a real concern and the unit's resources are not being stretched, it is perfectly reasonable to create one profile that covers the range of uses found in your environment. This example is one possible default configuration.

Context:

- This is an edited default profile and will be used on all security policies
- It will need to scan for malware on all available protocols.
- Malware, botnets, and grayware should be blocked
- The inspection method should be flow-based
- A current FortiCloud account is available

Creating the profile - GUI

1. In the following fields, enter the indicated values or selections:

Name	default
Comments	Scans all traffic from Internet for malware
Inspection Mode	Flow-based
Detect Virus	Block
Send Files to FortiSandbox for Inspection	checked
• **Suspicious Files Only**	checked (not applicable in FortiOS 5.4.1 and later)
Detect Connections to Botnet C&C Servers	checked
• **Block**	checked

2. Check the appropriate protocols:

Inspected Protocols	Virus Scan and Block
HTTP	checked
SMTP	checked
POP3	checked
IMAP	checked
MAPI	checked
FTP	checked
NNTP	checked

3. Select **Apply**.
4. Enable grayware scanning

```
config antivirus settings
   set grayware enable
   end
```

Creating the profile - CLI

1. Enter the CLI by one of the following methods:
   - SSH through a terminal emulator
   - CLI Console widget
   - FortiExplorer's CLI mode
2. Enter the following commands:

```
config antivirus profile
   edit default
      set comment "scan and delete virus"
      set inspection-mode flow-based
      set scan-botnet-connections block
```

```
set ftgd-analytics suspicious
config http
   set options scan
   end
config ftp
   set options scan
   end
config imap
   set options scan
   end
config pop3
   set options scan
   end
config smtp
   set options scan
   end
config nntp
   set options scan
   end
config smb
   set options scan
   end
end
```

3. Enable grayware scanning

```
config antivirus settings
   set grayware enable
   end
```

Setting up a basic proxy-based AntiVirus profile for email traffic

Small offices, whether they are small companies, home offices, or satellite offices, often have very simple needs. This example details how to enable antivirus protection on a FortiGate unit located in a satellite office.

Context:

- The satellite office does not have an internal email server. To send and retrieve email, the employees connect to an external mail server.
- There is a specific firewall security profile that handles the email traffic from the Internet to the mail server. The only traffic on this policy will be POP3 and IMAP and SMTP
- The company policy is to block viruses and connections to botnets.
- The FortiGate unit is a small model and the Internet bandwidth is limited so the policy is to not submit files to the FortiSandbox.

Creating the profile - GUI

1. In the following fields, enter the indicated values or selections:

Name	email-av
Comments	Scans email traffic from Internet for malware
Inspection Mode	Proxy

Detect Virus	Block
Send Files to FortiSandbox for Inspection	checked
• **Suspicious Files Only**	checked
Detect Connections to Botnet C&C Servers	checked
• **Block**	checked

2. Check the appropriate protocols:

Inspected Protocols	Virus Scan and Block
HTTP	checked
SMTP	checked
POP3	checked
IMAP	checked
MAPI	checked
FTP	checked
NNTP	checked

3. Select **Apply**.

Creating the profile - CLI

1. Enter the CLI by one of the following methods:
   - SSH through a terminal emulator
   - CLI Console widget
   - FortiExplorer's CLI mode
2. Enter the following commands:

```
Config antivirus profile
   edit "email-av"
      set comment "Scans email traffic from Internet for malware"
      set inspection-mode proxy
      config imap
         set options scan
         end
      config pop3
         set options scan
         end
      config smtp
         set options scan
         end
      end
```

Adding the profile to a policy

In this scenario the following assumptions will be made:

- The policy that the profile is going to be added to is an IPv4 policy.
- The ID number of the policy is 11.
- The AntiVirus profile being added will be the "default" profile
- The SSL/SSH Inspection profile used will be the "default" profile

FortiClient enforcement has been moved from the Policy page to **Network > Interfaces** to enforce FortiClient registration on a desired LAN interface rather than a policy.

Adding the profile - GUI

1. Go to **Policy & Objects > IPv4 Policy**.
2. Use your preferred method of finding a policy.
   - If the ID column is available you can use that.
   - You can also choose based on your knowledge of the parameters of the policy
   - Select the policy with ID value of 11
3. In the Edit Policy window, go to the Security Profiles section
4. Turn ON AntiVirus, and in the drop down menu for the field, select default
5. If the AntiVirus profile is proxy-based the Proxy Options field and drop down menu will be revealed.
6. The SSL/SSH Inspection field will automatically be set to ON and one of the profiles will need to be selected from the drop down menu. In this case default is selected.
7. The log options will depend on your requirements and resources but to verify that everything is working properly, it is a good idea to turn ON logging of All Sessions after setting up a new profile and after giving some time for logs to accumulate
8. Turn on Antivirus.
9. Select an antivirus profile.
10. Select **OK** to save the security policy.

Adding the profile - CLI

To select the antivirus profile in a security policy — CLI

```
config firewall policy
   edit 11
      set utm-status enable
      set profile-protocol-options default
      set av-profile basic_antivirus
   end
```

Block files larger than 8 MB

Set proxy options profile to block files larger than 8 MB

1. Go to **Security Profiles > Proxy Options**.
2. Edit the default or select Create New to add a new one.

3. Scroll down to the common Options Section and place a check in the box next to BlockOversized File/Email
4. The sub line Threshold (MB) will appear with a value field. Enter 8.
5. Select **OK** or **Apply**.

The proxy options profile is configured, but to block files, you must select it in the firewall policies handling the traffic that contains the files you want blocked.

To select the Proxy Options profile in a security policy

1. Go to **Policy & Objects > IPv4 Policy** (or **IPv6 Policy**, depending).
2. Edit or create a security policy.
3. Select a proxy-based security profile. You will know that there is a proxy component to the Security Profile because when a Security Profile is Proxy based the Proxy Options field will be visible (for example, select an Antivirus profile that includes proxy scanning).
4. Beside Proxy Options select the name of the MTU proxy options protocol.
5. Select **OK** to save the security policy.
6. Once you complete these steps, any files in the traffic subject to Security Profile scanning handled by this policy that are larger than 8MB will be blocked. If you have multiple firewall policies, examine each to determine if you want to apply similar file blocking the them as well.

Web filter

This section describes FortiGate web filtering for HTTP traffic. The three main parts of the web filtering function, the Web Content Filter, the URL Filter, and the FortiGuard Web Filtering Service interact with each other to provide maximum control over what users on your network can view as well as protection to your network from many Internet content threats. Web Content Filter blocks web pages containing words or patterns that you specify. URL filtering uses URLs and URL patterns to block or exempt web pages from specific sources. FortiGuard Web Filtering provides many additional categories you can use to filter web traffic.

This Handbook chapter includes Inside FortiOS: Web Filtering and provides readers an overview of the features and benefits of key FortiOS 5.4 components.

For readers needing to delve into greater detail, we provide the following topics:

- Web filter concepts
- Inspection Modes
- FortiGuard Web Filtering Service
- Overriding FortiGuard website categorization
- SafeSearch
- YouTube Education filter
- Static URL filter
- Web content filter
- Advanced web filter configurations
- Configuring Web Filter Profiles
- Web filtering example

Web filter concepts

Web filtering is a means of controlling the content that an Internet user is able to view. With the popularity of web applications, the need to monitor and control web access is becoming a key component of secure content management systems that employ antivirus, web filtering, and messaging security. Important reasons for controlling web content include:

- lost productivity because employees are accessing the web for non-business reasons
- network congestion — when valuable bandwidth is used for non-business purposes, legitimate business applications suffer
- loss or exposure of confidential information through chat sites, non-approved email systems, instant messaging, and peer-to-peer file sharing
- increased exposure to web-based threats as employees surf non-business-related web sites
- legal liability when employees access/download inappropriate and offensive material
- copyright infringement caused by employees downloading and/or distributing copyrighted material.

As the number and severity of threats increase on the World Wide Web, the risk potential increases within a company's network as well. Casual non-business related web surfing has caused many businesses countless hours of legal litigation as hostile environments have been created by employees who download and view offensive content. Web-based attacks and threats are also becoming increasingly sophisticated. Threats and web-based applications that cause additional problems for corporations include:

- spyware/grayware
- phishing
- pharming
- instant messaging
- peer-to-peer file sharing
- streaming media
- blended network attacks.

Spyware, also known as grayware, is a type of computer program that attaches itself to a user's operating system. It does this without the user's consent or knowledge. It usually ends up on a computer because of something the user does such as clicking on a button in a pop-up window. Spyware can track the user's Internet usage, cause unwanted pop-up windows, and even direct the user to a host web site. For further information, visit the FortiGuard Center.

Some of the most common types of grayware infection occur when:

- downloading shareware, freeware, or other forms of file-sharing services
- clicking on pop-up advertising
- visiting legitimate web sites infected with grayware.

Phishing is the term used to describe attacks that use web technology to trick users into revealing personal or financial information. Phishing attacks use web sites and email that claim to be from legitimate financial institutions to trick the viewer into believing that they are legitimate. Although phishing is initiated by spam email, getting the user to access the attacker's web site is always the next step.

Pharming is a next generation threat that is designed to identify and extract financial, and other key pieces of information for identity theft. Pharming is much more dangerous than phishing because it is designed to be completely hidden from the end user. Unlike phishing attacks that send out spam email requiring the user to click to a fraudulent URL, pharming attacks require no action from the user outside of their regular web surfing activities. Pharming attacks succeed by redirecting users from legitimate web sites to similar fraudulent web sites that have been created to look and feel like the authentic web site.

Instant messaging presents a number of problems. Instant messaging can be used to infect computers with spyware and viruses. Phishing attacks can be made using instant messaging. There is also a danger that employees may use instant messaging to release sensitive information to an outsider.

Peer-to-peer (P2P) networks are used for file sharing. Such files may contain viruses. Peer-to-peer applications take up valuable network resources and may lower employee productivity but also have legal implications with the downloading of copyrighted or sensitive company material.

Streaming media is a method of delivering multimedia, usually in the form of audio or video to Internet users. Viewing streaming media impacts legitimate business by using valuable bandwidth.

Blended network threats are rising and the sophistication of network threats is increasing with each new attack. Attackers learn from each successful attack and enhance and update their attack code to become more dangerous and to spread faster. Blended attacks use a combination of methods to spread and cause damage. Using virus or network worm techniques combined with known system vulnerabilities, blended threats can quickly spread through email, web sites, and Trojan applications. Examples of blended threats include Nimda, Code Red, Slammer, and Blaster. Blended attacks can be designed to perform different types of attacks, which include disrupting network services, destroying or stealing information, and installing stealthy backdoor applications to grant remote access.

Different ways of controlling access

The methods available for monitoring and controlling Internet access range from manual and educational methods to fully automated systems designed to scan, inspect, rate and control web activity.

Common web access control mechanisms include:

- establishing and implementing a well-written usage policy in the organization on proper Internet, email, and computer conduct
- installing monitoring tools that record and report on Internet usage
- implementing policy-based tools that capture, rate, and block URLs.

The final method is the focus of this topic. The following information shows how the filters interact and how to use them to your advantage.

Order of web filtering

The FortiGate unit applies web filters in a specific order:

1. URL filter
2. FortiGuard Web Filter
3. web content filter
4. web script filter
5. antivirus scanning.

If you have blocked a FortiGuard Web Filter category but want certain users to have access to URLs within that pattern, you can use the **Override** within the FortiGuard Web Filter. This will allow you to specify which users have access to which blocked URLs and how long they have that access. For example, if you want a user to be able to access www.example.com for one hour, you can use the override to set up the exemption. Any user listed in an override must fill out an online authentication form that is presented when they try to access a blocked URL before the FortiGate unit will grant access to it.

If you have blocked a FortiGuard Web Filter category but want users within a specific Web Filtwer profile to have access to URLs within that pattern, you can use the following CLI command below to override (this will have no timeout affiliated to it):

CLI Syntax:

```
config webfilter profile
   edit <profile>
      config web
      set whitelist exempt-av exempt-dlp exempt-rangeblock extended-log-others
      end
end
```

This command will set a Web Filter profile that exempts AV, DLP, RangeBlock, and supports extended log by FortiGuard whitelist.

Inspection Modes

This topic briefly discusses proxy and flow-based inspection modes. For more information on flow vs. proxy inspection modes on your FortiGate and how they impact web filtering, see Individual Security Profile considerations in the Inspection Modes section.

Proxy

Proxy-based inspection involves buffering traffic and examining it as a whole before determining an action. The process of having the whole of the data to analyze allows for the examination of more points of data than the flow-based or DNS methods.

The advantage of a proxy-based method is that the inspection can be more thorough than the other methods, yielding fewer false positive or negative results in the data analysis.

Flow-based

The flow-based inspection method examines the file as it passes through the FortiGate unit without any buffering. As each packet of the traffic arrives it is processed and forwarded without waiting for the complete file or web page.

The advantage of the flow-based method is that the user sees a faster response time for HTTP requests and there is less chance of a time-out error due to the server at the other end responding slowly.

The disadvantages of this method are: (1) there is a higher probability of a false positive or negative in the analysis of the data; and, (2) a number of security features that can be used in the proxy-based method are not available in the flow-based inspection method. There are also fewer actions available based on the categorization of the website by FortiGuard services.

See "What's New in FortiOS 5.4" on page 2599 and Individual Security Profile Considerations in the Inspection Modes section for more details on flow vs. proxy inspection modes on your FortiGate.

FortiGuard Web Filtering Service

FortiGuard Web Filtering is a managed web filtering solution available by subscription from Fortinet. Before you begin to use the FortiGuard Web Filtering options, verify that you have a valid subscription to the service for your FortiGate firewall.

FortiGuard Web Filtering enhances the web filtering features supplied with your FortiGate unit by sorting billions of web pages into a wide range of categories users can allow or block. The FortiGate unit accesses the nearest FortiGuard Web Filtering Service Point to determine the category of a requested web page, and then applies the security policy configured for that user or interface. FortiGuard Web Filtering service supports detection for traffic using HTTP protocol (versions 1.0, 1.1 and 2.0).

FortiGuard Web Filtering includes over 45 million individual ratings of web sites that apply to more than two billion pages. Pages are sorted and rated into several dozen categories administrators can allow or block. Categories may be added or updated as the Internet evolves. To make configuration simpler, you can also choose to allow or block entire groups of categories. Blocked pages are replaced with a message indicating that the page is not accessible according to the Internet usage policy.

FortiGuard Web Filtering ratings are performed by a combination of proprietary methods including text analysis, exploitation of the web structure, and human raters. Users can notify the FortiGuard Web Filtering Service Points if they feel a web page is not categorized correctly, so that the service can update the categories in a timely fashion.

FortiGuard Web Filtering and your FortiGate unit

When FortiGuard Web Filtering is enabled in a web filter or a DNS filter profile, the setting is applied to all firewall policies that use this profile. When a request for a web page appears in traffic controlled by one of these firewall policies, the URL is sent to the nearest FortiGuard server. The URL category is returned. If the category is blocked, the FortiGate unit provides a replacement message in place of the requested page. If the category is not blocked, the page request is sent to the requested URL as normal.

FortiGuard Web Filtering Actions

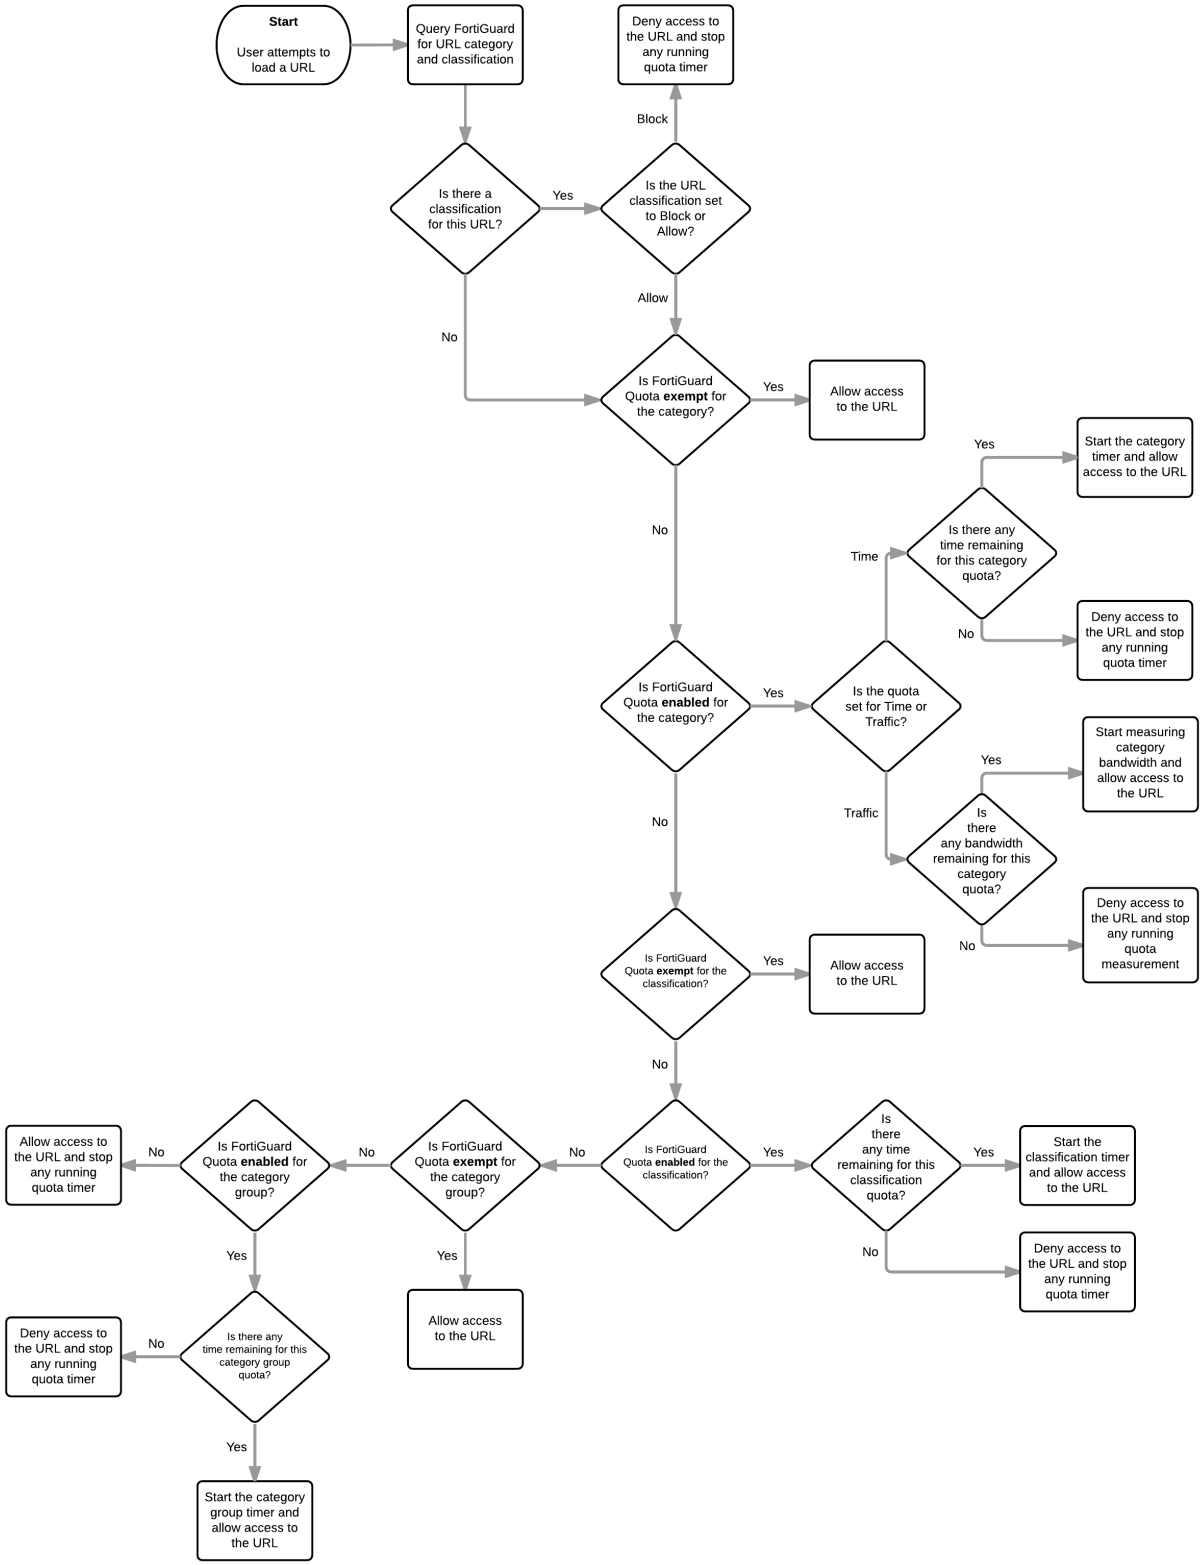
The possible actions are:

- **Allow** permits access to the sites within the category.
- **Block** prevents access to sites within the category. Users attempting to access a blocked site will receive a replacement message explaining that access to the site is blocked.
- **Monitor** permits and logs access to sites in the category. You may also enable user quotas when enabling the monitor action.
- **Warning** presents the user with a message, allowing them to continue if they choose.
- **Authenticate** requires a user to authenticate with the FortiGate unit before being allowed access to the category or category group.

The options of actions available will depend on the mode of inspection.

- Proxy - Allow, Block, Monitor, Warning, Authenticate and Disable.
- Flow-based - Allow, Block & Monitor.

Web Filtering flowchart



FortiGuard Web Filtering categories

The following tables identify each FortiGuard web filtering category (organized by group) along with associated category IDs. For a complete description of each web filtering category, visit http://www.fortiguard.com/webfilter.

Potentially Liable

ID	Category
1	Drug Abuse
3	Hacking
4	Illegal or Unethical
5	Discrimination
6	Explicit Violence

ID	Category
12	Extremist Groups
59	Proxy Avoidance
62	Plagiarism
83	Child Abuse

Adult/Mature Content

ID	Category
2	Alternative Beliefs
7	Abortion
8	Other Adult Materials
9	Advocacy Organizations
11	Gambling
13	Nudity and Risque
14	Pornography
15	Dating

ID	Category
16	Weapons (Sales)
57	Marijuana
63	Sex Education
64	Alcohol
65	Tobacco
66	Lingerie and Swimsuit
67	Sports Hunting and War Games

Bandwidth Consuming

ID	Category
19	Freeware and Software Downloads
24	File Sharing and Storage
25	Streaming Media and Download

ID	Category
72	Peer-to-peer File Sharing
75	Internet Radio and TV
76	Internet Telephony

Security Risk

ID	Category
26	Malicious Websites
61	Phishing

ID	Category
86	Spam URLs
88	Dynamic DNS

General Interest - Personal

ID	Category
17	Advertising
18	Brokerage and Trading
20	Games
23	Web-based Email
28	Entertainment
29	Arts and Culture
30	Education
33	Health and Wellness
34	Job Search
35	Medicine
36	News and Media
37	Social Networking
38	Political Organizations
39	Reference
40	Global Religion
42	Shopping
44	Society and Lifestyles
46	Sports

ID	Category
47	Travel
48	Personal Vehicles
54	Dynamic Content
55	Meaningless Content
58	Folklore
68	Web Chat
69	Instant Messaging
70	Newsgroups and Message Boards
71	Digital Postcards
77	Child Education
78	Real Estate
79	Restaurant and Dining
80	Personal Websites and Blogs
82	Content Servers
85	Domain Parking
87	Personal Privacy
89	Auction

General Interest - Business

ID	Category
31	Finance and Banking
41	Search Engines and Portals
43	General Organizations
49	Business
50	Information and Computer Security
51	Government and Legal Organizations

ID	Category
52	Information Technology
53	Armed Forces
56	Web Hosting
81	Secure Websites
84	Web-based Applications

Local categories

Users can define custom or local categories. See Overriding FortiGuard Website Categorization for details.

FortiGuard Web Filtering usage quotas

In addition to using category and classification blocks and overrides to limit user access to URLs, you can set a daily quota by category, category group, or classification. Quotas allow access for a specified length of time or a specific bandwidth, calculated separately for each user. Quotas are reset every day at midnight.

Users must authenticate with the FortiGate unit. The quota is applied to each user individually so the FortiGate must be able to identify each user. One way to do this is to configure a security policy using the identity-based policy feature. Apply the web filter profile in which you have configured FortiGuard Web Filter and FortiGuard Web Filter quotas to such a security policy.

The use of FortiGuard Web Filtering quotas requires that users authenticate to gain web access. The quotas are ignored if applied to a security policy in which user authentication is not required.

Editing the web filter profile resets the quota timers for all users.

When a user first attempts to access a URL, they're prompted to authenticate with the FortiGate unit. When they provide their user name and password, the FortiGate unit recognizes them, determines their quota allowances, and monitors their web use. The category and classification of each page they visit is checked and FortiGate unit adjusts the user's remaining available quota for the category or classification.

Quota hierarchy

You can apply quotas to categories and category groups. Only one quota per user can be active at any one time. The one used depends on how you configure the FortiGuard Web Filter.

When a user visits a URL, the FortiGate unit queries the FortiGuard servers for the category of the URL. From highest to lowest, the relative priority of the quotas are:

1. Category
2. Category group

Overriding FortiGuard website categorization

In most things there is an exception to the rule. When it comes to the rules about who is allowed to go to which websites in spite of the rules or in this case, policies, it seems that there are more exceptions than to most rules. There are numerous valid reasons and scenarios for exceptions so it follows that there needs to be a way to accommodate this exception.

The different methods of override

There are actually two different ways to override web filtering behavior based on FortiGuard categorization of a websites. The second method has two variations in implementation and each of the three has a different level of granularity.

1. Using Alternate Categories
   Web Rating Overrides

   This method manually assigns a specific website to a different Fortinet category or a locally created category.

2. Using Alternate Profiles
   Administrative Override or Allow Blocked Override

   In this method all of the traffic going through the FortiGate unit, using identity based policies and a Web Filtering profile has the option where configured users or IP addresses can use an alternative Web Filter profile when attempting to access blocked websites.

Using Alternate Categories

Web Rating Overrides

There are two approaches to overriding the FortiGuard Web Filtering. The first is an identity-based method that can be configured using a combination of identity-based policies and specifically designed webfilter profiles. This is addressed in the Firewall Handbook.

The second method is the system-wide approach that locally (on the FortiGate Firewall) reassigns a URL to a different FortiGuard Category or even subcategory. This is where you can assign a specific URL to the FortiGuard Category that you want to you can also set the URL to one of the Custom Categories that you have created

The Web Rating Overrides option is available because different people will have different criteria for how they categorize websites. Even if the criteria is the same an organization may have reason to block the bulk of a category but need to be able to access specific URLs that are assigned to that category.

A hypothetical example could be that a website, example.com is categorized as being in the Sub-Category Pornography. The law offices of Barrister, Solicitor, and Lawyer do not want their employees looking at pornography at work so they have used the FortiGuard Webfilter to block access to sites that have been assigned to the Category “Pornography”. However, the owners of example.com are clients of the law office and they are aware that example.com is for artists that specialize in nudes and erotic images. In this case two approaches can be taken. The first is that the Web Rating Override function can be used to assign example.com to Nudity and Risque instead of Pornography for the purposes of matching the criteria that the law office goes by or the site can be assigned to a Custom Category that is not blocked because the site belongs to one of their clients and they always want to be able to access the site.

Another hypothetical example from the other side of the coin. A private school has decided that a company that specializes in the online selling of books that could be considered inappropriate for children because of their violent subject matter, should not be accessible to anyone in the school. The categorization by Fortinet of the site example2.com is General Interest - Business with the subcategory of Shopping and Auction, which is a category that is allowed at the school. In this case they school could reassign the site to the Category Adult Material which is a blocked category.

Local or Custom Categories

User-defined categories can be created to allow users to block groups of URLs on a per-profile basis. The categories defined here appear in the global URL category list when configuring a web filter profile. Users can rate URLs based on the local categories.

Users can create user-defined categories then specify the URLs that belong to the category. This allows users to block groups of web sites on a per profile basis. The ratings are included in the global URL list with associated categories and compared in the same way the URL block list is processed.

Local categories and local rating features consume a large amount of CPU resources; use these features as little as possible.

The local assignment of a category overrides the FortiGuard server ratings and appear in reports as “Local” Categories or “Custom” Categories depending on the context.

CLI commands

In the CLI, the term is Local Categories.

To create a Local Category:

```
config webfilter ftgd-local-cat
   edit local_category_1
      set id 140
   end
```

To set a rating to a Local Category:

```
config webfilter ftgd-local-rating
   edit <url_str>
      set rating {[<category_int>] [group_str] . . .]
      set status {enable | disable}
   end
```

GUI commands

In the GUI you will see Local Categories on the Edit Web Filter profile page and Custom Categories on the Web Rating Overrides page. Both these pages will be used to create local categories and to apply actions to them.

Creating a Local or Custom Category

1. Go to **Security Profiles > Web Rating Overrides**.
2. Select **Custom Categories** in the top menu bar.
3. In the new window, click on **Create New**.

4. A new row will appear at the bottom of the list of categories with a field on the left highlighted and the message **This field is required**. Enter the name of the custom category in this field.
5. Select **Enter**.

Configuring Web Rating Overrides

1. Go to **Security Profiles > Web Rating Overrides.**
2. Select **Create New**
3. Type in the **URL** field the URL of the Website that you wish to recategorize. Do not use wildcard expressions when typing in the URL.
4. Select the **Lookup Rating** button to verify the current categorization that is being assigned to the URL.
5. Change the **Category** field to one of the more applicable options from the drop down menu, for example, one of the custom categories just created.
6. Change the **Sub-Category** field to a more narrowly defined option within the main category.
7. Select **OK**.

It is usually recommended that you choose a category that you know will be addressed in existing Web Filter profiles so that you will not need to engage in further configuration.

Applying an Action to a Local or Custom Category

1. Go to **Security Profiles > Web Filter**.
2. Expand the **Local Categories** icon in the top menu bar.
3. Right-click on a category from the list and set the action to **Allow**, **Block**, **Monitor**, **Warning**, **Authenticate**, or **Disable**.
4. Select **Apply**.

Local Category scenarios

Scenario 1: The configuration of the domain name overrides the configuration for the subdirectory.

Depending on the URL specified or other aspects of configuration, the configuration of a local

or custom category may not take effect. Consider a scenario where you have defined:

- example.com – local rating as “category 1”, action set to Block
- example.com/subdirectory – local rating as “category 2”, action set to Monitor
- example.com/subdirectory/page.html – local rating as “category 3”, action set to Warning.

If a user browses to “example.com", access will be blocked. If a user browses to example.com/subdirectory, access will also be blocked,even though that address was configured to be part of category2. The configuration of the domain name overrides the configuration for the subdirectory.

However, if you configure a specific HTML page differently than the domain name, then that configuration will apply. In this scenario, the user will see a Warning message but will be able to pass through to the page.

Scenario 2: User-defined local ratings and SNI matches

In this scenario, local categories are defined and sites are added to those categories.

- There is no behavioral difference if the hostname is sent from from ClientHello SNI or from HTTP request-url.
- The SNI will be used as hostname for https certificate-inspection or ssl-exempt.
- If a valid SNI exist, then SNI will be used as the domain name for url rating instead of CN inthe server certificate.
- For the local rating, "example.com" will match "test.example.com", but will not match "another_example.com".

Using Alternate Profiles

Allow Blocked Overrides or Web Overrides

The Administrative Override feature for Web Filtering was added and is found by going to **Security Profiles > Web Filter** and then enabling Allow Blocked Override. This opening window will display a listing of all of the overrides of this type. The editing window referred to the configuration as an Administrative Override.

The Concept

When a Web filter profile is overridden, it does not necessarily remove all control and restrictions that were previously imposed by the Web Filter. The idea is to replace a restrictive filter with a different one. In practice, it makes sense that this will likely be a profile that is less restrictive the original one but there is nothing that forces this. The degree to which the alternate profile is less restrictive is open. It can be as much as letting the user access everything on the Internet or as little as allowing only one addition website. The usual practice is to have as few alternate profiles as are needed to allow approved people to access what they need during periods when an exception to the normal rules is needed but still having enough control that the organizations web usage policies are not compromised.

You are not restricted to having only one alternative profile as an option to the existing profile. The new profile depends on the credentials or IP address making the connection. For example, John connecting through the "Standard" profile could get the "Allow_Streaming_Video" profile while George would get the "Allow_Social_ Networking_Sites" profile.

The other thing to take into account is the time factor on these overrides. They are not indefinite. The longest that an override can be enabled is for 1 year less a minute. Often these overrides are set up for short periods of time for specific reasons such as a project. Having the time limitation means that the System Administrator does not have to remember to go back and turn the feature off after the project is finished.

Identity or Address

In either case, these override features -- for specified users, user groups or IP addresses -- allow sites blocked by Web Filtering profiles to be overridden for a specified length of time. The drawback of this method of override is that it takes more planning and preparation than the rating override method. The advantage is that once this has been set up, this method requires very little in the way of administrative overhead to maintain.

When planning to use the alternative profile approach keep in mind the following: In Boolean terms, one of the following "AND" conditions has to be met before overriding the Web Filter is possible.

Based on the IP address:

- The Web Filter profile must be specified as allowing overrides
- AND the user's computer is one of the IP addresses specified
- AND the time is within the expiration time frame.

While the conditions are fewer for this situation, there is less control over who has the ability to bypass the filtering configured for the site. All someone has to do is get on a computer that is allowed to override the Web Filter and they have access.

Based on user group:

- The Web Filter profile must be specified as allowing overrides
- AND the policy the traffic is going through must be identity based
- AND the user's credentials matches the identity credentials specified
- AND the time is within the expiration time frame.

This method is the one most likely to be used as it gives more control in that the user has to have the correct credential and is more versatile because the user can use the feature from any computer that uses the correct policy to get out on the Internet.

Settings

When using an alternate profile approach to Web Filter overrides, the following settings are used to determine authentication and outcome. Not every setting is used in both methods but enough of them are common to describe them collectively.

Apply to Group(s)

This is found in the Allow Blocked Overrides configuration. Individual users can not be selected. You can select one or more of the User Groups that are recognized my the FortiGate unit, whether they are local to the system or from a third part authentication device such as a AD server through FSSO.

Original Profile

This is found in the Administrative Override configuration. In the Allow Blocked Overrides setting the configuration is right inside the profile so there is no need to specify which profile is the original one, but the Administrative Override setup is done separately from the profiles themselves.

Assign to Profile or New Profile

Despite the difference in the name of the field, this is the same thing in both variations of the feature. You select from the drop down menu the alternate Web Filter Profile that you wish to set up for this override.

Scope or Scope Range

When setting up the override in the "Allow Blocked Overrides" variation, you are given a drop-down menu next to the field name Scope while in the Administrative Override configuration you are asked to select a radio button next to the same options. In both cases this is just a way of selecting which form of credentials will be required to approve the overriding of the existing Web Filter profile.

When the Web Filter Block Override message page appears it will display a field named "Scope:" and depending on the selection, it will show the type of credentials used to determine whether or not the override is allowed. The available options are:

- **User**
  This means that the authentication for permission to override will be based on whether or not the user is using a specific user account.

- **User Group**
  This means that the authentication for permission to override will be based on whether on not the user account supplied as a credential is a member of the specified User Group.

- **IP**
  This means that the authentication for permission to override will be based on the IP address of the computer that was used to authenticate. This would be used with computers that have multiple users. Example: If Paul logs on to the computer, engages the override using his credentials and then logs off, if the scope was based on the IP address of the computer, anybody logging in with any account on that computer would now be using the alternate override Web Filter profile.

  When entering an IP address in the Administrative Override version, only individual IP addresses are allowed.

  Differences between IP and Identity based scope

  - Using the IP scope does not require the use of an Identity based policy.
  - When using the Administrative Override variation and IP scope, you may not see a warning message when you change from using the original Web Filter profile to using the alternate profile. There is no requirement for credentials from the user so, if allowed, the page will just come up in the browser.
- **Ask**
  This option is available only in the "Allowed Blocked Overrides" variation and when used configures the message page to ask which scope the user wished to use. Normally, when the page appears the scope options are greyed out and not editable, but by using the ask option the option is dark and the user can choose from the choice of:
  - User
  - User Group
  - IP Address
- **Duration Mode**
  This option is available only in the "Allowed Blocked Overrides" variation. The Administrative Override sets a specified time frame that is always used for that override. The available options from the drop down menu are:
  - **Constant**
    Using this setting will mean that what ever is set as the duration will be the length of time that the override will be in effect. If the Duration variable is set to 15 minutes the length of the override will always be 15 minutes. The option will be visible in the Override message page but the setting will be greyed out.
  - **Ask**

    Using this setting will give the person the option of setting the duration to the override when it is engaged. The duration time which is greyed out if the Constant setting is used will be dark and editable. The user can set the duration in terms of Day, Hours and or Minutes.

- **Duration**
  Duration is on of the areas where the two variations takes a different approach, on two aspects of the setting. As already indicated the "Administrative Override" only uses a static time frame there is no option for the user to select on the fly how long it will last. The other way in which the two variation differ is that the "Allow Blocked Overrides" starts the clock when the user logs in with his credentials. For example, if the duration is 1 hour and John initiates an override at 2:00 p.m. on January 1, at the end of that hour he will revert back to using the original profile but he can go back and re-authenticate and start the process over again. The Administrative override variation starts the clock from when the override was configured, which is why is shows an expiration date and time when your are configuring it.

This option, which is available when the Duration Mode is set to Constant is the time in minutes that the override will last when engaged by the user.

When setting up a constant duration in the Web Based Interface, minutes is the only option for units of time. To set a longer time frame or to use the units of hours or days you can use the CLI.

```
config webfilter profile
   edit <name of webfilter profile>
      config override
         set ovrd-dur <###d##h##m>
      end
```

When configuring the duration you don't have to set a value for a unit you are not using. If you are not using days or hours you can use:

```
set ovrd-dur 30m
```

instead of:

```
set ovrd-dur 0d0h30m
```

However, each of the units of time variable has their own maximum level:

```
###d cannot be more than 364
##h cannot be more than 23
##m cannot be more than 59
```

So the maximum length that the override duration can be set to is 364 days, 23 hours, and 59 minutes(a minute shy of 1 year) .

Using cookies to authenticate users in a Web Filter override

Cookies can be used to authenticate users when a web filter override is used. This feature is available in CLI only.

CLI Syntax:

```
config webfilter cookie-ovrd
   set redir-host <name or IP>
   set redir-port <port>
end

config webfilter profile
   edit <name>
      config override
         set ovrd-cookie [allow | deny]
         set ovrd-scope [user | user-group | ip | ask]
         set profile-type [list | radius]
         set ovrd-dur-mode [constant | ask]
         set ovrd-dur <duration>
         set ovrd-user-group <name>
         set profile <name>
      end
   end
end
```

Web Profile Overrides

This feature allows administrators to grant temporary access to sites that are otherwise blocked by a web filter profile. The temporary access can be granted to a user, user group, or source IP address. The time limit can be set in days, hours, or minutes. The default is 15 minutes.

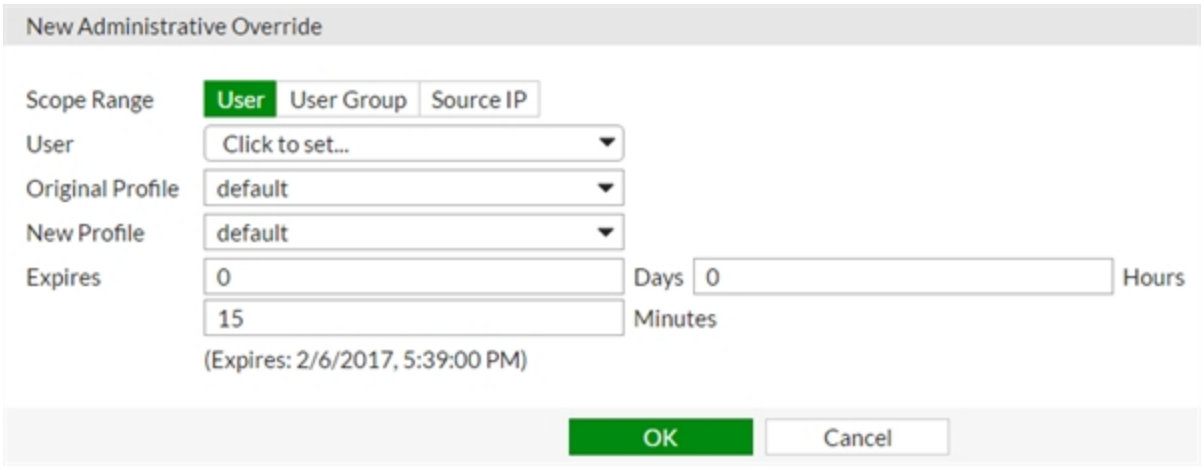
Temporary access can also be granted to a user, user group, or source IP address by enabling **Allow users to override blocked categories** in a Web Filter security profile and applying that profile to the appropriate policy. In this scenario, the user will have to authenticate to gain access.

When Web Profile Overrides is in effect, a blocked access page or replacement message will not appear and authentication will not be required.

Creating a Web Profile Override

Before creating a Web Profile Override, you will have to configure a user or user group if not granting temporary access to a Source IP. You will also have to configure the Web Filter security profile to be applied to the override.

1. Go to **Security Profiles > Web Profile Overrides.**
2. Select **Create New**.



3. Select:
   - **Scope Range**
   - **User** - **User** and **User Group** should be configured under **User & Device**
   - **Original Profile**
   - **New Profile** to apply for the override
   - time when the override **Expires**; default is 15 minutes

SafeSearch

SafeSearch is a feature of popular search sites that prevents explicit web sites and images from appearing in search results. Although SafeSearch is a useful tool, especially in educational environments, the resourceful user may be able to simply turn it off. Enabling SafeSearch for the supported search sites enforces its use by rewriting

the search URL to include the code to indicate the use of the SafeSearch feature. For example, on a Google search it would mean adding the string “&safe=active” to the URL in the search.

The search sites supported are:

- Google
- Yahoo
- Bing
- Yandex

Enabling SafeSearch — CLI

```
config webfilter profile
   edit default
      config web
         set safe-search url
      end
   end
```

This enforces the use of SafeSearch in traffic controlled by the firewall policies using the web filter you configure.

Search Keywords

There is also the capability to log the search keywords used in the search engines.

YouTube Education Filter

YouTube for Schools was a way to access educational videos from inside a school network. This YouTube feature gave schools the ability to access a broad set of educational videos on YouTube EDU and to select the specific videos that are accessible from within the school network.

Google decided to stop supporting YouTube for Schools (YTfS) as of July 1, 2016. Consequently, the current YouTube safe search does not work anymore.

Google provides an article entitled "Restrict YouTube content on your network or managed devices" on its support site. At this time, Google offers two options to restrict inappropriate content: DNS and HTTP header.

Restricting YouTube access in FortiOS 5.4 and 5.4.1

Below is a FortiGate configuration example for adding the HTTP header to YouTube requests to implement safe-search for YouTube.

1. Configure web proxy profile to add header:

```
config web-proxy profile
   edit Restrict
      set header-via-request add
      set header-via-response add
      config headers
         edit 1
            set name "YouTube-Restrict" --------(the name can be any value
            set content "Strict"
         next
      end
   next
end
```

2. Add profile to urlfilter profile:

```
config webfilter urlfilter
   edit 1
      set name "Youtube" --------(the name can be any value
      config entries
         edit 1
            set url "www.youtube.com"
            set action allow
            set web-proxy-profile "Restrict"
         next
         edit 2
            set url "m.youtube.com"
            set action allow
            set web-proxy-profile "Restrict"
         next
         edit 3
            set url "youtubei.googleapis.com"
            set action allow
            set web-proxy-profile "Restrict"
         next
         edit 4
            set url "youtube.googleapis.com"
            set action allow
            set web-proxy-profile "Restrict"
         next
         edit 5
            set url "www.youtube-nocookie.com"
            set action allow
            set web-proxy-profile "Restrict"
         next
      end
   next
end
```

3. Add urlfilter profile to webfilter:

```
config webfilter profile
   edit "Youtube-Restrict" --------(the name can be any value
      config web
         set urlfilter-table 1
      end
   next
end
```

4. Apply the above profile to the outgoing firewall policies

1. Enable the web-filter and select the web filter created in step 3.
2. Enable SSL Deep Inspection.

Restricting YouTube access in FortiOS 5.4.2

In FortiOS 5.4.2, YouTube access can be restricted through the GUI.

1. Go to **Security Profiles > Web Filter**.
2. Edit the default web filter or create a new one.
3. Expand **Search Engines** and enable Restrict YouTube Access.
4. Select **Strict** or **Moderate** level of restriction.

Google discusses the difference between **strict** and **moderate** levels of access in the article entitled on its support site.

Static URL Filter

You can allow or block access to specific URLs by adding them to the Static URL Filter list. You add the URLs by using patterns containing text and regular expressions. The FortiGate unit allows or blocks web pages matching any specified URLs or patterns and displays a replacement message instead.

URL blocking does not block access to other services that users can access with a web browser. For example, URL blocking does not block access to ftp:// ftp.example.com. Instead, use firewall policies to deny ftp connections.

When adding a URL to the URL filter list, follow these rules:

- Type a top-level URL or IP address to control access to all pages on a web site. For example, `www.example.com` or `192.168.144.155` controls access to all pages at this web site.
- Enter a top-level URL followed by the path and file name to control access to a single page on a web site. For example, `www.example.com/news.html` or `192.168.144.155/news.html` controls access to the news page on this web site.
- To control access to all pages with a URL that ends with example.com, add `example.com` to the filter list. For example, adding example.com controls access to www.example.com, mail.example.com, www.finance.example.com, and so on.
- Control access to all URLs that match patterns using text and regular expressions (or wildcard characters). For example, `example.*` matches example.com, example.org, example.net and so on.

URLs with an action set to exempt or monitor are not scanned for viruses. If users on the network download files through the FortiGate unit from a trusted web site, add the URL of this web site to the URL filter list with an action to pass it so the FortiGate unit does not virus scan files downloaded from this URL.

URL formats

How URL formats are detected when using HTTPS

Filter HTTPS traffic by entering a top level domain name, for example, `www.example.com` if:

- your unit does not support SSL content scanning and inspection
- you have selected the **URL filtering** option in web content profile for **HTTPS content filtering mode** under **Protocol Recognition**.

HTTPS URL filtering of encrypted sessions works by extracting the CN from the server certificate during the SSL negotiation. Since the CN only contains the domain name of the site being accessed, web filtering of encrypted HTTPS sessions can only filter by domain names.

If your unit supports SSL content scanning and inspection and if you have selected Deep Scan, you can filter HTTPS traffic in the same way as HTTP traffic.

How URL formats are detected when using HTTP

URLs with an action set to Exempt are not scanned for viruses. If users on the network download files through the unit from trusted web site, add the URL of this web site to the URL filter list with an action set to exempt so the unit does not virus scan files downloaded from this URL.

- Type a top-level URL or IP address to control access to all pages on a web site. For example, `www.example.com` or `192.168.144.155` controls access to all pages at this web site.
- Enter a top-level URL followed by the path and filename to control access to a single page on a web site. For example, `www.example.com/news.html` or `192.168.144.155/news.html` controls the news page on this web site.
- To control access to all pages with a URL that ends with `example.com`, add `example.com` to the filter list. For example, adding `example.com` controls access to `www.example.com`, `mail.example.com`, `www.finance.example.com`, and so on.
- Control access to all URLs that match patterns created using text and regular expressions (or wildcard characters). For example, `example.*` matches `example.com`, `example.org`, `example.net` and so on.
- Fortinet URL filtering supports standard regular expressions.

If virtual domains are enabled on the unit, web filtering features are configured globally. To access these features, select **Global Configuration** on the main menu.

URL Filter actions

You can select one of four actions for how traffic will be treated as it attempts to reach a site in the list.

Block

Attempts to access any URLs matching the URL pattern are denied. The user will be presented with a replacement message.

Allow

Any attempt to access a URL that matches a URL pattern with an allow action is permitted. The traffic is passed to the remaining antivirus proxy operations, including FortiGuard Web Filter, web content filter, web script filters, and antivirus scanning.

Allow is the default action. If a URL does not appear in the URL list, it is permitted.

Monitor

Traffic to, and reply traffic from, sites matching a URL pattern with **Monitor** action applied will be allowed through in the same way as the **Allow** action. The difference with the **Monitor** action is that a log message will be generated each time a matching traffic session is established. The requests will also be subject to all other Security Profiles inspections that would normally be applied to the traffic.

Exempt

Exempt allows trusted traffic to bypass the antivirus and dlp proxy operations by default, but it functions slightly differently. In general, if you're not certain that you need to use the **Exempt** action, use **Monitor**.

HTTP 1.1 connections are persistent unless declared otherwise. This means the connections will remain in place until closed or the connection times out. When a client loads a web page, the client opens a connection to the web server. If the client follows a link to another page on the same site before the connection times out, the same connection is used to request and receive the page data.

When you add a URL pattern to a URL filter list and apply the **Exempt** action, traffic sent to and replies traffic from sites matching the URL pattern will bypass all antivirus proxy operations. The connection itself inherits the exemption. This means that all subsequent reuse of the existing connection will also bypass all antivirus proxy operations. When the connection times out, the exemption is cancelled.

For example, consider a URL filter list that includes `example.com/files` configured with the **Exempt** action. A user opens a web browser and downloads a file from the URL `example.com/sample.zip`. This URL does not match the URL pattern so it is scanned for viruses. The user then downloads `example.com/files/beautiful.exe` and since this URL does match the pattern, the connection itself inherits the exempt action. The user then downloads `example.com/virus.zip`. Although this URL does not match the exempt URL pattern, a previously visited URL did, and since the connection inherited the exempt action and was re-used to download a file, the file is not scanned.

If the user next goes to an entirely different server, like `example.org/photos`, the connection to the current server cannot be reused. A new connection to example.org is established. This connection is not exempt. Unless the user goes back to example.com before the connection to that server times out, the server will close the connection. If the user returns after the connection is closed, a new connection to example.com is created and it is not exempt until the user visits a URL that matches the URL pattern.

Web servers typically have short time-out periods. A browser will download multiple components of a web page as quickly as possible by opening multiple connections. A web page that includes three photos will load more quickly if the browser opens four connections to the server and downloads the page and the three photos at the same time. A short time-out period on connections will close the connections faster, allowing the server to avoid unnecessarily allocating resources for a long period. The HTTP session time-out is set by the server and will vary with the server software, version, and configuration.

Using the **Exempt** action can have unintended consequences in certain circumstances. You have a web site at example.com and since you control the site, you trust the contents and configure `example.com` as exempt. But example.com is hosted on a shared server with a dozen other different sites, each with a unique domain name. Because of the shared hosting, they also share the same IP address. If you visit example.com, your connection your site becomes exempt from any antivirus proxy operations. Visits to any of the 12 other sites on the same server will reuse the same connection and the data you receive is exempt from scanned.

Use of the **Exempt** action is not suitable for configuration in which connections through the FortiGate unit use an external proxy. For example, you use proxy.example.net for all outgoing web access. Also, as in the first example, URL filter list that includes a URL pattern of `example.com/files` configured with the **Exempt** action. Users are protected by the antivirus protection of the FortiGate unit until a user visits a URL that matches

the of `example.com/files` URL pattern. The pattern is configured with the **Exempt** action so the connection to the server inherits the exemption. With a proxy however, the connection is from the user to the proxy. Therefore, the user is entirely unprotected until the connection times out, no matter what site he visits.

Ensure you are aware of the network topology involving any URLs to which you apply the **Exempt** action.

Status

The Web Site Filter has the option to either enable or disable individual web sites in the list. This allows for the temporary removal of the actions against a site so that it can be later reengaged without having to rewrite the configuration.

Configuring a URL filter

Consult the Maximum Values Table on the Fortinet Document Library site for the most current information on the number of URL filter entries allowed for your FortiGate.

For this example, the URL www.example*.com will be used. You configure the list by adding one or more URLs to it.

To add a URL to a URL filter

1. Go to **Security Profiles > Web Filter**.
2. Select a web filter to edit.
3. Under **Static URL Filter**, enable **URL Filter**, and select **Create New**.
4. Enter the URL, without the “http”, for example: `www.example*.com`.
5. Select a **Type**: **Simple** , **Regular Expression**, or **Wildcard**. In this example, select **Wildcard**.
6. Select the **Action** to take against matching URLs: **Exempt**, **Block**, **Allow**, or **Monitor**.
7. Select **Enable**.
8. Select **OK**.

'Simple' Filter type

If you select the **Simple** filter type for a URL filter, the syntax is performing an exact match. Note, however, that the domain and path are separate entities in HTTP despite the fact that a user types them as a single entity and, in the case of 'simple', the rules for each part (domain and path) are different.

The 'domain' part

For the domain part, the goal of the 'simple' format is to make it easy to block a domain and all its subdomains, such that the admin only has to type “address.xy" to block "address.xy", "www.address.xy", "talk.address.xy", etc. but *not* block “youraddress.xy" or "www.youraddress.xy" which are different domains from "address.xy”.

Also, the actual domain does not include http:// or https:// so this should *not* be entered or the URL filter will try to match a domain starting with http. For this reason, when you enter http:// in the URL filter via the GUI, it is automatically removed.

A trailing ‘/‘ with the domain is not needed. The GUI URL filter will automatically trim this, but when using the API to provide the per-user BWL it will not!

Please take this into account. Better not to use it as it might give unexpected results.

The 'path' part

For the path part, an exact match takes place. For example:

www.address.xy/news

blocks anything that starts with that exact path. So this matches:

www.address.xy/newsies
www.address.xy/newsforyou
www.address.xy/news/co
etc.

Also:

www.address.xy/new

likewise blocks the same as above but includes:

/newt
/newp
etc.

which is a much broader filter, matching:

www.address.xy/newstand/co
www.address.xy/news/co
etc.

In other words, the more you specify of the path, the more strictly it will match.

Here as well a trailing '/' with the URL path is not needed, the GUI URL filter will automatically trim this, but when using the API to provide the per-user BWL it will not!

Please take this into account. Better not to use it as it might give unexpected results.

Referrer URL

A new variable has been added to the Static URL Filter: `referrer-host`. If a referrer is specified, the hostname in the referrer field of the HTTP require will be compared for any entry that contains the matching URL. If the referrer matches, then the specified action will be performed by proxy.

Configuring in the GUI

The configuration can be done in the GUI but only if advance web filtering features have been enabled by entering the following commands in the CLI:

```
config system global
   set gui-webfilter-advanced enable
end
```

After this command is used, a new column will be created in **Security Profiles > Web Filter** to set the referrer.

Configuring in the CLI

When specifying the URL filter, it needs to be identified by its ID. The URLs are listed under each entry.

To find the ID number:

```
config webfilter urlfilter
   edit ?
```

A list of the current URL filters will be listed with their ID numbers in the left column.

The syntax in the CLI for configuring an entry is:

```
config webfilter urlfilter
   edit <ID>
      config entries
         edit 1
            set url <url>
            set referrer-host <url>
            set type {simple | regex | wildcard}
            set action {block | allow | monitor | exempt}
            set status {enable | disable}
         end
      end
   end
```

Web content filter

You can control web content by blocking access to web pages containing specific words or patterns. This helps to prevent access to pages with questionable material. You can also add words, phrases, patterns, wild cards and Perl regular expressions to match content on web pages. You can add multiple web content filter lists and then select the best web content filter list for each web filter profile.

Enabling web content filtering involves three separate parts of the FortiGate configuration.

- The security policy allows certain network traffic based on the sender, receiver, interface, traffic type, and time of day.
- The web filter profile specifies what sort of web filtering is applied.
- The web content filter list contains blocked and exempt patterns.

The web content filter feature scans the content of every web page that is accepted by a security policy. The system administrator can specify banned words and phrases and attach a numerical value, or score, to the importance of those words and phrases. When the web content filter scan detects banned content, it adds the scores of banned words and phrases in the page. If the sum is higher than a threshold set in the web filter profile, the FortiGate unit blocks the page.

General configuration steps

Follow the configuration procedures in the order given. Also, note that if you perform any additional actions between procedures, your configuration may have different results.

1. Create a web content filter list.
2. Add patterns of words, phrases, wildcards, and regular expressions that match the content to be blocked or exempted.
3. You can add the patterns in any order to the list. You need to add at least one pattern that blocks content.
4. In a web filter profile, enable the web content filter and select a web content filter list from the options list.

To complete the configuration, you need to select a security policy or create a new one. Then, in the security policy, enable **Webfilter** and select the appropriate web filter profile from the list.

Creating a web filter content list

You can create multiple content lists and then select the best one for each web filter profile. Creating your own web content lists can be accomplished only using the CLI.

This example shows how to create a web content list called inappropriate language, with two entries, offensive and rude.

To create a web filter content list

```
config webfilter content
   edit 3
      set name "inappropriate language"
      config entries
         edit offensive
            set action block
            set lang western
            set pattern-type wildcard
            set score 15
            set status enable
         next
         edit rude
            set action block
            set lang western
            set pattern-type wildcard
            set score 5
            set status enable
         end
      end
   end
```

Configuring a web content filter list

Once you have created the web filter content list, you need to add web content patterns to it. There are two types of patterns: **Wildcard** and **Regular Expression**.

You use the **Wildcard** setting to block or exempt one word or text strings of up to 80 characters. You can also use the wildcard symbols, such as “*” or “?”, to represent one or more characters. For example, as a wildcard expression, forti*.com will match fortinet.com and forticare.com. The “*” represents any kind of character appearing any number of times.

You use the **Regular Expression** setting to block or exempt patterns of Perl expressions, which use some of the same symbols as wildcard expressions, but for different purposes. The “*” represents the character before the symbol. For example, forti*.com will match fortiii.com but not fortinet.com or fortiice.com. The symbol “*” represents “i” in this case, appearing any number of times. RP: Add a regex example.

The maximum number of web content patterns in a list is 5000.

How content is evaluated

Every time the web content filter detects banned content on a web page, it adds the score for that content to the sum of scores for that web page. You set this score when you create a new pattern to block the content. The score can be any number from zero to 99999. Higher scores indicate more offensive content. When the sum of scores equals or exceeds the threshold score, the web page is blocked. The default score for web content filter is 10 and the default threshold is 10. This means that by default a web page is blocked by a single match. Blocked

pages are replaced with a message indicating that the page is not accessible according to the Internet usage policy.

Banned words or phrases are evaluated according to the following rules:

- The score for each word or phrase is counted only once, even if that word or phrase appears many times in the web page.
- The score for any word in a phrase without quotation marks is counted.
- The score for a phrase in quotation marks is counted only if it appears exactly as written.

The following table describes how these rules are applied to the contents of a web page. Consider the following, a web page that contains only this sentence: “The score for each word or phrase is counted only once, even if that word or phrase appears many times in the web page.”

Banned Pattern Rules

Banned pattern	Assigned score	Score added to the sum for the entire page	Threshold score	Comment
word	20	20	20	Appears twice but only counted once. Web page is blocked.
word phrase	20	40	20	Each word appears twice but only counted once giving a total score of 40. Web page is blocked
word sentence	20	20	20	“word” appears twice, “sentence” does not appear, but since any word in a phrase without quotation marks is counted, the score for this pattern is 20. Web page is blocked.
“word sentence”	20	0	20	“This phrase does not appear exactly as written. Web page is allowed.
“word or phrase”	20	20	20	This phrase appears twice but is counted only once. Web page is blocked.

Enabling the web content filter and setting the content threshold

When you enable the web content filter, the web filter will block any web pages when the sum of scores for banned content on that page exceeds the content block threshold. The threshold will be disregarded for any exemptions within the web filter list.

Advanced web filter configurations

Allow websites when a rating error occurs

Enable this setting to allow access to web pages that return a rating error from the FortiGuard Web Filter service.

If your FortiGate unit cannot contact the FortiGuard service temporarily, this setting determines the tye of access the FortiGate unit allows until contact is re-established. If enabled, users will have full unfiltered access to all web sites. If disabled, users will not be allowed access to any web sites.

ActiveX filter

Enable to filter ActiveX scripts from web traffic. Web sites using ActiveX may not function properly with this filter enabled.

Block HTTP redirects by rating

Enable to block HTTP redirects.

Many web sites use HTTP redirects legitimately but in some cases, redirects may be designed specifically to circumvent web filtering, as the initial web page could have a different rating than the destination web page of the redirect.

This option is not supported for HTTPS.

Block Invalid URLs

Select to block web sites when their SSL certificate CN field does not contain a valid domain name.

FortiGate units always validate the CN field, regardless of whether this option is enabled. However, if this option is not selected, the following behavior occurs:

- If the request is made directly to the web server, rather than a web server proxy, the FortiGate unit queries for FortiGuard Web Filtering category or class ratings using the IP address only, not the domain name.
- If the request is to a web server proxy, the real IP address of the web server is not known. Therefore, rating queries by either or both the IP address and the domain name is not reliable. In this case, the FortiGate unit does not perform FortiGuard Web Filtering.

Enabling the Web Filter profile to block a particular category and enabling the Application Control profile will not result in blocking the URL. This occurs because proxy and flow-based profiles cannot operate together.

To ensure replacement messages show up for blocked URLs, switch the Web Filter to flow-based inspection.

Cookie filter

Enable to filter cookies from web traffic. Web sites using cookies may not function properly with this enabled.

Provide Details for Blocked HTTP 4xx and 5xx Errors

Enable to have the FortiGate unit display its own replacement message for 400 and 500-series HTTP errors. If the server error is allowed through, malicious or objectionable sites can use these common error pages to circumvent web filtering.

HTTP POST action

Select the action to take with HTTP POST traffic. HTTP POST is the command used by your browser when you send information, such as a form you have filled-out or a file you are uploading, to a web server.

The available actions include:

Comfort

Use client comforting to slowly send data to the web server as the FortiGate unit scans the file. Use this option to prevent a server time-out when scanning or other filtering is enabled for outgoing traffic.

The client comforting settings used are those defined in the Proxy Options profile selected in the security policy.

Block

Block the HTTP POST command. This will limit users from sending information and files to web sites.

When the post request is blocked, the FortiGate unit sends the http-post-block replacement message to the web browser attempting to use the command.

Java applet filter

Enable to filter java applets from web traffic. Web sites using java applets may not function properly with this filter enabled.

Rate Images by URL

Enable to have the FortiGate retrieve ratings for individual images in addition to web sites. Images in a blocked category are not displayed even if they are part of a site in an allowed category.

Blocked images are replaced on the originating web pages with blank place-holders. Rated image file types include GIF, JPEG, PNG, BMP, and TIFF.

Rate URLs by Domain and IP Address

Enable to have the FortiGate unit request the rating of the site by URL and IP address separately, providing additional security against attempts to bypass the FortiGuard Web Filter.

If the rating determined by the domain name and the rating determined by the IP address defer the Action that is enforce will be determined by a weighting assigned to the different categories. The higher weighted category will take precedence in determining the action. This will have the side effect that sometimes the Action will be determined by the classification based on the domain name and other times it will be determined by the classification that is based on the IP address.

FortiGuard Web Filter ratings for IP addresses are not updated as quickly as ratings for URLs. This can sometimes cause the FortiGate unit to allow access to sites that should be blocked, or to block sites that should be allowed.

An example of how this would work would be if a URL's rating based on the domain name indicated that it belonged in the category Lingerie and Swimsuit, which is allowed but the category assigned to the IP address was Pornography which has an action of Block, because the Pornography category has a higher weight the effective action is Block.

Web resume download block

Enable to prevent the resumption of a file download where it was previously interrupted. With this filter enabled, any attempt to restart an aborted download will download the file from the beginning rather than resuming from where it left off.

This prevents the unintentional download of viruses hidden in fragmented files.

Note that some types of files, such as PDF, fragment files to increase download speed and enabling this option can cause download interruptions. Enabling this option may also break certain applications that use the Range Header in the HTTP protocol, such as YUM, a Linux update manager.

Restrict Google account usage to specific domains

This feature allow the blocking of access to some Google accounts and services while allowing access to accounts that are included in the domains specified in the exception list.

Block non-English character URLs

The FortiGate will not successfully block non-English character URLs if they are added to the URL filter. In order to block access to URLs with non-English characters, the characters must be translated into their international characters.

Browse to the non-English character URL (for example, http://www.fortinet.com/pages/ที่-นี่-ไม่มีเศษรัฐประหารให้ใครแดก/338419686287505?ref=stream).

On the FortiGate, use the URL shown in the FortiGate GUI and add it the list of blocked URLs in your URL filter (for example, http://www.fortinet.com/pages/%E0%B8%97%E0%B8%B5%E0%B9%88%E0%B8%99%E0%B8%B5%E0%B9%88-%E0%B9%84%E0%B8%A1%E0%B9%88%E0%B8%A1%E0%B8%B5%E0%B9%80%E0%B8%A8%E0%B8%A9%E0%B8%A3%E0%B8%B1%E0%B8%90%E0%B8%9B%E0%B8%A3%E0%B8%B0%E0%B8%AB%E0%B8%B2%E0%B8%A3%E0%B9%83%E0%B8%AB%E0%B9%89%E0%B9%83%E0%B8%84%E0%B8%A3%E0%B9%81%E0%B8%94%E0%B8%81/338419686287505?ref=stream).

Once added, further browsing to the URL will result in a blocked page.

CLI Syntax

```
config webfilter urlfilter
   edit 1
      set name "block_international_character_urls"
         config entries
            edit 1
               set url "www.fortinet.com/pages/2.710850E-3120%B8%E0%B8%B53.231533E-
                   3170%B9%E0%B8%E0%B8%B53.231533E-3170%B9%88-3.230415E-
                   3170%B9%E0%B80X0.000000063CD94P-102211.482197E-
                   3230%B9%E0%B80X0.0007FBFFFFCFP-102210.000000E+000%B8%B51.828043E-
                   3210%B9%E0%B80X0P+081.828043E-3210%B80X0P+092.710850E-
                   3120%B80X0.0000000407ED2P-102233.236834E-3170%B8%B19.036536E-
                   3130%B8%E0%B8%9B4.247222E-3140%B80X0P+039.036683E-3130%B8%B02.121996E-
                   3130%B80X0.0000000000008P-1022B2.710850E-3120%B8%B21.482197E-
                   3230%B80X0P+030.000000E+000%B9%E0%B80X0P+0B2.710850E-
                   3120%B9%E0%B9%E0%B8%E0%B80X0.0000000408355P-102232.023693E-
                   3200%B9%E0%B8%E0%B8%81/338419686287505?ref=stream"
               set action block
            next
         end
   next
end

config webfilter urlfilter
   edit 2
      set name "block_international_character_urls"
   next
end
```

```
config webfilter profile
   edit "block_international_character_urls"
   next
end

config firewall policy
   edit 3
      set uuid cf80d386-7bcf-51e5-6e87-db207e3f0fa8
      set srcintf "port1"
      set dstintf "port2"
      set srcaddr "all"
      set dstaddr "all"
      set action accept
      set schedule "always"
      set service "ALL"
      set utm-status enable
      set logtraffic all
      set webfilter-profile "block_international_character_urls"
      set profile-protocol-options "default"
      set ssl-ssh-profile "certificate-inspection"
      set nat enable
   next
end
```

Websense web filtering through WISP

WISP is a Websense protocol that allows for URLs to be extracted by a firewall and submitted to Websense systems for rating and approval checking.

This feature provides a solution for customers who have large, existing, deployed implementations of Websense security products to replace their legacy firewalls with a FortiGate family, such that they are not forced to make a change to their web filtering infrastructure at the same time.

When WISP is enabled, the FortiGate will maintain a pool of TCP connections to the WISP server. The TCP connections will be used to forward HTTP request information and log information to the WISP server and receive policy decisions.

Configuring the WISP server

In order to use Websense's web filtering service, a WISP server per VDOM must be defined and enabled first.

Example configuration

```
config web-proxy wisp
   edit 0
      set outgoing-ip 0.0.0.0
      set server-ip 0.0.0.0
      set server-port 15868
      set max-connections 64
      set timeout 5
   next
end
```

After configuring the WISP server, enable WISP in the web filter profile.

```
config webfilter profile
```

```
    edit "wisp_only"
       set wisp enable
       set wisp-servers 0
    next
end
```

Now you can apply the web filter profile to a firewall policy.

If you configure more than one WISP server, the load balance option can also be configured.

```
config webfilter profile
    edit "wisp_only"
       set wisp-algorithm {primary-secondary | round-robin | auto-learning}
    next
end
```

The options for the `wisp-algorithm` are:

- `primary-secondary`: select the first healthy server in order
- `round-robin`: select the next healthy server
- `auto-learning`: select the lightest loading healthy server

Configuring Web Filter Profiles

Enabling FortiGuard Web Filter

FortiGuard Web Filter is enabled and configured within web filter profiles by enabling FortiGuard Categories. The service is engaged by turning on the Web Filter profile and selecting a profile that has FortiGuard Categories enabled on one or more active policies being run by the firewall.

There is also a system wide setting for the enabling or disabling of FortiGuard Web Filter that is only in the CLI.

```
config system fortiguard
    set webfilter-force-off
```

The two options on this setting are enable or disable. The syntax of the settings name is “force-off” so in order to enable FortiGuard Webfilter you have to choose disable for the setting and enable if you want to turn it off.

General configuration steps

1. Go to **Security Profiles > Web Filter**.
2. Determine if you wish to create a new profile, edit an existing one, or clone and edit an existing one.
3. Select an **Inspection Mode**.
4. If you are using FortiGuard Categories, enable the FortiGuard Categories, select the categories and select the action to be performed.
5. Configure any **Quotas** needed. (Proxy Mode)
6. Allow blocked override if required.(Proxy Mode)
7. Set up **Safe Search** settings and/or YouTube Education settings. (Proxy & Flow-based)
8. Configure **Static URL Settings**. (All Modes)
9. Configure **Rating Options**. (All Modes)
10. Configure **Proxy Options**.
11. Save the filter and web filter profile.
12. To complete the configuration, you need to select the security policy controlling the network traffic you want to restrict. Then, in the security policy, enable Web Filter and select the appropriate web filter profile from the list.

Configuring FortiGuard Web Filter settings

FortiGuard Web Filter includes a number of settings that allow you to determine various aspects of the filtering behavior.

Getting to the Edit Web Filter Profile configuration window

Once you have gotten to the profile configuration window there are a number of settings that can be used, most of which are optional. We will treat each of these options separately, but present the common instructions of how to get to the profile editing page here.

1. Go to **Security Profiles > Web Filter**.
2. Determine if you wish to create a new profile, edit an existing one, or clone and then edit an existing one.
   a. New profile:
      i. Select the **Create New** icon, in the upper right of the window (looks like a plus sign in a circle) **OR**
      ii. Select the **List** icon, in the upper right (looks like a white rectangle with lines like text). Select the **Create New** icon in the upper left.
   b. Edit existing profile:
      i. Select the name of the profile that you wish to edit from the drop-down menu **OR**
      ii. Select the **List** icon, in the upper right (looks like a white rectangle with lines like text. Highlight the name of the profile from the list and select **Edit** from the options above the list.
   c. Clone a profile:
      i. Select **Clone** icon in the upper right corner of the window (looks like one square overlapping another) **OR**
      ii. Select the **List**icon, in the upper right (looks like a white rectangle with lines like text. Highlight the name of the profile from the list and select **Clone** from the options above the list.
3. Make sure there is a valid name, and comment if you want.
4. Configure the settings to best achieve your specific requirements
5. Select **Apply** or **OK**, depending on whether you are editing, creating, or cloning a profile.

In older versions of FortiOS there was a character limitation for the URL of 2048 bytes or approximately 321 characters. If the URL you were trying to reach was longer the URL sent to FortiGuard would be truncated and the service would be unable to categorize the site. Starting in version 5 of the firmware, the parsed URL has been increase to 4 Kilobytes, effectively doubling the length of a URL capable of being categorized.

To configure the FortiGuard Web Filter categories

1. Go to the **Edit Web Filter Profile** window.
2. The category groups are listed in a widget. You can expand each category group to view and configure every sub-category individually within the groups. If you change the setting of a category group, all categories within the group inherit the change.
3. Select the category groups and categories to which you want to apply an action.
   To assign an action to a category left click on the category and select from the pop up menu.
4. Select **Apply** or **OK**.

Apply the web filter profile to an identity-based security policy. All the users subject to that policy are restricted by the quotas.

If you look at your logs carefully, you may notice that not every URL connection in the log shows a category. They are left blank. If you take one of those URL and enter it in the FortiGuard website designed to show the category for a URL it will successfully categorize it.

The reason for this is that to optimize speed throughput and reduce the load on the FortiGuard servers the FortiGate does not determine a category rating on scripts and css files.

Configuring FortiGuard Category Quotas

1. Go to the **Edit Web Filter Profile** window
2. Verify that the categories that need to have quotas on them are set to one of these actions:
   - **Monitor**
   - **Warning**
   - **Authenticate**
3. Under **Category Usage Quota,** Select **Create New or Edit**
4. In the **New/Edit Quota** window that pops up, enable or disable the specific categories for that quota.
5. At the bottom of the widget, select a quota type and daily allowance for each user:
   - **Time** -- can be entered in **Hours**, **Minutes**, or **Seconds**.
   - **Traffic** -- can be entered in **Bytes**, **KB**, **MB**, or **GB**.
6. Select **Apply or OK**.
7. Continue with any other configuration in the profile
8. Select **Apply or OK**.

Apply the web filter profile to an identity-based security policy. All the users subject to that policy are restricted by the quotas.

The use of FortiGuard Web Filtering quotas requires that users authenticate to gain web access. The quotas are ignored if applied to a security policy in which user authentication is not required.

Editing the web filter profile resets the quota timers for all users.

Configure Allowed Blocked Overrides

1. Go to the **Edit Web Filter Profile** window.
2. Enable **Allow users to override blocked categories**.
3. Select the **Groups that can override**.
4. Designate a temporary web filter profile under **Profile can switch to**
5. Identify whether **Switch applies to** a **User**, **User Group**, **IP**, or **Ask**.
6. Set the **Switch Duration** to **Predefined** or **Ask**.

Configure Search Engine Section.

1. Go to the **Edit Web Filter Profile** window.
   There are three primary configuration settings in this section.
2. Enable any of the three settings:

- **Enforce 'Safe Search' on Google, Yahoo!, Bing, Yandex**
- **Restrict YouTube Access** and select **Strict** or **Moderate**. Google provides an article entitled "Restrict YouTube content on your network or managed devices" on its support site.
- **Log all search keywords**

Web Filter in flow mode does not support Safe Search

Configure Static URL Filter

Web Content Filter

To enable the web content filter and set the content block threshold

1. Go to the **Edit Web Filter Profile** window.
2. In the **Static URL Filter** section enable **Web Content Filter**.
3. Select **Create New**.
4. Select the **Pattern Type**.
5. Enter the content **Pattern**.
6. Enter the **Language** from the dropdown menu.
7. Select **Block** or **Exempt**, as required, from the **Action** list.
8. Select **Enable**.
9. Select **OK.**

Configure Rating Options

Allow Websites When a Rating error Occurs

In the GUI, the configuration setting is limited to a checkbox.

Rate URLs by Domain and IP Address

In the GUI, the configuration setting is limited to a checkbox.

Block HTTP Redirects by Rating

In the GUI, the configuration setting is limited to a checkbox.

Rate Images by URL (Blocked images will be replaced with blanks)

In the GUI, the configuration setting is limited to a checkbox.

Configure Proxy Options

Restrict Google Account Usage to Specific Domains

Configuring the feature in the GIU

Go to **Security Profiles > Web Filter**.

In the **Proxy Options** section, check the box next to **Restrict to Corporate Google Accounts Only**.

Use the **Create New** link within the widget to add the appropriate Google domains that will be allowed.

Configuring the feature in the CLI

To configure this option in the CLI, the URL filter must refer to a web-proxy profile that is using the Modifying HTTP Request Headers feature. The command is only visible when the action for the entry in the URL filter is set to either allow or monitor.

1. Configure the proxy options:

```
config web-proxy profile
   edit "googleproxy"
      config headers
         edit 1
            set name "X-GoogApps-Allowed-Domains"
            set content "fortinet.com, Ladan.ca"
            end
         end
      end
   end
```

2. Set a web filter profile to use the proxy options

```
config webfilter urlfilter
   edit 1
      config entries
         edit "*.google.com"
            set type wildcard
            set action {allow | monitor}
            set web-proxy-profile <profile>
            end
         end
      end
   end
```

In the CLI, you can also add, modify, and remove header fields in HTTP request when scanning web traffic in proxy-mode. If a header field exists when your FortiGate receives the request, its content will be modified based on the configurations in the URL filter.

Web Resume Download block

In the GUI, the configuration setting is limited to a checkbox.

Provide Details for Blocked HTTP 4xx and 5xx Errors

In the GUI, the configuration setting is limited to a checkbox.

HTTP POST Action

Remove Java Applet Filter

In the GUI, the configuration setting is limited to a checkbox.

Remove ActiveX Filter

In the GUI, the configuration setting is limited to a checkbox.

Remove Cookie Filter

In the GUI, the configuration setting is limited to a checkbox.

Web filtering example

Web filtering is particularly important for protecting school-aged children. There are legal issues associated with improper web filtering as well as a moral responsibility to keep children from viewing inappropriate material. The key is to design a web filtering system in such a way that students and staff do not fall under the same web filter profile in the FortiGate configuration. This is important because the staff may need to access websites that are off limits to the students.

School district

The background for this scenario is a school district with more than 2,300 students and 500 faculty and staff in a preschool, three elementary schools, a middle school, a high school, and a continuing education center. Each elementary school has a computer lab and the high school has three computer labs with connections to the Internet. Such easy access to the Internet ensures that every student touches a computer every day.

With such a diverse group of Internet users, it was not possible for the school district to set different Internet access levels. This meant that faculty and staff were unable to view websites that the school district had blocked. Another issue was the students' use of proxy sites to circumvent the previous web filtering system. A proxy server acts as a go-between for users seeking to view web pages from another server. If the proxy server has not been blocked by the school district, the students can access the blocked website.

When determining what websites are appropriate for each school, the district examined a number of factors, such as community standards and different needs of each school based on the age of the students.

The district decided to configure the FortiGate web filtering options to block content of an inappropriate nature and to allow each individual school to modify the options to suit the age of the students. This way, each individual school was able to add or remove blocked sites almost immediately and have greater control over their students' Internet usage.

In this simplified example of the scenario, the district wants to block any websites with the word **example** on them, as well as the website www.example.com. The first task is to create web content filter lists for the students and the teachers.

Web Filter in flow mode does not support Safe Search. The examples below use Web Filter in proxy mode.

Create a Web Filter profile for the students

1. Go to **Security Profiles > Web Filter**.
2. Select the **Create New** icon.
3. Enter the name "Students" in the name field.
4. For the Inspection mode, select **Proxy**.
5. Enable FortiGuard Categories.
   a. Set to block the following categories:

- Potentially Liable
- Adult/Mature Content
- Security Risk

URL Content

6. Enable **Enforce Safe Search**
   a. Check **Search Engine Safe Search - Google, Yahoo!, Bing, Yandex**
   b. Check **YouTube Education Filter** and enter the YouTube User ID
7. In the **Static URL Filter** section, enable **URL Filter**.
   a. In the **URL Filter** widget, Select **Create New**.
      i. In the **URL** field, enter *example*.*
      ii. For the **Type** field, select **Wildcard**
      iii. For the **Action** field, select **Block**
      iv. For the **Status** field, check **enable**
      v. Select **OK**

Web Content Filter

8. In the **Static URL Filter** section, enable **Web Content Filter**.
   a. In the **Web Content Filter** widget, select **Create New**.
   b. Enter the name “Teachers” in the name field.
      i. For the **Pattern Type** field, select
      ii. In the **Pattern** field, enter “example”
      iii. For the **Language** field, choose Western
      iv. For the **Action** field, select “Block”
      v. For the **Status** field, check Enable.
      vi. Select **OK**
9. Check **Rate URLs by Domain and IP Address**
10. Check Block HTTP Redirects by Rating
11. Check **Rate Images by URL (Blocked images will be replaced with blanks)**
12. Select **OK**

Create a Web Filter for the teachers

It might be more efficient if the Teacher Web Content List included the same blocked content as the student list. From time to time a teacher might have to view a blocked page. It would then be a matter of changing the **Action** from **Block** to **Allow** as the situation required. The following filter is how it could be set up for the teachers to allow them to see the “example” content if needed while keeping the blocking inappropriate material condition.

1. Go to **Security Profiles > Web Filter**.
2. Select the **Create New** icon.
3. Enter the name “Teachers” in the name field.
4. For the Inspection mode, select **Proxy**.
5. Enable FortiGuard Categories.
   a. Set to block the following categories:

- Potentially Liable
- Adult/Mature Content
- Security Risk

URL Content

6. Enable **Enforce Safe Search**
   a. Check **Search Engine Safe Search - Google, Yahoo!, Bing, Yandex**
   b. Check **YouTube Education Filter** and enter the YouTube User ID
7. In the Static URL Filter section, check Enable URL Filter.
   a. In the URL Filter widget, Select **Create New**.
      i. In the **URL** field, enter *example*.*
      ii. For the **Type** field, select Wildcard
      iii. For the **Action** field, select Block
      iv. For the **Status** field, check enable
      v. Select **OK**

Web Content Filter

8. In the Static URL Filter section, check Enable Web Content Filter.
   a. In the Web Content Filter widget, select **Create New**.
   b. Enter the name “Teachers” in the name field.
      i. For the **Pattern Type** field, select
      ii. In the **Pattern** field, enter “example”
      iii. For the **Language** field, choose Western
      iv. For the **Action** field, select “Exempt”
      v. For the **Status** field, check Enable.
      vi. Select **OK**
9. Check **Rate URLs by Domain and IP Address**
10. Check Block HTTP Redirects by Rating
11. Check **Rate Images by URL (Blocked images will be replaced with blanks)**
12. Select **OK**

To create a security policy for the students

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select the policy being used to manage student traffic.
3. Enable **Web Filter**.
4. Select **Students** from the web filter drop-down list.
5. Select **OK**.

To create a security policy for Teachers

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select the policy being used to manage teacher traffic.

3. Enable **Web Filter**.
4. Select **Teachers** from the web filter drop-down list.
5. Select **OK**.
6. Make sure that the student policy is in the sequence before the teachers' policy.

Domain Name System Filter concepts

With the release of FortiOS 5.4.0, users configure the Domain Name System (DNS) Filter security profile independent of the Web Filter security profile.

DNS-based web filtering

This feature is similar to the FortiGuard DNS web filtering available in FortiOS 5.2. You can configure DNS web filtering to allow, block, or monitor access to web content according to FortiGuard categories. When DNS web filtering is enabled, your FortiGate must use the FortiGuard DNS service for DNS lookups. DNS lookup requests sent to the FortiGuard DNS service return with an IP address and a domain rating that includes the FortiGuard category of the web page.

If that FortiGuard category is set to block, the result of the DNS lookup is not returned to the requester. If the category is set to redirect, then the address returned to the requester points at a FortiGuard redirect page.

You can also allow access or monitor access based on FortiGuard category.

Blocking DNS requests to known Botnet C&C addresses

A new FortiGuard database contains a list of known Botnet C&C addresses. This database is updated dynamically and stored on the FortiGate. This database is covered by FortiGuard web filter licensing, so you must have a FortiGuard web filtering license to use this feature.

When you block DNS requests to known Botnet C&C addresses, using IPS, DNS lookups are checked against the Botnet C&C database. All matching DNS lookups are blocked. Matching uses a reverse prefix match, so all sub-domains are also blocked.

To enable blocking of DNS requests to known Botnet C&C addresses, go to **Security Profiles > DNS Filter**, and enable **Block DNS requests to known botnet C&C**.

Static URL filter

The DNS inspection profile static URL filter allows you to block, exempt, or monitor DNS requests by using IPS to look inside DNS packets and match the domain being looked up with the domains on the static URL filter list. If there is a match the DNS request can be blocked, exempted, monitored, or allowed.

If blocked, the DNS request is blocked and so the user cannot look up the address and connect to the site.

If exempted, access to the site is allowed even if another method is used to block it.

CLI commands

Rename webfilter-sdns-server-ip and webfilter-sdns-server-port:

```
config system fortiguard
   set sdns-server-ip x.x.x.x
   set sdns-server-port 53
```

```
end
```

Configure DNS URL filter:

```
config dnsfilter urlfilter
   edit 1
      set name "url1"
      set comment ''
         config entries
            edit 1
               set url "www.google.com"
               set type simple
               set action block
               set status enable
            next
            edit 2
               set url "www.yahoo.com"
               set type simple
               set action monitor
               set status enable
            next
            edit 3
               set url "www.foritnet.com"
               set type simple
               set action allow
               set status enable
            next
         end
   next
end
```

Configure DNS filter profile:

```
config dnsfilter profile
   edit "dns_profile1"
      set comment ''
         config urlfilter
            set urlfilter-table 1
         end
         config ftgd-dns
               config filters
                  edit 1
                     set category 49
                     set action block
                     set log enable
                  next
                  edit 2
                     set category 71
                     set action monitor
                     set log enable
                  next
               end
         end
      set log-all-url disable
      set block-action redirect
      set redirect-portal 0.0.0.0
      set block-botnet enable
   next
```

```
end
```

Configure DNS profile in a firewall policy:

```
config firewall policy
   edit 1
      set srcintf "any"
      set dstintf "any"
      set srcaddr "all"
      set dstaddr "all"
      set action accept
      set schedule "always"
      set service "FTP"
      set utm-status enable
      set dnsfilter-profile "dns_profile1"
      set profile-protocol-options "default"
      set nat enable
   next
end
```

Configure DNS profile in profile group:

```
config firewall profile-group
   edit "pgrp1"
      set dnsfilter-profile "dns_profile1"
      set profile-protocol-options "default"
   next
end
```

FortiGuard Botnet protection

Preventing botnets from controlling your system is achieved by detecting and blocking connection attempts to known botnets. This feature also blocks connections to known phishing sites. The FortiGuard database is continually updated with addresses of known Command and Control (C&C) sites that botnet clients attempt to connect to, as well as a addresses of known phishing URLs.

To enable botnet and phishing protection in a DNS Filter profile, enable **Block DNS requests to known botnet C&C**.

The latest botnet database is available from FortiGuard. To see the version of the database and display its contents, go to **System > FortiGuard > Botnet Definitions**. You can also block, monitor, or allow outgoing connections to botnet sites for each FortiGate interface.

Both the DNS Filter security profile and Botnet protection feature are only available for proxy-based inspection in FortiOS versions 5.4.0 and 5.4.1.
These features are available for both proxy-based and flow-based inspection in FortiOS versions 5.4.2 and above.

Improved Visibility of Botnet and Command & Control (C&C) protection in FortiOS 5.4.1

Mobile & Botnet C&C license information is now displayed in the License Information widget in the Dashboard. Additionally, you can view the list of Botnet C&C packages in the IP Reputation Database (IRDB) and the Botnet Domain Database (BDDB) from the License Information widget.

A button has been added to the GUI on the DNS filter page allowing you to block DNS requests known to FortiGuard. When you enable this feature, you can open a definitions window by clicking on "botnet package."

Access to the IRDB is available to users through FortiCare support contracts purchased or renewed before October 1, 2016. After that date, users will have to subscribe to the IRDB either through the FortiGuard Mobility Security Service (FMSS) or the FortiGuard Enterprise Bundle.

Application Control

Using the Application Control Security Profile feature, your FortiGate unit can detect and take action against network traffic depending on the application generating the traffic. Based on FortiGate Intrusion Protection protocol decoders, application control is a user-friendly and powerful way to use Intrusion Protection features to log and manage the behavior of application traffic passing through the FortiGate unit. Application control uses IPS protocol decoders that can analyze network traffic to detect application traffic even if the traffic uses non-standard ports or protocols. Application control supports detection for traffic using HTTP protocol (versions 1.0, 1.1, and 2.0).

The FortiGate unit can recognize the network traffic generated by a large number of applications. You can create application control sensors that specify the action to take with the traffic of the applications you need to manage and the network on which they are active, and then add application control sensors to the firewall policies that control the network traffic you need to monitor.

Fortinet is constantly adding to the list of applications detected through maintenance of the FortiGuard Application Control Database. This database is part of the FortiGuard Intrusion Protection System Database because intrusion protection protocol decoders are used for application control and both of these databases have the same version number.

You can find the version of the application control database installed on your unit by going to the **License Information** widget on the **Dashboard** and locating the **IPS Definitions** version. Additionally, you can see the complete list of applications supported by FortiGuard Application Control on the FortiGuard site or http://fortiguard.com/appcontrol. This web page lists all of the supported applications. You can select any application name to see details about the application.

If you enable virtual domains (VDOMs) on the Fortinet unit, you need to configure application control separately for each virtual domain.

This Handbook chapter includes Inside FortiOS: Application Control and provides readers an overview of the features and benefits of key FortiOS 5.4 components.

For readers needing to delve into greater detail, we provide the following topics:

Application control concepts

You can control network traffic generally by the source or destination address, or by the port, the quantity or similar attributes of the traffic itself in the security policy. If you want to control the flow of traffic from a specific application, these methods may not be sufficient to precisely define the traffic. To address this problem, the application control feature examines the traffic itself for signatures unique to the application generating it. Application control does not require knowledge of any server addresses or ports. The FortiGate unit includes signatures for over 1000 applications, services, and protocols.

Updated and new application signatures are delivered to your FortiGate unit as part of your FortiGuard Application Control Service subscription. Fortinet is constantly increasing the number of applications that this feature can detect by adding applications to the FortiGuard Application Control Database. Because intrusion protection protocol decoders are used for application control, the application control database is part of the FortiGuard Intrusion Protection System Database. Both of these databases have the same version number.

To view the version of the application control database installed on your FortiGate unit, go to the **License Information** dashboard widget and find the **IPS Definitions** version.

To see the complete list of applications supported by FortiGuard Application Control go to the FortiGuard site or http://fortiguard.com/appcontrol. This web page lists all of the supported applications. You can select any application name to see details about the application.

Enable application control

Application control examines your network traffic for traffic generated by the applications you want it to control.

General configuration steps

Follow the configuration procedures in the order given. Also, note that if you perform any additional actions between procedures, your configuration may have different results.

1. Create an application sensor.
2. Configure the sensor to include the signatures for the application traffic you want the FortiGate unit to detect.
3. Enable any other applicable options.
4. Enable application control in a security policy and select the application sensor.

Creating an application sensor

You need to create an application sensor before you can enable application control.

To create an application sensor

1. Go to **Security Profiles > Application Control**.
2. Select the **Create New** icon in the title bar of the **Edit Application Sensor** window.
3. In the **Name** field, enter the name of the new application sensor.
4. Optionally, you may also enter a comment.

Adding applications to an application sensor

Once you have created an application sensor, you need to need to define the applications that you want to control. You can add applications and filters using categories, application overrides, and/or filter overrides. Categories will allow you to choose groups of signatures based on a category type. Application overrides allow you to choose individual applications. Filter overrides allow you to select groups of applications and override the application signature settings for them.

To add a category of signatures to the sensor.

1. Go to **Security Profiles > Application Control**.
2. Under **Categories**, you may select from the following:
   - Botnet
   - Business
   - Cloud.IT
   - Collaboration
   - Email
   - Game

- General.Interest
- Mobile
- Network.Service
- P2P
- Proxy
- Remote.Access
- Social.Media
- Storage.Backup
- Update
- Video/Audio
- VoIP
- Web.Clients
- Unknown Applications

When selecting the category that you intend to work with, left click on the icon next to the category name to produce a drop down menu that includes these actions:

- Allow
- Monitor
- Block
- Quarantine
- View Signatures

These actions are briefly defined under Application Control actions on page 2724.

3. If you wish to add individual applications, select **Add Signatures** under **Application Overrides**.
   a. Use the **Add Filter** search field to narrow down the list of possible signatures by a series of attributes.
   b. When finished, select **Use Selected Signatures**.
4. If you wish to add advanced filters, select **Add Filter** under **Filter Overrides**.
   a. Use the Add Filter search field to narrow down the list of possible filters by a series of attributes.
   b. When finished, select **Use Filters**.
4. Select, if applicable, from the following options:
   - **Allow and Log DNS Traffic**
   - **Replacement Messages for HTTP-based Applications**
6. Select **OK**.

   There is a disabled category called **Industrial**. This category is disabled by default, however it can be applied through use of the CLI command below. Note that `none` will mean no signatures are excluded, and that `industrial` will exclude all industrial signatures.

   CLI Syntax

```
config ips global
   set exclude-signatures [none | industrial]
end
```

Applying the application sensor to a security policy

An application sensor directs the FortiGate unit to scan network traffic only when it is selected in a security policy. When an application sensor is selected in a security policy, its settings are applied to all the traffic the security policy handles.

To select the application sensor in a security policy — GUI

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select a policy.
3. Click the **Edit** icon.
4. Under the heading **Security Profiles** toggle the button next to **Application Control** to enable the feature.
5. In the drop down menu field next to the **Application Control** select the application sensor you wish to apply to the policy.
6. Select **OK**.

Creating a new custom application signature

If you have to deal with an application that is not already in the **Application List** you have the option to create a new application signature.

1. Go to **Security Profiles > Application Control**.
2. Select the link in the upper right corner, **[View Application Signatures]**
3. Select the **Create New** icon
4. Give the new signature a name (no spaces) in the **Name** field.
5. Enter a brief description in the **Comments** field
6. Enter the text for the signature in the signature field. Use the rules found under Custom IPS signature to determine syntax.
7. Select **OK.**

You can configure rate-based application control signatures in the CLI Console using similar IPS signature rate CLI commands.

For more information on this and the CLI syntax, see IPS signature rate count threshold on page 2742

Messages in response to blocked applications

Once an Application Control sensor has been configured to block a specified application and applied to a policy it would seem inevitable that at some point an application will end up getting blocked, even if it is only to test the functionality of the control. When this happens, the sensor can be set to either display a message to offending user or to just block without any notification. The default setting is to display a message. Setting this up is done in the CLI.

```
config application list
   edit <name of the sensor>
      set app-replacemsg {enable | disable}
   end
```

When blocking applications, there is no replacement message for SSL traffic with certificate inspection applied.
When SSL deep inspection is enabled, a replacement message will appear depending on the protocol. For example, with HTTP2, the blocking is done in the SSL key exchange once the first server packet is delivered and replacement messages can not be displayed.

P2P application detection

P2P software tends to be evasive. You may be able to enhance P2P application detection by matching patterns found in the most recent three minutes of P2P traffic to determine if new traffic is P2P. Three minutes is the length of time information about matched P2P traffic remains in shared memory.

For example, the CLI commands below will result in the Intrusion Prevention System (IPS) looking for patterns formed by Skype traffic.

```
config application list
   edit <app_list_str>
      set p2p-black-list skype
   end
end
```

Application Control actions

The first four actions are edited by right-clicking in the Action column of **Application Overrides** or **Filter Overrides**. The last action is accessed at the upper right-hand corner of the screen.

All five actions are also available options when you left click on the icon next to an item in **Categories** to produce a drop down menu.

Allow

This action allows the targeted traffic to continue on through the FortiGate.

Monitor

This action allows the targeted traffic to continue on through the FortiGate unit but logs the traffic for analysis.

Block

This action prevents all traffic from reaching the application and logs all occurrences.

Quarantine

This action allows you to quarantine or block access to an application for a specified duration that can be entered in days, hours, and minutes. The default is 5 minutes.

View Signatures / View Application Signatures

This option is in the upper-right hand corner of the screen OR when you left click on the icon next to an item in **Categories** to produce a drop down menu. A window opens that displays a list of the signatures with the

following columns:

- Name
- Category
- Technology - Technology is broken down into 3 technology models as well as the more basic Network-Protocol which would can be used as a catch all for anything not covered by the more narrowly defined technologies of:
  - Browser-Based
  - Client-Server
  - Peer-to-Peer
- Popularity - Popularity is broken down into 5 levels of popularity represented by stars.
- Risk - The risk property does not indicate the level of risk but the type of impact that is likely to occur by allowing the traffic from that application to occur.

Resetting the Network in CLI

Through the CLI command `set action {pass | block | reset}`, you can also reset the network connection if traffic matches the specified application(s) on the application control list. The default of this command is `block`.

CLI Syntax

```
config application list
   edit default
      config entries
         edit 1
            set action reset
         end
      end
```

Traffic Shaping

Prior to the release of FortiOS 5.4.0, application control traffic shaping was configured in the **Security Profiles > Application Control** interface. There is now a specific section for traffic shaping policies in **Policy & Objects > Traffic Shaping Policy**. See Traffic shaping methods in the chapter on Traffic Shaping for details.

Application considerations

Some applications behave differently from most others. You should be aware of these differences before using application control to regulate their use.

IM applications

IM applications are controlled by either permitting or denying the users from logging in to the service. Individual IM accounts are configured as to whether or not they are permitted and then there is a global policy for how to action unknown users, by the application and whether to add the user to the black list or the white list. IM applications fall under the **Collaboration** category in the application signature database.

Skype

Based on the NAT firewall type, Skype takes advantage of several NAT firewall traversal methods, such as STUN (Simple Traversal of UDP through NAT), ICE (Interactive Connectivity Establishment) and TURN (Traversal Using Relay NAT), to make the connection.

The Skype client may try to log in with either UDP or TCP, on different ports, especially well-known service ports, such as HTTP (80) and HTTPS (443), because these ports are normally allowed in firewall settings. A client who has previously logged in successfully could start with the known good approach, then fall back on another approach if the known one fails.

The Skype client could also employ Connection Relay. This means if a reachable host is already connected to the Skype network, other clients can connect through this host. This makes any connected host not only a client but also a relay server.

SPDY

SPDY (pronounced speedy, it's a trademarked name not an acronym) is a networking protocol developed to increase the speed and security of HTML traffic. It was developed primarily by Google. The Application Control engine recognizes this protocol and its required SSL/TLS component within Application Control sensors. It is counted as part of application traffic for Google and other sources that use the protocol.

Application control monitor

The application monitor enables you to gain insight into the applications generating traffic on your network. When monitor is enabled in an application sensor entry and the list is selected in a security policy, all the detected traffic required to populate the selected charts is logged to the SQL database on the FortiGate unit hard drive. The charts are available for display in the **Applications** section of the **FortiView** menu.

Because the application monitor relies on an SQL database, the feature is available only on FortiGate units with an internal hard drive.

Application monitor data is stored on the hard drive and restarting the system does not affect the stored monitor data.

Application control data is available in **Log & Report**, if enabled.

Application control examples

The scenarios below provide a better understanding of how to implement Application Control and give some ideas as to why it would be used.

- Blocking instant messaging
- Allowing only software updates
- Blocking Windows XP with a custom signature

Blocking instant messaging

Instant messaging use is not permitted at the Example Corporation. Application control helps enforce this policy.

Steps in this process

1. First you will create an application sensor with a single entry that monitors the category that includes instant messaging applications. You will set the list action to **Monitor**.
2. Next you will assign the sensor to a policy.

3. Then you will identify the IM applications being used on your network and modify the application sensor to **Block** use of those messaging applications

To create the application sensor

1. Go to **Security Profiles > Application Control**.
2. Select the **Create New** icon in the title bar of the **Edit Application Sensor** window.
3. In the **Name** field, enter `no_IM` for the application sensor name.
4. If the **Collaboration** category is not already set to **Monitor**, then left-click on that category and select **Monitor** from the dropdown menu.
5. Select **OK** to save the new sensor.

To enable application control and select the application sensor

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select the security policy that allows the network users to access the Internet and choose **Edit**.
3. Under the heading **Security Profiles** toggle the button next to **Application Control** to turn it on.
4. In the drop down menu field next to the **Application Control** select the **no_IM** application sensor.
5. To inspect all traffic, **SSL/SSH inspection** must be set to **deep-inspection** profile.
6. Select **OK**.

To identify IM applications in use on your network

1. Go to **FortiView > Applications**.
2. Select a time period from the options in the upper-right corner of the window and examine the list of applications.
3. Identify any IM applications you wish to block.

To block IM applications in use on your network

1. Go to **Security Profiles > Application Control** and edit the **no_IM** application sensor.
2. Under **Application Overrides**, click on **Add Signatures**.
3. Filter by **Name** and select the IM applications you wish to block.
4. Click on **Use Selected Signatures**.

The selected application will appear under Application Overrides and the action will be set to Block.

5. Select **Apply**.

The IM applications identified will be blocked by the security policy that has the **no IM** application sensor applied to it. If other firewall policies handle traffic that users could use for applications in the same category, enable application control with the **no IM** application sensor for those policies as well.

Allowing only software updates

Some departments at Example Corporation do not require access to the Internet to perform their duties. Management therefore decided to block their Internet access. Software updates quickly became an issue because automatic updates will not function without Internet access and manual application of updates is time-consuming.

The solution is configuring application control to allow only automatic software updates to access the Internet.

To create an application sensor — web-based manager

1. Go to **Security Profiles > Application Control**.
2. Select the **Create New** icon in the title bar of the **Edit Application Sensor** window.
3. In the **Name** field, enter `Updates_Only` as the application sensor name.
4. Using the left-click and drop down on the items in the **Category** list…
   a. Select **Monitor** from the dropdown menu.
   b. Select **Block** for the rest of the categories.
5. Select **OK**.

To create an application sensor — CLI

```
config application list
   edit Updates_Only
      config entries
         edit 1
            set category 17
            set action pass
         end
      set other-application-action block
      set unknown-application-action block
   end
```

You will notice that there are some differences in the naming convention between the Web Based Interface and the CLI. For instance the **Action** in the CLI is "`pass`" and the **Action** in the Web Based Manager is "**Monitor".**

Selecting the application sensor in a security policy

An application sensor directs the FortiGate unit to scan network traffic only when it is selected in a security policy. When an application sensor is selected in a security policy, its settings are applied to all the traffic the security policy handles.

To select the application sensor in a security policy — GUI

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select a policy.
3. Select the **Edit** icon.
4. Under the heading **Security Profiles** toggle the button next to **Application Control** to turn it on.
5. In the drop down menu field next to the **Application Control** select the `Updates_only` list.
6. Select **OK**.

To select the application sensor in a security policy — CLI

```
config firewall policy
   edit 1
      set utm-status enable
      set profile-protocol-options default
      set application-list Updates_Only
   end
```

Traffic handled by the security policy you modified will be scanned for application traffic. Software updates are permitted and all other application traffic is blocked.

Blocking Windows XP with a custom signature

In this example, you will use application control to block web traffic from PCs running Windows operating systems NT 5, including Windows XP and Windows Server 2003 (includes Windows virtual machines).

When a computer's operating system lacks vendor support, it becomes a threat to the network because newly discovered exploits will not be patched. Using the FortiGate application control feature, you can restrict these computers from accessing external resources.

This example will only block web traffic from computers running the affected operating systems. If you wish to block these computers from being on the network entirely, further action will be necessary. However, the logs generated can be used to identify the computers you wish to block.

1. Go to **System > Feature Select**. Enable **Application Control** and **Apply** your changes.
2. Go to **Security Profiles > Application Control** and select **View Application Signatures**.
3. Create a new signature with the syntax below. You can copy and paste the text into the **Signature** field. Name the signature *Block-Windows-NT5*.

   ```
   F-SBID(--attack_id 8055;--vuln_id 8055;--name
   "Windows.NT.5.Web.Surfing";--flow from_client;--pattern !"FCT";--
   pattern "Windows NT 5.";--no_case;--context header;--weight 40;--
   service HTTP;--protocol tcp;--app_cat 25;--default_action drop_
   session;)
   ```

   If you do not include keyword / value pairs for `--attack_id` or `--vuln_ID` in the signature, the FortiGate will automatically assign values.

   The signature will appear at the top of the application list and be listed in the **Web.Client** category.
4. Go to **Security Profiles > Application Control** and edit the **default** policy.
5. Under **Application Overrides**, select **Add Signatures**. The new signature should appear at the top of the list. If it does not, search for the signature's name.
6. Select the signature, then select **Use Selected Signatures**.
7. Go to **Policy & Objects > IPv4 Policy** and edit the policy that allows connections from the internal network to the Internet.
8. Under **Security Profiles**, turn on **Application Control** and use the **default** profile.

Results

When a PC running one of the affected operating systems attempts to connect to the Internet using a browser, a blocked message appears. Because Application Control uses flow-based inspection, if you apply an additional security profile to your traffic that is proxy-based, the connection will simply timeout rather than display the replacement message. However, Application Control will still function.

PCs running other operating systems, including later versions of Windows, are not affected.

Go to **FortiView > All Sessions** and select the **5 minutes** view.

Filter the results to show sessions that were blocked.

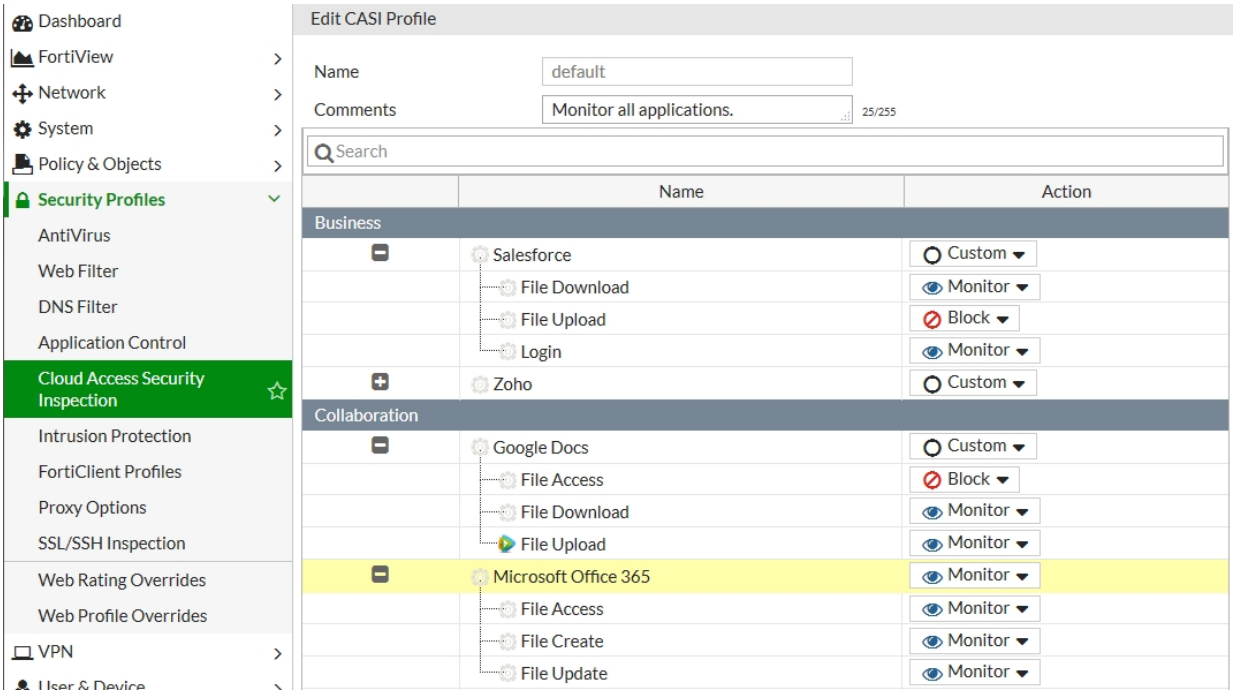
You will see that the Application Control signature, shown in the **Application Name** column, was used to block traffic from PCs running older Windows versions.

For further reading, see Custom Application & IPS Signatures.

Cloud Access Security Inspection (CASI)

This feature introduces a new security profile called Cloud Access Security Inspection (CASI) that provides support for fine-grained control on popular cloud applications, such as YouTube, Dropbox, Baidu, and Amazon. The CASI profile is applied to a policy much like any other security profile.

Unfortunately CASI does not work when using Proxy-based profiles for AV or Web filtering for example.
Make sure to only use Flow-based profiles in combination with CASI on a specific policy.



For this feature, **Deep Inspection of Cloud Applications** (`set deep-app-inspection [enable|disable]`) has been moved out of the **Application Control** security profile options.

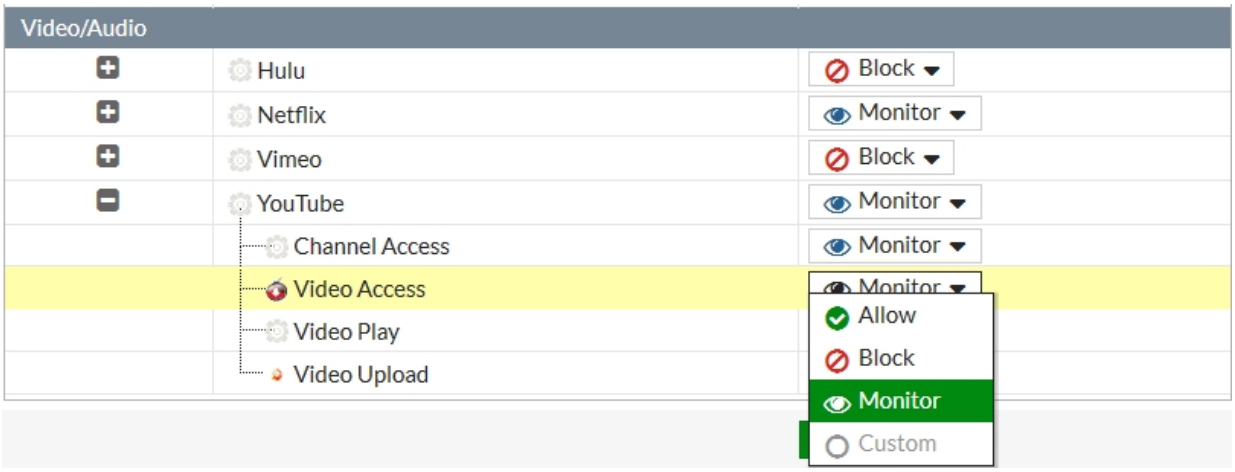
You will find the Cloud Access Security Inspection feature under **Security Profiles > Cloud Access Security Inspection**, but you must first enable it in the Feature store under **System > Feature Select > CASI**.

Editing CASI profiles

The CASI profile application list consists of the **Name**, **Category**, and **Action**. A default CASI profile exists, with the option to create custom profiles.

There is an **improvement to the CASI GUI (303760)** under release 5.4.1. When you search for a profile application to edit, you can hit enter after typing your search terms to see the results. Under release 5.4.0, hitting enter causes the screen to refresh and the profile to be applied.

For each CASI profile application, the user has the option to **Allow**, **Block**, or **Monitor** the selected cloud application. The following image demonstrates the ability to **Allow**, **Block**, or **Monitor** YouTube using CASI:



When the user drills down into a selected cloud application, the following options are available (depending on the type of service):

- **For business services, such as Salesforce and Zoho:** Option to allow, block, or monitor file download/upload and login.
- **For collaboration services, such as Google.Docs and Webex:** Option to allow, block, or monitor file access/download/upload and login.
- **For web email services, such as Gmail and Outlook:** Option to allow, block, or monitor attachment download/upload, chat, read/send message.
- **For general interest services, such as Amazon, Google, and Bing:** Option to allow, block, or monitor login, search phase, and file download/upload.
- **For social media services, such as Facebook, Twitter, and Instagram:** Option to allow, block, or monitor chat, file download/upload, post, login.
- **For storage backup services, such as Dropbox, iCloud, and Amazon Cloud Drive:** Option to allow, block, or monitor file access/download/upload and login.
- **For video/audio services, such as YouTube, Netflix, and Hulu**:
  Option to allow, block, or monitor channel access, video access/play/upload, and login.

CLI Syntax

```
configure application casi profile
   edit "profile name"
      set comment "comment"
      set replacemsg-group "xxxx"
      set app-replacemsg [enable|disable]
      configure entries
         edit
            set application "app name"
            set action [block|pass]
            set log [enable|disable]
         next
         edit 2
   next
end
```

```
configure firewall policy
   edit "1"
      set casi-profile "profile name"
   next
end

config firewall sniffer
   edit 1
      set casi-profile-status [enable|disable]
      set casi-profile "sniffer-profile"
   next
end

config firewall interface-policy
   edit 1
      set casi-profile-status [enable|disable]
      set casi-profile "2"
   next
end
```

New Entry

Intrusion protection

This section discusses the Security Profiles > Intrusion Protection feature in FortiOS 5.4.

The FortiOS Intrusion Prevention System (IPS) combines signature detection and prevention with low latency and excellent reliability. With intrusion protection, you can create multiple IPS sensors, each containing a complete configuration based on signatures. Then, you can apply any IPS sensor to any security policy.

This section describes how to configure the IPS settings.

If you enable virtual domains (VDOMs) on the FortiGate unit, intrusion prevention, called intrusion protection in the FOS 5.4 GUI, is configured separately for each virtual domain.

This Handbook chapter includes Inside FortiOS: Intrusion Prevention System providing readers an overview of the features and benefits of key FortiOS 5.4 components.

For readers needing to delve into greater detail, we provide the following topics:

- IPS concepts
- Enable IPS scanning
- Configure IPS options
- Enable IPS packet logging
- IPS examples

IPS concepts

The FortiOS Intrusion Prevention System (IPS) protects your network from outside attacks. Your FortiGate unit has two techniques to deal with these attacks: anomaly- and signature-based defense.

Anomaly-based defense

Anomaly-based defense is used when network traffic itself is used as a weapon. A host can be flooded with far more traffic than it can handle, making the host inaccessible. The most common example is the denial of service (DoS) attack, in which an attacker directs a large number of computers to attempt normal access of the target system. If enough access attempts are made, the target is overwhelmed and unable to service genuine users. The attacker does not gain access to the target system, but it is not accessible to anyone else.

The FortiGate DoS feature will block traffic above a certain threshold from the attacker and allow connections from other legitimate users. The DoS policy configuration can be found in the Firewall Handbook.

Access control lists in DoS Policies

This feature allows you to define a list of IPs/subnets/ranges in a DoS policy, and block those IPs from sending any traffic, by way of an ACL (access control list). The ACL looks similar to a firewall policy, but only checks source IP, destination IP, destination port, and protocol.

CLI Syntax

```
config firewall acl
   edit 1
      set interface "port1"
      set srcaddr "google-drive"
      set dstaddr "all"
      set service "ALL"
   next
end
```

Signature-based defense

Signature-based defense is used against known attacks or vulnerability exploits. These often involve an attacker attempting to gain access to your network. The attacker must communicate with the host in an attempt to gain access and this communication will include particular commands or sequences of commands and variables. The IPS signatures include these command sequences, allowing the FortiGate unit to detect and stop the attack.

Signatures

IPS signatures are the basis of signature-based intrusion protection. Every attack can be reduced to a particular string of commands or a sequence of commands and variables. Signatures include this information so your FortiGate unit knows what to look for in network traffic.

Signatures also include characteristics about the attack they describe. These characteristics include the network protocol in which the attack will appear, the vulnerable operating system, and the vulnerable application.

To view the complete list of signatures, go to **Security Profiles > Intrusion Protection**, and select **View IPS Signatures**. This will include the predefined signatures and any custom signatures that you may have created.

Protocol decoders

Before examining network traffic for attacks, the IPS engine uses protocol decoders to identify each protocol appearing in the traffic. Attacks are protocol-specific, so your FortiGate unit conserves resources by looking for attacks only in the protocols used to transmit them. For example, the FortiGate unit will only examine HTTP traffic for the presence of a signature describing an HTTP attack.

IPS engine

Once the protocol decoders separate the network traffic by protocol, the IPS engine examines the network traffic for the attack signatures.

IPS sensors

The IPS engine does not examine network traffic for all signatures. You must first create an IPS sensor and specify which signatures are included. Add signatures to sensors individually using signature entries, or in groups using IPS filters.

To view the IPS sensors, go to **Security Profiles > Intrusion Protection**.

There is a disabled group of industrial signatures. This category is disabled by default, however it can be applied through use of the CLI command below. Note that `none` will mean no signatures are excluded, and that `industrial` will exclude all industrial signatures.

CLI Syntax

```
config ips global
   set exclude-signatures [none | industrial]
end
```

IPS filters

IPS sensors contain one or more IPS filters. A filter is a collection of signature attributes that you specify. The signatures that have all of the attributes specified in a filter are included in the IPS filter.

For example, if your FortiGate unit protects a Linux server running the Apache web server software, you could create a new filter to protect it. By setting **OS** to **Linux**, and **Application** to **Apache,** the filter will include only the signatures that apply to both Linux and Apache. If you wanted to scan for all the Linux signatures and all the Apache signatures, you would create two filters, one for each.

To view the filters in an IPS sensor, go to **Security Profiles > Intrusion Protection**, select the IPS sensor containing the filters you want to view, and select **Edit**.

Custom/predefined signature entries

Signature entries allow you to add an individual custom or predefined IPS signature. If you need only one signature, adding a signature entry to an IPS sensor is the easiest way. Signature entries are also the only way to include custom signatures in an IPS sensor.

Another use for signature entries is to change the settings of individual signatures that are already included in a filter within the same IPS sensor. Add a signature entry with the required settings above the filter, and the signature entry will take priority.

Policies

To use an IPS sensor, you must select it in a security policy or an interface policy. An IPS sensor that it not selected in a policy will have no effect on network traffic.

IPS is most often configured as part of a security policy. Unless stated otherwise, discussion of IPS sensor use will be in regards to firewall policies in this document.

Session timers for IPS sessions

A session time-to-live (TTL) timer for IPS sessions is available to reduce synchronization problems between the FortiOS Kernel and IPS, and to reduce IPS memory usage. The timeout values can be customized.

Enable IPS scanning

Enabling IPS scanning involves two separate parts of the FortiGate unit:

- The security policy allows certain network traffic based on the sender, receiver, interface, traffic type, and time of day. Firewall policies can also be used to deny traffic, but those policies do not apply to IPS scanning.
- The IPS sensor contains filters, signature entries, or both. These specify which signatures are included in the IPS sensor.

When IPS is enabled, an IPS sensor is selected in a security policy, and all network traffic matching the policy will be checked for the signatures in the IPS sensor.

General configuration steps

For best results in configuring IPS scanning, follow the procedures in the order given. Also, note that if you perform any additional actions between procedures, your configuration may have different results.

1. Create an IPS sensor.
2. Add signatures and /or filters.
   These can be:
   - Pattern based
   - Rate based
   - Customized
3. Select a security policy or create a new one.
4. In the security policy, turn on **IPS**, and choose the IPS sensor from the list.

All the network traffic controlled by this security policy will be processed according to the settings in the policy. These settings include the IPS sensor you specify in the policy.

Creating an IPS sensor

You need to create an IPS sensor before specific signatures or filters can be chosen. The signatures can be added to a new sensor before it is saved. However, it is good practice to keep in mind that the sensor and its included filters are separate things, and that they are created separately.

To create a new IPS sensor

1. Go to **Security Profiles > Intrusion Protection**.
2. Select the **Create New** icon in the top of the Edit IPS Sensor window.
3. Enter the name of the new IPS sensor.
4. Optionally, you may also enter a comment. The comment will appear in the IPS sensor list and serves to remind you of the details of the sensor.
5. Select **OK**.

A newly created sensor is empty and contains no filters or signatures. You need to add one or more filters or signatures before the sensor will be of any use.

Adding an IPS filter to a sensor

While individual signatures can be added to a sensor, a filter allows you to add multiple signatures to a sensor by specifying the characteristics of the signatures to be added.

To create a new Pattern Based Signature and Filter

1. Go to **Security Profiles > Intrusion Protection**.
2. Select the IPS sensor to which you want to add the filter using the drop-down list in the top row of the Edit IPS Sensor window or by going to the list window.
3. Under **IPS Filters**, select **Add Filter**.
4. Configure the filter that you require. Signatures matching all of the characteristics you specify in the filter will be included in the filter. Once finished, select **Use Filters**.

Application refers to the application affected by the attack and filter options include over 25 applications.

OS refers to the Operating System affected by the attack. The options include **BSD**, **Linux**, **MacOS**, **Other**, **Solaris**, and **Windows**.

Protocol refers to the protocol that is the vector for the attack; filter options include over 35 protocols, including "other."

Severity refers to the level of threat posed by the attack. The options include **Critical**, **High**, **Medium**, **Low**, and **Info**.

Target refers to the type of device targeted by the attack. The options include **client** and **server**.

5. Once you have selected the filters you wish to add, right-click the filters and choose an action for when a signature is triggered:

Action	Description
Pass	Select **Pass** to allow traffic to continue to its destination. **Note:** to see what the default for a signature is, go to the **IPS Signatures** page and enable the column **Action**, then find the row with the signature name in it.
Monitor	Select **Monitor** to allow traffic to continue to its destination and log the activity. The log will appear under Log & Report but will only be visible in the GUI in the event of an intrusion.
Block	Select **Block** to drop traffic matching any the signatures included in the filter.
Reset	Select **Reset** to reset the session whenever the signature is triggered. In the CLI this action is referred to as Reject.
Default	Select **Default** to use the default action of the signature.
Quarantine	The quarantine based on the attacker's IP Address - Traffic from the Attacker's IP address is refused until the expiration time from the trigger is reached. You may set the **Quarantine Duration** to any number of **Days**, **Hours**, or **Minutes**.
Packet Logging	Select to enable packet logging for the filter. When you enable packet logging on a filter, the unit saves a copy of the packets that match any signatures included in the filter. The packets can be analyzed later. For more information about packet filtering, see "Configuring packet logging options".

6. Select **Apply**.

The filter is created and added to the filter list.

Adding Rate Based Signatures

These are a subset of the signatures that are found in the database that are normally set to monitor. This group of signatures is for vulnerabilities that are normally only considered a serious threat when the targeted connections come in multiples, a little like DoS attacks.

Adding a rate based signature is straight forward. Select the enable button in the Rate Based Signature table that corresponds with the desired signature.

Customized signatures

Customized signatures must be created before they can be added to the sensor. To get more details on customized signatures check the Custom Application & IPS Signatures chapter.

Updating predefined IPS signatures

The FortiGuard Service periodically updates the predefined signatures and adds new signatures to counter emerging threats as they appear.

To ensure that your system is providing the most protection available, these updates can be scheduled as often as on an hourly basis. To configure this feature, go to **System > FortiGuard**. Under **AntiVirus & IPS Updates**, enable **Scheduled Updates**. From here you can set the updates to occur on a consistent weekly, daily, or even hourly basis.

Because the signatures included in filters are defined by specifying signature attributes, new signatures matching existing filter specifications will automatically be included in those filters. For example, if you have a filter that includes all signatures for the Windows operating system, your filter will automatically incorporate new Windows signatures as they are added.

Viewing and searching predefined IPS signatures

Go to **Security Profiles > Intrusion Protection**. Select **[View IPS Signatures]** to view the list of existing IPS signatures. You may find signatures by paging manually through the list, apply filters, or by using the search field.

Searching manually

Signatures are displayed in a paged list, with 50 signatures per page. The bottom of the screen shows the current page and the total number of pages. You can enter a page number and press enter, to skip directly to that page. Previous Page and Next Page buttons move you through the list, one page at a time. The First Page and Last Page button take you to the beginning or end of the list.

Searching CVE-IDs

A **CVE-ID** column displaying CVE-IDs can be optionally added to the IPS Signatures list, however the column is only available if the IPS package contains CVE-IDs for signatures. CVE-IDs can be numerically filtered by selecting the CVE-ID column's arrows.

Applying filters

You can enter criteria for one of more columns, and only the signatures matching all the conditions you specify will be listed.

To apply filters

1. Go to **Security Profiles > Intrusion Protection.** Select **[View IPS Signatures] .**
2. Select column by which to filter.
3. Select the funnel/filter icon and enter the value or values to filter by.
4. Use additional columns as needed to refine search.

The available options vary by column. For example, **Enable** allows you to choose between two options, while OS has multiple options, and you may select multiple items together. Filtering by name allows you to enter a text string and all signature names containing the string will be displayed.

IPS processing in an HA cluster

IPS processing in an HA cluster is no different than with a single FortiGate unit, from the point of view of the network user. The difference appears when a secondary unit takes over from the primary, and what happens depends on the HA mode.

Active-passive

In an active-passive HA cluster, the primary unit processes all traffic just as it would in a stand-alone configuration. Should the primary unit fail, a secondary unit will assume the role of the primary unit and begin to process network traffic. By default, the state of active communication sessions are not shared with secondary units and will not survive the fail-over condition. Once the sessions are reestablished however, traffic processing will continue as normal.

If your network requires that active sessions are taken over by the new primary unit, select **Enable Session Pick-up** in your HA configuration. Because session information must be sent to all subordinate units on a regular basis, session pick-up is a resource-intensive feature and is not enabled by default.

Active-active

The fail-over process in an active-active cluster is similar to an active-passive cluster. When the primary unit fails, a secondary unit takes over and traffic processing continues. The load-balancing schedule used to distribute sessions to the cluster members is used by the new primary unit to redistribute sessions among the remaining subordinate units. If session pick-up is not enabled, the sessions active on the failed primary are lost, and the sessions redistributed among the secondary units may also be lost. If session pick-up is enabled, all sessions are handled according to their last-known state.

Configure IPS options

The following IPS configuration options are available:

- Malicious URL database for drive-by exploits detection
- Customizable replacement message when IPS blocks traffic
- Hardware Acceleration
- Extended IPS Database
- Configuring the IPS engine algorithm
- Configuring the IPS engine-count
- Configuring fail-open
- Configuring the session count accuracy
- Configuring IPS intelligence
- Configuring the IPS buffer size
- Configuring protocol decoders
- Configuring security processing modules
- IPS signature rate count threshold

Malicious URL database for drive-by exploits detection

This feature uses a local malicious URL database on the FortiGate to assist in drive-by exploits detection. The database contains all malicious URLs active in the last one month, and all drive-by exploit URLs active in the last

three months. The number of URLs are controlled in the one million range.

CLI Syntax

```
config ips sensor
   edit <profile>
      set block-malicious-url [enable | disable]
   next
end
```

Customizable replacement message when IPS blocks traffic

You can edit a replacement message that will appear specifically for IPS sensor blocked Internet access. Go to **System > Replacement Messages**, and find IPS Sensor Block Page under the Security heading.

Hardware Acceleration for flow-based security profiles (NTurbo and IPSA)

Some FortiGate models support a feature call NTurbo that can offload flow-based firewall sessions to NP4 or NP6 network processors. Some FortiGate models also support offloading enhanced pattern matching for flow-based security profiles to CP8 or CP9 content processors. You can use the following command to configure NTurbo and IPSA:

```
config ips global
   set np-accel-mode {none | basic}
   set cp-accel-mode {none | basic | advanced}
end
```

If the `np-accel-mode` option is available, your FortiGate supports NTurbo: `none` disables NTurbo and `basic` (the default) enables NTurbo. If the `cp-accel-mode` option is available your FortiGate supports IPSA: `none` disables IPSA, `basic` enables basic IPSA and `advanced` enables enhanced IPSA which can offload more types of pattern matching than basic IPSA. `advanced` is only available on FortiGate models with two or more CP8 processors or one or more CP9 processors.

See the *Hardware Acceleration* handbook chapter for more information about NTurbo and IPSA.

Extended IPS Database

Some models have access to an extended IPS Database. The extended database may affect the performance of the FortiGate unit so depending on the model of the FortiGate unit the extended database package may not be enabled by default. For example, the D-series Desktop model have this option disabled by default.

This feature can only be enbled through the CLI.

```
config ips global
   set database extended
end
```

Configuring the IPS engine algorithm

The IPS engine is able to search for signature matches in two ways. One method is faster but uses more memory, the other uses less memory but is slower. Use the `algorithm` CLI command to select one method:

```
config ips global
   set algorithm {super | high | low | engine-pick}
end
```

Specify `high` to use the faster more memory intensive method or `low` for the slower memory efficient method. The setting `super` improves the performance for FortiGate units with more than 4GB of memory. The default setting is `engine-pick`, which allows the IPS engine to choose the best method on the fly.

Configuring the IPS engine-count

FortiGate units with multiple processors can run more than one IPS engine concurrently. The `engine-count` CLI command allows you to specify how many IPS engines are used at the same time:

```
config ips global
   set engine-count <int>
end
```

The recommended and default setting is `0`, which allows the FortiGate unit to determine the optimum number of IPS engines.

Configuring fail-open

IPS is likely more important to your network than uninterrupted flow of network traffic, so the fail-open behaviour of the IPS engine is disabled by default. If you would like to enable the fail-open option, use the following syntax. When enabled, if the IPS engine fails for any reason, it will fail open. This applies for inspection of all the protocols inspected by FortiOS IPS protocol decoders, including but not limited to HTTP, HTTPS, FTP, SMTP, POP3, IMAP, etc. This means that traffic continues to flow without IPS scanning. To enable:

```
config ips global
   set fail-open {enable | disable}
end
```

The default setting is disable.

Configuring the session count accuracy

The IPS engine can keep track of the number of open session in two ways. An accurate count uses more resources than a less accurate heuristic count.

```
config ips global
   set session-limit-mode {accurate | heuristic}
end
```

The default is heuristic.

Configuring IPS intelligence

Starting with FortiOS 5.2, `intelligent-mode` is a new adaptive detection method. This command is enabled the default and it means that the IPS engine will perform adaptive scanning so that, for some traffic, the FortiGate can quickly finish scanning and offload the traffic to NPU or kernel. It is a balanced method which could cover all known exploits. When disabled, the IPS engine scans every single byte.

```
config ips global
   set intelligent-mode {enable|disable}
end
```

Configuring the IPS buffer size

Set the size of the IPS buffer.

```
config ips global
   set socket-size <int>
```

```
end
```

The acceptable range is from 1 to 64 megabytes. The default size varies by model. In short, `socket-size` determines how much data the kernel passes to the IPS engine each time the engine samples packets.

Configuring protocol decoders

The FortiGate IPS uses protocol decoders to identify the abnormal traffic patterns that do not meet the protocol requirements and standards. For example, the HTTP decoder monitors traffic to identify any HTTP packets that do not meet the HTTP protocol standards.

To change the ports a decoder examines, you must use the CLI. In this example, the ports examined by the DNS decoder are changed from the default 53 to 100, 200, and 300.

```
config ips decoder dns_decoder
   set port_list "100,200,300"
end
```

You cannot assign specific ports to decoders that are set to **auto** by default. These decoders can detect their traffic on any port. Specifying individual ports is not necessary.

Configuring security processing modules

FortiGate Security Processing Modules, such as the CE4, XE2, and FE8, can increase overall system performance by accelerating some security and networking processing on the interfaces they provide. They also allow the FortiGate unit to offload the processing to the security module, thereby freeing up its own processor for other tasks. The security module performs its own IPS and firewall processing, but you can configure it to favor IPS in hostile high-traffic environments.

If you have a security processing module, use the following CLI commands to configure it to devote more resources to IPS than firewall. This example shows the CLI commands required to configure a security module in slot 1 for increased IPS performance.

```
config system amc-slot
   edit sw1
      set optimization-mode fw-ips
      set ips-weight balanced
      set ips-p2p disable
      set ips-fail-open enable
      set fp-disable none
      set ipsec-inb-optimization enable
      set syn-proxy-client-timer 3
      set syn-proxy-server-timer 3
   end
```

In addition to offloading IPS processing, security processing modules provide a hardware accelerated SYN proxy to defend against SYN flood denial of service attacks. When using a security module, configure your DoS anomaly check for `tcp_syn_flood` with the **Proxy** action. The **Proxy** action activates the hardware accelerated SYN proxy.

IPS signature rate count threshold

The IPS signature threshold can allow configuring a signature so that it will not be triggered until a rate count threshold is met. This provides a more controlled recording of attack activity. For example, if multiple login

attempts produce a failed result over a short period of time then an alert would be sent and perhaps traffic blocked. This would be a more rational response than sending an alert every time a login failed.

The syntax for this configuration is as follows:

```
config ips sensor
   edit default
      config entries
         edit <Filter ID number>
            set rule <*id>
            set rate-count <integer between 1 - 65535>
            set rate-duration <integer between 1 - 65535>
```

The value of the rate-duration is an integer for the time in seconds.

```
set rate-mode <continuous | periodical>
```

The rate-mode refers to how the count threshold is met.

If the setting is "`continuous`", and the action is set to block, as soon as the `rate-count` is reached the action is engaged. For example, if the count is 10, as soon as the signature is triggered 10 times the traffic would be blocked.

If the setting is "periodical", the FortiGate allows up to the value of the rate-count incidents where the signature is triggered during the rate-duration. For example, if the rate count is 100 and the duration is 60, the signature would need to be triggered 100 times in 60 seconds for the action to be engaged.

```
set rate-track <dest-ip | dhcp-client-mac | dns-domain | none | src-ip>
```

This setting allows the tracking of one of the protocol fields within the packet.

Enable IPS packet logging

Packet logging saves the network packets containing the traffic matching an IPS signature to the attack log. The FortiGate unit will save the logged packets to wherever the logs are configured to be stored, whether memory, internal hard drive, a FortiAnalyzer unit, or the FortiGuard Analysis and Management Service.

You can enable packet logging in the filters. Use caution in enabling packet logging in a filter. Filters configured with few restrictions can contain thousands of signatures, potentially resulting in a flood of saved packets. This would take up a great deal of space, require time to sort through, and consume considerable system resources to process. Packet logging is designed as a focused diagnostic tool and is best used with a narrow scope.

Although logging to multiple FortiAnalyzer units is supported, packet logs are not sent to the secondary and tertiary FortiAnalyzer units. Only the primary unit receives packet logs.

To enable packet logging for a filter

1. Create a filter in an IPS sensor.
2. After creating the filter, right-click the filter, and select **Enable** under **Packet Logging**.
3. Select the IPS sensor in the security policy that allows the network traffic the FortiGate unit will examine for the signature.

When you enable packet

IPS logging changes

IPS operations severely affected by disk logging are moved out of the quick scanning path, including logging, SNMP trap generation, quarantine, etc.

Scanning processes are dedicated to nothing but scanning, which results in more evenly distributed CPU usage. Slow (IPS) operations are taken care of in a dedicated process, which usually stays idle.

Setting `packet-log-history` to a value larger than `1` can affect the performance of the FortiGate unit because network traffic must be buffered. The performance penalty depends on the model, the setting, and the traffic load.

Other IPS examples

Configuring basic IPS protection

Small offices, whether they are small companies, home offices, or satellite offices, often have very simple needs. This example details how to enable IPS on a FortiGate unit located in a satellite office. The satellite office contains only Windows clients.

Creating an IPS sensor

Most IPS settings are configured in an IPS sensor. IPS sensors are selected in firewall policies. This way, you can create multiple IPS sensors, and tailor them to the traffic controlled by the security policy in which they are selected. In this example, you will create one IPS sensor.

To create an IPS sensor— GUI

1. Go to **Security Profiles > Intrusion Protection**.
2. Select the **Create New** icon in the top of the **Edit IPS Sensor** window.
3. In the **Name** field, enter `basic_ips`.
4. In the **Comments** field, enter `IPS for Windows clients`.
5. Under **IPS Filters**, select **Add Filter**. *A new window will open.*
6. Click on **Add Filter** and choose the following:
   a. For **Severity**: select all of the options. *You will need to repeat this step.*
   b. For **Target**: select **Client** only.
   c. For **OS**: select **Windows** only.
8. Select **Use Filters**. *You will return to the IPS Sensor page.*
9. In the **Action** column of the filter details, you will see that the Action is set to **Default**. Right-clicking on **Action** will show you the options. Leave the **Action** at **Default**. Matching traffic will either pass or be dropped, depending on the default action of each signature.
10. Select **OK** to save the IPS sensor.

To create an IPS sensor — CLI

```
config ips sensor
   edit basic_ips
      set comment "IPS for Windows clients"
```

```
        config entries
           edit 1
              set location client
              set os windows
              set severity all
              set action default
        end
end
```

Selecting the IPS sensor in a security policy

An IPS sensor directs the FortiGate unit to scan network traffic only when it is selected in a security policy. When an IPS sensor is selected in a security policy, its settings are applied to all the traffic the security policy handles.

To select the IPS sensor in a security policy — GUI

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select a policy.
3. Select the **Edit** icon.
4. Enable the **IPS** option under **Security Profiles**.
5. Select the preferred IPS sensor from the dropdown menu.
6. Select **OK** to save the security policy.

To select the IPS sensor in a security policy — CLI

```
config firewall policy
   edit 1
      set utm-status enable
      set ips-sensor basic_ips
   end
```

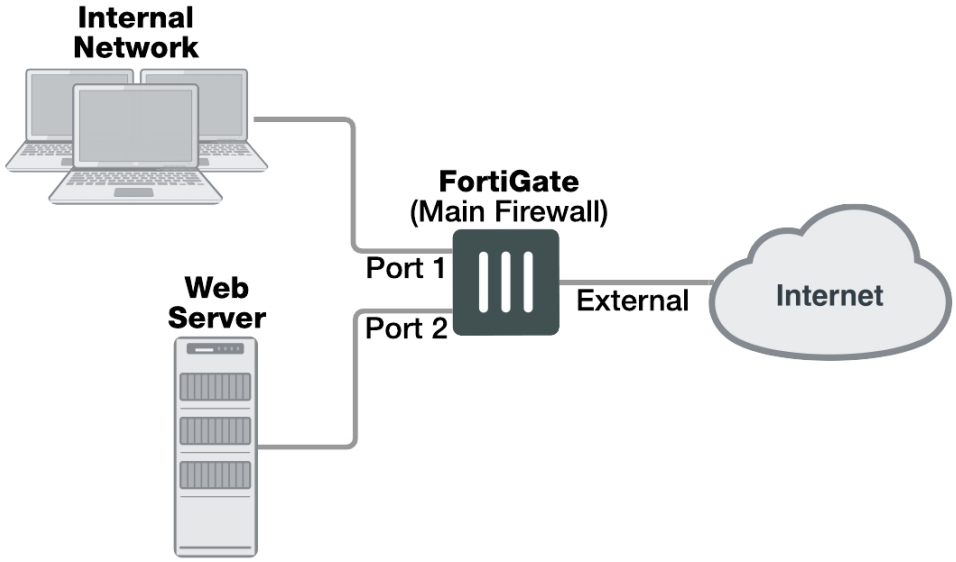
The IPS default sensor is `basic_ips`. All traffic handled by the security policy you modified will be scanned for attacks against Windows clients. A small office may have only one security policy configured. If you have multiple policies, consider enabling IPS scanning for all of them.

Using IPS to protect your web server

Many companies have web servers and they must be protected from attack. Since web servers must be accessible, protection is not as simple as blocking access. IPS is one tool your FortiGate unit has to allow you to protect your network.

In this example, we will configure IPS to protect a web server. As shown below, a FortiGate unit protects a web server and an internal network. The internal network will have its own policies and configuration but we will concentrate on the web server in this example.

A simple network configuration



The FortiGate unit is configured with:

- a virtual IP to give the web server a unique address accessible from the Internet.
- a security policy to allow access to the web server from the Internet using the virtual IP.

To protect the web server using the Security Profiles > Intrusion Protection feature, you need to create an IPS sensor, populate it with filters, then enable IPS scanning in the security policy.

To create an IPS sensor

1. Go to **Security Profiles > Intrusion Protection**.
2. Select **Create New**.
3. Enter `web_server` as the name of the new IPS sensor.

The new IPS sensor is created but it has no filters, and therefore no signatures are included.

The web server operating system is Linux, so you need to create a filter for all Linux server signatures.

To create the Linux server filter

4. Under **IPS Filters**, select **Add Filter**. *A new window will open.*
5. Click on **Add Filter** and choose the following:
   a. For **Severity**: select all of the options. *You will need to repeat this step.*
   b. For **Target**: select **Client** only.
   c. For **OS**: select **Windows** only.
6. Select **Use Filters**. *You will return to the IPS Sensor page.*
7. In the **Action** column of the filter details, you will see that the Action is set to **Default**. Right-clicking on **Action** will show you the options. Leave the **Action** at **Default**. Matching traffic will either pass or be dropped, depending on the default action of each signature.
8. Select **OK** to save the IPS sensor.

The filter is saved and the IPS sensor page reappears. To view the signatures matching a filter's settings, double-click on the filter in the list. The

To edit the security policy

1. Go to **Policy & Objects > IPv4 Policy** select security policy that allows access to the web server, and select the **Edit** icon.
2. Enable IPS option and choose the `web_server` IPS sensor from the list.
3. Select **OK**.

Since IPS is enabled and the `web_server` IPS sensor is specified in the security policy controlling the web server traffic, the IPS sensor examines the web server traffic for matches to the signatures it contains.

Create and test a packet logging IPS sensor

In this example, you create a new IPS sensor and include a filter that detects the EICAR test file and saves a packet log when it is found. This is an ideal first experience with packet logging because the EICAR test file can cause no harm, and it is freely available for testing purposes.

Create an IPS senor

1. Go to **Security Profiles > Intrusion Protection**.
2. Select **Create New**.
3. Name the new IPS sensor `EICAR_test`.
4. Under **IPS Signatures**, select **Add Signatures**.
   A new window will appear.
5. Enter `EICAR` in the **Search** field.
6. Click on the `Eicar.Virus.Test.File` signature to highlight it.
7. Click on **Use Selected Signatures**.
   You will return to the IPS Sensor page.
8. Right-click in the **Action** column for the signature and select **Block**.
9. Right click in the **Packet Logging** column and scroll down to the bottom of the menu that appears to enable packet logging.
10. Select **OK** to save the IPS sensor.

Add the IPS sensor to the security policy allowing Internet access

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select the security policy that allows you to access the Internet.
3. Select the **Edit** icon.
4. Enable the **IPS** option under Security Profiles and choose `EICAR test` from the available IPS sensors.
5. Enable **SSL/SSH Inspection** and select **deep-inspection**.
6. Enable **Log Allowed Traffic** under **Logging Options** and select **All Sessions**.
7. Select **OK**.

With the IPS sensor configured and selected in the security policy, the FortiGate unit blocks any attempt to download the EICAR test file.

When you enable packet logging within an IPS signature override or filter, the FortiGate examines network packets, and if a match is found, saves them to the attack log. Packet logging is designed to be used as a diagnostic tool that can focus on a narrow scope of diagnostics, rather than a log that informs you of what is occurring on your network.

You should use caution when enabling packet logging, especially within IPS filters. Filter configuration that contains thousands of signatures could potentially cause a flood of saved packets, which would take up a lot of storage space on the log device. It would also take a great deal of time to sort through all the log messages, as well as consume considerable system resources to process.

Testing the IPS sensor

1. Using your web browser, go to http://www.eicar.org/85-0-Download.html.
2. Scroll to the bottom of the page and select **eicar.com** from the row labeled as using the secure, SSL enabled HTTPS protocol.
3. The browser attempts to download the requested file and,
   - If the file is successfully downloaded, the custom signature configuration failed at some point. Check the custom signature, the IPS sensor, and the firewall profile.
   - If the download is blocked with a high security alert message explaining that you're not permitted to download the file, the EICAR test file was blocked by the FortiGate unit antivirus scanner before the IPS sensor could examine it. Disable antivirus scanning and try to download the EICAR test file again.
   - If no file is downloaded and the browser eventually times out, the custom signature successfully detected the EICAR test file and blocked the download.

Viewing the packet log

1. Go to **Log & Report > Forward Traffic**.
2. Locate the log entry that recorded the blocking of the EICAR test file block. The Message field data will be `tools: EICAR.AV.Test.File.Download`.
3. Select the **View Packet Log** icon in the **Packet Log** column.
4. The packet log viewer is displayed.

Configuring a Fortinet Security Processing module

The Example Corporation has a web site that is the target of SYN floods. While they investigate the source of the attacks, it's very important that the web site remain accessible. To enhance the ability of the company's FortiGate-100D to deal with SYN floods, the administrator will install an ASM-CE4 Fortinet Security Processing module and have all external access to the web server come though it.

The security processing modules not only accelerate and offload network traffic from the FortiGate unit's processor, but they also accelerate and offload security and content scanning. The ability of the security module to accelerate IPS scanning and DoS protection greatly enhances the defense capabilities of the FortiGate-100D.

Assumptions

As shown in other examples and network diagrams throughout this document, the Example Corporation has a pair of FortiGate-100D units in an HA cluster. To simplify this example, the cluster is replaced with a single FortiGate-100D.

An ASM-CE4 is installed in the FortiGate-100D.

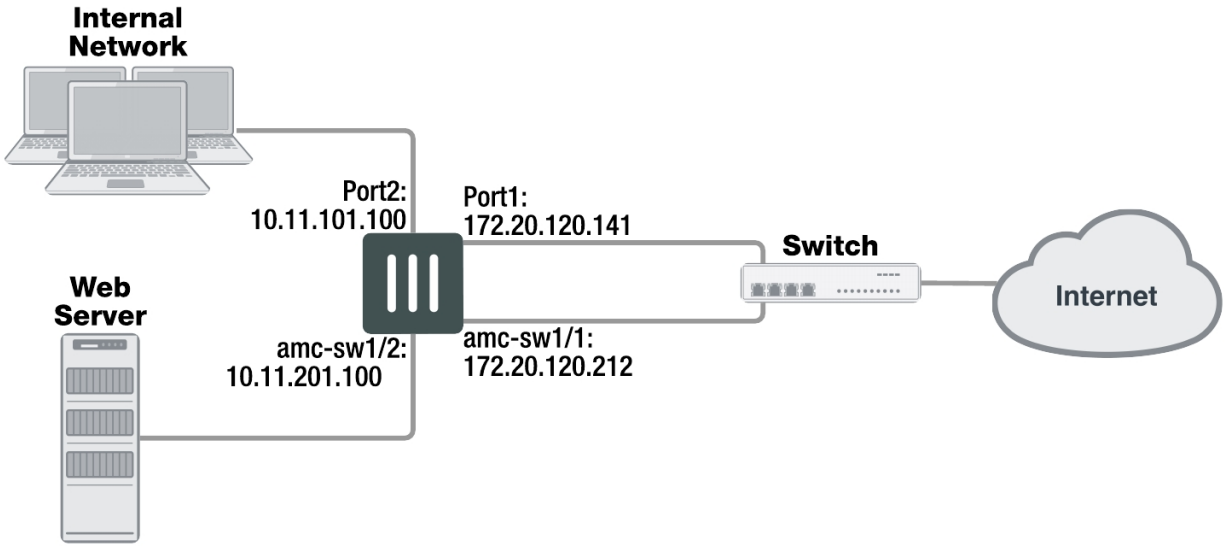
The network is configured as shown below.

Network configuration

The Example Corporation network needs minimal changes to incorporate the ASM-CE4. Interface amc-sw1/1 of the ASM-CE4 is connected to the Internet and interface amc-sw1/1 is connected to the web server.

Since the main office network is connected to port2 and the Internet is connected to port1, a switch is installed to allow both port1 and amc-sw1/1 to be connected to the Internet.

The FortiGate-100D network configuration



The switch used to connect port1 and amc-sw1/1 to the Internet must be able to handle any SYN flood, all of the legitimate traffic to the web site, and all of the traffic to and from the Example Corporation internal network. If the switch can not handle the bandwidth, or if the connection to the service provider can not provide the required bandwidth, traffic will be lost.

Security module configuration

The Fortinet security modules come configured to give equal priority to content inspection and firewall processing. The Example Corporation is using a ASM-CE4 module to defend its web server against SYN flood attacks so firewall processing is a secondary consideration.

Use these CLI commands to configure the security module in ASM slot 1 to devote more resources to content processing, including DoS and IPS, than to firewall processing.

```
config system amc-slot
   edit sw1
      set optimization-mode fw-ips
      set ips-weight balanced
      set ips-p2p disable
      set ips-fail-open enable
      set fp-disable none
      set ipsec-inb-optimization enable
      set syn-proxy-client-timer 3
      set syn-proxy-server-timer 3
   end
```

These settings do not disable firewall processing. Rather, when the security module nears its processing capacity, it will chose to service content inspection over firewall processing.

IPS Sensor

You can group signatures into IPS sensors for easy selection when applying to firewall policies. You can define signatures for specific types of traffic in separate IPS sensors, and then select those sensors in profiles designed to handle that type of traffic. For example, you can specify all of the web-server related signatures in an IPS sensor, and that sensor can then be applied to a firewall policy that controls all of the traffic to and from a web server protected by the unit.

The FortiGuard Service periodically updates the pre-defined signatures, with signatures added to counter new threats. Since the signatures included in filters are defined by specifying signature attributes, new signatures matching existing filter specifications will automatically be included in those filters. For example, if you have a filter that includes all signatures for the Windows operating system, your filter will automatically incorporate new Windows signatures as they are added.

Each IPS sensor consists of two parts: filters and overrides. Overrides are always checked before filters.

Each filter consists of a number of signatures attributes. All of the signatures with those attributes, and only those attributes, are checked against traffic when the filter is run. If multiple filters are defined in an IPS Sensor, they are checked against the traffic one at a time, from top to bottom. If a match is found, the unit takes the appropriate action and stops further checking.

A signature override can modify the behavior of a signature specified in a filter. A signature override can also add a signature not specified in the sensor's filters. Custom signatures are included in an IPS sensor using overrides.

The signatures in the overrides are first compared to network traffic. If the IPS sensor does not find any matches, it then compares the signatures in each filter to network traffic, one filter at a time, from top to bottom. If no signature matches are found, the IPS sensor allows the network traffic.

The signatures included in the filter are only those matching every attribute specified. When created, a new filter has every attribute set to **all** which causes every signature to be included in the filter. If the severity is changed to high, and the target is changed to server, the filter includes only signatures checking for high priority attacks targeted at servers.

Anti-Spam filter

This section describes how to configure FortiGate email filtering for IMAP, POP3, and SMTP email. Email filtering includes both spam filtering and filtering for any words or files you want to disallow in email messages. If your FortiGate unit supports SSL content scanning and inspection, you can also configure spam filtering for IMAPS, POP3S, and SMTPS email traffic.

The following topics are included in this section:

Anti-Spam concepts

You can configure the FortiGate unit to manage unsolicited commercial email by detecting and identifying spam messages from known or suspected spam servers.

The FortiGuard Anti-Spam service uses both a sender IP reputation database and a spam signature database, along with sophisticated spam filtering tools, to detect and block a wide range of spam messages. Using FortiGuard Anti-Spam profile settings, you can opt to filter with IP address checking, URL checking, email checksum checking, detection of phishing URLs in email, and spam submission. Updates to the IP reputation and spam signature databases are provided continuously via the global FortiGuard Distribution Network.

From the FortiGuard Anti-Spam service page in the FortiGuard Center, you can find out whether an IP address is blacklisted in the FortiGuard Anti-Spam IP reputation database, or whether a URL or email address is in the signature database.

Anti-Spam techniques

The FortiGate unit has a number of techniques available to help detect spam. Some use the FortiGuard Anti-Spam service and require a subscription. The remainder use your DNS servers or use lists that you must maintain.

Black white list

These are the types of black white lists available. They include:

- **IP/Netmask**
  The FortiGate unit compares the IP address of the client delivering the email to the addresses in the IP address black / white list specified in the email filter profile. If a match is found, the FortiGate unit will take the action configured for the matching black / white list entry against all delivered email.
  The default setting of the `smtp-spamhdrip` CLI command is `disable`. If enabled, the FortiGate unit will check all the IP addresses in the header of SMTP email against the specified IP address black / white list.
- **Email Wildcard**
  The FortiGate unit compares the sender email address, as shown in the message header and envelope MAIL FROM, to the pattern in the patterned field. The wildcard symbol is used in the place of characters in the address that may vary from the pattern. If a match is found, the FortiGate unit will take the action configured for the matching black / white list entry.
- **Email Regular Expression**
  The FortiGate unit compares the sender email address, as shown in the message envelope MAIL FROM, to the

pattern in the patterned field. The regular expression that can be used is much more sophisticated than a simple wildcard variable. If a match is found, the FortiGate unit will take the action configured for the matching black/white list entry.

Pattern

The pattern field is for entering the identifying information that will enable the filter to correctly identify the email messages.

- If the type is IP/Netmask the filter will be an IP address with a subnet mask.
- If the type is Email Wildcard the filter will be an email address with a wildcard symbol in place of the variable characters. For example *.example.com or fred@*.com.
- If the type is Email Regular Expression, regular expression can be used to create a more granular filter for email addresses. For example, ^[_a-z0-9-]+(\.[_a-z0-9-]+)*@(example|xmple|examp).(com|org|net) could be used filter based on a number of combinations of email domain names.

Action

- **Mark as Spam**
  If this is the selected action, the email will be allowed through but it will be tagged with an indicator that clearly marks the email as spam.
- **Mark as Clear**
  If this is the selected action, the email will be allowed to go through to its destination on the assumption that the message is not spam.
- **Mark as Reject**
  If this is the selected action, the email will be dropped at the before reaching its destination.

Status

Indicates whether this particular list is enabled or disabled.

Banned word check

When you enable banned word checking, your FortiGate unit will examine the email message for words appearing in the banned word list specified in the Anti-Spam profile. If the total score of the banned word discovered in the email message exceeds the threshold value set in the Anti-Spam profile, your FortiGate unit will treat the message as spam.

When determining the banned word score total for an email message, each banned word score is added once no matter how many times the word appears in the message. Use the command `config spamfilter bword` to add an email banned word list. Use the command `config spamfilter profile` to add a banned word list to an Anti-Spam profile.

How content is evaluated

Every time the banned word filter detects a pattern in an email message, it adds the pattern score to the sum of scores for the message. You set this score when you create a new pattern to block content. The score can be any number from zero to 99999. Higher scores indicate more offensive content. When the total score equals or exceeds the threshold, the email message is considered as spam and treated according to the spam action configured in the email filter profile. The score for each pattern is counted only once, even if that pattern appears many times in the email message. The default score for banned word patterns is 10 and the default threshold is 10. This means that by default, an email message is blocked by a single match.

A pattern can be part of a word, a whole word, or a phrase. Multiple words entered as a pattern are treated as a phrase. The phrase must appear as entered to match. You can also use wildcards or regular expressions to have a pattern match multiple words or phrases.

For example, the FortiGate unit scans an email message that contains only this sentence: “The score for each word or phrase is counted only once, even if that word or phrase appears many times in the email message.”

Banned word pattern	Pattern type	Assigned score	Score added to the sum for the entire page	Comment
word	Wildcard	20	20	The pattern appears twice but multiple occurrences are only counted once.
word phrase	Wildcard	20	0	Although each word in the phrase appears in the message, the words do not appear together as they do in the pattern. There are no matches.
word*phrase	Wildcard	20	20	The wildcard represents any number of any character. A match occurs as long as “word” appears before “phrase” regardless of what is in between them.
mail*age	Wildcard	20	20	Since the wildcard character can represent any characters, this pattern is a match because “email message” appears in the message.

In this example, the message is treated as spam if the banned word threshold is set to 60 or less.

Adding words to a banned word list

When you enter a word, set the `Pattern-type` to wildcards or regular expressions.

Wildcard uses an asterisk (“*”) to match any number of any character. For example, re* will match all words starting with “re”.

Regular expression uses Perl regular expression syntax. See http://perldoc.perl.org/perlretut.html for detailed information about using Perl regular expressions.

DNS-based Blackhole List (DNSBL)

A DNSBL is a list of IP addresses, usually maintained by a third party, which are identified as being associated with spamming.

FortiGuard Antispam Service

FortiGuard IP address check

The FortiGate unit queries the FortiGuard Anti-Spam Service to determine if the IP address of the client delivering the email is blacklisted. A match will cause the FortiGate unit to treat delivered messages as spam.

The default setting of the `smtp-spamhdrip` CLI command is `disable`. When you enable FortiGuard IP address checking, your FortiGate unit will submit the IP address of the client to the FortiGuard service for

checking. If the IP address exists in the FortiGuard IP address black list, your FortiGate unit will treat the message as spam.

FortiGuard URL check

When you enable FortiGuard URL checking, your FortiGate unit will submit all URLs appearing in the email message body to the FortiGuard service for checking. If a URL exists in the FortiGuard URL black list, your FortiGate unit will treat the message as spam.

FortiGuard email checksum check

When you enable FortiGuard email checksum checking, your FortiGate unit will submit a checksum of each email message to the FortiGuard service for checking. If a checksum exists in the FortiGuard checksum black list, your FortiGate unit will treat the message as spam.

Detect phishing URLs in email

When you enable FortiGuard phishing URL detection, your FortiGate unit will submit all URL hyperlinks appearing in the email message body to the FortiGuard service for checking. If a URL exists in the FortiGuard URL phishing list, your FortiGate unit will remove the hyperlink from the message. The URL will remain in place, but it will no longer be a selectable hyperlink.

FortiGuard spam submission

Spam submission is a way you can inform the FortiGuard Anti-Spam service of non-spam messages incorrectly marked as spam. When you enable this setting, the FortiGate unit adds a link to the end of every message marked as spam. You then select this link to inform the FortiGuard Anti-Spam service when a message is incorrectly marked.

Trusted IP Addresses

A list of IP addresses that are trusted by the FortiGate is created. Any email traffic coming in from these IP address will be exempted to perform IP based check, such as DNSBL/RBL, FortiShield SPAM IP or locally defined IP black list check.

If the FortiGate unit sits behind a company's Mail Transfer Units, it may be unnecessary to check email IP addresses because they are internal and trusted. The only IP addresses that need to be checked are those from outside of the company. In some cases, external IP addresses may be added to the list if it is known that they are not sources of spam.

MIME header

This feature filters by the MIME header. MIME header settings are configured in a separate part of the command tree but MIME header filtering is enabled within each profile.

HELO DNS lookup

Whenever a client opens an SMTP session with a server, the client sends a HELO command with the client domain name. The FortiGate unit takes the domain name specified by the client in the HELO and does a DNS lookup to determine if the domain exists. If the lookup fails, the FortiGate unit determines that any messages delivered during the SMTP session are spam.

The HELO DNS lookup is available only for SMTP traffic.

Return email DNS check

The FortiGate unit performs a DNS lookup on the If no such record exists, the message is treated as spam.

When you enable return email DNS checking, your FortiGate unit will take the domain in the reply-to email address and reply-to domain and check the DNS servers to see if there is an A or MX record for the domain. If the domain does not exist, your FortiGate unit will treat the message as spam.

Configuring Anti-Spam

FortiGuard email filtering techniques us FortiGuard services to detect the presence of spam among your email. A FortiGuard subscription is required to use the FortiGuard email filters. To enable email filtering an email filter needs to be created and then the filter needs to be associated with a security policy.

The filter can be created as follows:

- Go to **Security Profiles > Anti-Spam**.
  - Select the Create New icon (a plus symbol in a circle in the upper right hand corner).
  - Select the List icon (a page symbol in the upper right hand corner) and in the new window select **Create New**.

An existing filter can be edited as follows:

- Go to **Security Profiles > Anti-Spam**.
  - Select the filter that you wish to edit from the dropdown menu in the upper right corner.
  - Select the List icon (a page symbol in the upper right hand corner) and select the filter that you wish to edit from the list.

Once you are in the proper **Edit Email Filter Profile** window, you can enter a name in the Name field if it's a new filter.

The Comments field is for a description or other information that will assist in understanding the function or purpose of the this particular filter.

Using the radio buttons for the Inspection Mode field, select either Proxy or Flow-based.

Before any of the other features or options of the filter appear the checkbox next to Enable Spam Detection and Filtering must be checked.

Spam detection by protocol

This matrix includes three rows that represent the email protocols IMAP, POP3 and SMTP.

There are also columns for:

Spam Action

For the client protocols, IMAP and POP3 the options are:

- **Tag** - This action will insert a tag into the email somewhere so that when the recipients view the email they will be warned that it is likely a spam.
- **Pass** - This action will allow any emails marked as spam to pass through without change. If this option is chosen, the Tag comments will be greyed out.

For the transfer protocol, SMTP, the options are:

- **Tag** - This action will insert a tag into the email somewhere so that when the recipients view the email they will be warned that it is likely a spam.
- **Discard** - The action will drop the email before it reaches its destination.
- **Pass** - This action will allow any emails marked as spam to pass through without change. If this option is chosen, the Tag comments will be greyed out.

Tag Location

- **Subject** - The contents of the Tag Format will be inserted into the subject line. The subject line is the most commonly used.
- **MIME** - The contents of the Tag Format will be inserted in with the MIME header.

Tag Format

The contents of this field will be entered into the tag location specified. The most common tag is something along the lines of [Spam] or **SPAM**

FortiGuard Spam Filtering

The options in the section are ones that require a FortiGuard subscription.

The options available in this section, to be selected by checkbox are:

- IP Address Check
- URL Check
- Detect Phishing URLs in Email
- Email Checksum Check
- Spam Submission

Local Spam Filtering

The options in the section are ones can be managed on the local device without the need for a FortiGuard subscription.

The options available in this section:

- HELO DNS Lookup
- Return Email DNS Check
- Black White List - checking this option will produce a table that can be edited to create a number of BWL lists that can be separately configured and enabled.

Another local spam filter profile option that can only be configured in the CLI is the banned word.check. To configure this, enter the following commands in the CLI:

```
config spamfilter profile
   edit <filter_name>
      set options bannedword
      set spam-bword-table 1
   next
end
```

See the section on banned word checking for more information on how content is evaluated.

Order of spam filtering

The FortiGate unit checks for spam using various filtering techniques. The order in which the FortiGate unit uses these filters depends on the mail protocol used.

Filters requiring a query to a server and a reply (FortiGuard Anti-Spam service and DNSBL/ORDBL) are run simultaneously. To avoid delays, queries are sent while other filters are running. The first reply to trigger a spam action takes effect as soon as the reply is received.

Each spam filter passes the email to the next if no matches or problems are found. If the action in the filter is **Mark as Spam**, the FortiGate unit tags the email as spam according to the settings in the email filter profile.

For SMTP and SMTPS, if the action is **Discard**, the email message is discarded or dropped.

If the action in the filter is **Mark as Clear**, the email is exempt from any remaining filters. If the action in the filter is **Mark as Reject**, the email session is dropped.

Order of SMTP and SMTPS spam filtering

The FortiGate unit scans SMTP and SMTPS email for spam in a specific order, depending on whether or not the local override feature has been enabled. By default, local override is disabled on the FortiGate. Enabling local override will give priority to local spam filters.

You can enable local override with the CLI command `set local-override {enable | disable}` when configuring a spamfilter profile. Enable this command to override SMTP or SMTPS remote check with the locally defined black/white antispam list. The remote check includes IP RBL check, IP FortiGuard AntiSpam check and HELO DNS check, .

SMTPS spam filtering is available on FortiGate units that support SSL content scanning and inspection.

Enabling local override of Anti-Spam filter

CLI Syntax

```
config spamfilter profile
   edit <fliter_name>
      set spam-filtering enable
      set options spambwl spamfsip spamfsurl spamhelodns spamfsphish
      config smtp
         set local-override enable
      end
      set spam-bwl-table 1
   next
end
```

Order of SMTP and SMTPS spam filtering with local-override disabled

1. HELO DNS Lookup, Last Hop IP check against ORDBL
2. Return email DNS check, FortiGuard email checksum check, FortiGuard URL check, FortiGuard IP address check, Phishing URLs detection
3. Last Hop IP check local black/white list (BWL)
4. Envelope Address check local BWL
5. Headers IPs local BWL, MIME header checks based on local list of patterns (mheader)

6. Headers email address local BWL
7. Banned words (subject first, then body) based on local BWL (bword)

Order of SMTP and SMTPS spam filtering with local-override enabled

1. Last Hop IP check local black/while list (BWL)
2. Envelope Address check local BWL
3. Headers IPs local BWL, MIME header checks based on local list of patterns (mheader)
4. Headers email address local BWL
5. Banned words (subject first, then body) based on local list of patterns (bword)
6. HELO DNS Lookup, Last Hop IP check against ORDBL
7. Return email DNS check, FortiGuard email checksum check, FortiGuard URL check, FortiGuard IP address checks, Phishing URLs detection

Order of IMAP, POP3, IMAPS and POP3S spam filtering

The FortiGate unit scans IMAP, POP3, IMAPS and POP3S email for spam in the order given below. IMAPS and POP3S spam filtering is available on FortiGate units that support SSL content scanning and inspection.

1. MIME headers check, E-mail address BWL check
2. Banned word check on email subject
3. IP BWL check
4. Banned word check on email body
5. Return email DNS check, FortiGuard Antispam email checksum check, FortiGuard Antispam URL check, DNSBL & ORDBL check

Spam actions

When spam is detected, the FortiGate unit will deal with it according to the **Spam Action** setting in the anti-spam profile. Note that POP3S, IMAPS and SMTPS spam filtering is available only on FortiGate units that support SSL content scanning and inspection. POP3, IMAP, POP3S and IMAPS mail can only be tagged. SMTP and SMTPS mail can be set to **Discard** or **Tagged**:

Discard

When the spam action is set to **Discard**, messages detected as spam are deleted. No notification is sent to the sender or recipient.

Pass

When the spam action is set to pass, the spam filter is disabled for the related protocol.

Tag

When the spam action is set to **Tagged**, messages detected as spam are labeled and delivered normally. The text used for the label is set in the **Tag Format** field and the label is placed in the subject or the message header, as set with the **Tag Location** option.

Email traffic types to inspect

The FortiGate unit examines IMAP, POP3, and SMTP email traffic. If your FortiGate unit supports content inspection, it can also examine IMAPS, POP3S, and SMTPS traffic. The options that you will see in the profile window are IMAP, POP3 and SMTP.

Anti-Spam examples

Configuring simple Anti-Spam protection

Small offices, whether they are small companies, home offices, or satellite offices, often have very simple needs. This example details how to enable Anti-Spam protection on a FortiGate unit located in a satellite office.

Creating an email filter profile

Most Anti-Spam settings are configured in an Anti-Spam profile. Anti-Spam profiles are selected in firewall policies. This way, you can create multiple Anti-Spam profiles, and tailor them to the traffic controlled by the security policy in which they are selected. In this example, you will create one Anti-Spam profile.

To create an Anti-Spam profile — web-based manager

1. Go to **Security Profiles > Anti-Spam**.
2. Select the **Create New** icon in the Edit Anti-Spam Profile window title.
3. In the **Name** field, enter `basic_anti-spam`
4. Select **Enable Spam Detection and Filtering**.
5. Ensure that **IMAP**, **POP3**, and **SMTP** are selected in the header row.

   These header row selections enable or disable examination of each Anti-Spam type. When disabled, the email traffic of that type is ignored by the FortiGate unit and no Anti-Spam options are available.
6. Under **FortiGuard Spam Filtering**, enable **IP Address Check**.
7. Under **FortiGuard Spam Filtering**, enable **URL Check**.
8. Under **FortiGuard Spam Filtering**, enable **E-mail Checksum Check**.
9. Select **OK** to save the email filter profile.

To create an Anti-Spam profile — CLI

```
config spamfilter profile
   edit basic_anti-spam
      set options spamfsip spamfsurl spamfschksum
   end
```

Selecting the Anti-Spam profile in a security policy

An Anti-Spam profile directs the FortiGate unit to scan network traffic only when it is selected in a security policy. When an Anti-Spam profile is selected in a security policy, its settings are applied to all the traffic the security policy handles.

To select the Anti-Spam profile in a security policy — web-based manager

1. Go to **Policy & Objects > IPv4 Policy**.
2. Create a new or edit a policy.
3. Turn on Anti-Spam.
4. Select the `basic_anti-spam` profile from the list.
5. Select **OK** to save the security policy.

To select the Anti-Spam profile in a security policy — CLI

```
config firewall policy
   edit 1
      set utm-status enable
      set profile-protocol-options default
      set spamfilter-profile basic_anti-spam
   end
```

IMAP, POP3, and SMTP email traffic handled by the security policy you modified will be scanned for spam. Spam messages have the text “Spam” added to their subject lines. A small office may have only one security policy configured. If you have multiple policies, consider enabling spam scanning for all of them.

Blocking email from a user

Employees of the Example.com corporation have been receiving unwanted email messages from a former client at a company called example.net. The client’s email address is client@example.net. All ties between the company and the client have been severed, but the messages continue. The FortiGate unit can be configured to prevent these messages from being delivered.

To enable Anti-Spam

1. Go to **Security Profiles > Anti-Spam**.
2. Select the Anti-Spam profile that is used by the firewall policies handling email traffic from the Anti-Spam profile drop down list.
3. In the row **Tag Location**, select **Subject** for all three mail protocols.
4. In the row **Tag Format**, enter `SPAM:` in all three fields.
   This means that normal spam will be tagged in the subject line.
5. Select **Enable Spam Detection and Filtering**.
6. Under **Local Spam Filtering**, enable **Black White List** and select **Create New**.
7. In the Black White List widget, select **Create New**.
8. Select **Email Address Wildcard**.
9. Enter `client@example.net` in the **Pattern** field.
   - If you wanted to prevent everyone’s email from the client’s company from getting through you could have used *@example.net instead.
10. Set the **Action** to **Mark as Spam**.
11. Set the **Status** to **Enable**.
12. Confirm that the SMTP protocol is set to **Discard**.
13. Select **OK**.

Now that the email address list is created, you must enable the email filter in the Anti-Spam profile.

When this Anti-Spam profile is selected in a security policy, the FortiGate unit will reject any email message from an address ending with @example.net for all email traffic handled by the security policy.

Data leak prevention

The FortiGate data leak prevention (DLP) system allows you to prevent sensitive data from leaving your network. When you define sensitive data patterns, data matching these patterns will be blocked, or logged and allowed, when passing through the FortiGate unit. You configure the DLP system by creating individual filters based on file type, file size, a regular expression, an advanced rule, or a compound rule, in a DLP sensor and assign the sensor to a security policy.

Although the primary use of the DLP feature is to stop sensitive data from leaving your network, it can also be used to prevent unwanted data from entering your network and to archive some or all of the content passing through the FortiGate unit.

This section describes how to configure the DLP settings. DLP can only be configured for FortiGate's in proxy-based inspection.

The following topics are included:

- Data leak prevention concepts
- Enable data leak prevention
- Creating or editing a DLP sensor
- DLP archiving
- DLP examples

Data leak prevention concepts

Data leak prevention examines network traffic for data patterns you define through the use of the GUI and CLI commands. The DLP feature is broken down into a number of parts.

DLP sensors and filters can only be configured for FortiGate's in proxy-based inspection.

DLP sensor

A DLP sensor is a package of filters. To use DLP, you must enable it in a security policy and select the DLP sensor to use. The traffic controlled by the security policy will be searched for the patterns defined in the filters contained in the DLP sensor. Matching traffic will be passed or blocked according to how you configured the filters.

DLP filter

Each DLP sensor has one or more filters configured within it. Filters can examine traffic for known files using DLP fingerprints, for files of a particular type or name, for files larger than a specified size, for data matching a specified regular expression, or for traffic matching an advanced rule or compound rule.

DLP Filter Actions

You can configure the action taken when a match is detected. The actions include:

- Allow
- Log Only
- Block
- Quarantine IP address

Log Only is enabled by default.

Allow

No action is taken even if the patterns specified in the filter are matched.

Log Only

The FortiGate unit will take no action on network traffic matching a rule with this action. The filter match is logged, however. Other matching filters in the same sensor may still operate on matching traffic.

Block

Traffic matching a filter with the block action will not be delivered. The matching message or download is replaced with the data leak prevention replacement message.

Quarantine IP Address/ Source IP ban

Starting in FortiOS 5.2, the quarantine, as a place where traffic content was held in storage so it couldn't interact with the network or system, was removed. The term quarantine was kept to describe preventing selected source IPs from interacting with the network and protected systems. This source IP ban is kept in the kernel rather than in any specific application engine and can be queried by APIs. The features that can use the APIs to access and use the banned source IP addresses are antivirus, DLP, DoS and IPS. Both IPv4 and IPv6 version are included in this feature.

If the **quarantine-ip** action is used, the additional variable of expiry time will become available. This variable determines for how long the source IP address will be blocked. In the GUI it is shown as a field before minutes. In the CLI the option is called `expiry` and the duration is in the format `<###d##h##m>`. The maximum days value is 364. The maximum hour value is 23 and the maximum minute value is 59. The default is 5 minutes.

If a DLP sensor has contains a DLP filter with action set to **Allow** certain files and another DLP filter with action set to **Block** those same files, then the order of the filters within that sensor will determine which action is taken first.

Configuring using the CLI

To configure the DLP sensor to add the source IP address of the sender of a protected file to the quarantine or list of banned source IP addresses edit the DLP Filter, use these CLI commands:

```
config dlp sensor
   edit <sensor name>
      config filter
         edit <id number of filter>
            set action quarantine-ip
            set expiry 5m
            end
         end
```

Preconfigured sensors

A number of preconfigured sensors are provided with your FortiGate unit. These can be edited to more closely match your needs.

Two of the preconfigured sensors with filters ready for you to enable are:

- Credit-Card - This sensor logs the traffic, both files and messages, that contain credit card numbers in the formats used by American Express, MasterCard and Visa.
- SSN-Sensor - This sensor logs the traffic, both files and messages, that contain Social Security Numbers with the exception of those that are WebEx invitation emails.

These rules affect only unencrypted traffic types. If you are using a FortiGate unit that can decrypt and examine encrypted traffic, you can enable those traffic types in these rules to extend their functionality if required.

Before using the rules, examine them closely to ensure you understand how they will affect the traffic on your network.

DLP document fingerprinting

One of the DLP techniques to detect sensitive data is fingerprinting (also called document fingerprinting). Most DLP techniques rely on you providing a characteristic of the file you want to detect, whether it's the file type, the file name, or part of the file contents. Fingerprinting is different in that you provide the file itself. The FortiGate unit then generates a checksum fingerprint and stores it. The FortiGate unit generates a fingerprint for all files detected in network traffic, and it is compared to all of the fingerprints stored in its fingerprint database. If a match is found, the configured action is taken.

The document fingerprint feature requires a FortiGate unit with internal storage.

Any type of file can be detected by DLP fingerprinting and fingerprints can be saved for each revision of your files as they are updated.

To use fingerprinting you:

- select the documents to be fingerprinted
- add fingerprinting filters to DLP sensors
- add the sensors to firewall policies that accept the traffic to which to apply fingerprinting.

Fingerprinting

Fingerprint scanning allows you to create a library of files for the FortiGate unit to examine. It will create checksum fingerprints so each file can be easily identified. Then, when files appear in network traffic, the FortiGate will generate a checksum fingerprint and compare it to those in the fingerprint database. A match triggers the configured action.

You must configure a document source or uploaded documents to the FortiGate unit for fingerprint scanning to work.

Fingerprinted Documents

The FortiGate unit must have access to the documents for which it generates fingerprints.

Configuring the document source

To configure a DLP fingerprint document source in FortiOS 5.4.0, you must use CLI commands.

```
config dlp fp-doc-source
```

```
edit <name_str>
   set name <string>
   set server-type {smb}
   set server <string>
   set period {none | daily | weekly | monthly}
   set vdom {mgmt | current}
   set scan-subdirectories {enable | disable}
   set remove-deleted {enable | disable}
   set keep-modified {enable | disable}
   set username <string>
   set password <password>
   set file-path <string>
   set file-pattern <string>
   set sensitivity <string>
   set tod-hour <integer>
   set tod-min <integer>
   set weekday {sunday | monday | tuesday | wednesday | thursday | friday | saturday}
   set date <integer>
end
```

Configuring a DLP fingerprint sensor

To configure a DLP fingerprint sensor in FortiOS 5.4.0, you must use CLI commands.

```
config dlp sensor
   edit <sensor name>
      config filter
         edit <id number of filter>
            set proto {smtp | pop3 | imap http-get | http-post | ftp | nntp | mapi}
            set filter-by fingerprint
            set fp-sensitivity { critical | private | warning}
            set action {allow | log-only | block | ban | quarantine-ip | quarantine-
                port}
         next
      end
   next
```

Once you have set the document source and configured the DLP sensor for fingerprinting, add the DLP sensor to the applicable firewall policy. This can be done through the GUI.

File size

This filter-type checks for files exceeding a configured size. All files larger than the specified size are subject to the configured action. The value of the field is measured in kilobytes (KB).

DLP filtering by specific file types

File filters use file filter lists to examine network traffic for files that match either file names or file types. For example, you can create a file filter list that will find files called secret.* and also all JPEG graphic files. You can create multiple file filter lists and use them in filters in multiple DLP sensors as required.

Specify File Types is a DLP option that allows you to block files based on their file name or their type.

- **File types** are a means of filtering based on examination of the file contents, regardless of the file name. If you block the file type **Archive (zip)**, all zip archives are blocked even if they are renamed with a different file extension. The FortiGate examines the file contents to determine what type of file it is and then acts accordingly.
- **File Name patterns** are a means of filtering based purely on the names of files. They may include wildcards (*). For example, blocking `*.scr` will stop all files with an `.scr` file extension, which is commonly used for Windows screen saver files. Files trying to pass themselves off as Windows screen saver files by adopting the file-naming convention will also be stopped.
  - Files can specify the full or partial file name, the full or partial file extension, or any combination. File pattern entries are not case sensitive. For example, adding `*.exe` to the file pattern list also blocks any files ending with `.exe`.
  - Files are compared to the enabled file patterns from top to bottom, in list order.

If DLP detects a file inside an archive that should be blocked, the entire archive will be blocked.

Watermarking

Watermarking is essentially marking files with a digital pattern to mark the file as being proprietary to a specific company. Fortinet provides a Linux-based utility that applies a digital watermark to files. The utility adds a small (approx. 100 byte) pattern to the file that is recognized by the DLP watermark filter. The pattern is invisible to the end user.

When watermarking a file it should be verified that the pattern matches up to a category found on the FortiGate firewall. For example, if you are going to watermark a file with the sensitivity level of “Secret” you should verify that “Secret” is a sensitivity level that has been assigned in the FortiGate unit.

Watermark Sensitivity

If you are using watermarking on your files you can use this filter to check for watermarks that correspond to sensitivity categories that you have set up.

The Corporate Identifier is to make sure that you are only blocking watermarks that your company has place on the files, not watermarks with the same name by other companies.

Software Versions

Before planning on using watermarking software it is always best to verify that the software will work with your OS. Currently, the only utility available to watermark files is a Linux-based command line tool. It is available for download from the Fortinet Customer Service & Support website, with a valid support contract and access to the site. To access the file:

1. Sign into the Fortinet Customer Service & Support website.
2. Go to https://support.fortinet.com/Download/FirmwareImages.aspx.
3. Navigate to the image file path for /FortiGate / v5.00 / 5.0 / WATERMARK
4. Download the file **fortinet-watermark-linux.out**.

File types

The watermark utility does not work with every file type. The following file types are supported by the watermark tool: .txt; .pdf; .doc; .xls; .ppt; .docx; pptx; and, .xlsx.

Syntax of the watermark utility

The tool is executed in a Linux environment by passing in files or directories of files to insert a watermark.

USAGE:

```
watermark_linux_amd64 <options> -f <file name> -i <identifier> -l <sensitivity level>
watermark_linux_amd64 <options> -d <directory> -i <identifier> -l <sensitivity level>
```

Options:

```
-h print help
-I inplace watermarking (don't copy file)
-o output file (or directory in directory mode)
-e encode <to non-readable>
-i add watermark identifier
-l add watermark sensitivity level
-D delete watermark identifier
-L delete watermark sensitivity level
```

Regular expression

The FortiGate unit checks network traffic for the regular expression specified in a regular expression filter. The regular expression library used by Fortinet is a variation of a library called PCRE (Perl Compatible Regular Expressions). A number of these filters can be added to a sensor making a sort of 'dictionary' subset within the sensor.

Some other, more limited DLP implementations, use a list of words in a text file to define what words are searched for. While the format used here is slightly different than what some people are used to, the resulting effect is similar. Each regular expression filter can be thought of as a more versatile word to be searched against. In this dictionary (or sensor), the list of words is not limited to just predefined words. It can include expressions that accommodate complex variations on those words and even target phrases. Another advantage of the individual filter model of this dictionary over the list is that each word can be assigned its own action, making this implementation much more granular.

Encrypted

This filter is a binary one. If the file going through the policy is encrypted the action is triggered.

Examining specific services

To assist in optimizing the performance of the firewall, the option exists to select which services or protocol traffic will be checked for the targeted content. This setting gives you a tool to save the resources of the FortiGate unit by only using processing cycles on the relevant traffic. Just check the boxes associated with the service / protocol that you want to have checked for filter triggers.

Enable data leak prevention

DLP examines your network traffic for data patterns you specify. The FortiGate unit then performs an action based on the which pattern is found and a configuration set for each filter trigger.

DLP can only be configured for FortiGate's in proxy-based inspection.

General configuration steps

Follow the configuration procedures in the order given. Also, note that if you perform any additional actions between procedures, your configuration may have different results.

1. Create a DLP sensor.
   New DLP sensors are empty. You must create one or more filters in a sensor before it can examine network traffic.
2. Add one or more filters to the DLP sensor.
   Each filter searches for a specific data pattern. When a pattern in the active DLP sensor appears in the traffic, the FortiGate unit takes the action configured in the matching filter. Because the order of filters within a sensor cannot be changed, you must configure DLP in sequence.
3. Add the DLP sensor to one or more firewall policies that control the traffic to be examined.

Creating/editing a DLP sensor

DLP sensors are collections of filters. You must also specify an action for the filter when you create it in a sensor. Once a DLP sensor is configured, you add it to a security policy profile. Any traffic handled by that security policy will be examined according to the DLP sensor configuration.

DLP sensors and filters can only be configured for FortiGate's in proxy-based inspection.

To create/edit a DLP sensor in the GUI

1. Go to **Security Profiles > Data Leak Prevention**.
2. Choose whether you want to edit an existing sensor or create a new one.
   - The default sensor is the one displayed by default.
   - To edit an existing sensor, select it by either using the drop down menu in the upper right hand corner of the window or by selecting the **List** icon (the furthest right of the 3 icons in the upper right of the window, resembling a page with some lines on it), and then selecting the profile you want to edit from the list.
   - To create a new sensor, select the **Create New** icon (a plus sign within a circle) or the List icon and then select the Create New link in the upper left corner of the window that appears.
3. Enter a name in the **Name** field for any new DLP sensors.
4. Optionally, you may also enter a comment. The comment appears in the DLP sensor list and can remind you of the details of the sensor.
5. At this point you can add filters to the sensor (see adding filters to a DLP sensor) or select **OK** to save the sensor.

Without filters, the DLP sensor will do nothing.

Adding filters to a DLP sensor

Once you have created a DLP sensor, you need to add filters.

1. To add filters to a DLP sensor
2. Go to **Security Profiles > Data Leak Prevention**.
3. Select the sensor you wish to edit using the drop-down menu or the sensor list window.
4. Within the Edit DLP Sensor window select **Create New**. A New Filter window should pop up.
5. Select the type of filter. You can choose either **Messages** or **Files**, depending on which of these two are chosen different options will be available.

   Message filter will have these configuration options:

- [radio button] Containing: [drop-down menu including: Credit Card # or SSN]
- [radio button] Regular Expression [input field]

Examine the following services:

Web Access

- HTTP-POST

Email

- [check box] SMTP
- [check box] POP3
- [check box] IMAP
- [check box] MAPI

Others

- [check box] NNTP

Action [from drop-down menu]

- Allow
- Log Only (default)
- Block
- Quarantine IP address

Files filter will have these options:

- [radio button] Containing: drop-down menu including: Credit Card # or SSN
- [radio button] File Size >= [ ]KB
- [radio button] Specify File Types
  File Types: [“Click to add…”drop-down menu of File extensions]
  File Name Patterns:[“Click to add…”drop-down menu]
- [radio button] Regular Expression [input field]
- [radio button] Encrypted

Examine the following Services:

Web Access

- [check box] HTTP-POST
- [check box] HTTP-GET

Email

- [check box] SMTP
- [check box] POP3
- [check box] IMAP
- [check box] MAPI

Others

- [check box] FTP
- [check box] NNTP

Action [from drop-down menu]

- Allow
- Log Only (default)
- Block
- Quarantine IP address

6. Select **OK**.
7. Repeat Steps 6 and 7 for each filter.
8. Select **Apply** to confirm the settings of the sensor.

If you have configured DLP to block IP addresses and if the FortiGate unit receives sessions that have passed through a NAT device, all traffic from that NAT device — not just traffic from individual users — could be blocked. You can avoid this problem by implementing authentication.

To view or modify the replacement message text, go to **System > Replacement Messages**.

DLP archiving

DLP is typically used to prevent sensitive information from getting out of your company network, but it can also be used to record network use. This is called DLP archiving. The DLP engine examines email, FTP, NNTP, and web traffic. Enabling archiving for rules when you add them to sensors directs the FortiGate unit to record all occurrences of these traffic types when they are detected by the sensor.

Since the archive setting is configured for each rule in a sensor, you can have a single sensor that archives only the things you want.

You can archive Email, FTP, HTTP, and session control content:

- Email content includes IMAP, POP3, and SMTP sessions. Email content can also include email messages tagged as spam by Email filtering. If your unit supports SSL content scanning and inspection, email content can also include IMAPS, POP3S, and SMTPS sessions.
- HTTP content includes HTTP sessions. If your unit supports SSL content scanning and inspection HTTP content can also include HTTPS sessions.

DLP archiving comes in two forms: **Summary** and **Full**.

Summary archiving records information about the supported traffic types. For example, when an email message is detected, the sender, recipient, message subject, and total size are recorded. When a user accesses the Web, every URL the user visits recorded. The result is a summary of all activity the sensor detected.

For more detailed records, use full archiving . When an email message is detected, the message itself, including any attachments, is archived. When a user accesses the Web, every page the user visits is archived. Far more detailed than a summary, full DLP archives require more storage space and processing.

Because both types of DLP archiving require additional resources, DLP archives are saved to a FortiAnalyzer unit or the FortiGuard Analysis and Management Service (subscription required).

You can use DLP archiving to collect and view historical logs that have been archived to a FortiAnalyzer unit or the FortiGuard Analysis and Management Service. DLP archiving is available for FortiAnalyzer when you add a

FortiAnalyzer unit to the Fortinet configuration. The FortiGuard Analysis server becomes available when you subscribe to the FortiGuard Analysis and Management Service.

Two sample DLP sensors are provided with DLP archiving capabilities enabled. If you select the `Content_Summary` sensor in a security policy, it will save a summary DLP archive of all traffic the security policy handles. Similarly, the `Content_Archive` sensor will save a full DLP archive of all traffic handled the security policy you apply it to. These two sensors are configured to detect all traffic of the supported types and archive them. You can see these sensors in the GUI but the configuration is only visible through the CLI; DLP archiving is set in the CLI only.

To set the archive to Summary

```
config dlp sensor
   edit <name of sensor>
      set summary-proto smtp pop3 imap http ftp nntp msn yahoo mapi
   end
```

To set the archive to Full

```
config dlp sensor
   edit <name of sensor>
      set full-archive-proto smtp pop3 imap http ftp nntp msn yahoo mapi
   end
```

If you set the `full-archive-proto` filter to include one or more of the protocols set by the `proto`option, then the archive action is disabled.

DLP examples

DLP sensors and filters can only be configured for FortiGate's in proxy-based inspection.

- Blocking content with credit card numbers
- Blocking emails larger than 15 MB and logging emails from 5 MB to 15 MB
- Blocking selectively based on a fingerprint

Blocking content with credit card numbers

When the objective is to block credit card numbers one of the important things to remember is that two filters will need to be used in the sensor. One filter is to prevent sensitive files from being leaked and another is to retain any sensitive data that is not a file (for example, messages or email content).

In the default Credit-Card sensor, you will notice a few things.

- The **Action** is set to **Log Only**
- In the **Files** filter not all of the services are being examined.

If you wish to block as much content as possible with credit card numbers in it instead of just logging most the traffic that has it, the existing sensor will have to be edited.

1. Go to **Security Profiles > Data Leak Prevention**.

Some configurations will have a preconfigured Credit Card sensor where you can use the drop down menu to select **Credit-Card**. If your configuration doesn't already have one create a new sensor.

2. Use the **Create New** icon to add a new sensor.
3. *Create/edit the first filter.* Set **Type** to **Messages** and select **Containing Credit Card #**.
4. Go to **Examine the Following Services** and select all services .
5. Set **Action** to **Block**.
6. Select **OK** or **Apply**.
7. *Create/edit the second filter.* Set **Type** to **Files** and select **Containing Credit Card #**.
8. Go to **Examine the Following Services** and select all services .
9. Set **Action** to **Block**.
10. Select **OK** or **Apply**.
11. Edit the appropriate policies so that under **Security Profiles**, **DLP** is turned on and the **Credit-Card** sensor is selected.

Blocking emails larger than 15 MB and logging emails from 5 MB to 15 MB

Multiple filters will have to be used in this case and the order that they are used is important. Because there is no mechanism to move the filters within the sensor the order that they are added to the sensor is important.

1. Go to **Security Profiles > Data Leak Prevention**.
2. Use the **Create New** icon to add a new sensor. Give it a descriptive **Name**, such as *block_large_emails*. Optionally, enter a descriptive comment.

Once the sensor has been created, a new filter will need to be added.

3. *Create the filter to block the emails over 15 MB*. In the filters table select **Create New**.
4. Set **Type** to **Messages** and enter 15360 in the field next to **File size over**. (1MB = 1024KB, 15 MB = 15 x 1024KB = 15360KB)
5. Go to **Examine the Following Services** and select all **Email** services .
6. Set **Action** to **Block**.
7. Select **OK**.
8. *Create the filter to log emails between 5 MB and 10 MB*. In the filters table select **Create New**.
9. Set **Type** to **Files**.
10. Enter 5120 in the field next to **File size over**. (1MB = 1024KB, 5 MB = 5 x 1024KB = 5124KB)
11. Go to **Examine the Following Services** and select all the email services .
12. Set action to **Log Only**.
13. Select **OK.**

The reason that the block filter is placed first is because the filters are applied in sequence and once the traffic triggers a filter, the action is applied and then the traffic is passed on to the next test. If the Log Only filter which checks for anything over 1MB is triggered this would include traffic over 15MB, so a 16 MB file would only be logged. In the described order, the 16 MB file will be blocked and the 3 MB file will be logged.

Blocking selectively based on a fingerprint

The following is a fairly complex example but shows what can be done by combining various components in the correct configuration.

The company has a number of copyrighted documents that it does not want “escaping” to the Internet but it does want to be able to send those documents to the printers for turning into hardcopy.

The policies and procedures regarding this issue state that:

- Only members of the group **Senior_Editors** can send copyrighted material to the printers.
- Every member of the company by default is included in the group **employees**.
- Even permitted transmission of copyrighted material should be recorded.
- All of the printers IP addresses are in a group called **approved_printers**.
- There is a file share called **copyrighted** where any file that is copyrighted is required to have a copy stored.
- It doesn’t happen often but for legal reasons sometimes these files can be changed, but all versions of a file in this directory need to be secured.
- All network connections to the Internet must have AntiVirus enabled using at least the default profile.
- The SSL/SSH Inspection profile used will be **default**.

It is assumed for the purposes of this example that:

- Any addresses or address groups have been created.
- User accounts and groups have been created.
- The account used by the FortiGate is fgtaccess.
- The copyrighted sensitivity level needs to be created.
- The copyrighted material is stored at \\192.168.27.50\books\copyrighted\

1. Add a new Sensitivity Level by running the following commands in the CLI:

```
config dlp fp-sensitivity
   edit copyrighted
end
```

2. Apply files to the fingerprint database by running these commands in the CLI:

```
config dlp fp-doc-source
   edit "copyrighted_material"
      set server-type smb
      set server 192.168.27.50
      set username fgtaccess
      set password ******
      set file-path books/copyrighted/
      set file-pattern *.pdf
      set sensitivity copyrighted
      set period daily
      set tod-hour 2
      set tod-min 0
      set scan-subdirectories enable
      set remove-deleted disable
      set keep-modified enable
   next
end
```

Two Sensors need to be created. One for blocking the transmission of copyrighted material and a second for allowing the passing of copyrighted material under specific circumstances.

3. Create the first DLP Sensor with the following commands in CLI:

```
config dlp sensor
   edit block_copyrighted
```

```
      config filter
         edit 1
            set proto smtp pop3 imap http-get http-post ftp nntp mapi
            set filter-by fingerprint
            set fp-sensitivity copyrighted
            set action block
         next
      end
   next
```

4. Create the second DLP Sensor

```
config dlp sensor
   edit allow_copyrighted
      config filter
         edit 2
            set proto smtp pop3 imap http-get http-post ftp nntp mapi
            set filter-by fingerprint
            set fp-sensitivity copyrighted
            set action log-only
         next
      end
   next
```

5. Create a policy to allow transmission of copyrighted material.
   a. Go to **Policy & Objects > IPv4 Policy**.
   b. Select **Create New**.
   c. Use the following values in the policy:

Incoming Interface	LAN
Source Address	all
Outgoing Interface	wan1
Destination Address	all
Schedule	always
Service	all
Action	ACCEPT
Enable NAT	enabled -- Use Destination Interface Address
AntiVirus	<ON> default
DLP	<ON> Copyrighted
SSL/SSH Inspection	<ON> default
Enable this policy	<ON>

This policy should be placed as close to the beginning of the list of policies so the it is among the first tested against.

6. Create a policy to block transmission of copyrighted material.
   This will in effect be the default template for all following policies in that they will have to use the DLP profile that blocks the transmission of the copyrighted material.

   a. Go to **Policy & Objects > IPv4 Policy**.

   b. Select **Create New** or Edit an existing policy.

   c. Use the following values in the Policy:

   The fields should include what ever values you need to accomplish your requirements are but each policy should include the DLP sensor block_copyrighted. Alternatively, if a different DLP configuration is required it should include a filter that blocks **copyrighted** fingerprinted file.

   If you need to create a policy that is identity based make sure that there is an Authentication rule for the group **employees** that uses the DLP sensor that blocks copyrighted material.

ICAP support

ICAP is the acronym for Internet Content Adaptation Protocol The purpose of the feature is to offload work that would normally take place on the firewall to a separate server specifically set up for the specialized processing of the incoming traffic. This takes some of the resource strain off of the FortiGate firewall leaving it to concentrate its resources on things that only it can do.

Offloading value-added services from Web servers to ICAP servers allows those same web servers to be scaled according to raw HTTP throughput versus having to handle these extra tasks.

ICAP servers are focused on a specific function, for example:

- Ad insertion
- Virus scanning
- Content translation
- HTTP header or URL manipulation
- Language translation
- Content filtering

ICAP does not appear by default in the GUI. You must enable it in **System > Feature Select** to display ICAP in the GUI.

The following topics are included in this section:

- The Protocol
- Offloading using ICAP
- Configuration Settings
- Example ICAP sequence
- Example Scenario

The Protocol

The protocol is a lightweight member of the TCP/IP suite of protocols. It is an Application layer protocol and its specifications are set out in RFC 3507. The default TCP that is assigned to it is 1344. Its purpose is to support HTTP content adaptation by providing simple object-based content vectoring for HTTP services. ICAP is usually used to implement virus scanning and content filters in transparent HTTP proxy caches. Content Adaptation refers to performing the particular value added service, or content manipulation, for an associated client request/response.

Essentially it allows an ICAP client, in this case the FortiGate firewall, to pass HTTP messages to an ICAP server like a remote procedure call for the purposes of some sort of transformation or other processing adaptation. Once the ICAP server has finished processing the the content, the modified content is sent back to the client.

The messages going back and forth between the client and server are typically HTTP requests or HTTP responses. While ICAP is a request/response protocol similar in semantics and usage to HTTP/1.1 it is not HTTP nor does it run over HTTP, as such it cannot be treated as if it were HTTP. For instance, ICAP messages can not be forwarded by HTTP surrogates.

Offloading using ICAP

If you enable ICAP in a security policy, HTTP traffic intercepted by the policy is transferred to an ICAP server in the ICAP profile added to the policy. Responses from the ICAP server are returned to the FortiGate unit which forwards them to an HTTP client or server.

You can offload HTTP responses or HTTP requests (or both) to the same or different ICAP servers.

If the FortiGate unit supports HTTPS inspection, HTTPS traffic intercepted by a policy that includes an ICAP profile is also offloaded to the ICAP server in the same way as HTTP traffic.

When configuring ICAP on the FortiGate unit, you must configure an ICAP profile that contains the ICAP server information; this profile is then applied to a security policy.

Configuration Settings

There are two sections where ICAP is configured:

Servers

Go to **Security Profiles > ICAP Servers**.

The available settings to be configured regarding the server are

- **Name**
- **IP Type** (in the GUI) or IP address version (in the CLI)
  The options for this field in the GUI are 2 radio buttons labelled “IPv4” and “IPv4”. In the CLI the approach is slightly different. There is a field “ip-version” that can be set to “4” or “6”.
- **IP Address**
  Depending on whether you’ve set the IP version to 4 or 6 will determine the format that the content of this field will be set into. In the GUI it looks like the same field with a different format but in the CLI it is actually 2 different fields named “ip-address” and ip6-address.
- **Port**
  1344 is default TCP port used for the ICAP traffic. The range can be from 1 to 65535.

Maximum Connections

This value refers to the maximum number of concurrent connections that can be made to the ICAP server. The default setting is 100. This setting can only be configured in the CLI.

The syntax is:

```
config icap server
   edit <icap_server_name>
      set max-connections <integer>
      end
```

Profiles

Name

Just like any other profile each of the ICAP profiles needs to be assigned a name.

Enable Request Processing

Enabling this setting allows the ICAP server to process request messages.

If enabled this setting will also require:

- **Server** - This is the name of the ICAP server. It is chosen from the drop down menu in the field. The servers are configure in the Security Profiles > ICAP > Server section.
- **Path** - This is the path on the server to the processing compent. For instance if the Windows share name was “Processes” and the directory within the share was “Content-Filter” the path would be “/Processes/Content-Filter/”
- **On Failure** - There are 2 options. You can choose by the use of radio buttons either **Error** or **Bypass**.

Enable Response Processing

Enabling this setting allows the ICAP server to process response messages.

If enabled this setting will also require:

- **Server** - This is the name of the ICAP server. It is chosen from the drop down menu in the field. The servers are configure in the Security Profiles > ICAP > Server section.
- **Path** - This is the path on the server to the processing compent. For instance if the Windows share name was “Processes” and the directory within the share was “Content-Filter” the path would be “/Processes/Content-Filter/”
- **On Failure** - There are 2 options. You can choose by the use of radio buttons either **Error** or **Bypass**.

Enable Streaming Media Bypass

Enabling this setting allows streaming media to ignore offloading to the ICAP server.

Example ICAP sequence

This example is for an ICAP server performing web URL filtering on HTTP requests

1. A user opens a web browser and sends an HTTP request to connect to a web server.
2. The FortiGate unit intercepts the HTTP request and forwards it to an ICAP server.
3. The ICAP server receives the request and determines if the request is for URL that should be blocked or allowed.
   - If the URL should be blocked the ICAP server sends a response to the FortiGate unit. The FortiGate unit returns this response to the user’s web browser. This response could be a message informing the user that their request was blocked.
   - If the URL should be allowed the ICAP server sends a request to the FortiGate unit. The FortiGate unit forwards the request to the web server that the user originally attempted to connect to.
   - When configuring ICAP on the FortiGate unit, you must configure an ICAP profile that contains the ICAP server information; this profile is then applied to a security policy.

Example Scenario

Information relavent to the following example:

- The ICAP server is designed to do proprietary content filtering specific to the organization so it will have to receive the messages and sent back appropriate responses.
- The content filter is a required security precaution so it if the message cannot be processed it is not allowed through.

- Resources on both the FortiGate and the ICAP server are considerable so the maximum connections setting will set at a double the default value to analyze the impact on performance.
- The ICAP server's IP address is 172.16.100. 55.
- The path to the processing component is "/proprietary_code/content-filter/".
- Streaming media is not something that the filter considers, but is allowed through the policy so processing it would be a waste of resources.
- The ICAP profile is to be added to an existing firewall policy.
- It is assumed that the display of the policies has already been configured to show the column "ID".

1. Enter the following to configure the ICAP server:

   Go to **Security Profiles > ICAP Servers**.
   Use the following values:

Name	content-filtration-server4
IP Type	IPv4
IP Address	172.16.100.55
Port	1344

   Use the CLI to set the max-connections value.

```
config icap server
   edit content-filtration-server4
      set max-connections 200
      end
```

2. Enter the following to configure the ICAP profile to then apply to a security policy:

   Use the following values:

Name	Prop-Content-Filtration
Enable Request Processing	enable
Server	content-filtration-server4
Path	/proprietary_code/content-filter/
On Failure	Error
Enable Response Processing	enable
Server	content-filtration-server4
Path	/proprietary_code/content-filter/
On Failure	Error
Enable Streaming Media Bypass	enable

3. Apply the ICAP profile to policy:

The purposes of this particular ICAP profile is to filter the content of the traffic coming through the firewall via policy ID#17.

a. Go to **Policy & Objects > IPv4 Policy**.

b. Open the existing policy ID# 17 for editing.

c. Go to the section **Security Profiles.**

d. Select the button next to **ICAP** so that it indicates that it's status is **ON**.

e. Select the field with the profile name and use the drop down menu to select **Prop-Content-Filtration.**

f. Select **OK**.

FortiClient Profiles

This section describes the FortiClient Profiles endpoint protection features and configuration. It also highlights changes to FortiClient configuration that first appear in FortiOS 5.4.1.

In FortiOS 5.4.1, FortiClient Profiles are used primarily to make sure connected devices are compliant with Endpoint Control and to protect against vulnerabilities. Both **Endpoint Vulnerability Scan on Client** and **System compliance** are enabled by default, while other settings are disabled by default. This allows FortiClient to work as part of a Cooperative Security Fabric.

You must first enable this feature. Go to System > Feature Select and enable Endpoint Control. This will reveal the Security Profiles > FortiClient Profiles menu item.

The following topics are included in this section:

Endpoint protection overview

Endpoint Protection enforces the use of up-to-date FortiClient Endpoint Security software on endpoints (workstation computers and mobile devices). It pushes a FortiClient profile to the FortiClient application, specifying security settings, including:

- Real-time antivirus protection - on or off
- FortiClient web category filtering based on web filters defined in a FortiGate Web Filter profile
- FortiClient Application Control (application firewall) using application sensors defined in the FortiGate Application Control profile

The FortiClient profile can also:

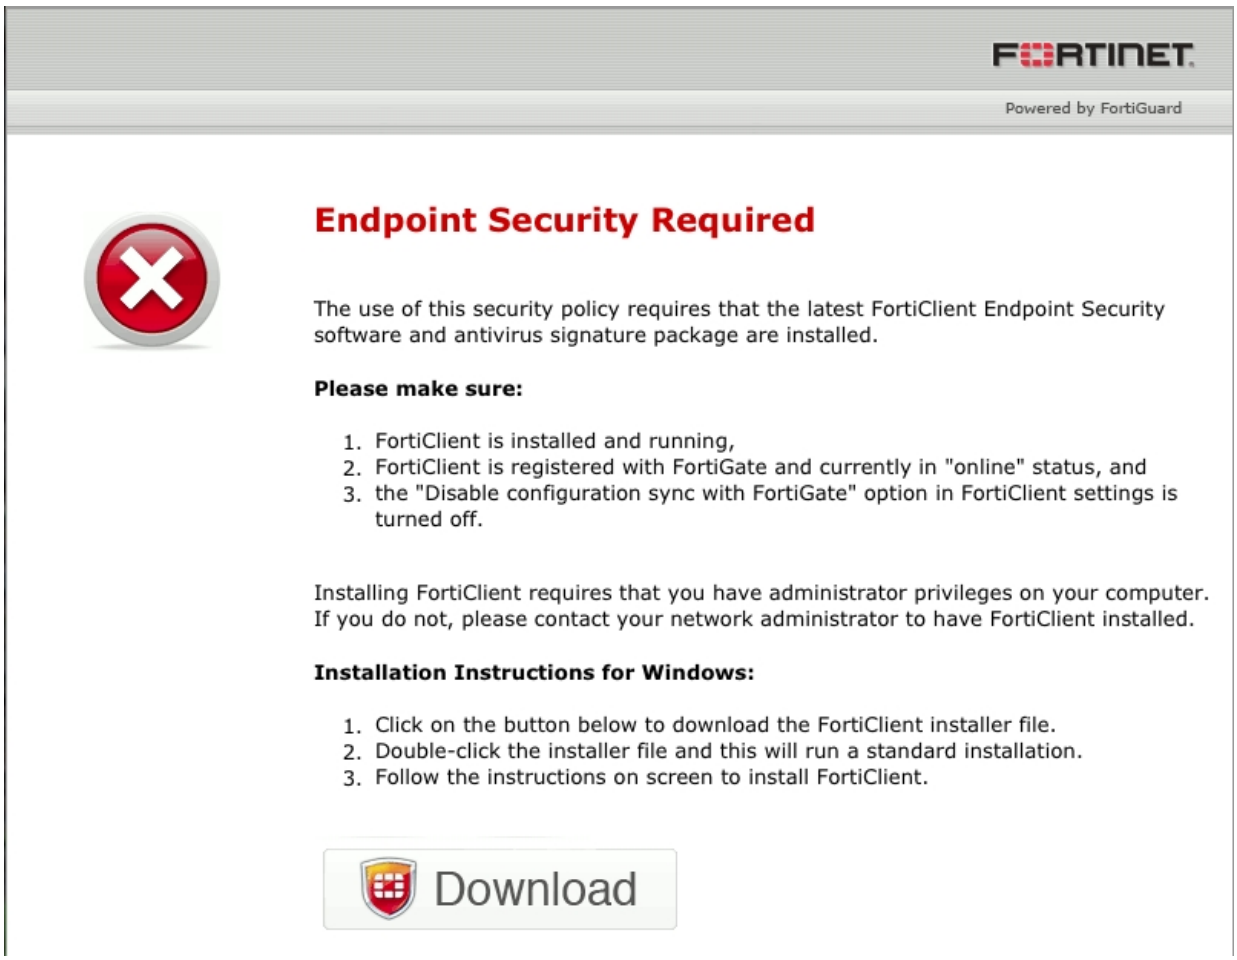
- Create VPN configurations
- Install CA certificates
- Upload logs to FortiAnalyzer or FortiManager
- Enable use of FortiManager for client software/signature update
- Enable a dashboard banner
- Enable client-based logging while on-net
- Output a mobile configuration profile (.mobileconfig file for iOS)

User experience

When using a web browser, the user of a non-compliant endpoint receives a replacement message HTML page from the FortiGate unit. The message explains that the user needs to install FortiClient Endpoint Security and provides a link to do so. The user cannot continue until the FortiClient software is installed.

For information about modifying the replacement message, see Modifying the endpoint protection replacement messages on page 2789.

Default FortiClient non-compliance message for Windows



After installing FortiClient Endpoint Security, the user will receive an invitation to register with the FortiGate unit. If the user accepts the invitation, the FortiClient profile is sent to the device's FortiClient application. Now the user is compliant and can connect to the network. FortiClient Endpoint Security registered with a FortiGate unit does not need to be separately licensed with FortiGuard.

The FortiGate unit can also register endpoints connecting over the Internet through a VPN. The user can accept an invitation to register with the FortiGate unit. See Configuring endpoint registration over a VPN on page 2788.

FortiGate endpoint registration limits

To view the number of endpoints that are registered and the total that can be registered, go to **Dashboard**. Under **License Information**, find **FortiClient**. You will see a line like "Clients Registered 4 of 10". This means that there are four registered endpoints and a total of ten are allowed.

When the registration limit is reached, the next FortiClient-compatible device will not be able to register with the FortiGate unit. The user of the device sees a message in the FortiClient application. The FortiClient profile is not sent to client and the client cannot connect through the FortiGate unit.

For all FortiGate models, the maximum number of registered endpoints is ten. For all models except 20C, you can purchase an endpoint license to increase this capacity:

To add an endpoint license - GUI

1. Go to **Dashboard**.
2. In the **License Information** widget, under **FortiClient**, select **Enter License**, enter the license key, and select **OK**.

Maximum registered endpoints with endpoint license

Model type	Max Registered Endpoints
30 to 90 series	200
100 to 300 series	600
500 to 800 series, VM1, VM2	2 000
1000 series, VM4	8 000
3000 to 5000 series, VM8	20 000

Configuring endpoint protection

Endpoint Protection requires that all hosts connecting to an interface have the FortiClient Endpoint Security application installed. Make sure that all endpoints behind the interface are able to install this application. Currently, FortiClient Endpoint Security is available for Microsoft Windows (2000 and later), Apple (Mac OS X and later), and Android devices only.

By default, the FortiGuard service provides the FortiClient installer. If you prefer to host it on your own server, see Changing the FortiClient installer download location, below.

To set up Endpoint Protection, complete the following:

- Create a FortiClient Profile or use the default profile. See Creating a FortiClient profile on page 2783. Enable the application sensor and web category filtering profiles that you want to use.
- Configure the FortiGate unit to support endpoint registration using FortiHeartBeat (under **Network > Interfaces**, allow FortiHeartBeat admission control).
- Optionally, enforce FortiClient registration. See Enforcing FortiClient registration on page 2787.
- Optionally, configure application sensors and web filter profiles as needed to monitor or block applications.
- Optionally, modify the **Endpoint NAC Download Portal** replacement messages (one per platform). See Modifying the endpoint protection replacement messages on page 2789.

Creating a FortiClient profile

The default FortiClient profile has only AntiVirus, Web Filter, and VPN options enabled. You can modify this profile or create your own FortiClient profiles, including settings for iOS and Android devices.

It is possible for more than one profile to be assigned to a device type. As with security policies, clients are matched to FortiClient profiles in the order that the profiles appear in the list.

Features involving general settings have been removed from the FortiClient profile GUI in 5.4.1. Features emphasizing compliance of the endpoint devices have been added. These enhancements facilitate integration with the Cooperative Security Fabric.

To create a FortiClient profile - GUI - FortiOS 5.4.0

1. If you plan to use the Application Firewall feature, go to **Security Profiles > Application Control** to create the Application Sensors that you will need.
2. If you plan to use the Web Category Filtering, go to **Security Profiles > Web Filter** to create the Web Filter Profile that you will need.
3. Go to **Security Profiles > FortiClient Profiles**.
   If there is only the default FortiClient profile, it will be displayed and ready to edit. At the top right of the page you can select or create other profiles.
4. Select **Create New** or select an existing profile and **Edit** it.
5. In **Assign Profile To**, select the device groups, user groups, and users to which this FortiClient profile applies. ***This is not available for the* default *profile.***
6. Configure the FortiClient Profile under the following tabs: **Security**, **VPN**, **Advanced**, and **Mobile.** ***These tabs are removed in FortiOS 5.4.1 and later.***

Security option	Description
AntiVirus	
Realtime Protection	Enable to configure AV options, including **Scan File Downloads**, **Block malicious websites**, and **Block attack channels**.
Scheduled Scan	Enable to configure the following: • **Type:** Select from **Quick**, **Full**, or **Custom**. • **Schedule:** Select from **Daily**, **Weekly**, or **Monthly**. • **Time:** Select when the scan should take place.
Excluded Paths	Enable to add paths you wish to be excluded from AV scanning.
Web Filter	
Profile	Select which Web Filter Profile you wish to use.
Client Side when On-Net	Select to enable client side web filtering when the device is On-Net.
Application Firewall	
Application Control list	Select which Application Control Sensor you wish to use.
Monitor unknown applications	Enable to monitor any applications that do not fall into any Application Control categories.

VPN option	Description
VPN	
Client VPN Provisioning	Enable to configure the FortiClient VPN client, and enter the VPN configuration details.
Allow user defined VPN	Enable to accept VPN tunnels for specific users.
VPN before Windows logon	Enable to establish the VPN connection before logging in to Windows.

Advanced option	Description
Install CA Certificates	Enable to force the FortiClient endpoint to download CA Certificates from the FortiGate.
Disable Unregister Option	Enable to prevent managed endpoints from unregistering.
Upload Logs to FortiAnalyzer	Enable to determine where FortiClient will upload its logs. **Same as System** will send the logs as configured via **Log & Report > Log Settings**. Select **Specify** to upload them elsewhere.
FortiManager updates	Enable to download client signature updates from FortiManager from specified IP addresses. Also, you can **Failover to FDN** when FortiManager is not available.
Dashboard Banner	Enable to display the dashboard banner.
Client-based Logging when On-Net	Enable to always save logs on the client. Logs can be viewed with the FortiClient Console.
Single Sign-on Mobility Agent	Enable to configure a specific server with a pre-shared key for SSO.

Mobile option	Description
iOS	
Web Filter	Select which Web Filter Profile you wish to use, and select **Client Side when On-Net** to enable client side web filtering when the iOS device is On-Net.
Client VPN Provisioning	Enable to configure the FortiClient VPN client, and enter the VPN configuration details.
Distribute Configuration Profile	Enable to select and upload a '.mobileconfig' file that will be distributed to iOS devices.

Mobile option	Description
Android	
Web Filter	Select which Web Filter Profile you wish to use, and select **Client Side when On-Net** to enable client side web filtering when the Android device is On-Net.
Client VPN Provisioning	Enable to configure the FortiClient VPN client, and enter the VPN configuration details.

7. Select **Apply**.

To create a FortiClient profile - GUI - FortiOS 5.4.1 and later

NOTE: Follow steps **1** through **5** above.

6. Under FortiClient endpoint compliance, select the action to take if a unit is non-compliant: **Block**, **Warning**, or **Auto-update**. For information on what each action means, see **FortiClient Profile changes (356205)** in What's New in FortiOS 5.4 on page 2599 of this chapter.
7. Use the drop-down menu to select the quarantine level for **Endpoint Vulnerability Scan on Client**.
8. Set the minimum FortiClient version in **System compliance** and, if you have a FortiAnalyzer configured, enable the log to upload to FortiAnalyzer compliance option.
9. Select which Security Profiles to enable: **AntiVirus**, **Web Filter**, and / or **Application Firewall**.
10. Select **Apply**.

To create a FortiClient profile - CLI:

This example creates a profile for Windows and Mac computers.

```
config endpoint-control profile
   edit ep-profile1
      set device-groups mac windows-pc
      config forticlient-winmac-settings
         set forticlient-av enable
         set forticlient-wf enable
         set forticlient-wf-profile default
      end
   end
```

To install CA certificates - CLI:

```
config endpoint-control profile
   edit <profile>
      config forticlient-winmac-settings
         set install-ca-certificate [enable | disable]
      end
   next
end
```

FortiOS 5.4.0 permits you to install CA certificates through the CLI. FortiOS 5.4.1 only allows CA certificates to be installed through the GUI by going to **System > Certificates**.

Enforcing FortiClient registration

When you enable FortiTelemetry (formerly known as FortiHeartbeat) on an interface, the option to enforce FortiClient registration becomes available. Devices connecting to that interface are forced to register to the FortiGate and install FortiClient before gaining access to network services.

The following example includes editing the default FortiClient Profile to enforce real time antivirus protection and malicious website blocking.

To enforce FortiClient registration on the internal interface - GUI:

1. On the FortiGate, go to **System > Feature Select** and make sure that **Endpoint Control** is enabled.
2. Go to **Network > Interfaces** and edit the internal interface.
3. Under **Restrict Access**, enable **FortiClient Telemetry**.
4. Under **Admission Control**, enable **Enforce FortiClient Telemetry for all FortiClients**. Optionally, you can also **Exempt Sources** and/or **Exempt Destinations/Services**. If you were to exempt a source device, that device would not require FortiClient registration to access network services or the Internet.
5. Go to **Security Profiles > FortiClient Profiles**.
6. Under the **Security** tab, enable **Realtime Protection**, **Scan File Downloads**, **Block malicious websites**, and **Block attack channels**.

Changing the FortiClient installer download location

By default, FortiClient installers are downloaded from the FortiGuard network. You can also host these installers on a server for your users to download. In that case, you must configure FortiOS with this custom download location. For example, to set the download location to a customer web server with address custom.example.com, enter the following command:

```
config endpoint-control settings
   set download-location custom
   set download-custom-link "http://custom.example.com"
end
```

Storing FortiClient configuration files

Advanced FortiClient configuration files of up to 32k may be stored:

1. Enable the advanced FortiClient configuration option in the endpoint profile:

```
config endpoint-control profile
   edit "default"
      set forticlient-config-deployment enable
      set fct-advanced-cfg enable
      set fct-advanced-cfg-buffer "hello"
      set forticlient-license-timeout 1
      set netscan-discover-hosts enable
   next
end
```

2. Export the configuration from FortiClient (xml format).
3. Copy the contents of the configuration file and paste in the advanced FortiClient configuration box.

If the configure file is greater than 32k, you need to use the following CLI:

```
config endpoint-control profile
```

```
    edit <profile>
       config forticlient-winmac-settings
          config extra-buffer-entries
             edit <entry_id>
                set buffer xxxxxx
             next
          end
       end
    next
end
```

Configuring endpoint registration over a VPN

FortiGate units can register FortiClient-equipped endpoints over either an interface-based IPsec VPN or a tunnel-mode SSL VPN. After the user authenticates, the FortiGate unit sends the FortiClient application the IP address and port to be used for registration. If the user accepts the FortiGate invitation to register, registration proceeds and the FortiClient profile is downloaded to the client.

Users without FortiClient Endpoint Security connecting to the SSL VPN through a browser are redirected to a captive portal to download and install the FortiClient software.

Endpoint registration on an IPsec VPN

You can enable endpoint registration when you configure the FortiClient VPN or you can enable it on an existing FortiClient VPN.

To enable endpoint registration while configuring the VPN

- Enable **Allow Endpoint Registration** on the Policy & Routing page of the VPN Wizard when creating the FortiClient VPN.

This is only available when **Template Type** is set to **Remote Access** with a FortiClient **Remote Device Type**.

To enable endpoint registration on an existing VPN

1. Go to **Network > Interfaces** and edit the VPN's tunnel interface.
   The tunnel is a virtual interface under the physical network interface.
2. In **Admission Control**, enable **FortiClient Telemetry**.
   Optionally, you can also enable **Enforce FortiClient Telemetry for all FortiClients**. This forces endpoints to register with FortiClient before they have network access.
3. Select **OK**.

Endpoint registration on an SSL-VPN

To enable endpoint registration on the SSL-VPN

1. Go to **VPN > SSL-VPN Settings.**
2. In **Tunnel Mode Client Settings**, make sure **Allow Endpoint Registration** is enabled.
3. Select **Apply**.
4. Go to **Network > Interfaces** and edit the **ssl.root** interface.

5. In **Admission Control**, enable **FortiHeartBeat**.
   Optionally, you can also enable **Enforce FortiClient Telemetry for all FortiClients**. This forces endpoints to register with FortiClient before they have network access.
6. Select **OK**.

This procedure does not include all settings needed to configure a working SSL-VPN.

Synchronizing endpoint registrations

To support roaming users in a network with multiple FortiGate units, you need to configure synchronization of the endpoint registration databases between the units. The registered endpoints are then recognized on all of the FortiGate units. This is configured in the CLI. For example, to synchronize this FortiGate unit's registered endpoint database with another unit named `other1` at IP address 172.20.120.4, enter:

```
config endpoint-control forticlient-registration-sync
   edit other1
      set peer-ip 172.20.120.4
   end
```

Modifying the endpoint protection replacement messages

If the security policy has **Redirect all non-compliant/unregistered FortiClient compatible devices to a captive portal** enabled, users of non-compliant devices are redirected to a captive portal that is defined by the **Endpoint NAC Download Portal** replacement message. There are different portals for Android, iOS, Mac, Windows, Quarantine, and "other" devices.

To modify the the endpoint protection replacement messages

1. Go to **System > Replacement Messages** and select **Extended View**.
2. In the **Endpoint Control** section select the message that you want to edit.
   The replacement message and its HTML code appear in a split screen in the lower half of the page.
3. Modify the text as needed and select **Save**.

Monitoring endpoints

Go to **Monitor > FortiClient Monitor** to monitor endpoints.

With the release of FortiOS 5.4.1, updates to the **Monitor** page all the user to view FortiClient endpoint devices grouped by interface and then sub-grouped by compliance status. See **FortiClient Monitor page updates (304254)** in What's New in FortiOS 5.4 on page 2599 of this chapter.

SSL/SSH Inspection

At one point deep inspection was something that was either enabled or not. Now individual deep inspection security profiles can be created depending on the requirements of the policy. Depending on the Inspection Profile, you can:

- Configure which Certificate Authority (CA) certificate will be used to decrypt the Secure Sockets Layer (SSL) encrypted traffic.
- Configure which SSL protocols will be inspected.

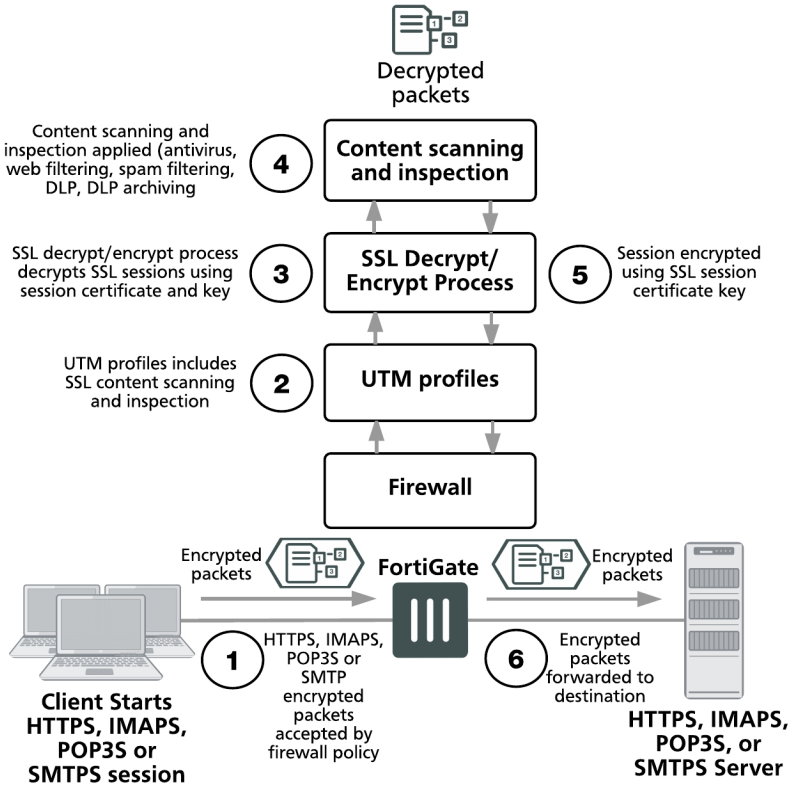
- Configure which ports will be associated with which SSL protocols for the purpose of inspection.
- Configure which websites will be exempt from SSL inspection
- Configure whether or not to allow invalid SSL certificates.
- Configure whether or not Secure Shell (SSH) traffic will be inspected.

SSL inspection

Secure Sockets Layer (SSL) content scanning and inspection allows you to apply antivirus scanning, web filtering, FortiGuard Web Filtering, and email filtering to encrypted traffic. To perform SSL content scanning and inspection, the FortiGate unit does the following:

- intercepts and decrypts HTTPS, IMAPS, POP3S, SMTPS, and FTPS sessions between clients and servers (FortiGate SSL acceleration speeds up decryption)
- applies content inspection to decrypted content, including:
- HTTPS, IMAPS, POP3S, and SMTPS Antivirus, DLP, and DLP archiving
- HTTPS web filtering and FortiGuard web filtering
- IMAPS, POP3S, and SMTPS email filtering
- encrypts the sessions and forwards them to their destinations.

FortiGate SSL content scanning and inspection packet flow



.

Inspection Exemption

When you are using a browser to visit SSL encrypted sites and you are using a certificate that does not match the certificate of the site, you are presented with a warning message and the option of continuing, using the untrusted certificate, or terminating the session. However, there are a number of applications that use SSL encrypted traffic. If the application detects SSL traffic that wasn't signed with a certificate that it trusts it will not allow the traffic. The applications do not give the option to manually indicate that we trust the certificate or the site.

If the option is available, you may choose to import needed SSL certificates into Local Certificates and configure a policy for communication for that application.

The assist in preventing loss of access to these site but still enabling the SSL inspection of the rest of the internet traffic, a method of exempting either Website categories or specific sites has been developed. To exempt a large group of sites the profile can be configure to exempt FortiGuard Categories. There are 3 of these categories preselected due to the high likelihood of issues with associated applications with the type of websites included in these categories.

- Heath and Wellness
- Personal Privacy
- Finance and Banking

Other more specific websites can be added to the exemption list by going to **Security Profiles> SSL/SSH Inspection** and adding addresses under **Exempt from SSL Inspection** for the appropriate profile. The adding of addresses is done by selection from a drop down menu.

With the release of FortiOS 5.4.0, some common sense exemptions have been added to the default SSL deep inspection profile so that there will be no interference due to certificate issues. For example: Fortinet, Android, Apple, Skype, and many more.

HTTP Strict Transport Security (HSTS) Protocol

HSTS is a protocol used by Google and other web browsers to prevent man-in-the-middle attacks.

When performing deep inspection, the FortiGate intercepts the https traffic and would send its own self-signed CA certificate to the browser. If the browser is configured to use HSTS connections, it would refuse the FortiGate CA certificate since it is not on the trusted list for Google servers.

To keep the CA certificate from being refused, the HSTS settings should be cleared from the browser. Instructions for this vary between browsers.

Allow Invalid SSL Certificate

This setting was something that used to be part of the **Proxy Options**, but now that SSL inspection has it's own configuration setting it is configured with those. It might seem like a straightforward decision that the allowing of invalid SSL certificates must be bad and, therefore, should not be allowed. However, there can be some reasons that applying this feature should be considered.

At a purely technical level, a properly formed certificate will encrypt the data so that it can only be read by the intended parties and not be read by anyone sniffing traffic on the network. For this reason, people will often use self-signed certificates. These self-signed certificates are free and will encrypt the data just as securely as a purchased certificate. The self-signed certificates, however, are not likely to recognized by the CA certificate store so will be considered by any checks against that store as invalid.

On the other hand, one of the services the vendors provide is verification of identity of those that purchase their certificates. This means that if you see a valid certificate from a site that identified itself as being from “valid-company.com” that you can be reasonably sure that the site does belong to that company and not a false site masquerading as being part of that company.

You can allow invalid SSL certificates by going to **Security Profiles> SSL/SSH Inspection**, selecting the appropriate profile, and enabling **Allow Invalid SSL Certificates**.

During the SSL handshake, a number of checks are made to verify the validity of the certificate.

One source of the checks, is against a CA certificate store inside FortiOS. This is the same CA bundle used by the browser Mozilla Firefox. Update to the store are:

- made with each new version of FortiOS
- available through internal FGD
- Possible with some builds via FTP

Details of the CA certificate store can be found at: https://curl.haxx.se/docs/caextract.html

The following checks are made for validity:

Validity Check	Description
Signature	One of the things being checked against the CA bundle is the certificate signature. These signatures are generated via directly signing by the CA's private key.
Expiration date	All certificates have an expiry date. The date, based on the devices clock/calendar is compared to the expiry date of the certificate.
Revoked list	Periodically, certificates are revoked. If a certificate has been revoked it is put on a list. Whenever a certificate is being verified, it is checked against this list.
Self signed certificate	In the case of self-signed certificates, the IPS engine and proxy have different handling. IPS engine will keep and use the certificate self-signed certificate, but the public key will be replaced so that SSL inspection can take place. The proxy engine will re-sign the certificate with the untrusted CA certificate. The mechanics are similar but the net effect for the user is similar. The user will get warnings from browsers. The users can choose to remember the self-signed certificate in some browsers, but cannot do the same thing with the certificate re-signed with the untrusted CA.

Validity Check	Description
Intermediate CA with a weak hash algorithm, such as MD5, SHA1	Some browsers like Chrome or Firefox will give a warning because of a weak signature algorithm (visit https://sha1-intermediate.badssl.com to test). In the IPS Engine, in order to convey the weak intermediate CA back to client, signature hash algorithm is downgraded in the re-signed server certificate to the weakest algorithm used in the original certificate chain. In the Proxy Engine - In the case of a weak signature algorithm, the Proxy engine will treat the connection as untrusted, and re-sign the server certificate with the untrusted CA. The final user experience is different. Instead of a warning like "NET::ERR_CERT_WEAK_SIGNATURE_ALGORITHM" that you would get in Chrome, you will get a warning that the certificate couldn't be verified (because of the signing CA is not trusted or imported into the user's web browser).

Why use SSL inspection

Most of us are familiar with Hypertext Transfer Protocol Secure (HTTPS) and how it protects a variety of activities on the Internet by applying Secure Sockets Layer (SSL) encryption to the web traffic. However, there are risks associated with its use, since encrypted traffic can be used to get around your network's normal defenses.

For example, you might download a file containing a virus during an e-commerce session. Or you could receive a phishing email containing a seemingly harmless downloader file that, when launched, creates an encrypted session to a command and control (C&C) server and downloads malware onto your computer. Because the sessions in these attacks are encrypted, they might get past your network's security measures.

To protect your network from these threats, SSL inspection is the key your FortiGate uses to unlock encrypted sessions, see into encrypted packets, find threats, and block them. SSL inspection not only protects you from attacks that use HTTPS, but also from other commonly used SSL-encrypted protocols, such as SMTPS, POP3S, IMAPS, and FTPS.

Full SSL inspection

To make sure that all SSL encrypted content is inspected, you must use full SSL inspection (also known as deep inspection). When full SSL inspection is used, the FortiGate impersonates the recipient of the originating SSL session, then decrypts and inspects the content. The FortiGate then re-encrypts the content, creates a new SSL session between the FortiGate and the recipient by impersonating the sender, and sends the content to the sender.

When the FortiGate re-encrypts the content it uses a certificate stored on the FortiGate. The client must trust this certificate to avoid certificate errors. Whether or not this trust exists depends on the client, which can be the computer's OS, a browser, or some other application, which will likely maintain it's own certificate repository. For more information about this, see the recipe Preventing certificate warnings on the Fortinet Cookbook site.

There are two deployment methods for full SSL inspection:

1. Multiple Clients Connecting to Multiple Servers:

- Uses a CA certificate (which can be uploaded using the **Certificates** menu).
- Typically applied to outbound policies where destinations are unknown (i.e. normal web traffic).
- Address and web category whitelists can be configured to bypass SSL inspection.

2. Protecting SSL Server

- Uses a server certificate (which can be uploaded using the **Certificates** menu) to protect a single server.
- Typically used on inbound policies to protect servers available externally through Virtual IPs
- Since this is typically deployed “outside-in” (clients on the Internet accessing server(s) on the internal side of the FortiGate), server certificates using the public FQDN of the server are often purchased from a commercial Certificate Authority and uploaded to the FortiGate. This avoids client applications generating SSL certificate errors due to certificate mismatch.

More detail is available in the FortiOS Handbook. Also, check the Fortinet Knowledge Base for these technical notes:

- How to Enable SSL inspection from the CLI and Apply it to a Policy
- How to block web-based chat on Gmail webmail using App Sensor + SSL inspection

SSL certificate inspection

FortiGates also supports a second type of SSL inspection, called SSL certificate inspection. When certificate inspection is used, the FortiGate only inspects the header information of the packets.

Certificate inspection is used to verify the identity of web servers and can be used to make sure that HTTPS protocol isn't used as a workaround to access sites you have blocked using web filtering.

The only security feature that can be applied using SSL certificate inspection mode is web filtering. However, since only the packet is inspected, this method does not introduce certificate errors and can be a useful alternative to full SSL inspection when web filtering is used.

Troubleshooting

The most common problem with SSL inspection is users receiving SSL errors when the CA certificate is not trusted. This is because by default the FortiGate uses a certificate that is not trusted by the client. There are two ways to fix this:

1. All users must import the FortiGate’s default certificate into their client applications as a trusted certificate.
2. Configure the FortiGate to use a certificate that is already trusted by your clients. For example, a certification signed by a CA that your clients already trust.

The first method can be more labor intensive because you have to distribute a certification to all clients. This can also be an ongoing problem as new clients are added to your network. The second method is usually less work but may require paying for a CA. Both of these methods are covered in the recipe Preventing Certificate Warnings.

If you choose to install the certificate on client applications, this can be done with greater ease in a Microsoft Active Directory domain environment by using Group Policy Objects to install the certificate on domain members. Check that the Group Policy has propagated to all computers by opening Internet Explorer on a workstation PC, opening **Tools > Internet Options > Content > Certificates >Trusted Root Certification Authorities**, and ensuring that the FortiGate's certificate is present.

For corporate-owned mobile devices, MDM solutions like AirWatch, MobileIron, or Fiberlink, use Simple Certificate Enrollment Protocol (SCEP) to ease certificate enrollment.

Best practices

Because all traffic needs to be decrypted, inspected, and re-encrypted, using SSL inspection can reduce overall performance of your FortiGate. To make sure you aren't using too many resources for SSL inspection, do the

following:

- **Know your traffic** – Know how much traffic is expected and what percent of the traffic is encrypted. You can also limit the number of policies that allow encrypted traffic.
- **Be selective** – Use white lists or trim your policy to apply SSL inspection only where it is needed.
- **Use hardware acceleration** - FortiGate models with either the CP6 or CPU processor have an SSL/TLS protocol processor for SSL content scanning and SSL acceleration. For more information about this, see the Hardware Acceleration handbook.
- **Test real-world SSL inspection performance yourself** - Use the flexibility of FortiGate's security policy to gradually deploy SSL inspection, rather than enabling it all at once.

Creating or editing an SSL/SSH Inspection profile

1. Go to **Security Profiles > SSL/SSH Inspection**.
   This will open to one of the existing profiles.
   The links for the actions are located in the upper right hand corner of the window.
   - To view a list of the existing profiles select the List icon (a page) at the far right.
   - To clone an existing profile, select the Clone icon (one page behind another), second from the right
   - To create a new profile, select the Create New icon ("+ "symbol), third from the right.
   - To view or edit an existing profile, choose it from the dropdown menu field.
2. **Name Field:**
   Give the profile an easily identifiable name that references its intent.
3. **Comments Field:**
   Enter any additional information that might be needed by administrators, as a reminder of the profile's purpose and scope.
4. **SSL Inspection Options:**

   a. Enable SSL Inspection of:

   - Multiple Clients Connecting to Multiple Servers - Use this option for generic policies where the destination is unknown.
   - Protecting SSL Server - Use this option when setting up a profile customized for a specific SSL server with a specific certificate.

   b. Inspection Method
   The options here are:
   - SSL Certificate Inspection - only inspects the certificate, not the contents of the traffic.
   - Full SSL Inspection - inspects all of the traffic.

   c. CA Certificate
   Use the drop down menu to choose which one of the installed certificates to use for the inspection of the packets or click on **Download Certificate.**

   d. Untrusted SSL Certificates
   Select an action for untrusted SSL certificates.

   d. **Protocol Port Mapping** / Inspect All Ports
   Enable the ability to inspect all ports by checking the box. If the feature is not enabled, specify in the field next to the listed protocols, the port through which that protocols traffic will be inspected. Traffic of that protocol going through any other port will not be inspected.

If you select **Inspect All Ports**, then only the IPS engine is used for inspection.

5. **Exempt from SSL Inspection**:
   Use the dropdown menus in this section to specify any reputable websites, FortiGuard Web Categories, or addresses will be exempt from SSL inspection.
   - Reputable Websites - Enable this option to exempt any websites identified by FortiGuard as reputable.
   - Web Categories - By default the categories of Health and Wellness, Personal Privacy, and Finance and Banking have been added as these are one that are most likely to have applications that will require a specific certificate.
   - Addresses - These can be any of the Address objects that have an interface of "Any".
   - Log SSL exemptions - Enable this option to log all SSL exemptions
6. **SSH Inspection Options:**

   a. SSH Deep Scan
   Toggle to disable or enable the feature

   b. SSH Port
   The available options are:

   - **Any** - choosing this option will search all of the traffic regardless of service or TCP/IP port for packets that conform to the SSH protocol
   - **Specify** - choosing this option will restrict the search for SSH protocol packets to the TCP/IP port number specified in the field. This is not as comprehensive but it is easier on the performance of the firewall.

   d. Protocol Actions

   - Exec - Block, Log or neither. Select using check boxes.
   - Port-Forward - Block, Log or neither. Select using check boxes.
   - SSH-Shell - Block, Log or neither. Select using check boxes.
   - X11-Filter - Block, Log or neither. Select using check boxes.

6. **Common Options:**

   a. Allow Invalid SSL Certificates
   Check the box to enable the passing of traffic with invalid certificate

   b. Log SSL anomalies
   Check the box to alow the Logging function to record traffic sessions containing invalid certificates

The **Enable SSH Deep Scan** feature is enabled by default when creating a new SSL/SSH Inspection profile. There are situations were this feature can cause issues so be sure that you would like it enabled before applying the inspection profile.

The context location for configuring the SSL/SSH Inspection in the CLI is:

```
config firewall ssl-ssh-profile
```

Secure white list database

You can enable a feature that gathers a list of reputable domain names that can be excluded from SSL deep inspection. This list is periodically updated and downloaded to FortiGate units through FortiGuard.

Go to **Security Profiles > SSL Inspection**, enable **Exempt from SSL Inspection**, and enable **Reputable Websites**.

CLI Syntax:

```
config firewall ssl-ssh-profile
   edit deep-inspection
      set whitelist enable
end
```

SSL server table for SSL offloading

An SSL server table can now be used for SSL offloading. This feature was introduced with the release of FortiOS 5.4.0.

CLI Syntax

```
config firewall ssl-ssh-profile
   edit <name>
      set use-ssl-server {enable|disable}
   next
end
```

Custom Application & IPS Signatures

Creating a custom IPS signature

The FortiGate predefined signatures cover common attacks. If you use an unusual or specialized application or an uncommon platform, add custom signatures based on the security alerts released by the application and platform vendors.

You can add or edit custom signatures using the GUI or the CLI.

To create a custom signature

1. Go to **Security Profiles > Intrusion Protection**.
2. Select **[View IPS Signatures]**
3. Select **Create New** to add a new custom signature.
4. Enter a **Name** for the custom signature.
5. Enter the **Signature**. For information about completing this field, see Custom signature syntax and Custom signature keywords.
6. Select **OK**.

Custom signature syntax

All custom signatures follow a particular syntax. Each begins with a header and is followed by one or more keywords. A custom signature definition is limited to a maximum length of 512 characters. A definition can be a single line or span multiple lines connected by a backslash (\) at the end of each line.

A custom signature definition begins with a header, followed by a set of keyword/value pairs enclosed by parenthesis [( )]. The keyword and value pairs are separated by a semi colon (;) and consist of a keyword and a value separated by a space. The basic format of a definition is HEADER (KEYWORD VALUE;)

You can use as many keyword/value pairs as required within the 512 character limit. To configure a custom signature, go to **Security Profiles > Intrusion Protection,** select **View IPS Signatures**, select **Create New**, and enter the data directly into the **Signature** field, following the guidance in the next topics.

The table below shows the valid characters and basic structure. For details about each keyword and its associated values, see Custom signature keywords.

Valid syntax for custom signature fields

Field	Valid Characters	Usage
HEADER	F-SBID	The header for an attack definition signature. Each custom signature must begin with this header.

Field	Valid Characters	Usage
KEYWORD	Each keyword must start with a pair of dashes (--), and consist of a string of 1 to 19 characters. Normally, keywords are an English word or English words connected by an underscore (_). Keywords are case insensitive.	The keyword is used to identify a parameter.
VALUE	Double quotes (") must be used around the value if it contains a space and/or a semicolon (;). If the value is NULL, the space between the KEYWORD and VALUE can be omitted. Values are case sensitive. Note: If double quotes are used for quoting the value, the double quotes are not considered as part of the value string.	The value is set specifically for a parameter identified by a keyword.

Custom signature keywords

- information
- session
- content
- IP header
- TCP header
- UDP header
- ICMP
- other

Information keywords

attack_id

Syntax: `--attack_id <id_int>;`

Description:

Use this optional value to identify the signature. It cannot be the same value as any other custom rules. If an attack ID is not specified, the FortiGate automatically assigns an attack ID to the signature. If you are using VDOMs, custom signatures appear only in the VDOM in which you create them. You can use the same attack ID for signatures in different VDOMs.

An attack ID you assign must be between 1000 and 9999.

Example: `--attack_id 1234;`

name

Syntax: `--name <name_str>;`

Description:

Enter the name of the rule. A rule name must be unique. If you are using VDOMs, custom signatures appear only in the VDOM in which you create them. You can use the same rule name for signatures in different VDOMs. The name you assign must be a string greater than 0 and less than 64 characters in length.

Example: `--name "Buffer_Overflow";`

Session keywords

flow

Syntax: `--flow {from_client[,reversed] | from_server[,reversed] | bi_direction };`

Description:

Specify the traffic direction and state to be inspected. They can be used for all IP traffic.

Example: `--src_port 41523; --flow bi_direction;`

The signature checks traffic to and from port 41523.

If you enable “quarantine attacker”, the optional reversed keyword allows you to change the side of the connection to be quarantined when the signature is detected.

For example, a custom signature written to detect a brute-force log in attack is triggered when “Login Failed” is detected from_server more than 10 times in 5 seconds. If the attacker is quarantined, it is the server that is quarantined in this instance. Adding reversed corrects this problem and quarantines the actual attacker.

Previous FortiOS versions used to_client and to_server values. These are now deprecated, but still function for backwards compatibility.

service

Syntax: `--service {HTTP | TELNET | FTP | DNS | SMTP | POP3 | IMAP | SNMP | RADIUS | LDAP | MSSQL | RPC | SIP | H323 | NBSS | DCERPC | SSH | SSL};`

Description:

Specify the protocol type to be inspected. This keyword allows you to specify the traffic type by protocol rather than by port. If the decoder has the capability to identify the protocol on any port, the signature can be used to detect the attack no matter what port the service is running on. Currently, HTTP, SIP, SSL, and SSH protocols can be identified on any port based on the content.

app_cat

Syntax: `--app_cat <category_int>;`

Description:

Specify the category of the application signature. Signatures with this keyword are considered as application rules. These signatures will appear under Application Control instead of IPS configuration. To display a complete list of application signature categories, enter the following CLI commands:

```
config application list
   edit default
      config entries
         edit 1
            set category ?
```

weight

Syntax: `--weight <weight_int>;`

Description:

Specify the weight to be assigned to the signature. This keyword allows a signature with the higher weight to have priority over a signature with a lower weight.

The weight must be between 0 an 255. Most of the signatures in the Application Control signature database have weights of 10; botnet signatures are set to 250. A range of 20 to 50 is recommended for custom signatures.

Content keywords

byte_extract

Syntax: `byte_extract:<bytes_to_extract>, <offset>, <name> \ [, relative][, multiplier <multiplier value>][, <endian>]\ [, string][, hex][, dec][, oct][, align <align value>][, dce];`

Description:

Use the `byte_extract` option to write rules against length-encoded protocols. This reads some of the bytes from the packet payload and saves it to a variable.

byte_jump

Syntax: `--byte_jump <bytes_to_convert>, <offset>[, multiplier][, relative] [, big] [, little] [, string] [, hex] [, dec] [, oct] [, align];`

Description:

Use the `byte_jump` option to extract a number of bytes from a packet, convert them to their numeric representation, and jump the match reference up that many bytes (for further pattern matching or byte testing). This keyword allows relative pattern matches to take into account numerical values found in network data. The available keyword options include:

- `<bytes_to_convert>`: The number of bytes to examine from the packet.
- `<offset>`: The number of bytes into the payload to start processing.
- `[multiplier]`: multiplier is optional. It must be a numerical value when present. The converted value multiplied by the number is the result to be skipped.
- `relative`: Use an offset relative to last pattern match.
- `big`: Process the data as big endian (default).
- `little`: Process the data as little endian.

- `string`: The data is a string in the packet.
- `hex`: The converted string data is represented in hexadecimal notation.
- `dec`: The converted string data is represented in decimal notation.
- `oct`: The converted string data is represented in octal notation.
- `align`: Round up the number of converted bytes to the next 32-bit boundary.

byte_test

Syntax: `--byte_test <bytes_to_convert>, <operator>, <value>, <offset> [multiplier][, relative] [, big] [, little] [, string] [, hex] [, dec] [, oct];`

Description:

Use the `byte_test` keyword to compare a byte field against a specific value (with operator). This keyword is capable of testing binary values or converting representative byte strings to their binary equivalent and testing them. The available keyword options include:

- `<bytes_to_convert>`: The number of bytes to compare.
- `<operator>`: The operation to perform when comparing the value (<,>,=,!,&).
- `<value>`: The value to compare the converted value against.
- `<offset>`: The number of bytes into the payload to start processing.
- `[multiplier]`: multiplier is optional. It must be a numerical value when present. The converted value multiplied by the number is the result to be skipped.
- `relative`: Use an offset relative to last pattern match.
- `big`: Process the data as big endian (default).
- `little`: Process the data as little endian.
- `string`: The data is a string in the packet.
- `hex`: The converted string data is represented in hexadecimal notation.
- `dec`: The converted string data is represented in decimal notation.
- `oct`: The converted string data is represented in octal notation.

depth

Syntax: `--depth <depth_int>;`

Description:

Use the depth keyword to search for the contents within the specified number of bytes after the starting point defined by the offset keyword. If no offset is specified, the offset is assumed to be equal to 0.

If the value of the depth keyword is smaller than the length of the value of the content keyword, this signature will never be matched.

The depth must be between 0 and 65535.

distance

Syntax: `--distance <dist_int>;`

Description:

Use the distance keyword to search for the contents within the specified number of bytes relative to the end of the previously matched contents. If the within keyword is not specified, continue looking for a match until the end of the payload.

The distance must be between 0 and 65535.

content

Syntax: `--content [!]"<content_str>";`

Description:

Deprecated, see pattern and context keywords. Use the content keyword to search for the content string in the packet payload. The content string must be enclosed in double quotes.

To have the FortiGate search for a packet that does not contain the specified context string, add an exclamation mark (!) before the content string.

Multiple content items can be specified in one rule. The value can contain mixed text and binary data. The binary data is generally enclosed within the pipe (|) character.

The double quote ("), pipe sign(|) and colon(:) characters must be escaped using a back slash if specified in a content string.

If the value of the content keyword is greater than the length of the value of the depth keyword, this signature will never be matched.

context

Syntax: `--context {uri | header | body | host};`

Description:

Specify the protocol field to look for the pattern. If context is not specified for a pattern, the FortiGate unit searches for the pattern anywhere in the packet buffer. The available context variables are:

- `uri`: Search for the pattern in the HTTP URI line.
- `header`: Search for the pattern in HTTP header lines or SMTP/POP3/SMTP control messages.
- `body`: Search for the pattern in HTTP body or SMTP/POP3/SMTP email body.
- `host`: Search for the pattern in HTTP HOST line.

no_case

Syntax: `--no_case;`

Description:

Use the no-case keyword to force the FortiGate unit to perform a case-insensitive pattern match.

offset

Syntax: `--offset <offset_int>;`

Description:

Use the offset keyword to look for the contents after the specified number of bytes into the payload. The specified number of bytes is an absolute value in the payload. Follow the offset keyword with the depth

keyword to stop looking for a match after a specified number of bytes. If no depth is specified, the FortiGate unit continues looking for a match until the end of the payload.

The offset must be between 0 and 65535.

pattern

Syntax: `--pattern [!]"<pattern_str>";`

Description:

The FortiGate unit will search for the specified pattern. A pattern keyword normally is followed by a context keyword to define where to look for the pattern in the packet. If a context keyword is not present, the FortiGate unit looks for the pattern anywhere in the packet buffer. To have the FortiGate search for a packet that does not contain the specified URI, add an exclamation mark (!) before the URI.

Example: `--pattern "/level/" --pattern "|E8 D9FF FFFF|/bin/sh" --pattern !"|20|RTSP/"`

pcre

Syntax: `--pcre [!]"/<regex>/[ismxAEGRUB]";`

Description:

Similarly to the pattern keyword, use the pcre keyword to specify a pattern using Perl-compatible regular expressions (PCRE). A pcre keyword can be followed by a context keyword to define where to look for the pattern in the packet. If no context keyword is present, the FortiGate unit looks for the pattern anywhere in the packet buffer.

For more information about PCRE syntax, go to http://www.pcre.org.

The switches include:

- `i`: Case insensitive.
- `s`: Include newlines in the dot metacharacter.
- `m`: By default, the string is treated as one big line of characters. ^ and $ match at the beginning and ending of the string. When m is set, ^ and $ match immediately following or immediately before any newline in the buffer, as well as the very start and very end of the buffer.
- `x`: White space data characters in the pattern are ignored except when escaped or inside a character class.
- `A`: The pattern must match only at the start of the buffer (same as ^).
- `E`: Set $ to match only at the end of the subject string. Without E, $ also matches immediately before the final character if it is a newline (but not before any other newlines).
- `G`: Invert the “greediness” of the quantifiers so that they are not greedy by default, but become greedy if followed by ?.
- `R`: Match relative to the end of the last pattern match. (Similar to distance:0;).
- `U`: Deprecated, see the context keyword. Match the decoded URI buffers.

uri

Syntax: `--uri [!]"<uri_str>";`

Description:

Deprecated, see pattern and context keywords. Use the uri keyword to search for the URI in the packet payload. The URI must be enclosed in double quotes ("). To have the FortiGate unit search for a packet that does not contain the specified URI, add an exclamation mark (!) before the URI. Multiple content items can be specified in one rule. The value can contain mixed text and binary data. The binary data is generally enclosed within the pipe (|) character. The double quote ("), pipe sign (|) and colon (:) characters must be escaped using a back slash (\) if specified in a URI string.

within

Syntax: `--within <within_int>;`

Description:

Use this together with the distance keyword to search for the contents within the specified number of bytes of the payload.

The within value must be between 0 and 65535.

IP header keywords

dst_addr

Syntax: `--dst_addr [!]<ipv4>;`

Description:

Use the dst_addr keyword to search for the destination IP address. To have the FortiGate search for a packet that does not contain the specified address, add an exclamation mark (!) before the IP address. You can define up to 28 IP addresses or CIDR blocks. Enclose the comma separated list in square brackets.

Example: `dst_addr [172.20.0.0/16, 10.1.0.0/16,192.168.0.0/16]`

ip_dscp

Syntax: `--ip_dscp`

Description:

Use the ip_dscp keyword to check the IP DSCP field for the specified value.

ip_id

Syntax: `--ip_id <field_int>;`

Description:

Check the IP ID field for the specified value.

ip_option

Syntax: `--ip_option {rr | eol | nop | ts | sec | lsrr | ssrr | satid | any};`

Description:

Use the ip_option keyword to check various IP option settings.

The available options include:

- `rr`: Check if IP RR (record route) option is present.
- `eol`: Check if IP EOL (end of list) option is present.
- `nop`: Check if IP NOP (no op) option is present.
- `ts`: Check if IP TS (time stamp) option is present.
- `sec`: Check if IP SEC (IP security) option is present.
- `lsrr`: Check if IP LSRR (loose source routing) option is present.
- `ssrr`: Check if IP SSRR (strict source routing) option is present.
- `satid`: Check if IP SATID (stream identifier) option is present.
- `any`: Check if IP any option is present.

ip_tos

Syntax: `--ip_tos <field_int>;`

Description:

Check the IP TOS field for the specified value.

ip_ttl

Syntax: `--ip_ttl [< | >] <ttl_int>;`

Description:

Check the IP time-to-live value against the specified value. Optionally, you can check for an IP time-to-live greater-than (>) or less-than (<) the specified value with the appropriate symbol.

protocol

Syntax: `--protocol {<protocol_int> | tcp | udp | icmp};`

Description:

Check the IP protocol header.

Example: `--protocol tcp;`

src_addr

Syntax: `--src_addr [!]<ipv4>;`

Description:

Use the src_addr keyword to search for the source IP address. To have the FortiGate unit search for a packet that does not contain the specified address, add an exclamation mark (!) before the IP address. You can define up to 28 IP addresses or CIDR blocks. Enclose the comma separated list in square brackets.

Example: `src_addr 192.168.13.0/24`

TCP header keywords

ack

Syntax: `--ack <ack_int>;`

Description:

Check for the specified TCP acknowledge number.

dst_port

Syntax: `--dst_port [!]{<port_int> | :<port_int> | <port_int>: | <port_int>:<port_int>};`

Description:

Use the `dst_port` keyword to specify the destination port number.

You can specify a single port or port range:

- `<port_int>` is a single port.
- `:<port_int>` includes the specified port and all lower numbered ports.
- `<port_int>:` includes the specified port and all higher numbered ports.
- `<port_int>:<port_int>` includes the two specified ports and all ports in between.

seq

Syntax: `--seq [operator,]<number>[,relative];`

Description:

Check for the specified TCP sequence number.

- `operator` includes =,<,>,!.
- `relative` indicates it's relative to the initial sequence number of the TCP session.

src_port

Syntax: `--src_port [!]{<port_int> | :<port_int> | <port_int>: | <port_int>:<port_int>};`

Description:

Use the src_port keyword to specify the source port number. You can specify a single port or port range:

- `<port_int>` is a single port.
- `:<port_int>` includes the specified port and all lower numbered ports.
- `<port_int>:` includes the specified port and all higher numbered ports.
- `<port_int>:<port_int>` includes the two specified ports and all ports in between.

tcp_flags

Syntax: `--tcp_flags <SAFRUP120>[!|*|+] [,<SAFRUP120>];`

Description:

Specify the TCP flags to match in a packet.

- `S`: Match the SYN flag.
- `A`: Match the ACK flag.
- `F`: Match the FIN flag.
- `R`: Match the RST flag.

- `U`: Match the URG flag.
- `P`: Match the PSH flag.
- `1`: Match Reserved bit 1.
- `2`: Match Reserved bit 2.
- `0`: Match No TCP flags set.
- `!`: Match if the specified bits are not set.
- `*`: Match if any of the specified bits are set.
- `+`: Match on the specified bits, plus any others.

The first part if the value (`<SAFRUP120>`) defines the bits that must be present for a successful match.

Example:

`--tcp_flags AP` only matches the case where both `A` and `P` bits are set.

The second part (`[,<SAFRUP120>]`) is optional, and defines the additional bits that can be present for a match.

For example `tcp_flags S,12` matches the following combinations of flags: S, S and 1, S and 2, S and 1 and 2. The modifiers !, * and + cannot be used in the second part.

window_size

Syntax: `--window_size [!]<window_int>;`

Description:

Check for the specified TCP window size. You can specify the window size as a hexadecimal or decimal integer. A hexadecimal value must be preceded by `0x`. To have the FortiGate search for the absence of the specified window size, add an exclamation mark (`!`) before the window size.

UDP header keywords

dst_port

Syntax: `--dst_port [!]{<port_int> | :<port_int> | <port_int>: | <port_int>:<port_int>};`

Description:

Specify the destination port number. You can specify a single port or port range:

- `<port_int>` is a single port.
- `:<port_int>` includes the specified port and all lower numbered ports.
- `<port_int>:` includes the specified port and all higher numbered ports.
- `<port_int>:<port_int>` includes the two specified ports and all ports in between.

src_port

Syntax: `--src_port [!]{<port_int> | :<port_int> | <port_int>: | <port_int>:<port_int>};`

Description:

Specify the destination port number. You can specify a single port or port range:

- <port_int> is a single port.
- :<port_int> includes the specified port and all lower numbered ports.
- <port_int>: includes the specified port and all higher numbered ports.
- <port_int>:<port_int> includes the two specified ports and all ports in between.

ICMP keywords

icmp_code

Syntax: --icmp_code <code_int>;

Description:

Specify the ICMP code to match.

icmp_id

Syntax: --icmp_id <id_int>;

Description:

Check for the specified ICMP ID value.

icmp_seq

Syntax: --icmp_seq <seq_int>;

Description:

Check for the specified ICMP sequence value.

icmp_type

Syntax: --icmp_type <type_int>;

Description:

Specify the ICMP type to match.

Other keywords

data_size

Syntax: --data_size {<size_int> | <<size_int> | ><size_int>;

Description:

Test the packet payload size. With data_size specified, packet reassembly is turned off automatically. So a signature with data_size and only_stream values set is wrong.

- <size_int> is a particular packet size.
- <<size_int> is a packet smaller than the specified size.
- ><size_int> is a packet larger than the specified size.

Examples:

- `--data_size 300;`
- `--data_size <300;`
- `--data_size >300;`

data_at

Syntax: `--data_at <offset_int>[, relative];`

Description:

Verify that the payload has data at a specified offset, optionally looking for data relative to the end of the previous content match.

dump-all-html

Syntax: `--dump-all-html`

Description:

Dump all HTML files for benchmarking via iSniff. When there is no file type specified, all HTML files are dumped.

rate

Syntax: `--rate <matches_int>,<time_int>;`

Description:

Instead of generating log entries every time the signature is detected, use this keyword to generate a log entry only if the signature is detected a specified number of times within a specified time period.

- `<matches_int>` is the number of times a signature must be detected.
- `<time_int>` is the length of time in which the signature must be detected, in seconds.

For example, if a custom signature detects a pattern, a log entry will be created every time the signature is detected. If `--rate 100,10;` is added to the signature, a log entry will be created if the signature is detected 100 times in the previous 10 seconds. Use this command with `--track` to further limit log entries to when the specified number of detections occur within a certain time period involving the same source or destination address rather than all addresses.

rpc_num

Syntax: `--rpc_num <app_int>[, <ver_int> | *][, <proc_int> | *>];`

Description:

Check for RPC application, version, and procedure numbers in SUNRPC CALL requests. The * wild card can be used for version and procedure numbers.

same_ip

Syntax: `--same_ip;`

Description:

Check that the source and the destination have the same IP addresses.

track

Syntax: `--track {SRC_IP |DST_IP |DHCP_CLIENT |DNS_DOMAIN}[,block_int];`

Description:

When used with `--rate`, this keyword narrows the custom signature rate totals to individual addresses.

- `SRC_IP`: tracks the packet's source IP.
- `DST_IP`: tracks the packet's destination IP.
- `DHCP_CLIENT`: tracks the DHCP client's MAC address.
- `DNS_DOMAIN`: counts the number of any specific domain name.
- `block_int` has the FortiGate unit block connections for the specified number of seconds, from the client or to the server, depending on which is specified.

  For example, if `--rate 100,10` is added to the signature, a log entry will be created if the signature is detected 100 times in the previous 10 seconds. The FortiGate unit maintains a single total, regardless of source and destination address.

  If the same custom signature also includes `--track` client; matches are totaled separately for each source address. A log entry is added when the signature is detected 100 times in 10 seconds within traffic from the same source address.

  The `--track` keyword can also be used without `--rate`. If an integer is specified, the client or server will be blocked for the specified number of seconds every time the signature is detected.

Creating a custom signature to block access to example.com

In this first example, you will create a custom signature to block access to the example.com URL.

This example describes the use of the custom signature syntax to block access to a URL. To create the custom signature entry in the FortiGate's GUI, see Custom Application & IPS Signatures.

1. Enter the custom signature basic format.

   All custom signatures have a header and at least one keyword/value pair. The header is always the same:

   ```
   F-SBID( )
   ```

   The keyword/value pairs appear within the parentheses and each pair is followed by a semicolon.

2. Choose a name for the custom signature

   Every custom signature requires a name, so it is a good practice to assign a name before adding any other keywords.Use the `--name` keyword to assign the custom signature a name. The name value follows the keyword after a space. Enclose the name value in double-quotes:

   ```
   F-SBID( --name "Block.example.com"; )
   ```

   The signature, as it appears here, will not do anything if you try to use it. It has a name, but does not look for any patterns in network traffic. You must specify a pattern that the FortiGate unit will search for.

3. Add a signature pattern

   Use the `--pattern` keyword to specify what the FortiGate unit will search for:

   ```
   F-SBID( --name "Block.example.com"; --pattern "example.com"; )
   ```

   The signature will now detect the example.com URL appearing in network traffic. The custom

signature should only detect the URL in HTTP traffic, however. Any other traffic with the URL should be allowed to pass. For example, an email message to or from example.com should not be stopped.

4. Specify the service

   Use the `--service` keyword to limit the effect of the custom signature to only the HTTP protocol.

   ```
   F-SBID( --name "Block.example.com"; --pattern "example.com"; --service HTTP; )
   ```

   The FortiGate unit will limit its search for the pattern to the HTTP protocol. Even though the HTTP protocol uses only TCP traffic, the FortiGate will search for HTTP protocol communication in TCP, UDP, and ICMP traffic. This is a waste of system resources that you can avoid by limiting the search further, as shown below.

5. Specify the traffic type.

   Use the `--protocol tcp keyword` to limit the effect of the custom signature to only TCP traffic. This will save system resources by not unnecessarily scanning UDP and ICMP traffic.

   ```
   F-SBID( --name "Block.example.com"; --pattern "example.com"; --service HTTP; --
       protocol tcp; )
   ```

   The FortiGate unit will limit its search for the pattern to TCP traffic and ignore UDP and ICMP network traffic.

6. Ignore case sensitivity

   By default, patterns are case sensitive. If a user directed his or her browser to Example.com, the custom signature would not recognize the URL as a match.

   Use the `--no_case` keyword to make the pattern matching case insensitive.

   ```
   F-SBID( --name "Block.example.com"; --pattern "example.com"; --service HTTP; --
       protocol tcp; --no_case; )
   ```

   Unlike all of the other keywords in this example, the `--no_case` keyword has no value. Only the keyword is required.

7. Limit pattern scans to only traffic sent from the client

   The `--flow` command can be used to further limit the network traffic being scanned to only that send by the client or by the server.

   ```
   F-SBID( --name "Block.example.com"; --pattern "example.com"; --service HTTP; --
       protocol tcp; --no_case; --flow from_client; )
   ```

   Web servers do not contact clients until clients first open a communication session. Therefore, using the `--flow from_client` command will force the FortiGate to ignore all traffic from the server. Since the majority of HTTP traffic flows from the server to the client, this will save considerable system resources and still maintain protection.

8. Specify the context

   When the client browser tries to contact example.com, a DNS is first consulted to get the example.com server IP address. The IP address is then specified in the URL field of the HTTP communication. The domain name will still appear in the host field, so this custom signature will not function without the `--context host` keyword/value pair.

   ```
   F-SBID( --name "Block.example.com"; --pattern "example.com"; --service HTTP; --no_
       case; --flow from_client; --context host; )
   ```

Creating a custom signature to block the SMTP “vrfy” command

The SMTP “vrfy” command can be used to verify the existence of a single email address or to list all of the valid email accounts on an email server. A spammer could potentially use this command to obtain a list of all valid email users and direct spam to their inboxes.

In this example, you will create a custom signature to block the use of the vrfy command. Since the custom signature blocks the vrfy command from coming through the FortiGate unit, the administrator can still use the command on the internal network.

This example describes the use of the custom signature syntax to block the vrfy command. To create the custom signature entry in the FortiGate's GUI, see Custom Application & IPS Signatures.

1. Enter the custom signature basic format

   All custom signatures have a header and at least one keyword/value pair. The header is always the same:

   ```
   F-SBID( )
   ```

   The keyword/value pairs appear within the parentheses and each pair is followed by a semicolon.

2. Choose a name for the custom signature

   Every custom signature requires a name, so it is a good practice to assign a name before you add any other keywords.

   Use the `--name` keyword to assign the custom signature a name. The name value follows the keyword after a space. Enclose the name value in double-quotes:

   ```
   F-SBID( --name "Block.SMTP.VRFY.CMD"; )
   ```

   The signature, as it appears here, will not do anything if you try to use it. It has a name, but does not look for any patterns in network traffic. You must specify a pattern that the FortiGate unit will search for.

3. Add a signature pattern

   Use the `--pattern` keyword to specify what the FortiGate unit will search for:

   ```
   F-SBID( --name "Block.SMTP.VRFY.CMD"; --pattern "vrfy"; )
   ```

   The signature will now detect the vrfy command appearing in network traffic. The custom signature should only detect the command in SMTP traffic, however. Any other traffic with the pattern should be allowed to pass. For example, an email message discussing the vrfy command should not be stopped.

4. Specify the service.

   Use the `--service` keyword to limit the effect of the custom signature to only the HTTP protocol.

   ```
   F-SBID( --name "Block.SMTP.VRFY.CMD"; --pattern "vrfy"; --service SMTP; )
   ```

   The FortiGate unit will limit its search for the pattern to the SMTP protocol.

   Even though the SMTP protocol uses only TCP traffic, the FortiGate will search for SMTP protocol communication in TCP, UDP, and ICMP traffic. This is a waste of system resources that you can avoid by limiting the search further, as shown below.

5. Specify the traffic type.

   Use the `--protocol tcp keyword` to limit the effect of the custom signature to only TCP traffic. This will save system resources by not unnecessarily scanning UDP and ICMP traffic.

```
F-SBID( --name "Block.SMTP.VRFY.CMD"; --pattern "vrfy"; --service SMTP; --
    protocol tcp; )
```

The FortiGate unit will limit its search for the pattern to TCP traffic and ignore the pattern in UDP and ICMP network traffic.

6. Ignore case sensitivity.

   By default, patterns are case sensitive. If a user directed his or her browser to Example.com, the custom signature would not recognize the URL as a match.

   Use the `--no_case` keyword to make the pattern matching case insensitive.

   ```
   F-SBID( --name "Block.SMTP.VRFY.CMD"; --pattern "vrfy"; --service SMTP; --no_case; )
   ```

   Unlike all of the other keywords in this example, the `--no_case` keyword has no value. Only the keyword is required.

7. Specify the context.

   The `SMTP vrfy` command will appear in the SMTP header. The `--context host` keyword/value pair allows you to limit the pattern search to only the header.

   ```
   F-SBID( --name "Block.SMTP.VRFY.CMD"; --pattern "vrfy"; --service SMTP; --no_case; -
       -context header; )
   ```

Creating a custom signature to block files according to the file's hash value

In this example, you will create a custom signature that allows you to specify a hash value (or checksum) of a file that you want to block. To block multiple files you can create a custom signature for each file with that file's hash value in it and then add all of the custom signatures to an IPS sensor and set the action to block for each one. When IPS encounters a file with a matching hash value the file is blocked.

This example uses a CRC32 checksum of the file as the hash value of the file to be blocked. You can use any utility that supports CRC32 checksums to generate the hash value.

1. Enter the custom signature basic format.

   All custom signatures have a header and at least one keyword/value pair. The header is always the same:

   ```
   F-SBID( )
   ```

   The keyword/value pairs appear within the parentheses and each pair is followed by a semicolon.

2. Choose a name for the custom signature

   Every custom signature requires a name, so it is a good practice to assign a name before adding any other keywords. Use the `--name` keyword to assign the custom signature a name. The name value follows the keyword after a space. Enclose the name value in double-quotes:

   ```
   F-SBID( --name "File.Hash.Example"; )
   ```

   The signature, as it appears here, will not do anything if you try to use it. It has a name, but does not look for any patterns in network traffic.

3. Specify the traffic type.

   Use the `--protocol tcp keyword` to limit the effect of the custom signature to only TCP traffic. This will save system resources by not unnecessarily scanning UDP and ICMP traffic.

   ```
   F-SBID( --name "File.Hash.Example"; --protocol tcp; )
   ```

   The FortiGate unit will limit its search for the pattern to TCP traffic and ignore UDP and ICMP network traffic.

4. Add the CRC32 hash value.

   Use the `--crc32` keyword. This indicates that the value that follows is a hexadecimal number that represents the CRC32 checksum of the file. The `--crc32` keyword also requires that you include the file length. The syntax is `--crc32 <checksum>,<file-length>;`. The following example shows the syntax for a file with checksum 51480492 and file length 822.

   ```
   F-SBID( --name "File.Hash.Example"; --protocol tcp; --crc32 51480492,822; )
   ```

Other Security Profiles considerations

The following topics are included in this section:

- Security Profiles and Virtual domains (VDOMs)
- Conserve mode
- Using wildcards and Perl regular expressions
- Adding External Security Devices
- CPU allocation and tuning commands to survive reboot

Security Profiles and Virtual domains (VDOMs)

If you enable virtual domains (VDOMs) on your FortiGate unit, any Security Profiles configuration is limited to the VDOM in which you configure it.

While configuration is not shared, the various databases used by Security Profiles features are shared. The FortiGuard antivirus and IPS databases and updates to the databases are shared. The FortiGuard web filter and spam filter features access the FortiGuard distribution network and read the same information when checking email for spam and web site categories and classification.

Conserve mode

FortiGate units perform all Security Profiles processing in physical RAM. Since each model has a limited amount of memory, conserve mode is activated when the remaining free memory is nearly exhausted or the AV proxy has reached the maximum number of sessions it can service. While conserve mode is active, the AV proxy does not accept new sessions.

A warning will appear in the top bar of the FortiGate, regardless of which page in the FortiGate GUI you are on.

The AV proxy

Most content inspection the FortiGate unit performs requires that the files, email messages, URLs, and web pages be buffered and examined as a whole. The AV proxy performs this function, and because it may be buffering many files at the same time, it uses a significant amount of memory. Conserve mode is designed to prevent all the component features of the FortiGate unit from trying to use more memory than it has. Because the AV proxy uses so much memory, conserve mode effectively disables it in most circumstances. As a result, the content inspection features that use the AV proxy are also disabled in conserve mode.

All of the Security Profiles features use the AV proxy with the exception of IPS, application control, DoS as well as flow-based antivirus, DLP, and web filter scanning. These features continue to operate normally when the FortiGate unit enters conserve mode.

Entering and exiting conserve mode

A FortiGate unit will enter conserve mode because it is nearly out of physical memory, or because the AV proxy has reached the maximum number of sessions it can service. The memory threshold that triggers conserve mode varies by model, but it is about 20% free memory. When memory use rises to the point where less than 20% of the physical memory is free, the FortiGate unit enters conserve mode.

The FortiGate unit will leave conserve mode only when the available physical memory exceeds about 30%. When exiting conserve mode, all new sessions configured to be scanned with features requiring the AV proxy will be scanned as normal, with the exception of a unit configured with the one-shot option.

Conserve mode effects

What happens when the FortiGate unit enters conserve mode depends on how you have `av-failopen` configured. There are four options:

off

The off setting forces the FortiGate unit to stop all traffic that is configured for content inspection by Security Profiles features that use the AV proxy. New sessions are not allowed but current sessions continue to be processed normally unless they request more memory. Sessions requesting more memory are terminated.

For example, if a security policy is configured to use antivirus scanning, the traffic it permits is blocked while in conserve mode. A policy with IPS scanning enabled continues as normal. A policy with both IPS and antivirus scanning is blocked because antivirus scanning requires the AV proxy.

Use the off setting when security is more important than a loss of access while the problem is rectified.

pass

The pass setting allows traffic to bypass the AV proxy and continue to its destination. Since the traffic is bypassing the proxy, no Security Profiles scanning that requires the AV proxy is performed. Security Profiles scanning that does not require the AV proxy continues normally.

Use the pass setting when access is more important than security while the problem is rectified.

Pass is the default setting.

one-shot

The one-shot setting is similar to pass in that traffic is allowed when conserve mode is active. The difference is that a system configured for one-shot will force new sessions to bypass the AV proxy even after it leaves conserve mode. The FortiGate unit resumes use of the AV proxy only when the `av-failopen` setting is changed or the unit is restarted.

idledrop

The idledrop setting will recover memory and session space by terminating all the sessions associated with the host that has the most sessions open. The FortiGate may force this session termination a number of times, until enough memory is available to allow it to leave conserve mode.

The idledrop setting is primarily designed for situations in which malware may continue to open sessions until the AV proxy cannot accept more new sessions, triggering conserve mode. If your FortiGate unit is operating near capacity, this setting could cause the termination of valid sessions. Use this option with caution.

Configuring the av-failopen command

You can configure the av-failopen command using the CLI.

```
config system global
   set av-failopen {off | pass | one-shot | idledrop}
end
```

The default setting is pass.

Using wildcards and Perl regular expressions

Many Security Profiles feature list entries can include wildcards or Perl regular expressions.

For more information about using Perl regular expressions, see http://perldoc.perl.org/perlretut.html.

Regular expression vs. wildcard match pattern

A wildcard character is a special character that represents one or more other characters. The most commonly used wildcard characters are the asterisk (*), which typically represents zero or more characters in a string of characters, and the question mark (?), which typically represents any one character.

In Perl regular expressions, the '.' character refers to any single character. It is similar to the '?' character in wildcard match pattern. As a result:

- example.com not only matches example.com but also examplea.com, exampleb.com, examplec.com, and so on.

To add a question mark (`?`) character to a regular expression from the FortiGate CLI, enter Ctrl+V followed by ?. To add a single backslash character (`\`) to a regular expression from the CLI you must add precede it with another backslash character. For example, `example\\.com`.

To match a special character such as '.' and '*' use the escape character '\'. For example:

- To match example.com, the regular expression should be: example\.com

In Perl regular expressions, '*' means match 0 or more times of the character before it, not 0 or more times of any character. For example:

- exam*.com matches exammmm.com but does not match example.com

To match any character 0 or more times, use '.*' where '.' means any character and the '*' means 0 or more times. For example, the wildcard match pattern exam*.com should be exam.*\.com.

Word boundary

In Perl regular expressions, the pattern does not have an implicit word boundary. For example, the regular expression "test" not only matches the word "test" but also any word that contains "test" such as "atest", "mytest", "testimony", "atestb". The notation "\b" specifies the word boundary. To match exactly the word "test", the expression should be \btest\b.

Case sensitivity

Regular expression pattern matching is case sensitive in the web and Email Filter filters. To make a word or phrase case insensitive, use the regular expression `/i`. For example, `/bad language/i` will block all instances of "bad language", regardless of case.

Perl regular expression formats

The following table lists and describes some example Perl regular expressions.

Perl regular expression formats

Expression	Matches
abc	“abc” (the exact character sequence, but anywhere in the string)
^abc	“abc” at the beginning of the string
abc$	“abc” at the end of the string
a|b	Either “a” or “b”
^abc|abc$	The string “abc” at the beginning or at the end of the string
ab{2,4}c	“a” followed by two, three or four “b”s followed by a “c”
ab{2,}c	“a” followed by at least two “b”s followed by a “c”
ab*c	“a” followed by any number (zero or more) of “b”s followed by a “c”
ab+c	“a” followed by one or more b's followed by a c
ab?c	“a” followed by an optional “b” followed by a” c”; that is, either “abc” or ”ac”
a.c	“a” followed by any single character (not newline) followed by a” c “
a\.c	“a.c” exactly
[abc]	Any one of “a”, “b” and “c”
[Aa]bc	Either of “Abc” and “abc”
[abc]+	Any (nonempty) string of “a”s, “b”s and “c”s (such as “a”, “abba”, ”acbabcacaa”)
[^abc]+	Any (nonempty) string which does not contain any of “a”, “b”, and “c” (such as “defg”)
\d\d	Any two decimal digits, such as 42; same as \d{2}
/i	Makes the pattern case insensitive. For example, `/bad language/i` blocks any instance of `bad language` regardless of case.
\w+	A “word”: A nonempty sequence of alphanumeric characters and low lines (underscores), such as foo and 12bar8 and foo_1
100\s*mk	The strings “100” and “mk” optionally separated by any amount of white space (spaces, tabs, newlines)
abc\b	“abc” when followed by a word boundary (for example, in “abc!” but not in “abcd”)

Expression	Matches
perl\B	“perl” when not followed by a word boundary (for example, in “perlert” but not in “perl stuff”)
\x	Tells the regular expression parser to ignore white space that is neither preceded by a backslash character nor within a character class. Use this to break up a regular expression into (slightly) more readable parts.
/x	Used to add regular expressions within other text. If the first character in a pattern is forward slash '/', the '/' is treated as the delimiter. The pattern must contain a second '/'. The pattern between ‘/’ will be taken as a regular expressions, and anything after the second ‘/’ will be parsed as a list of regular expression options ('i', 'x', etc). An error occurs if the second '/' is missing. In regular expressions, the leading and trailing space is treated as part of the regular expression.

Examples of regular expressions

Block any word in a phrase

```
/block|any|word/
```

Block purposely misspelled words

Spammers often insert other characters between the letters of a word to fool spam blocking software.

```
/^.*v.*i.*a.*g.*r.*o.*$/i
/cr[eéèêë][\+\-\*=<>\.\,;!\?%&$@\^°\$£€\{\}()\[\]\|\\_01]dit/i
```

Block common spam phrases

The following phrases are some examples of common phrases found in spam messages.

```
/try it for free/i
/student loans/i
/you’re already approved/i
/special[\+\-\*=<>\.\,;!\?%&~#$@\^°\$£€\{\}()\[\]\|\\_1]offer/i
```

Adding External Security Devices

External Security Devices

External Security Devices can be configured as means to offload processes to other devices, such as a FortiWeb, FortiCache, or FortiMail. Example processes could include HTTP inspection, web caching, and anti- spam.

Offloading HTTP traffic to FortiWeb

Use the following steps to offload HTTP traffic to FortiWeb to apply Web Application Firewall features to the traffic. Using these steps you can select the HTTP traffic to offload by adding a web application firewall profile configured for external inspection to selected firewall policies. Only the HTTP traffic accepted by those firewall policies is offloaded.

If you offload HTTP traffic to FortiWeb you can also apply other HTTP inspection to it from your FortiGate including virus scanning and web filtering.

A single FortiGate cannot offload HTTP traffic to both FortiCache and FortiWeb.

To offload HTTP traffic to FortiWeb:

1. Go to the **System Information** dashboard widget and make sure **Inspection Mode** is set to **Proxy-based**.
2. Go to **System > Feature Select** and turn on **Web Application Firewall**.
3. Go to **System > Cooperative Security Fabric**, enable **HTTP Service**, select **FortiWeb** and add the IP addresses of your FortiWeb devices. You can also select **Authentication** add a **password** if required.
4. Go to **Security Profiles > Web Application Firewall** and add or edit a Web Application Firewall profile and set **Inspection Device** to **External**.
5. Go to **Policy & Objects > IPv4 Policy**, add or edit a firewall policy, select **Web Application Firewall**, and select the profile that you set to use the external inspection device.

These steps add the following configuration to the CLI:

```
config system wccp
   set service-id 51
   set router-id 5.5.5.5 (the IP address of the FortiGate interface that communicates with
       the FortiWeb)
   set group address 0.0.0.0
   set server-list 5.5.5.25 255.255.255.255 (the IP address of the FortiWeb)
   set authentication enable
   set forward-method GRE
   set return-method GRE
   set assignment-method HASH
   set password *
end
```

Offloading HTTP traffic to FortiCache

To offload Web Caching to FortiCache a FortiGate must support WAN Optimization and WAN Optimization must be enabled. For some FortiGate models you need to turn off disk logging to support WAN Optimization. See "WAN Optimization" on page 218 in What's New for details.

Use the following steps to offload web caching to FortiCache. Using these steps you can select the web traffic to offload by selecting web caching in firewall policies. Only the web traffic accepted by those firewall policies will be offloaded.

A single FortiGate cannot offload HTTP traffic to both FortiCache and FortiWeb.

1. Go to the **System Information** dashboard widget and make sure **Inspection Mode** is set to **Proxy-based**.
2. Go to **System > Advanced > Disk Settings** and assign at least one disk to **WAN Optimization**.
3. Go to **System > Feature Select** and turn on **WAN Opt. & Cache**.
4. Go to **System > Cooperative Security Fabric**, enable **HTTP Service**, select **FortiCache** and add the IP addresses of your FortiCache devices. You can also select **Authentication** add a **password** if required.
5. Go to **Policy & Objects > IPv4 Policy**, add or edit a firewall policy and select **Web Cache**.

These steps add the following configuration to the CLI:

```
config system wccp
   set service-id 51
   set router-id 5.5.5.5 (the IP address of the FortiGate interface that communicates with
       the FortiCache)
   set group address 0.0.0.0
```

```
    set server-list 5.5.5.45 255.255.255.255 (the IP address of the FortiCache)
    set authentication enable
    set forward-method GRE
    set return-method GRE
    set assignment-method HASH
    set password *
end
```

Offloading SMTP traffic to FortiMail

Use the following steps to offload SMTP traffic to FortiMail to apply FortiMail features to the traffic. Using these steps you can select the SMTP traffic to offload by adding an AntiSpam profile configured for external inspection to selected firewall policies. Only the SMTP traffic accepted by those firewall policies is offloaded.

If you offload HTTP traffic to FortiWeb you can also apply other HTTP inspection to it from your FortiGate including virus scanning and web filtering.

To be able to offload Anti-Spam processing to a FortiMail device you should:

1. Go to the **System Information** dashboard widget and make sure **Inspection Mode** is set to **Proxy-based**.
2. Go to **System > Feature Select** and turn on **Anti-Spam Filter**.
3. Go to **System > Cooperative Security Fabric**, enable **SMTP Service - FortiMail** and add the IP address of your FortiMail devices. You can also select **Authentication** add a **password** if required.
4. Go to **Security Profiles > Anti-Spam** and edit an Anti-Spam profile and set **Inspection Device** to **External**.
5. Go to **Policy & Objects > IPv4 Policy**, add or edit a Firewall policy, enable **Anti-Spam** and select the profile for which you set Inspection Device to External.

These steps add the following configuration to the CLI:

```
config system wccp
    set service-id 52
    set router-id 5.5.5.5 (the IP address of the FortiGate interface that communicates with
        the FortiMail)
    set group address 0.0.0.0
    set server-list 5.5.5.65 255.255.255.255 (the IP address of the FortiMail)
    set authentication enable
    set forward-method GRE
    set return-method GRE
    set assignment-method HASH
    set password *
end
```

For more information on this configuration and others, see the *FortiWeb Administration Guide*.

CPU allocation and tuning commands to survive reboot

CPU affinity, whereby a process will execute on a specific CPU, can be changed so it survives a reboot.

CLI Syntax:

```
config system global
    set av-affinity
    set ips-affinity
    set miglog-affinity
end
```

av-affinity: Affinity setting for AV scanning (64-bit hexadecimal value in the format of xxxxxxxx_xxxxxxxx).

ips-affinity: Affinity setting for IPS (64-bit hexadecimal value in the format of xxxxxxxx_xxxxxxxx; allowed CPUs must be less than total number of IPS engine daemons). This option is only available if the FortiGate includes NP6 processors and support NTurbo.

miglog-affinity: Affinity setting for logging (64-bit hexadecimal value in the format of xxxxxxxx_xxxxxxxx).

Chapter 27 - Server Load Balancing

This FortiOS Handbook chapter contains the following sections:

Inside FortiOS: Server Load Balancing highlights the features and benefits of FortiOS server load balancing.

Basic load balancing configuration example introduces FortiOS server load balancing by providing a basic configuration example.

Configuring load balancing describes how to configure FortiOS server load balancing.

HTTP and HTTPS load balancing, multiplexing, and persistence describes FortiOS server load balancing features that support load balancing HTTP and HTTPS sessions.

SSL/TLS load balancingdescribes FortiOS server load balancing features that support load balancing SSL and TLS sessions.

IP, TCP, and UDP load balancing describes FortiOS server load balancing features that support load balancing IP, TCP, and UDP sessions.

The following configuration examples are also included:

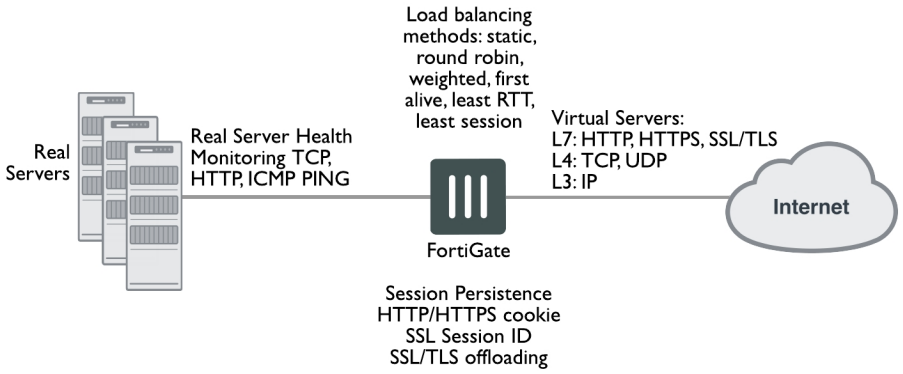
- Example HTTP load balancing to three real web servers
- Example Basic IP load balancing configuration
- Example Adding a server load balance port forwarding virtual IP
- Example Weighted load balancing configuration
- Example HTTP and HTTPS persistence configuration

Inside FortiOS: Server Load Balancing

Server load balancing distributes workloads across multiple network servers, allowing simultaneous requests to be handled quickly and reliably.

Server Load Balancing combined with NGFW and UTM protection

By introducing comprehensive server load balancing functionality to Next Generation Firewall (NGFW) and Unified Threat Management (UTM) solutions FortiOS takes threat protection to a whole new level. Rather than going to the expense of deploying multiple solutions to protect your server farm, you can combine firewalling, NGFW, UTM and load balancing into a single FortiGate unit or cluster. The benefit of consolidation is not only limited to cost.



Key Features & Benefits

Increased resilience	A consolidated solution results in significantly simplified network architecture. High availability can be provided for all technologies with just a pair of devices rather than several.
Reduced operational overheads	A unified management solution consisting of a single GUI, logging and reporting, SNMP monitoring and other management functions will significantly reduce the resources required to manage the multiple technology areas. A consolidated solution provides a single point of contact for support and renewals rather than having to deal with multiple vendors.

The FortiOS server load balancing feature set contains all of the features you would expect of a server load balancing solution. Traffic can be balanced across multiple backend servers based on multiple load balancing schedules including static (failover), round robin, weighted to account for different sized servers, or based on the health and performance of the server including round trip time and number of connections.

The load balancer supports HTTP, HTTPS, IMAPS, POP3S, SMTPS, SSL/TLS, and generic TCP/UDP and IP protocols. Session persistence is supported based on the SSL session ID, based on an injected HTTP cookie, or based on the HTTP or HTTPS host. SSL/TLS load balancing includes protection from protocol downgrade attacks. Server load balancing is supported on most FortiGate devices and includes up to 10,000 virtual servers on our high end systems.

SSL/TLS offloading

With more and more critical business applications being made available online and in the cloud, the demand for secure remote continues to increase. While securing web and email applications with SSL/TLS is essential, this protection adds significant performance overheads. An SSL/TLS protected application running on a standard server will perform all the costly encryption/decryption and key exchange routines in software which uses vital CPU resources that should be available for running the application. The consequence of this is that many more or more powerful servers are required to deliver the application.

FortiGate SSL/TLS offloading is designed with the explosion of SSL/TLS applications in mind. The key exchange and encryption/decryption tasks are offloaded to the FortiGate unit where they are accelerated using FortiASIC technology providing significantly more performance than a standard server or load balancer could handle. This frees up valuable resources on the server farm which can be used to run a more responsive business. Server load

balancing offloads most SSL/TLS versions including SSL 3.0, TLS 1.0 and TLS 1.2 and supports full mode or half mode SSL offloading with DH key sizes up to 4096 bits.

SSL/TLS content inspection

Traditionally, SSL encrypted application data would be invisible to any border gateway filtering solution. This is because the encryption process prevents the payload of any connection from being seen other than by the communicating systems. FortiGate SSL Offloading allows the application payload to be inspected before it reaches your servers; preventing intrusion attempts, blocking viruses, stopping unwanted applications, and preventing data leakage.

Health Check

Health checking can be enabled to prevent load balancing traffic from being sent to a non-functioning real server. Real server health can be monitored using ICMP ping or more sophisticated TCP testing. The most comprehensive test is HTTP which verifies that the HTTP application is responding and that it is returning the correct content.

Health checking removes real servers from the load balancing cluster which are returning invalid content. The removal of real servers from the clusters is based on the Interval, Timeout and Retry Settings:

Interval	How often to test the server.
Timeout	What maximum response time is permissible before a server is treated as non-functional.
Retry	How many failures before the server is considered “dead” and removed from the cluster.

Server Monitoring and Management

The health and performance of real servers can be monitored from the FortiGate GUI. Virtual servers and their assigned real servers can be monitored for health status, if there have been any monitor events, number of active sessions, round trip time and number of bytes processed. Should a server become problematic and require administration, it can be gracefully removed from the Real Server pool to enable disruption free maintenance. When a removed real server is able to operate it can gracefully be added back to the virtual server.

HTTP Multiplexing

A performance saving feature of HTTP/1.1 compliant web servers is the ability to pipeline requests on the same connection. This allows a single HTTPD process on the server to interleave and server multiple requests. HTTP multiplexing reduces the number idle sessions, too many of which can exhaust the resources on a server. The Fortinet solution has the ability to take multiple separate inbound sessions and multiplex them over the same internal session. This reduces the load on the backend server and increases the overall performance.

New load balancing features in FortiOS 5.4

This chapter describes new load balancing features added to FortiOS 5.4.0 and FortiOS 5.4.1.

FortiOS 5.4.1

These features first appeared in FortiOS 5.4.1.

Separate virtual-server client and server TLS version and cipher configuration (308040)

In previous versions of FortiOS you can configure minimum and maximum SSL/TLS versions that a virtual server will accept. Those versions primarily applied to the client to FortiGate connection; but, they are also applied to the FortiGate to server connection. In some cases you may want to use different versions of SSL or TLS on the client to FortiGate connection than on the FortiGate to server connection. For example, you may want to use the FortiGate to protect a legacy SSL 3.0 or TLS 1.0 server while making sure that client to FortiGate connections must always use the higher level of protection offered by TLS 1.1 or greater.

Similarly in previous versions of FortiOS you could control the cypher suites that can be used by the FortiGate to negotiate with the client and with the server. But you could only configure the same configuration for both client and server connections. Also, in some cases you might want to protect a server that only has weak ciphers (for example, DES or RC4) while making sure that all connections between the FortiGate and the client use a strong cipher for better protection.

The following new options are available when configuring server load balancing for HTTPS sessions configured with the following command:

```
config firewall vip
   edit server-name
      set type server-load-balance
      set server-type https
      set ssl-mode full
      ...
```

Different SSL/TLS versions for server and client connections

New `ssl-server-min-version` and `ssl-server-max-version` configuration options allow the minimum and maximum SSL/TLS versions for the client to FortiGate connection to be independent of the FortiGate to server configuration. By default these options are both set to `client` and the configured `ssl-min-version` and `ssl-max-version` settings are applied to both the client and the server connection.

You can change the `ssl-server-min-version` and `ssl-server-max-version` to apply different options to the server connection. The `ssl-min-version` and `ssl-max-version` settings are still applied to the client connection. If you set the `ssl-server-min-version` and `ssl-server-max-version` to an explicit version then both must be set to an explicit version.

The `ssl-server-min-version` and `ssl-server-max-version` options allow you to specify the minimum and maximum SSL/TLS versions the FortiGate will offer to the server (in the record header of the ClientHello) when performing full mode SSL offloading and thus the minimum and maximum SSL/TLS versions the FortiGate accepts from the server (in a ServerHello). If the server responds with a version in its ServerHello that is lower than `ssl-server-min-version` or higher than the `ssl-server-max-version` then the FortiGate terminates the connection.

Command syntax is:

```
config firewall vip
   edit server-name
      set type server-load-balance
      set server-type https
      set ssl-mode full
```

```
set ssl-min-version {ssl-3.0 | tls-1.0 | tls-1.1 | tls-1.2}
set ssl-max-version {ssl-3.0 | tls-1.0 | tls-1.1 | tls-1.2}
set ssl-server-min-version {ssl-3.0 | tls-1.0 | tls-1.1 | tls-1.2 | client}
set ssl-server-max-version {ssl-3.0 | tls-1.0 | tls-1.1 | tls-1.2 | client}
```

Different cipher choices for server and client connections

New `ssl-server-algorithm` configuration option allows the cipher choice for the FortiGate to server connection to be independent of the client to FortiGate connection. By default, `ssl-server-algorithm` is set to `client` and the configured `ssl-algorithm` setting is applied to both the client and the server connection.

You can change the `ssl-server-algorithm` to apply different options to the server connection. The `ssl-algorithm` setting is still applied to the client connection.

The following `ssl-server-algorithm` options are available:

- `high`, offer AES or 3DES cypher suites in the ServerHello
- `medium`, use AES, 3DES, or RC4 cypher suites in the ServerHello
- `low`, use AES, 3DES, RC4, or DES cypher suites in the ServerHello
- `custom`, specifiy custom cypher suites using the `config ssl-server-cipher-suites` and offer these custom cypher suites in the ServerHello.
- `client`, offer the cypher suites in the ServerHello that are offered in the ClientHello.

Command syntax is:

```
config firewall vip
   edit server-name
      set type server-load-balance
      set server-type https
      set ssl-mode full
      set ssl-algorithm {high | medium | low | custom}
      set ssl-server-algorithm {high | medium | low | custom | client}
```

If you set ssl-server-algorithm to custom, the syntax is:

```
config firewall vip
   edit server-name
      set type server-load-balance
      set server-type https
      set ssl-mode full
      set ssl-server-algorithm custom
         config ssl-server-cipher-suites
            edit 10
               set cipher <cipher-suite>
               set versions {ssl-3.0 | tls-1.0 | tls-1.1 | tls-1.2}
            next
            edit 20
               set cipher <cipher-suite>
               set versions {ssl-3.0 | tls-1.0 | tls-1.1 | tls-1.2}
            end
         end
```

Protection from downgrade attacks

The new `ssl-client-fallback` option, when enabled (the default configuration), performs downgrade attack prevention (RFC 7507).

Command syntax is:

```
config firewall vip
   edit server-name
      set type server-load-balance
      set server-type https
      set ssl-client-fallback {disable | enable}
```

Allow 3072- and 4096-bit Diffie-Hellman values

New settings added to the `ssl-dh-bits` option to allow 3072 and 4096 bit DH values.

Command syntax is:

```
config firewall vip
   edit server-name
      set type server-load-balance
      set server-type https
      set ssl-dh-bits {768 | 1024 | 1536 | 2048 | 3072 | 4096}
```

The reason for adding these larger sizes is that the previous largest value of 2048 only provides the equivalent of a symmetric cipher in the range of 112 - 128 bits. This means that if AES 256 is used then the weakest point is the DH of 2048 and at least a value of 3072 should be use if the goal is to have 256 bits of security.

FortiGate models with CP9 processors support 3072 and 4096 DH bit sizes in hardware. All FortiGate models up to and including those with CP8 processors only support offloading DH bit sizes up to 2048 so any sizes larger than that are done in software and thus are relatively resource intensive.

FortiOS 5.4.0

These features first appeared in FortiOS 5.4.0.

ChaCha20 and Poly1305 cipher suites added for SSL load balancing (264785)

FortiOS 5.4 adds support for ChaCha20 and Poly1305 for SSL load balancing (see RFC 7539 for information about ChaCha20 and Poly1305). You can use the following command to view the complete list of supported cipher suites:

```
config firewall vip
   edit <vip-name>
      set type server-load-balance
      set server-type https
      set ssl-algorithm custom
         config ssl-cipher-suites
            edit 0
            set cipher ?
```

In most configurations the matching cipher suite is automatically selected.

All of these cipher suites are available to all of FortiOS's implementations of SSL but the complete list of supported cipher suites is only viewable using the above command.

You can also use the above command to limit the set of cipher suites that are available for a given SSL offloading configuration. For example, use the following command to limit an SSL load balancing configuration to use the three cipher suites that support ChaCha20 and Poly1305:

```
config firewall vip
   edit <vip-name>
      set type server-load-balance
      set server-type https
      set ssl-algorithm custom
         config ssl-cipher-suites
            edit 1
            set cipher TLS-ECDHE-RSA-WITH-CHACHA20-POLY1305-SHA256
            next
            edit 2
            set cipher TLS-ECDHE-ECDSA-WITH-CHACHA20-POLY1305-SHA256
            next
            edit 3
            set cipher TLS-DHE-RSA-WITH-CHACHA20-POLY1305-SHA256
            end
         end
```

TLS 1.2 support for SSL offloading (241817)

You can use the following command to configure SSL offloading to support TLS 1.2:

```
config firewall vip
   edit <name>
      set type server-load-balance
      set server-type https
      set ssl-min-version {ssl-3.0 | tls-1.0 | tls-1.1 | tls-1.2}
      set ssl-max-version {ssl-3.0 | tls-1.0 | tls-1.1 | tls-1.2}
      ...
```

The default `ssl-min-version` is `tls-1.0` and the default `ssl-max-version` is `tls-1.2`.

The following AES-GCM TLS 1.2-only cipher suites have also been added. These cipher suites are not supported by the CPx or NPx processors so if you select one of these, all processing is done without hardware acceleration.

TLS 1.2 support does not require setting `ssl-algorithm` to `custom` and configuring a custom cipher suite.

```
TLS-DHE-RSA-WITH-AES-128-GCM-SHA256
TLS-DHE-DSS-WITH-AES-128-GCM-SHA256
TLS-DHE-RSA-WITH-AES-256-GCM-SHA384
TLS-DHE-DSS-WITH-AES-256-GCM-SHA384
TLS-ECDHE-RSA-WITH-AES-128-GCM-SHA256
TLS-ECDHE-RSA-WITH-AES-256-GCM-SHA384
TLS-ECDHE-ECDSA-WITH-AES-128-GCM-SHA256
TLS-ECDHE-ECDSA-WITH-AES-256-GCM-SHA384
TLS-RSA-WITH-AES-128-GCM-SHA256
TLS-RSA-WITH-AES-256-GCM-SHA384
```

You can use the following command to select one of these cipher suites:

```
config firewall vip
```

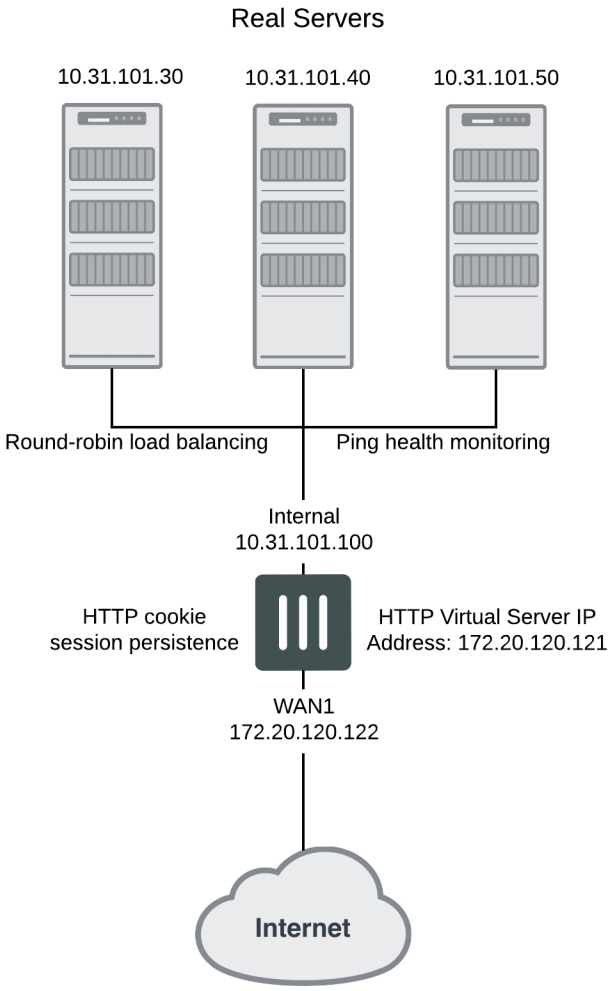
```
edit <name>
   set type server-load-balance
   set server-type https
   set ssl-max-version tls-1.2
   set ssl-algorithm custom
      config ssl-cipher-suites
         edit 100
            set cipher TLS-DHE-RSA-WITH-AES-128-GCM-SHA256
            ...
```

Basic load balancing configuration example

This section describes the steps required to configure the load balancing configuration shown below. In this configuration a FortiGate-51B unit is load balancing HTTP traffic from the Internet to three HTTP servers on the Internal network. HTTP sessions are accepted at the wan1 interface with destination IP address 172.20.120.121 on TCP port 8080 and forwarded from the internal interface to the web servers. When forwarded the destination address of the sessions is translated to the IP address of one of the web servers.

The load balancing configuration also includes session persistence using HTTP cookies, round-robin load balancing, and TCP health monitoring for the real servers. Ping health monitoring consists of the FortiGate unit using ICMP ping to make sure the web servers can respond to network traffic.

Virtual server and real servers setup



To configure the example load balancing configuration - general configuration steps

1. Add a load balance ping health check monitor.
   A ping health check monitor causes the FortiGate unit to ping the real servers every 10 seconds. If one of the servers does not respond within 2 seconds, the FortiGate unit will retry the ping 3 times before assuming that the HTTP server is not responding.
2. Add a load balance virtual server.
3. Add the three load balance real servers. Include the virtual server in each real server configuration.
4. Add a security policy that includes the load balance virtual server as the destination address.

To configure the example load balancing configuration

1. Go to **Policy & Objects > Health Check**and add the following health check monitor.

Name	Ping-mon-1
Type	Ping
Interval	10 seconds
Timeout	2 seconds
Retry	3

2. Go to **Policy & Objects > Virtual Servers** and add virtual server that accepts the traffic to be load balanced.

Name	Vserver-HTTP-1
Type	HTTP
Interface	wan1
Virtual Server IP	172.20.120.121
Virtual Server Port	8080
Load Balance Method	Round Robin
Persistence	HTTP Cookie
HTTP Multiplexing	Do not select
Health Check	Move Ping-mon-1 to the Selected list.

3. Go to **Policy & Objects > Real Servers**and add the real servers.

Virtual Server	Vserver-HTTP-1
IP Address	10.31.101.30
Port	80
Weight	n/a
Max Connections	0
Mode	Active

Virtual Server	Vserver-HTTP-1
IP Address	10.31.101.40
Port	80
Weight	n/a
Max Connections	0
Mode	Active

Virtual Server	Vserver-HTTP-1
IP Address	10.31.101.50
Port	80
Weight	n/a
Max Connections	0
Mode	Active

4. Go to **Policy & Objects > IPv4 Policy** and add a wan1 to internal security policy that includes the virtual server. This policy also applies an Antivirus profile to the load balanced sessions.

Incoming Interface	wan1
Source Address	all
Outgoing Interface	internal
Destination Address	Vserver-HTTP-1
Schedule	always
Service	ALL
Action	ACCEPT
NAT	Turn on NAT and select **Use Destination Interface Address**.
Antivirus	Turn ON and select an Antivirus profile.

5. Select **OK**.

To configure the example load balancing configuration from the CLI

1. Use the following command to add a Ping health check monitor.

```
config firewall ldb-monitor
   edit ping-mon-1
      set type ping
      set interval 10
      set timeout 2
      set retry 3
   end
```

2. Use the following command to add the virtual server that accepts HTTP sessions on port 8080 at the wan1 interface and load balances the traffic to three real servers.

```
config firewall vip
   edit Vserver-HTTP-1
      set type server-load-balance
      set server-type http
      set ldb-method round-robin
      set extip 172.20.120.30
      set extintf wan1
      set extport 8080
      set persistence http-cookie
```

```
      set monitor tcp-mon-1
         config realservers
            edit 1
               set ip 10.31.101.30
               set port 80
            next
            edit 2
               set ip 10.31.101.40
               set port 80
            end
end
```

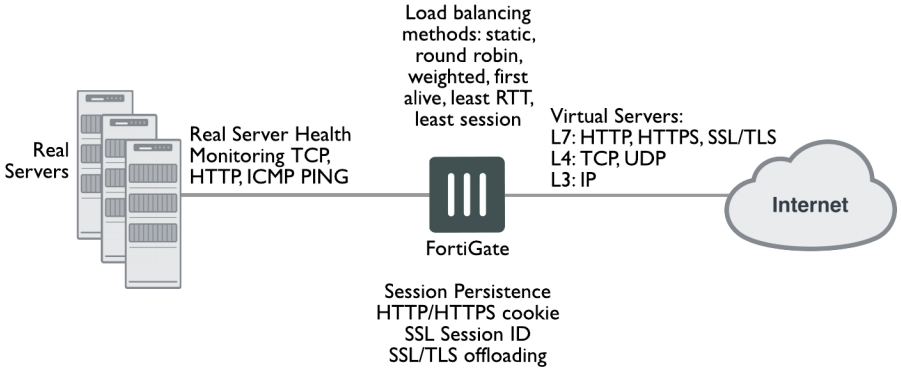
3. Use the following command to add a security policy that includes the load balance virtual server as the destination address.

```
config firewall policy
   edit 0
      set srcintf wan1
      set srcaddr all
      set dstintf internal
      set dstaddr Vserver-HTTP-1
      set action accept
      set schedule always
      set service ALL
      set nat enable
      set utm-status enable
      set profile-protocol-options default
      set av-profile scan
   end
```

Configuring load balancing

This section describes how to use the FortiOS server load balancing to load balance traffic to multiple backend servers.

You can configure FortiOS load balancing to intercept incoming traffic with a virtual server and distribute it among one or more backend real servers. By doing so, FortiOS enables multiple real servers to respond as if they were a single device or virtual server. This in turn means that more simultaneous requests can be handled by the servers.

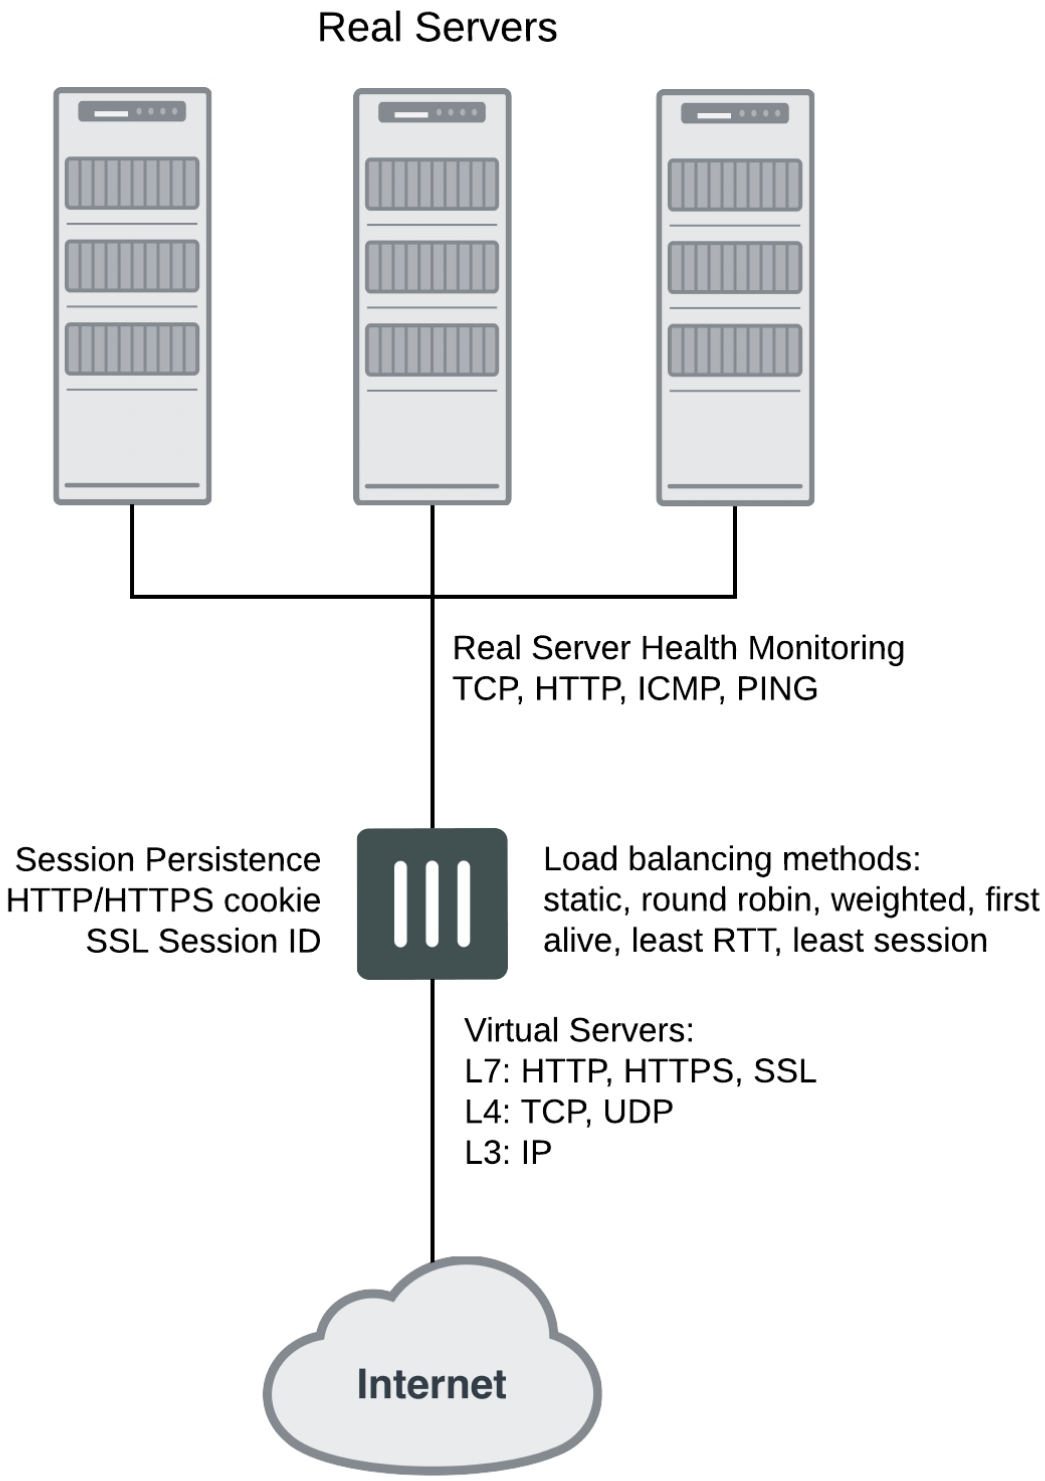


Traffic can be balanced across multiple backend real servers based on a selection of load balancing methods including static (failover), round robin, weighted to account for different sized servers, or based on the health and performance of the server including round trip time, number of connections. The load balancer can balance layer 7 HTTP, HTTPS, SSL, generic layer 4 TCP, UDP and generic layer 3 IP protocols. Session persistence is supported based on injected HTTP/HTTPS cookies or the SSL session ID.

You can bind up to 8 real servers can to one virtual server. The real server topology is transparent to end users, and the users interact with the system as if it were only a single server with the IP address and port number of the virtual server. The real servers may be interconnected by high-speed LAN or by geographically dispersed WAN. The FortiGate unit schedules requests to the real servers and makes parallel services of the virtual server to appear to involve a single IP address.

There are additional benefits to load balancing. First, because the load is distributed across multiple servers, the service being provided can be highly available. If one of the servers breaks down, the load can still be handled by the other servers. Secondly, this increases scalability. If the load increases substantially, more servers can be added behind the FortiGate unit to cope with the increased load.

Server load balancing configuration



Real Servers
Real Server Health Monitoring
TCP, HTTP, ICMP, PING
Session Persistence
HTTP/HTTPS cookie
SSL Session ID
Load balancing methods:
static, round robin, weighted, first alive, least RTT, least session
Virtual Servers:
L7: HTTP, HTTPS, SSL
L4: TCP, UDP
L3: IP
Internet

Traffic can be balanced across multiple backend real servers based on a selection of load balancing methods including static (failover), round robin, weighted to account for different sized servers, or based on the health and performance of the server including round trip time, number of connections. The load balancer can balance layer 7 HTTP, HTTPS, SSL, generic layer 4 TCP, UDP and generic layer 3 IP protocols. Session persistence is supported based on injected HTTP/HTTPS cookies or the SSL session ID.

You can bind up to 8 real servers can to one virtual server. The real server topology is transparent to end users, and the users interact with the system as if it were only a single server with the IP address and port number of the virtual server. The real servers may be interconnected by high-speed LAN or by geographically dispersed WAN. The FortiGate unit schedules requests to the real servers and makes parallel services of the virtual server to appear to involve a single IP address.

Load balancing and other FortiOS features

Flow-based and proxy-based security features such as virus scanning, IPS, DLP, application control, and web filtering can be applied to load balanced sessions. This includes SSL offloading and multiplexing. Applying these UTM features to load balancing traffic may reduce load balancing performance.

Authentication is not supported for load balancing sessions. Usually FortiGate load balancing is used to allow public access to services on servers protected by a FortiGate unit. Authentication is not generally not required for this kind of configuration.

Features such web proxying, web caching, and WAN optimization also do not work with load balanced sessions. However, most other features that can be applied by a security policy are supported.

Configuring load balancing from the GUI

A virtual server is a specialized firewall virtual IP that performs server load balancing. From the web-based manager you add load balancing virtual server by going to **Policy & Objects > Virtual Servers**.

Name

Enter the name for the virtual server.

Type

Select the protocol to be load balanced by the virtual server. If you select a general protocol such as **IP**, **TCP**, or **UDP** the virtual server load balances all IP, TCP, or UDP sessions. If you select specific protocols such as **HTTP**, **HTTPS**, or **SSL** you can apply additional server load balancing features such as **Persistence** and **HTTP Multiplexing**.

- Select **HTTP** to load balance only HTTP sessions with destination port number that matches the **Virtual Server Port** setting. Change **Virtual Server Port** to match the destination port of the sessions to be load balanced (usually port 80 for HTTP sessions). You can also select **HTTP Multiplex**. You can also set **Persistence** to **HTTP Cookie** to select cookie-based persistence.
- Select **HTTPS** to load balance only HTTPS sessions with destination port number that matches the **Virtual Server Port** setting. Change **Virtual Server Port** to match the destination port of the sessions to be load balanced (usually port 443 for HTTPS sessions). You can also select **Multiplex HTTP requests/responses.** You can also set **Persistence** to **HTTP Cookie** to select cookie-based persistence. You can also set **Persistence** to **SSL Session ID**.

- Select **IMAPS** to load balance only IMAPS sessions with destination port number that matches the **Virtual Server Port** setting. Change **Virtual Server Port** to match the destination port of the sessions to be load balanced (usually port 993 for IMAPS sessions). You can also set **Persistence** to **SSL Session ID**.
- Select **POP3S** to load balance only POP3S sessions with destination port number that matches the **Virtual Server Port** setting. Change **Virtual Server Port** to match the destination port of the sessions to be load balanced (usually port 995 for POP3S sessions). You can also set **Persistence** to **SSL Session ID**.
- Select **SMTPS** to load balance only SMTPS sessions with destination port number that matches the **Virtual Server Port** setting. Change **Virtual Server Port** to match the destination port of the sessions to be load balanced (usually port 465 for SMTPS sessions). You can also set **Persistence** to **SSL Session ID**.
- Select **SSL** to load balance only SSL sessions with destination port number that matches the **Virtual Server Port** setting. Change **Virtual Server Port** to match the destination port of the sessions to be load balanced.
- Select **TCP** to load balance only TCP sessions with destination port number that matches the **Virtual Server Port** setting. Change **Virtual Server Port** to match the destination port of the sessions to be load balanced.
- Select **UDP** to load balance only UDP sessions with destination port number that matches the **Virtual Server Port** setting. Change **Virtual Server Port** to match the destination port of the sessions to be load balanced.
- Select **IP** to load balance all sessions accepted by the security policy that contains this virtual server.

Interface

Select the virtual server external interface from the list. The external interface is connected to the source network and receives the packets to be forwarded to the destination network.

Virtual Server IP

The IP address of the virtual server. This is an IP address on the external interface that you want to map to an address on the destination network.

Virtual Server Port

Enter the external port number that you want to map to a port number on the destination network. Sessions with this destination port are load balanced by this virtual server.

Load Balance Method

Select the load balancing method used by the virtual server.

Persistence

Configure persistence to make sure that a user is connected to the same server every time they make a request that is part of the same session. Session persistence is supported for HTTP and SSL sessions.

HTTP Multiplexing

Select to use the FortiGate unit to multiplex multiple client connections into a few connections between the FortiGate unit and the real server.

Preserve Client IP

Select to preserve the IP address of the client in the `X-Forwarded-For` HTTP header. This can be useful if you want log messages on the real servers to the client's original IP address. If this option is not selected, the header will contain the IP address of the FortiGate unit.

This option appears only if **HTTP** or **HTTS** are selected for **Type**, and is available only if **HTTP Multiplexing** is selected.

SSL Offloading

Select to accelerate clients' SSL connections to the server by using the Fortinet FortiGate unit to perform SSL operations, then select which segments of the connection will receive SSL offloading.

Certificate

Select the certificate to use with **SSL Offloading**. The certificate key size must be 1024 or 2048 bits. 4096-bit keys are not supported.

This option appears only if **HTTPS** or **SSL** are selected for **Type**, and is available only if **SSL Offloading** is selected.

Health Check

Select which health check monitor configuration will be used to determine a server's connectivity status.

Configuring load balancing from the CLI

From the CLI you configure load balancing by adding a firewall virtual IP and setting the virtual IP type to server load balance:

```
config firewall vip
   edit Vserver-HTTP-1
      set type server-load-balance
      ...
```

A virtual server includes a virtual server IP address bound to an interface. The virtual server IP address is the destination address incoming packets to be load balanced and the virtual server is bound to the interface that receives the packets to be load balanced.

For example, if you want to load balance incoming HTTP traffic from the Internet to a group of web servers on a DMZ network, the virtual server IP address is the known Internet IP address of the web servers and the virtual server binds this IP address to the FortiGate interface connected to the Internet.

When you bind the virtual server's external IP address to a FortiGate unit interface, by default, the network interface responds to ARP requests for the bound IP address. Virtual servers use proxy ARP, as defined in RFC 1027, so that the FortiGate unit can respond to ARP requests on a network for a real server that is actually installed on another network. In some cases you may not want the network interface sending ARP replies. You can use the `arp-reply` option disable sending ARP replies:

```
config firewall vip
   edit Vserver-HTTP-1
      set type server-load-balance
      set arp-reply disable
      ...
```

The load balancing virtual server configuration also includes the virtual server port. This is the TCP port on the bound interface that the virtual server listens for traffic to be load balanced on. The virtual server can listen on any port.

Load balancing methods

The load balancing method defines how sessions are load balanced to real servers. A number of load balancing methods are available as listed below.

All load balancing methods will not send traffic to real servers that are down or not responding. However, the FortiGate unit can only determine if a real server is not responding by using a health check monitor. You should always add at least one health check monitor to a virtual server or to individual real servers, or load balancing methods may attempt to distribute sessions to real servers that are not functioning.

Source IP Hash

The traffic load is statically spread evenly across all real servers. However, sessions are not assigned according to how busy individual real servers are. This load balancing method provides some persistence because all sessions from the same source address always go to the same real server. However, the distribution is stateless, so if a real server is added or removed (or goes up or down) the distribution is changed and persistence could be lost.

Round Robin

Directs new requests to the next real server, and treats all real servers as equals regardless of response time or number of connections. Dead real servers or non responsive real servers are avoided.

Weighted

Real servers with a higher weight value receive a larger percentage of connections. Set the real server weight when adding a real server.

First Alive

Always directs sessions to the first alive real server. This load balancing schedule provides real server failover protection by sending all sessions to the first alive real server and if that real server fails, sending all sessions to the next alive real server. Sessions are not distributed to all real servers so all sessions are processed by the “first” real server only.

First refers to the order of the real servers in the virtual server configuration. For example, if you add real servers A, B and C in that order, then all sessions always go to A as long as it is alive. If A goes down then sessions go to B and if B goes down sessions go to C. If A comes back up sessions go back to A. Real servers are ordered in the virtual server configuration in the order in which you add them, with the most recently added real server last. If you want to change the order you must delete and re-add real servers in the required order.

Least RTT

Directs sessions to the real server with the least round trip time. The round trip time is determined by a Ping health check monitor and is defaulted to 0 if no Ping health check monitors are added to the virtual server.

Least Session

Directs requests to the real server that has the least number of current connections. This method works best in environments where the real servers or other equipment you are load balancing all have similar capabilities. This load balancing method uses the FortiGate session table to track the number of sessions being processed by each real server. The FortiGate unit cannot detect the number of sessions actually being processed by a real server.

HTTP Host

Load balances HTTP host connections across multiple real servers using the host's HTTP header to guide the connection to the correct real server.

Session persistence

Use persistence to make sure that a user is connected to the same real server every time they make an HTTP, HTTPS, or SSL request that is part of the same user session. For example, if you are load balancing HTTP and HTTPS sessions to a collection of eCommerce web servers, when a user is making a purchase they will be starting multiple sessions as they navigate the eCommerce site. In most cases all of the sessions started by this user during on eCommerce session should be processed by the same real server. Typically, the HTTP protocol keeps track of these related sessions using cookies. HTTP cookie persistence makes sure that all sessions that are part of the same user session are processed by the same real server

When you configure persistence, the FortiGate unit load balances a new session to a real server according to the load balance method. If the session has an HTTP cookie or an SSL session ID, the FortiGate unit sends all subsequent sessions with the same HTTP cookie or SSL session ID to the same real server. For more information about HTTP and HTTPS persistence, see "HTTP and HTTPS persistence".

Real servers

Add real servers to a load balancing virtual server to provide the information the virtual server requires to be able to send sessions to the server. A real server configuration includes the IP address of the real server and port number that the real server receives sessions on. The FortiGate unit sends sessions to the real server's IP address using the destination port number in the real server configuration.

When configuring a real server you can also specify the weight (used if the load balance method is set to weighted) and you can limit the maximum number of open connections between the FortiGate unit and the real server. If the maximum number of connections is reached for the real server, the FortiGate unit will automatically switch all further connection requests other real servers until the connection number drops below the specified limit. Setting Maximum Connections to 0 means that the FortiGate unit does not limit the number of connections to the real server.

Real server active, standby, and disabled modes

By default the real server mode setting is active indicating that the real server is available to receive connections. If the real server is removed from the network (for example, for routine maintenance or because of a hardware or software failure) you can change the mode to standby or disabled. In disabled mode the FortiGate unit no longer sends sessions to the real server.

If a real server is in standby mode the FortiGate also does not send sessions to it unless other real servers added to the same virtual server become unavailable. For example:

- A virtual server that includes two real servers one in active mode and one in standby mode. If the real server in active mode fails, the real server in standby mode is changed to active mode and all sessions are sent to this real server.
- A virtual server includes three real servers, two in active mode and one in standby mode, if one of the real servers in active mode fails, the real server in standby mode is changed to active mode and sessions are load balanced between it and still operating real server. If both real servers in active mode fail, all sessions are sent to the real server in standby mode.

Adding real servers from the web-based manager

To add a real server from the web-based manager go to **Policy & Objects > Real Servers**.

Virtual Server

Select the virtual server that will send sessions to this real server.

IP Address

Enter the IP address of the real server.

Port

Enter the port number on the destination network to which the external port number is mapped.

Weight

Enter the weight value of the real server. The higher the weight value, the higher the percentage of connections the server will handle. A range of 1-255 can be used. This option is available only if the associated virtual server's load balance method is **Weighted**.

Max Connections

Enter the limit on the number of active connections directed to a real server. A range of 1-99999 can be used. If the maximum number of connections is reached for the real server, the FortiGate unit will automatically switch all further connection requests to another server until the connection number drops below the specified limit.

Setting **Maximum Connections** to **0** means that the FortiGate unit does not limit the number of connections to the real server.

HTTP Host

Enter the HTTP header for load balancing across multiple real servers. This feature is used for load balancing HTTP host connections across multiple real servers using the host's HTTP header to guide the connection to the correct real server, providing better load balancing for those specific connections.

Mode

Select a mode for the real server.

Adding real servers from the CLI

To add a real server from the CLI you configure a virtual server and add real servers to it. For example, to add three real servers to a virtual server that load balances UDP sessions on port 8190 using weighted load balancing. For each real server the port is not changed. The default real server port is 0 resulting in the traffic being sent the real server with destination port 8190. Each real sever is given a different weight. Servers with higher weights have a max-connections limit to prevent too many sessions from being sent to them.

```
config firewall vip
   edit Vserver-UDP-1
      set type server-load-balance
      set server-type udp
      set ldb-method weighted
      set extip 172.20.120.30
```

```
      set extintf wan1
      set extport 8190
      set monitor ping-mon-1
         config realservers
            edit 1
               set ip 10.31.101.30
               set weight 100
               set max-connections 10000
            next
            edit 2
               set ip 10.31.101.40
               set weight 100
               set max-connections 10000
            next
            edit 3
               set ip 10.31.101.50
               set weight 10
            end
end
```

Health check monitoring

From the FortiGate GUI you can go to **Policy & Objects > Health Check** and configure health check monitoring so that the FortiGate unit can verify that real servers are able respond to network connection attempts. If a real server responds to connection attempts the load balancer continues to send sessions to it. If a real server stops responding to connection attempts the load balancer assumes that the server is down and does not send sessions to it. The health check monitor configuration determines how the load balancer tests the real servers. You can use a single health check monitor for multiple load balancing configurations.

You can configure TCP, HTTP and Ping health check monitors. Usually you would want the health check monitor to use the same protocol for checking the health of the server as the traffic being load balanced to it. For example, for an HTTP load balancing configuration you would normally use an HTTP health check monitor.

For the TCP and HTTP health check monitors you can specify the destination port to use to connect to the real servers. If you set the port to 0, the health check monitor uses the port defined in the real server. This allows you to use the same health check monitor for multiple real servers using different ports. You can also configure the interval, timeout and retry. A health check occurs every number of seconds indicated by the interval. If a reply is not received within the timeout period the health check is repeated every second. If no response is received after the number of configured retires, the virtual server is considered unresponsive, and load balancing does not srend traffic to that real server. The health check monitor will continue to contact the real server and if successful, the load balancer can resume sending sessions to the recovered real server.

The default health check configuration has an interval of 10 seconds, a timeout of 2 seconds and a retry of 3. This means that the health check monitor checks the health of a real server every 10 seconds. If a reply is not received within 2 seconds the health check monitor re-checks the server every second for 3 retries. If no response is received for 2 seconds after the final retry the server is considered unresponsive. This entire process takes a total of 7 seconds to consider a virtual server as unresponsive (2 second timeout + (3 re-checks x 1 second) + 2 second timeout = 7 seconds). Since this health check process is repeated every 10 seconds, a server can be down for a maximum of 10 + 7 = 17 seconds before the health check monitor considers it down.

For HTTP health check monitors, you can add URL that the FortiGate unit connects to when sending a get request to check the health of a HTTP server. The URL should match an actual URL for the real HTTP servers. The URL is optional.

The URL would not usually include an IP address or domain name. Instead it should start with a "/" and be followed by the address of an actual web page on the real server. For example, if the IP address of the real server is 10.31.101.30, the URL "/test_page.htm" causes the FortiGate unit to send an HTTP get request to "http://10.31.101.30/test_page.htm".

For HTTP health check monitors, you can also add a matched content phrase that a real HTTP server should include in response to the get request sent by the FortiGate unit using the content of the URL option. If the URL returns a web page, the matched content should exactly match some of the text on the web page. You can use the URL and Matched Content options to verify that an HTTP server is actually operating correctly by responding to get requests with expected web pages. Matched content is only required if you add a URL.

For example, you can set matched content to "server test page" if the real HTTP server page defined by the URL option contains the phrase "server test page". When the FortiGate unit receives the web page in response to the URL get request, the system searches the content of the web page for the matched content phrase.

Name

Enter the name of the health check monitor configuration.

Type

Select the protocol used to perform the health check.

- TCP
- HTTP
- PING

Port

Enter the port number used to perform the health check. If you set the **Port** to 0, the health check monitor uses the port defined in the real server. This way you can use a single health check monitor for different real servers.

This option does not appear if the **Type** is **PING**.

Interval

Enter the number of seconds between each server health check.

URL

For HTTP health check monitors, add a URL that the FortiGate unit uses when sending a get request to check the health of a HTTP server. The URL should match an actual URL for the real HTTP servers. The URL is optional.

The URL would not usually include an IP address or domain name. Instead it should start with a "/" and be followed by the address of an actual web page on the real server. For example, if the IP address of the real server is 10.10.10.1, the **URL** "/test_page.htm" causes the FortiGate unit to send an HTTP get request to "http://10.10.10.1/test_page.htm".

This option appears only if **Type** is **HTTP**.

Matched Content

For HTTP health check monitors, add a phrase that a real HTTP server should include in response to the get request sent by the FortiGate unit using the content of the **URL** option. If the **URL** returns a web page, the **Matched Content** should exactly match some of the text on the web page. You can use the **URL** and **Matched**

Content options to verify that an HTTP server is actually operating correctly by responding to get requests with expected web pages. Matched content is only required if you add a URL.

For example, you can set **Matched Content** to “server test page” if the real HTTP server page defined by the URL option contains the phrase “server test page”. When the FortiGate unit receives the web page in response to the URL get request, the system searches the content of the web page for the **Matched Content** phrase.

This option appears only if **Type** is **HTTP**.

Timeout

Enter the number of seconds which must pass after the server health check to indicate a failed health check.

Retry

Enter the number of times, if any, a failed health check will be retried before the server is determined to be inaccessible.

Load balancing limitations

The following limitations apply when adding virtual IPs, load balancing virtual servers, and load balancing real servers. Load balancing virtual servers are actually server load balancing virtual IPs. You can add server load balance virtual IPs from the CLI.

- Virtual IP **External IP Address/Range** entries or ranges cannot overlap with each other or with load balancing virtual server **Virtual Server IP** entries.
- A virtual IP **Mapped IP Address/Range** cannot be 0.0.0.0 or 255.255.255.255.
- A real server **IP** cannot be 0.0.0.0 or 255.255.255.255.
- If a static NAT virtual IP **External IP Address/Range** is 0.0.0.0, the **Mapped IP Address/Range** must be a single IP address.
- If a load balance virtual IP **External IP Address/Range** is 0.0.0.0, the **Mapped IP Address/Range** can be an address range.
- When port forwarding, the count of mapped port numbers and external port numbers must be the same. The web-based manager does this automatically but the CLI does not.
- Virtual IP and virtual server names must be different from firewall address or address group names.

Monitoring load balancing

From the GUI you can go to **Monitor > Load Balance Monitor** to monitor the status of configured virtual servers and real server and start or stop the real servers. You can also use the `get test ipldb` command from the CLI to display similar information.

For each real server the monitor displays health status (up or down), active sessions, round trip time and the amount of bytes of data processed. From the monitor page you can also stop sending new sessions to any real server. When you select to stop sending sessions the FortiGate unit performs of graceful stop by continuing to send data for sessions that were established or persistent before you selected stop. However, no new sessions are started.

Virtual Server

The IP addresses of the existing virtual servers.

Real Server

The IP addresses of the existing real servers.

Health Status

Displays the health status according to the health check results for each real server. A green arrow means the server is up. A red arrow means the server is down.

Mode

The mode of the health check monitor. Can be active, standby, or disabled.

Monitor Events

Display each real server's up and down times.

Active Sessions

Display each real server's active sessions.

RTT (ms)

Displays the Round Trip Time (RTT) of each real server. By default, the RTT is "<1". This value will change only when ping monitoring is enabled on a real server.

Bytes Processed

Displays the traffic processed by each real server.

Graceful Stop/Start

Select to start or stop real servers. When stopping a server, the FortiGate unit will not accept new sessions but will wait for the active sessions to finish.

Load balancing diagnose commands

You can also use the following diagnose commands to view status information for load balancing virtual servers and real servers:

```
diagnose firewall vip realserver {down | flush | healthcheck | list | up}
diagnose firewall vip virtual-server {filter | log | real-server | session | stats}
```

For example, the following command lists and displays status information for all real servers:

```
diagnose firewall vip virtual-server real-server

vd root/0 vs vs/2 addr 10.31.101.30:80 status 1/1
conn: max 0 active 0 attempts 0 success 0 drop 0 fail 0

vd root/0 vs vs/2 addr 10.31.101.20:80 status 1/1
conn: max 0 active 0 attempts 0 success 0 drop 0 fail 0
```

Many of the diagnostic commands involve retrieving information about one or more virtual servers. To control which servers are queried you can define a filter:

```
diagnose firewall vip virtual-server filter <filter_str>
```

Where `<filter_str>` can be:

- `clear` erase the current filter
- `dst` the destination address range to filter by
- `dst-port` the destination port range to filter by
- `list` display the current filter
- `name` the vip name to filter by
- `negate` negate the specified filter parameter
- `src` the source address range to filter by
- `src-port` the source port range to filter by
- `vd` index of virtual domain. -1 matches all

The default filter is empty so no filtering is done.

Logging Diagnostics

The logging diagnostics provide information about two separate features:

```
diagnose firewall vip virtual-server log {console | filter}
```

Where

- `console {disable | enable}` enables or disables displaying the event log messages generated by virtual server traffic on the console to simplify debugging.
- `filter` sets a filter for the virtual server debug log
- The filter option controls what entries the virtual server daemon will log to the console if `diagnose debug application vs` level is non-zero. The filtering can be done on source, destination, virtual-server name, virtual domain, and so on:

```
diagnose firewall vip virtual-server log filter <filter_str>
```

Where `<filter_str>` can be

- `clear` erase the current filter
- `dst` the destination address range to filter by
- `dst-port` the destination port range to filter by
- `list` display the current filter
- `name` the virtual-server name to filter by
- `negate` negate the specified filter parameter
- `src` the source address range to filter by
- `src-port` the source port range to filter by
- `vd` index of virtual domain. -1 matches all

The default filter is empty so no filtering is done.

Real server diagnostics

Enter the following command to list all the real servers:

```
diag firewall vip virtual-server real-server list
```

In the following example there is only one virtual server called `slb` and it has two real-servers:

```
diag firewall vip virtual-server server
vd root/0 vs slb/2 addr 172.16.67.191:80 status 1/1
conn: max 10 active 0 attempts 0 success 0 drop 0 fail 0
http: available 0 total 0
```

```
vd root/0 vs slb/2 addr 172.16.67.192:80 status 1/1
conn: max 10 active 1 attempts 4 success 4 drop 0 fail 0
http: available 1 total 1
```

The `status` indicates the administrative and operational status of the real-server.

- `max` indicates that the real-server will only allow 10 concurrent connections.
- `active` is the number of current connections to the server attempts is the total number of connections attempted success is the total number of connections that were successful.
- `drop` is the total number of connections that were dropped because the active count hit max.
- `fail` is the total number of connections that failed to complete due to some internal problem (for example, lack of memory).

If the virtual server has HTTP multiplexing enabled then the HTTP section indicates how many established connections to the real-sever are available to service a HTTP request and also the total number of connections.

HTTP and HTTPS load balancing, multiplexing, and persistence

In a firewall load balancing virtual server configuration, you can select HTTP to load balance only HTTP sessions. The virtual server will load balance HTTP sessions received at the virtual server interface with destination IP address that matches the configured virtual server IP and destination port number that matches the configured virtual server port. The default virtual server port for HTTP load balancing is 80, but you can change this to any port number. Similarly for HTTPS load balancing, set the virtual server type to HTTPS and then select the interface, virtual server IP, and virtual server port that matches the HTTPS traffic to be load balanced. Usually HTTPS traffic uses port 443.

You can also configure load balancing to offload SSL processing for HTTPS and SSL traffic. See SSL/TLS load balancing on page 2854.

HTTP and HTTPS multiplexing

For both HTTP and HTTPS load balancing you can multiplex HTTP requests and responses over a single TCP connection. HTTP multiplexing is a performance saving feature of HTTP/1.1 compliant web servers that provides the ability to pipeline many unrelated HTTP or HTTPS requests on the same connection. This allows a single HTTPD process on the server to interleave and serve multiple requests. The result is fewer idle sessions on the web server so server resources are used more efficiently. HTTP multiplexing can take multiple separate inbound sessions and multiplex them over the same internal session. This may reduce the load on the backend server and increase the overall performance.

HTTP multiplexing may improve performance in some cases. For example, if users web browsers are only compatible with HTTP 1.0. HTTP multiplexing can also improve performance between a web server and the FortiGate unit if the FortiGate unit is performing SSL acceleration. However, in most cases HTTP multiplexing should only be used if enabling it leads to a measurable improvement in performance.

To enable HTTP multiplexing from the web-based manager, select multiplex HTTP requests/responses over a single TCP connection. To enable HTTP multiplexing from the CLI enable the `http-multiplex` option.

Preserving the client IP address

Select preserve client IP from the GUI or enable the `http-ip-header` option from the CLI to preserve the IP address of the client in the `X-Forwarded-For` HTTP header. This can be useful in an HTTP multiplexing configuration if you want to be able to see the original client IP address in log messages on the destination web

server. If this option is not selected, the `X-Forwarded-For` HTTP header contains the IP address of the FortiGate unit.

Preserving the client IP address in a different HTTP header

If you select preserve client IP from the web-based manager or enable the `http-ip-header` option from the CLI you can also preserve the client IP in a different HTTP header. This can be useful if you want to use a custom header name instead of `X-Forwarded-For`.

You can add the custom header name from the CLI. When `http-ip-header` is enabled you can add a custom header name to the `http-ip-header-name` option. If you don't add a name the `X-Forwarded-For` header is used.

HTTP and HTTPS persistence

Configure load balancing persistence for HTTP or HTTPS to make sure that a user is connected to the same server every time they make a request that is part of the same session. HTTP cookie persistence uses injected cookies to enable persistence.

When you configure persistence, the FortiGate unit load balances a new session to a real server according to the **Load Balance Method**. If the session has an HTTP cookie or an SSL session ID, the FortiGate unit sends all subsequent sessions with the same HTTP cookie or SSL session ID to the same real server.

The following example shows how to enable cookie persistence and set the cookie domain to .example.org.

```
config firewall vip
   edit HTTP_Load_Balance
      set type server-load-balance
      set server-type http
      set extport 8080
      set extintf port2
      set extip 192.168.20.20
      set persistence http-cookie
      set http-cookie-domain .example.org
         config realservers
         edit 1
               set ip 10.10.10.1
               set port 80
         next
         edit 2
               set ip 10.10.10.2
               set port 80
         next
         edit 3
               set ip 10.10.10.3
               set port 80
         end
```

How HTTP cookie persistence options work

The following options are available for the `config firewall vip` command when `type` is set to `server-load-balance`, `server-type` is set to `http` or `https` and `persistence` is set to `http-cookie`:

```
http-cookie-domain-from-host
http-cookie-domain
http-cookie-path
http-cookie-generation
```

```
http-cookie-age
http-cookie-share
https-cookie-share
```

When HTTP cookie persistence is enabled the FortiGate unit inserts a header of the following form into each HTTP response unless the corresponding HTTP request already contains a `FGTServer` cookie:

```
Set-Cookie: FGTServer=E7D01637C4B08E89A6714213A9D85D9C7E4D8158; Version=1; Max-Age=3600
```

The value of the `FGTServer` cookie encodes the server that traffic should be directed to. The value is encoded so as to not leak information about the internal network.

Enable `http-cookie-domain-from-host` to extract the cookie domain from the `host:` header in the HTTP request. For example, to restrict the cookie to `.server.com`, enter:

The generated cookies could have the following form if the **Host:** header contains **exhost.com**:

```
Set-Cookie: FGTServer=E7D01637C4B08E89A6714213A9D85D9C7E4D8158; Version=1;
    Domain=.exhost.com; Max-Age=3600
```

For more information, see "HTTP host-based load balancing".

Use `http-cookie-domain` to restrict the domain that the cookie should apply to. For example, to restrict the cookie to `.server.com`, enter:

```
set http-cookie-domain .server.com
```

Now all generated cookies will have the following form:

```
Set-Cookie: FGTServer=E7D01637C4B08E89A6714213A9D85D9C7E4D8158; Version=1;
    Domain=.server.com; Max-Age=3600
```

Use `http-cookie-path` to limit the cookies to a particular path. For example, to limit cookies to the path `/sales`, enter:

```
set http-cookie-path /sales
```

Now all generated cookies will have the following form:

```
Set-Cookie: FGTServer=E7D01637C4B08E89A6714213A9D85D9C7E4D8158; Version=1;
    Domain=.server.com; Path=/sales; Max-Age=3600
```

Use `http-cookie-age` to change how long the browser caches the cookie. You can enter an age in minutes or set the age to 0 to make the browser keep the cookie indefinitely:

```
set http-cookie-age 0
```

Now all generated cookies will have the following form:

```
Set-Cookie: FGTServer=E7D01637C4B08E89A6714213A9D85D9C7E4D8158; Version=1;
    Domain=.server.com; Path=/sales
```

Use `http-cookie-generation` to invalidate all cookies that have already been generated. The exact value of the generation is not important, only that it is different from any generation that has already been used for cookies in this domain. The simplest approach is to increment the generation by one each time invalidation is required. Since the default is 0, enter the following to invalidate all existing cookies:

```
set http-cookie-generation 1
```

Use `http-cookie-share {disable | same-ip}` to control the sharing of cookies across virtual servers in the same virtual domain. The default setting `same-ip` means that any `FGTServer` cookie generated by one virtual server can be used by another virtual server in the same virtual domain. For example, if you have an application that starts on HTTP and then changes to HTTPS and you want to make sure that the same server is used for the HTTP and HTTPS traffic then you can create two virtual servers, one for port 80 (for HTTP) and one for port 443 (for HTTPS). As long as you add the same real servers to both of these virtual servers (and as long as both virtual servers have the same number of real servers with the same IP addresses), then cookies generated by accessing the HTTP server are reused when the application changes to the HTTPS server.

If for any reason you do not want this sharing to occur then select `disable` to make sure that a cookie generated for a virtual server cannot be used by other virtual servers.

Use `https-cookie-secure` to enable or disable using secure cookies. Secure cookies are disabled by default because secure cookies can interfere with cookie sharing across HTTP and HTTPS virtual servers. If enabled, then the `Secure` tag is added to the cookie inserted by the FortiGate unit:

```
Set-Cookie: FGTServer=E7D01637C4B08E89A6714213A9D85D9C7E4D8158; Version=1; Max-Age=3600;
    Secure
```

HTTP host-based load balancing

When configuring HTTP or HTTPS load balancing you can select HTTP host load balancing to load balance HTTP host connections across multiple real servers using the host's HTTP header to guide the connection to the correct real server. HTTP 1.1 includes the concept of a virtual server which allows a HTTP or HTTPS server with a single external IP address to serve requests for multiple DNS domains by using the mandatory `Host:` header in a HTTP request to indicate which DNS domain the request is destined for.

FortiOS can load-balance HTTP and HTTPS connections among multiple real servers using the `Host:` header to guide the connection to the correct real server. The host load balancing method allows a real server to specify a `http-host` attribute which is the domain name of the traffic for that real server. Each real server can only specify a single domain name. The same domain name can appear in more than one real server but only the first one that is up will be used, any others are purely for redundancy. If the Host: header contains a domain that does not match any http-host entry then the connection will be dropped. A real server with no http-host can be matched by any Host: domain.

For example, consider a FortiGate unit that is load-balancing traffic to three real servers. Traffic for www.example1.com should go to 192.168.2.1, traffic for www.example2.com should go to 192.168.2.2 and traffic to any other domain should go to 192.168.2.3. To enable this configuration you would add a virtual server and set the load balance method to HTTP host. Then you would add three real servers and set the HTTP host of the real server with IP address 192.168.2.1 to www.example1.com, the HTTP host of the real server with IP address 192.168.2.2 to www.example2.com and you would not specify an HTTP host for the third real server.

The configuration of a virtual IP to achieve this result would be:

```
config firewall vip
   edit "http-host-ldb"
      set type server-load-balance
      set extip 172.16.67.195
      set extintf "lan"
      set server-type http
      set ldb-method http-host
      set extport 80
         config realservers
         edit 1
               set http-host "www.example1.com"
               set ip 192.168.2.1
               set port 80
         next
         edit 2
               set http-host "www.example2.com"
               set ip 192.168.2.2
               set port 80
         next
         edit 3
               set ip 192.168.2.3
```

```
            set port 80
        next
        end
end
```

Host load balancing and HTTP cookie persistence

In an HTTP host-based load balancing configuration with HTTP cookie persistence enabled you can optionally configure cookie persistence to use the domain set in the host header as the cookie domain. You can do this by enabling the `http-cookie-domain-from-host` option, for example:

```
config firewall vip
   edit "http-host-ldb"
      set type server-load-balance
      set extip 172.16.67.195
      set extintf "lan"
      set server-type http
      set ldb-method http-host
      set extport 80
      set persistence http-cookie
      set http-cookie-domain-from-host enable
         config realservers
            edit 1
               set http-host "www.example1.com"
               set ip 192.168.2.1
               set port 80
            next
            edit 2
               set http-host "www.example2.com"
               set ip 192.168.2.2
               set port 80
            next
            edit 3
               set ip 192.168.2.3
               set port 80
            next
            end
end
```

SSL/TLS load balancing

In a firewall load balancing virtual server configuration, you can select SSL to load balance only SSL and TLS sessions. The virtual server will load balance SSL and TLS sessions received at the virtual server interface with destination IP address that matches the configured virtual server IP and destination port number that matches the configured virtual server port. Change this port to match the destination port of the sessions to be load balanced.

For SSL load balancing you can also set persistence to SSL session ID. Persistence is achieved by the FortiGate unit sending all sessions with the same SSL session ID to the same real server. When you configure persistence, the FortiGate unit load balances a new session to a real server according to the **Load Balance Method**. If the session has an SSL session ID, the FortiGate unit sends all subsequent sessions with the same SSL session ID to the same real server.

SSL/TLS offloading

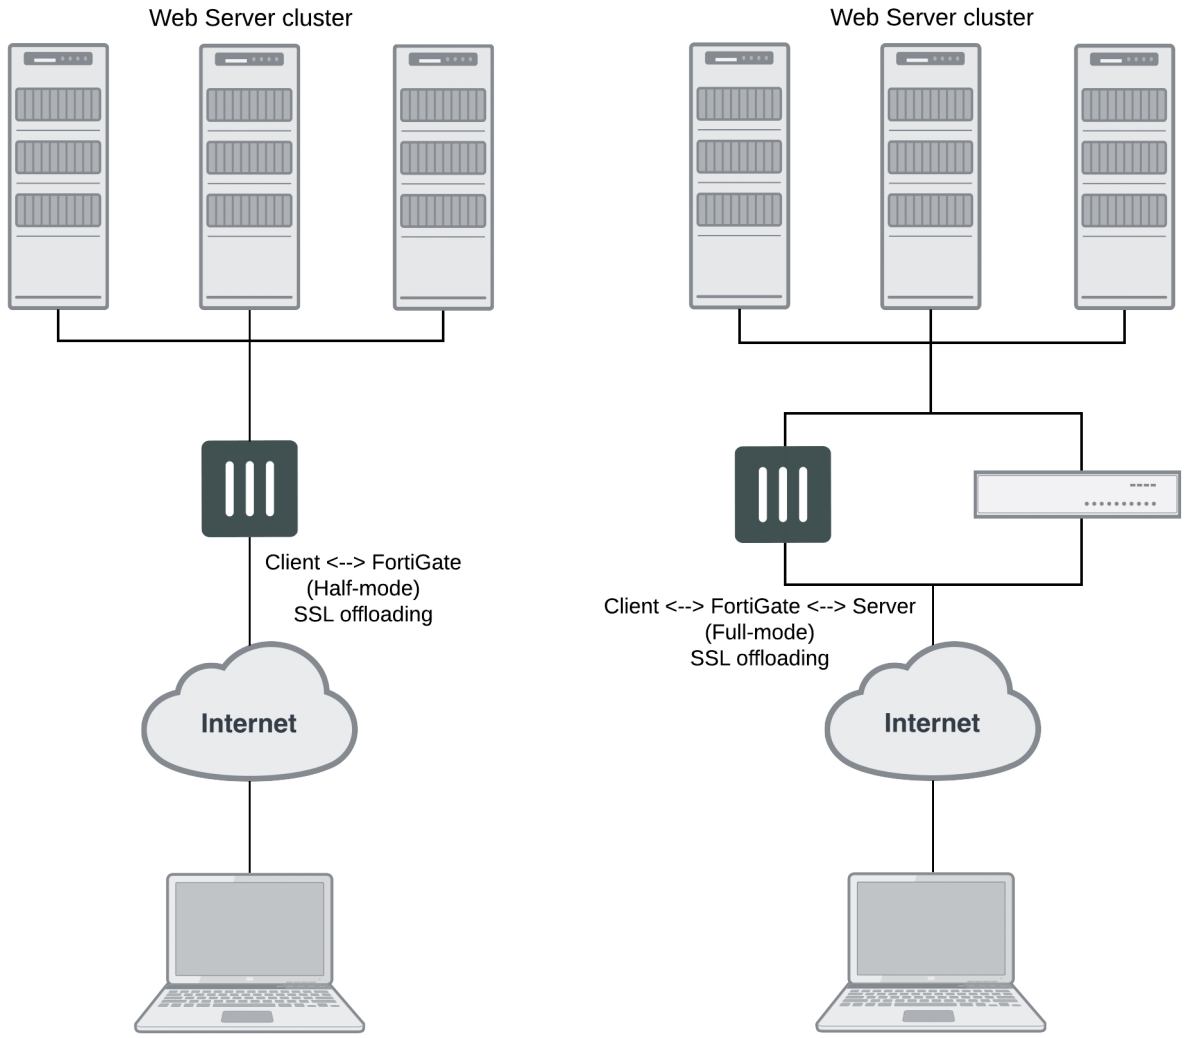
Use SSL offloading to accelerate clients' SSL or HTTPS connections to real servers by using the FortiGate unit to perform SSL/TLS operations (offloading them from the real servers using the FortiGate unit's SSL acceleration hardware). FortiGate units can offload most versions of SSL/TLS, including SSL 3.0, TLS 1.0 and TLS 1.2. SSL/TLS offloading is available on FortiGate units that support SSL acceleration.

To configure SSL offloading from the web-based manager go to **Policy & Objects > Virtual Servers**. Add a virtual server and set the type to HTTPS or SSL and select the SSL offloading type (**Client <-> FortiGate** or **Client <-> FortiGate <-> Server**).

Select **Client <-> FortiGate** to apply hardware accelerated SSL/TLS processing only to the part of the connection between the client and the FortiGate unit. This mode is called half mode SSL offloading. The segment between the FortiGate unit and the server will use clear text communications. This results in best performance, but cannot be used in failover configurations where the failover path does not have an SSL accelerator.

Select **Client <-> FortiGate <->Server** to apply hardware accelerated SSL processing to both parts of the connection: the segment between client and the FortiGate unit, and the segment between the FortiGate unit and the server. This mode is called full mode SSL offloading. The segment between the FortiGate unit and the server will use encrypted communications, but the handshakes will be abbreviated. This is not as efficient as half mode SSL offloading, but still improves performance. As well full-mode SSL offloading can be used in failover configurations where the failover path does not have an SSL accelerator. If the server is already configured to use SSL, this also enables SSL acceleration without requiring changes to the server's configuration.

SSL Offloading modes (Half Mode and Full Mode)



Configuring SSL offloading also requires selecting a certificate to use for the SSL offloading sessions. SSL offloading supports key sizes up to 4096. FortiGate models with CP9 processors support 3072 and 4096 DH bit sizes in hardware. All FortiGate models up to and including those with CP8 processors only support offloading DH bit sizes up to 2048 so any sizes larger than that are done in software and thus are relatively resource intensive

The following CLI command shows an example half mode HTTPS SSL offloading configuration. In the example the `ssl-mode` option sets the SSL offload mode to `half` (which is the default mode).

```
config firewall vip
   edit Vserver-ssl-offload
      set type server-load-balance
      set server-type https
      set ldb-method round-robin
      set extip 172.20.120.30
      set extintf wan1
      set extport 443
```

```
        set persistence ssl-session-id
        set ssl-mode half
        set ssl-certificate my-cert
        set monitor tcp-mon-1
           config realservers
              edit 1
                 set ip 10.31.101.30
                 set port 443
              next
              edit 2
                 set ip 10.31.101.40
                 set port 443
              end
    end
```

Separate virtual-server client and server TLS version and cipher configuration

In previous versions of FortiOS you can configure minimum and maximum SSL/TLS versions that a virtual server will accept. Those versions primarily applied to the client to FortiGate connection; but, they are also applied to the FortiGate to server connection. In some cases you may want the to use different versions of SSL or TLS on the client to FortiGate connection than on the FortiGate to server connection. For example, you may want to use the FortiGate to protect a legacy SSL 3.0 or TLS 1.0 server while making sure that client to FortiGate connections must always use the higher level of protection offered by TLS 1.1 or greater.

Similarly in previous versions of FortiOS you could control the cypher suites that can be used by the FortiGate to negotiate with the client and with the server. But you could only configure the same configuration for both client and server connections. Also, in some cases you might want to protect a server that only has weak ciphers (for example, DES or RC4) while making sure that all connections between the FortiGate and the client use a strong cipher for better protection.

The following new options are available when configuring server load balancing for HTTPS sessions configured with the following command:

```
config firewall vip
   edit server-name
      set type server-load-balance
      set server-type https
      set ssl-mode full
      ...
```

Setting the SSL/TLS versions to use for server and client connections

The `ssl-server-min-version`, `ssl-server-max-version`, `ssl-min-version` and `ssl-max-version` configuration options allow the minimum and maximum SSL/TLS versions for the client to FortiGate connection to be independent of the FortiGate to server configuration. By default these options are both set to `client` and the configured `ssl-min-version` and `ssl-max-version` settings are applied to both the client and the server connection.

You can change the `ssl-server-min-version` and `ssl-server-max-version` to apply different options to the server connection. The `ssl-min-version` and `ssl-max-version` settings are still applied to the client connection. If you set the `ssl-server-min-version` and `ssl-server-max-version` to an explicit version then both must be set to an explicit version.

The `ssl-server-min-version` and `ssl-server-max-version` options allow you to specify the minimum and maximum SSL/TLS versions the FortiGate will offer to the server (in the record header of the ClientHello) when performing full mode SSL offloading and thus the minimum and maximum SSL/TLS versions the FortiGate accepts from the server (in a ServerHello). If the server responds with a version in its ServerHello that is lower than `ssl-server-min-version` or higher than the `ssl-server-max-version` then the FortiGate terminates the connection.

Command syntax is:

```
config firewall vip
   edit server-name
      set type server-load-balance
      set server-type https
      set ssl-mode full
      set ssl-min-version {ssl-3.0 | tls-1.0 | tls-1.1 | tls-1.2}
      set ssl-max-version {ssl-3.0 | tls-1.0 | tls-1.1 | tls-1.2}
      set ssl-server-min-version {ssl-3.0 | tls-1.0 | tls-1.1 | tls-1.2 | client}
      set ssl-server-max-version {ssl-3.0 | tls-1.0 | tls-1.1 | tls-1.2 | client}
```

Setting the SSL/TLS cipher choices for server and client connections

The `ssl-algorithm` and `ssl-server-algorithm` configuration options allow the cipher choice for the FortiGate to server connection to be independent of the client to FortiGate connection. By default, `ssl-server-algorithm` is set to `client` and the configured `ssl-algorithm` setting is applied to both the client and the server connection.

You can change the `ssl-server-algorithm` to apply different options to the server connection. The `ssl-algorithm` setting is still applied to the client connection.

The following `ssl-server-algorithm` options are available:

- `high`, offer AES or 3DES cypher suites in the ServerHello
- `medium`, use AES, 3DES, or RC4 cypher suites in the ServerHello
- `low`, use AES, 3DES, RC4, or DES cypher suites in the ServerHello
- `custom`, specifiy custom cypher suites using the `config ssl-server-cipher-suites` and offer these custom cypher suites in the ServerHello.
- `client`, offer the cypher suites in the ServerHello that are offered in the ClientHello.

Command syntax is:

```
config firewall vip
   edit server-name
      set type server-load-balance
      set server-type https
      set ssl-mode full
      set ssl-algorithm {high | medium | low | custom}
      set ssl-server-algorithm {high | medium | low | custom | client}
```

If you set ssl-server-algorithm to custom, the syntax is:

```
config firewall vip
   edit server-name
      set type server-load-balance
      set server-type https
      set ssl-mode full
      set ssl-server-algorithm custom
         config ssl-server-cipher-suites
```

```
edit 10
   set cipher <cipher-suite>
   set versions {ssl-3.0 | tls-1.0 | tls-1.1 | tls-1.2}

edit 20
   set cipher <cipher-suite>
   set versions {ssl-3.0 | tls-1.0 | tls-1.1 | tls-1.2}
end
```

Protection from TLS protocol downgrade attacks

The `ssl-client-fallback` option, when enabled (the default configuration), performs downgrade attack prevention (RFC 7507).

Command syntax is:

```
config firewall vip
   edit server-name
      set type server-load-balance
      set server-type https
      set ssl-client-fallback {disable | enable}
```

Setting 3072- and 4096-bit Diffie-Hellman values

The `ssl-dh-bits` option allows you to specify the number of bits of the prime number used in the Diffie-Hellman exchange for RSA encryption of the SSL connection. Larger prime numbers are associated with greater cryptographic strength. You can set DH values from 768 to 4096 bits.

Command syntax is:

```
config firewall vip
   edit server-name
      set type server-load-balance
      set server-type https
      set ssl-dh-bits {768 | 1024 | 1536 | 2048 | 3072 | 4096}
```

Setting the DH bits to 2048 only provides the equivalent of a symmetric cipher in the range of 112 - 128 bits. This means that if AES 256 is used then the weakest point is the DH of 2048 and a value of at least 3072 should be use if the goal is to have 256 bits of security.

FortiGate models with CP9 processors support 3072 and 4096 DH bit sizes in hardware. All FortiGate models up to and including those with CP8 processors only support offloading DH bit sizes up to 2048 so any sizes larger than that are done in software and thus are relatively resource intensive.

Additional SSL load balancing and SSL offloading options

The following SSL load balancing and SSL offloading options are only available from the CLI:

```
ssl-client-session-state-max <sessionstates_int>
```

Enter the maximum number of SSL session states to keep for the segment of the SSL connection between the client and the FortiGate unit.

```
ssl-client-session-state-timeout <timeout_int>
```

Enter the number of minutes to keep the SSL session states for the segment of the SSL connection between the client and the FortiGate unit.

```
ssl-client-session-state-type {both | client | disable | time}
```

Select which method the FortiGate unit should use when deciding to expire SSL sessions for the segment of the SSL connection between the client and the FortiGate unit.

- both: Select to expire SSL session states when either ssl-client-session-state-max or ssl-client-session-state-timeout is exceeded, regardless of which occurs first.
- count: Select to expire SSL session states when ssl-client-session-state-max is exceeded.
- disable: Select to keep no SSL session states.
- time: Select to expire SSL session states when ssl-client-session-state-timeout is exceeded.

```
ssl-http-location-conversion {enable | disable}
```

Select to replace http with https in the reply's Location HTTP header field. For example, in the reply, Location: http://example.com/ would be converted to Location: https://example.com/

```
ssl-http-match-host {enable | disable}
```

Select to apply Location conversion to the reply's HTTP header only if the host name portion of Location matches the request's Host field, or, if the Host field does not exist, the host name portion of the request's URI. If disabled, conversion occurs regardless of whether the host names in the request and the reply match.

For example, if host matching is enabled, and a request contains Host: example.com and the reply contains Location: http://example.cc/, the Location field does not match the host of the original request and the reply's Location field remains unchanged. If the reply contains Location: http://example.com/, however, then the FortiGate unit detects the matching host name and converts the reply field to Location: https://example.com/.

This option appears only if ssl-http-location-conversion is enable.

```
ssl-send-empty-frags {enable | disable}
```

Select to precede the record with empty fragments to protect from attacks on CBC IV. You might disable this option if SSL acceleration will be used with an old or buggy SSL implementation which cannot properly handle empty fragments.

```
ssl-server-session-state-max <sessionstates_int>
```

Enter the maximum number of SSL session states to keep for the segment of the SSL connection between the server and the FortiGate unit.

```
ssl-server-session-state-timeout <timeout_int>
```

Enter the number of minutes to keep the SSL session states for the segment of the SSL connection between the server and the FortiGate unit. This option appears only if ssl-mode is full.

```
ssl-server-session-state-type {both | count | disable | time}
```

Select which method the FortiGate unit should use when deciding to expire SSL sessions for the segment of the SSL connection between the server and the FortiGate unit. This option appears only if ssl-mode is full.

- both: Select to expire SSL session states when either ssl-server-session-state-max or ssl-server-session-state-timeout is exceeded, regardless of which occurs first.
- count: Select to expire SSL session states when ssl-server-session-state-max is exceeded.
- disable: Select to keep no SSL session states.
- time: Select to expire SSL session states when ssl-server-session-state-timeout is exceeded.

SSL offloading support for Internet Explorer 6

In some cases the Internet Explorer 6 web browser may be able to access real servers. To resolve this issue, disable the ssl-send-empty-frags option:

```
config firewall vip
   edit vip_name
```

```
      set ssl-send-empty-frags disable
   end
```

You can disable this option if SSL acceleration will be used with an old or buggy SSL implementation that cannot properly handle empty fragments.

Selecting the cipher suites available for SSL load balancing

You can use the following command to view the complete list of cipher suites available for SSL offloading:

```
config firewall vip
   edit <vip-name>
      set type server-load-balance
      set server-type https
      set ssl-algorithm custom
         config ssl-cipher-suites
            edit 0
            set cipher ?
```

In most configurations the matching cipher suite is automatically selected but you can limit the set of cipher suites that are available for a given SSL offloading configuration. For example, use the following command to limit an SSL load balancing configuration to use the three cipher suites that support ChaCha20 and Poly1305:

```
config firewall vip
   edit <vip-name>
      set type server-load-balance
      set server-type https
      set ssl-algorithm custom
         config ssl-cipher-suites
            edit 1
            set cipher TLS-ECDHE-RSA-WITH-CHACHA20-POLY1305-SHA256
            next
            edit 2
            set cipher TLS-ECDHE-ECDSA-WITH-CHACHA20-POLY1305-SHA256
            next
            edit 3
            set cipher TLS-DHE-RSA-WITH-CHACHA20-POLY1305-SHA256
            end
         end
```

Disabling SSL/TLS re-negotiation

The vulnerability CVE-2009-3555 affects all SSL/TLS servers that support re-negotiation. FortiOS when configured for SSL/TLS offloading is operating as a SSL/TLS server. The IETF is working on a TLS protocol change that will fix the problem identified by CVE-2009-3555 while still supporting re-negotiation. Until that protocol change is available, you can use the `ssl-client-renegotiation` option to disable support for SSL/TLS re-negotiation. The default value of this option is `allow`, which allows an SSL client to renegotiate. You can change the setting to `deny` to abort any attempts by an SSL client to renegotiate. If you select `deny` as soon as a `ClientHello` message indicating a re-negotiation is received from the client FortiOS terminates the TCP connection.

Since SSL offloading does not support requesting client certificates the only circumstance in which a re-negotiation is required is when more than 2^32 bytes of data are exchanged over a single handshake. If you are sure that this volume of traffic will not occur then you can disable re-negotiation and avoid any possibility of the attack described in CVE-2009-3555.

The re-negotiation behavior can be tested using OpenSSL. The OpenSSL s_client application has the feature that the user can request that it do renegotiation by typing “R”. For example, the following shows a successful re-negotiation against a FortiGate unit configured with a VIP for 192.168.2.100:443:

```
$ openssl s_client -connect 192.168.2.100:443
   CONNECTED(00000003)
   depth=1 /C=US/ST=California/L=Sunnyvale/O=Fortinet/OU=Certificate

    RENEGOTIATING
19916:error:1409E0E5:SSL routines:SSL3_WRITE_BYTES:ssl handshake failure:s3_pkt.c:530:
```

Use the following command to check the SSL stats to see that the `renegotiations blocked` counter is now 1:

```
diagnose firewall vip virtual-server stats ssl
   ssl
      client
         connections total 0 active 0 max 0
         handshakes total 4 active 0 max 0 completed 4 abbreviated 0
         session states total 4 active 4 max 4
         cipher-suite failures 0
         embryonics total 0 active 0 max 0 terminated 0
         renegotiations blocked 1
      server
         connections total 0 active 0 max 0
         handshakes total 3 active 0 max 0 completed 2 abbreviated 1
         session states total 1 active 1 max 1
         cipher-suite failures 0
      internal error 0
      bad handshake length 0
      bad change cipher spec length 0
      pubkey too big 0
      persistence
         find 0 found 0 clash 0 addr 0 error 0
```

If the virtual server debug log is examined (diagnose debug appl vs -1) then at the point the re-negotiation is blocked there is a log:

```
vs ssl 12 handshake recv ClientHello
   vs ssl 12 handshake recv 1
       (0100005403014b5e056c7f573a563bebe0258c3254bbaff7046a461164f34f94f4f3d019c418000026

vs src 12 closed
vs ssl 12 close
vs sock 12 free
```

IP, TCP, and UDP load balancing

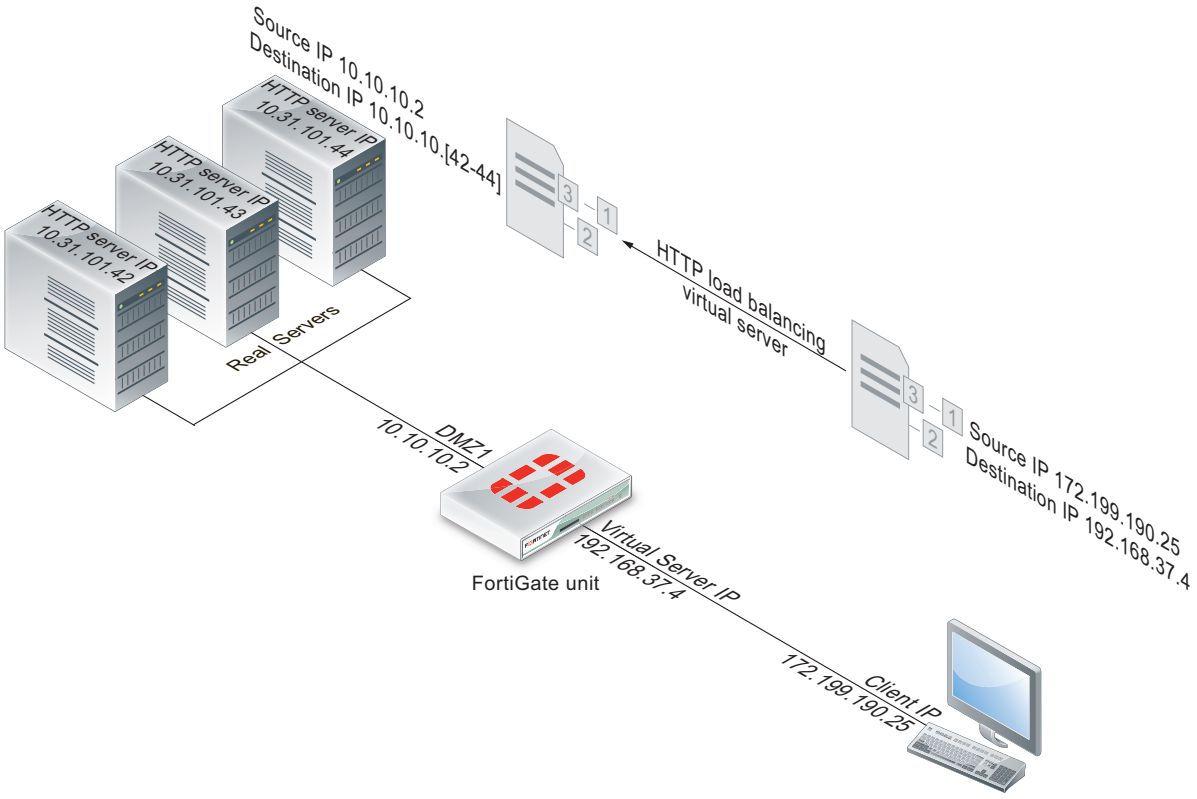
You can load balance all IP, TCP or UDP sessions accepted by the security policy that includes a load balancing virtual server with the type set to IP, TCP, or UDP. Traffic with destination IP and port that matches the virtual server IP and port is load balanced. For these protocol-level load balancing virtual servers you can select a load balance method and add real servers and health checking. However, you can't configure persistence, HTTP multiplexing and SSL offloading.

Example HTTP load balancing to three real web servers

In this example, a virtual web server with IP address 192.168.37.4 on the Internet, is mapped to three real web servers connected to the FortiGate unit dmz1 interface. The real servers have IP addresses 10.10.123.42, 10.10.123.43, and 10.10.123.44. The virtual server uses the **First Alive** load balancing method. The configuration also includes an HTTP health check monitor that includes a URL used by the FortiGate unit for get requests to monitor the health of the real servers.

Connections to the virtual web server at IP address 192.168.37.4 from the Internet are translated and load balanced to the real servers by the FortiGate unit. First alive load balancing directs all sessions to the first real server. The computers on the Internet are unaware of this translation and load balancing and see a single virtual server at IP address 192.168.37.4 rather than the three real servers behind the FortiGate unit.

Virtual server configuration example



Web-based manager configuration

Use the following procedures to configure this load balancing setup from the web-based manager.

To add an HTTP health check monitor

In this example, the HTTP health check monitor includes the **URL** "/index.html" and the **Matched Phrase** "Fortinet products".

1. Go to **Policy & Objects > Health Check**.
2. Select **Create New**.
3. Add an HTTP health check monitor that sends get requests to http://<real_server_IP_address>/index.html and searches the returned web page for the phrase "Fortinet products".

Name	HTTP_health_chk_1
Type	HTTP
Port	80
URL	/index.html
Matched Content	Fortinet products

Interval	10 seconds
Timeout	2 seconds
Retry	3

4. Select **OK**.

To add the HTTP virtual server

1. Go to **Policy & Objects > Virtual Servers**.
2. Select **Create New**.
3. Add an HTTP virtual server that allows users on the Internet to connect to the real servers on the internal network. In this example, the FortiGate wan1 interface is connected to the Internet.

Name	Load_Bal_VS1
Type	HTTP
Interface	wan1
Virtual Server IP	192.168.37.4 The public IP address of the web server. The virtual server IP address is usually a static IP address obtained from your ISP for your web server. This address must be a unique IP address that is not used by another host and cannot be the same as the IP address of the external interface the virtual IP will be using. However, the external IP address must be routed to the selected interface. The virtual IP address and the external IP address can be on different subnets. When you add the virtual IP, the external interface responds to ARP requests for the external IP address.
Virtual Server Port	80
Load Balance Method	First Alive
Persistence	HTTP cookie
HTTP Multiplexing	Select. The FortiGate unit multiplexes multiple client into a few connections between the FortiGate unit and each real HTTP server. This can improve performance by reducing server overhead associated with establishing multiple connections.
Preserve Client IP	Select The FortiGate unit preserves the IP address of the client in the `X-Forwarded-For` HTTP header.
Health Check	Move the HTTP_health_chk_1 health check monitor to the **Selected** list.

4. Select **OK**.

To add the real servers and associate them with the virtual server

1. Go to **Policy & Objects > Real Servers**.
2. Select **Create New**.
3. Configure three real servers that include the virtual server Load_Bal_VS1. Each real server must include the IP address of a real server on the internal network.
   Configuration for the first real server.

Virtual Server	Load_Bal_VS1
IP Address	10.10.10.42
Port	80
Weight	Cannot be configured because the virtual server does not include weighted load balancing.
Maximum Connections	0 Setting **Maximum Connections** to 0 means the FortiGate unit does not limit the number of connections to the real server. Since the virtual server uses **First Alive** load balancing you may want to limit the number of connections to each real server to limit the traffic received by each server. In this example, the **Maximum Connections** is initially set to 0 but can be adjusted later if the real servers are getting too much traffic.

   Configuration for the second real server.

Virtual Server	Load_Bal_VS1
IP Address	10.10.10.43
Port	80
Weight	Cannot be configured because the virtual server does not include weighted load balancing.
Maximum Connections	0 Setting **Maximum Connections** to 0 means the FortiGate unit does not limit the number of connections to the real server. Since the virtual server uses **First Alive** load balancing you may want to limit the number of connections to each real server to limit the traffic received by each server. In this example, the **Maximum Connections** is initially set to 0 but can be adjusted later if the real servers are getting too much traffic.

   Configuration for the third real server.

Virtual Server	Load_Bal_VS1
IP Address	10.10.10.44
Port	80

Weight	Cannot be configured because the virtual server does not include weighted load balancing.
Maximum Connections	0 Setting **Maximum Connections** to 0 means the FortiGate unit does not limit the number of connections to the real server. Since the virtual server uses **First Alive** load balancing you may want to limit the number of connections to each real server to limit the traffic received by each server. In this example, the **Maximum Connections** is initially set to 0 but can be adjusted later if the real servers are getting too much traffic.

To add the virtual server to a security policy

Add a wan1 to dmz1 security policy that uses the virtual server so that when users on the Internet attempt to connect to the web server's IP address, packets pass through the FortiGate unit from the wan1 interface to the dmz1 interface. The virtual IP translates the destination address of these packets from the virtual server IP address to the real server IP addresses.

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select **Create New**.
3. Configure the security policy:

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	wan1
Source Address	all (or a more specific address)
Outgoing Interface	dmz1
Destination Address	Load_Bal_VS1
Schedule	always
Service	HTTP
Action	ACCEPT
Log Allowed Traffic	Select to log virtual server traffic
Enable NAT	Select this option and select **Use Destination Interface Address**.

4. Select other security policy options as required.
5. Select **OK**.

CLI configuration

Use the following procedure to configure this load balancing setup from the CLI.

To configure HTTP load balancing

1. Use the following command to add an HTTP health check monitor that sends get requests to http://<real_server_IP_address>/index.html and searches the returned web page for the phrase “Fortinet products”.

```
config firewall ldb-monitor
   edit HTTP_health_chk_1
      set type http
      set port 80
      set http-get /index.html
      set http-match "Fortinet products"
      set interval 10
      set timeout 2
      set retry 3
   end
```

2. Use the following command to add an HTTP virtual server that allows users on the Internet to connect to the real servers on the internal network. In this example, the FortiGate wan1 interface is connected to the Internet.

```
config firewall vip
   edit Load-Bal_VS1
      set type server-load-balance
      set server-type http
      set ldb-method first-alive
      set http-multiplex enable
      set http-ip-header enable
      set extip 192.168.37.4
      set extintf wan1
      set extport 80
      set persistence http-cookie
      set monitor HTTP_health_chk_1
         config realservers
            edit 1
               set ip 10.10.10.42
               set port 80
            next
            edit 2
               set ip 10.10.10.43
               set port 80
            next
            edit 3
               set ip 10.10.10.44
               set port 80
         end
   end
```

3. Use the following command to add a security policy that includes the load balance virtual server as the destination address.

```
config firewall policy
   edit 0
      set srcintf wan1
      set srcaddr all
      set dstintf dmz1
      set dstaddr Load-Bal_VS1
      set action accept
      set schedule always
      set service ALL
      set nat enable
```

```
end
```

Configure other security policy settings as required.

Example Basic IP load balancing configuration

This example shows how to add a server load balancing virtual IP that load balances all traffic among 3 real servers. In the example the Internet is connected to `port2` and the virtual IP address of the virtual server is 192.168.20.20. The load balancing method is `weighted`. The IP addresses of the real servers are 10.10.10.1, 10.10.10.2, and 10.10.10.3. The weights for the real servers are 1, 2, and 3. The default weight is 1 and does not have to be changed for the first real server.

```
config firewall vip
   edit All_Load_Balance
      set type server-load-balance
      set server-type ip
      set extintf port2
      set extip 192.168.20.20
      set ldb-method weighted
         config realservers
            edit 1
               set ip 10.10.10.1
            next
            edit 2
               set ip 10.10.10.2
               set weight 2
            next
            edit 3
               set ip 10.10.10.3
               set weight 3
            end
   end
```

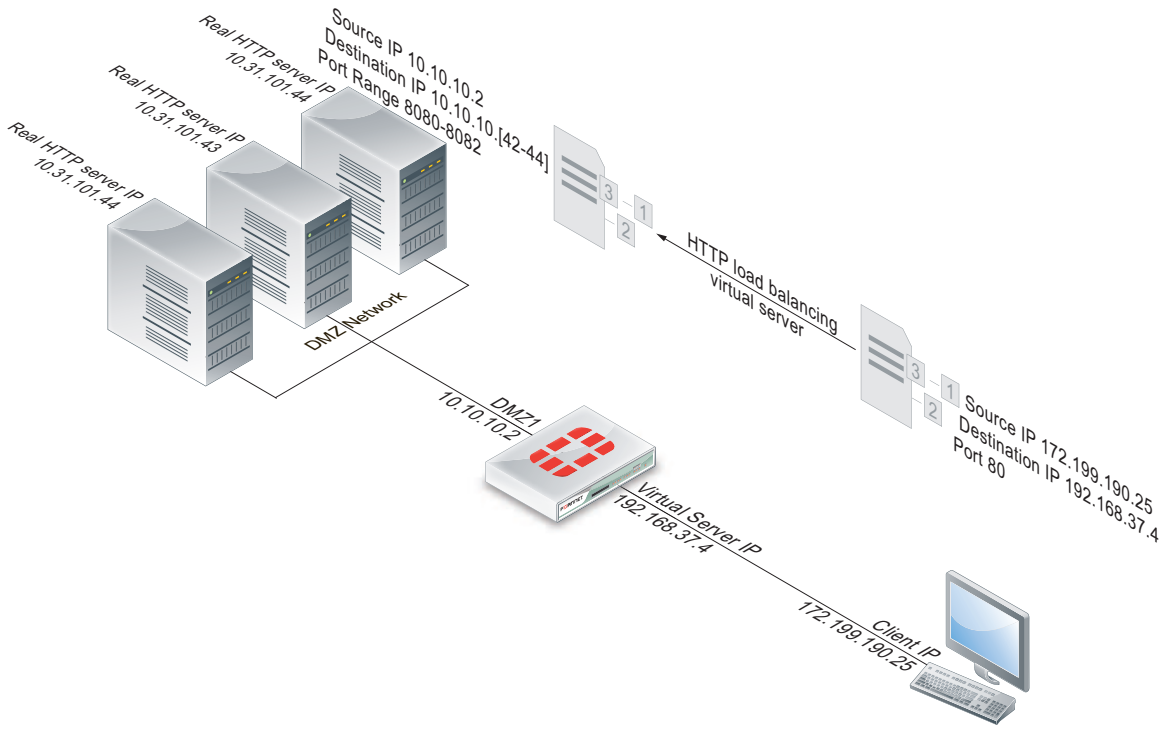
Example Adding a server load balance port forwarding virtual IP

In this example, a virtual web server with IP address 192.168.37.4 on the Internet, is mapped to three real web servers connected to the FortiGate unit dmz1 interface. The real servers have IP addresses 10.10.123.42, 10.10.123.43, and 10.10.123.44. The virtual server uses the **First Alive** load balancing method.

Each real server accepts HTTP connections on a different port number. The first real server accepts connections on port 8080, the second on port 8081, and the third on 8082. The configuration also includes an HTTP health check monitor that includes a URL used by the FortiGate unit for get requests to monitor the health of the real servers.

Connections to the virtual web server at IP address 192.168.37.4 from the Internet are translated and load balanced to the real servers by the FortiGate unit. First alive load balancing directs all sessions to the first real server. The computers on the Internet are unaware of this translation and load balancing and see a single virtual server at IP address 192.168.37.4 rather than the three real servers behind the FortiGate unit.

Server load balance virtual IP port forwarding



To complete this configuration, all of the steps would be the same as in Example Adding a server load balance port forwarding virtual IP on page 2871 except for configuring the real servers.

To add the real servers and associate them with the virtual server

Use the following steps to configure the FortiGate unit to port forward HTTP packets to the three real servers on ports 8080, 8081, and 8082.

1. Go to **Policy & Objects > Real Servers**.
2. Select **Create New**.
3. Configure three real servers that include the virtual server Load_Bal_VS1. Each real server must include the IP address of a real server on the internal network and have a different port number.

   Configuration for the first real server.

Virtual Server	Load_Bal_VS1
IP	10.10.10.42
Port	8080
Weight	Cannot be configured because the virtual server does not include weighted load balancing.
Maximum Connections	0

   Configuration for the second real server.

Virtual Server	Load_Bal_VS1
IP	10.10.10.43
Port	8081
Weight	Cannot be configured because the virtual server does not include weighted load balancing.
Maximum Connections	0

Configuration for the third real server.

Virtual Server	Load_Bal_VS1
IP	10.10.10.44
Port	8082
Weight	Cannot be configured because the virtual server does not include weighted load balancing.
Maximum Connections	0

Example Weighted load balancing configuration

This example shows how to using firewall load balancing to load balances all traffic among 3 real servers. In the example the Internet is connected to `port2` and the virtual IP address of the virtual server is 192.168.20.20. The load balancing method is `weighted`. The IP addresses of the real servers are 10.10.10.1, 10.10.10.2, and 10.10.10.3. The weights for the real servers are 1, 2, and 3.

This configuration does not include a health check monitor.

GUI configuration

Use the following procedures to configure this load balancing setup from the FortiGate GUI.

To add the HTTP virtual server

1. Go to **Policy & Objects > Virtual Servers**.
2. Select **Create New**.
3. Add an IP virtual server that allows users on the Internet to connect to the real servers on the internal network. In this example, the FortiGate port2 interface is connected to the Internet.

Name	HTTP_weghted_LB
Type	IP
Interface	port2
Virtual Server IP	192.168.20.20
Load Balance Method	Weighted

All other virtual server settings are not required or cannot be changed.

4. Select **OK**.

To add the real servers and associate them with the virtual server

1. Go to **Policy & Objects > Real Servers**.
2. Select **Create New**.
3. Configure three real servers that include the virtual server All_Load _Balance. Because the **Load Balancing Method** is **Weighted**, each real server includes a weight. Servers with a greater weight receive a greater proportion of forwarded connections,

   Configuration for the first real server.

Virtual Server	HTTP_weghted_LB
IP Address	10.10.10.1
Port	Cannot be configured because the virtual server is an IP server.
Weight	1
Maximum Connections	0 Setting **Maximum Connections** to 0 means the FortiGate unit does not limit the number of connections to the real server. Since the virtual server uses **First Alive** load balancing you may want to limit the number of connections to each real server to limit the traffic received by each server. In this example, the **Maximum Connections** is initially set to 0 but can be adjusted later if the real servers are getting too much traffic.

   Configuration for the second real server.

Virtual Server	HTTP_weghted_LB
IP Address	10.10.10.2
Port	Cannot be configured because the virtual server is an IP server.
Weight	2
Maximum Connections	0 Setting **Maximum Connections** to 0 means the FortiGate unit does not limit the number of connections to the real server. Since the virtual server uses **First Alive** load balancing you may want to limit the number of connections to each real server to limit the traffic received by each server. In this example, the **Maximum Connections** is initially set to 0 but can be adjusted later if the real servers are getting too much traffic.

   Configuration for the third real server.

Virtual Server	HTTP_weghted_LB
IP Address	10.10.10.3
Port	Cannot be configured because the virtual server is an IP server.
Weight	3
Maximum Connections	0 Setting **Maximum Connections** to 0 means the FortiGate unit does not limit the number of connections to the real server. Since the virtual server uses **First Alive** load balancing you may want to limit the number of connections to each real server to limit the traffic received by each server. In this example, the **Maximum Connections** is initially set to 0 but can be adjusted later if the real servers are getting too much traffic.

To add the virtual server to a security policy

Add a port2 to port1 security policy that uses the virtual server so that when users on the Internet attempt to connect to the web server's IP address, packets pass through the FortiGate unit from the wan1 interface to the dmz1 interface. The virtual IP translates the destination address of these packets from the virtual server IP address to the real server IP addresses.

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select **Create New**.
3. Configure the security policy:

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	port2
Source Address	all (or a more specific address)
Outgoing Interface	port1
Destination Address	HTTP_weghted_LB
Schedule	always
Service	ALL
Action	ACCEPT
Enable NAT	Select this option and select **Use Destination Interface Address**.

4. Select other security policy options as required.
5. Select **OK**.

CLI configuration

Load balancing is configured from the CLI using the `config firewall vip` command and by setting `type` to `server-load-balance`. The default weight is 1 and does not have to be changed for the first real server.

Use the following command to add the virtual server and the three weighted real servers.

```
config firewall vip
   edit HTTP_weghted_LB
      set type server-load-balance
      set server-type ip
      set extintf port2
      set extip 192.168.20.20
      set ldb-method weighted
         config realservers
            edit 1
               set ip 10.10.10.1
            next
            edit 2
               set ip 10.10.10.2
               set weight 2
            next
            edit 3
               set ip 10.10.10.3
               set weight 3
            end
   end
```

Example HTTP and HTTPS persistence configuration

This example shows how to add a virtual server named **HTTP_Load_Balance** that load balances HTTP traffic using port 80 and a second virtual server named **HTTPS_Load_Balance** that load balances HTTPS traffic using port 443. The Internet is connected to port2 and the virtual IP address of the virtual server is 192.168.20.20. Both server load balancing virtual IPs load balance sessions to the same three real servers with IP addresses 10.10.10.2, 10.10.10.2, and 10.10.10.3. The real servers provide HTTP and HTTPS services.

For both virtual servers, persistence is set to **HTTP Cookie** to enable HTTP cookie persistence.

To add the HTTP and HTTPS virtual servers

1. Go to **Policy & Objects > Virtual Servers**.
2. Add the HTTP virtual server that includes HTTP Cookie persistence.

Name	HTTP_Load_Balance
Type	HTTP
Interface	port2
Virtual Server IP	192.168.20.20

Virtual Server Port	80 In this example the virtual server uses port 8080 for HTTP sessions instead of port 80.
Load Balance Method	Static
Persistence	HTTP cookie

3. Select **OK**.
4. Select **Create New**.
5. Add the HTTPs virtual server that also includes HTTP Cookie persistence.

Name	HTTPS_Load_Balance
Type	HTTPS
Interface	port2
Virtual Server IP	192.168.20.20
Virtual Server Port	443
Load Balance Method	Static
Persistence	HTTP cookie

6. Select **OK**.

To add the real servers and associate them with the virtual servers

1. Go to **Policy & Objects > Real Servers**.
2. Select **Create New**.
3. Configure three real servers for HTTP that include the virtual server HTTP_Load_Balance.

   Configuration for the first HTTP real server.

Virtual Server	HTTP_Load_Balance
IP Address	10.10.10.1
Port	80
Weight	Cannot be configured because the virtual server does not include weighted load balancing.
Maximum Connections	0

   Configuration for the second HTTP real server.

Virtual Server	HTTP_Load_Balance
IP Address	10.10.10.2

Port	80
Weight	Cannot be configured because the virtual server does not include weighted load balancing.
Maximum Connections	0

Configuration for the third HTTP real server.

Virtual Server	HTTP_Load_Balance
IP Address	10.10.10.3
Port	80
Weight	Cannot be configured because the virtual server does not include weighted load balancing.
Maximum Connections	0

4. Configure three real servers for HTTPS that include the virtual server HTTPS_Load_Balance.

Configuration for the first HTTPS real server.

Virtual Server	HTTP_Load_Balance
IP Address	10.10.10.1
Port	443
Weight	Cannot be configured because the virtual server does not include weighted load balancing.
Maximum Connections	0

Configuration for the second HTTPS real server.

Virtual Server	HTTP_Load_Balance
IP Address	10.10.10.2
Port	443
Weight	Cannot be configured because the virtual server does not include weighted load balancing.
Maximum Connections	0

Configuration for the third HTTPS real server.

Virtual Server	HTTPS_Load_Balance
IP Address	10.10.10.3

Port	443
Weight	Cannot be configured because the virtual server does not include weighted load balancing.
Maximum Connections	0

To add the virtual servers to security policies

Add a port2 to port1 security policy that uses the virtual server so that when users on the Internet attempt to connect to the web server's IP address, packets pass through the FortiGate unit from the wan1 interface to the dmz1 interface. The virtual IP translates the destination address of these packets from the virtual server IP address to the real server IP addresses.

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select **Create New**.
3. Configure the HTTP security policy:

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	port2
Source Address	all
Outgoing Interface	port1
Destination Address	HTTP_Load_Balance
Schedule	always
Service	HTTP
Action	ACCEPT
Enable NAT	Select this option and select **Use Destination Interface Address**.

4. Select other security policy options as required.
5. Select **OK**.
6. Select **Create New**.
7. Configure the HTTP security policy:

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	port2
Source Address	all
Outgoing Interface	port1
Destination Address	HTTPS_Load_Balance

Schedule	always
Service	HTTPS
Action	ACCEPT
Enable NAT	Select this option and select **Use Destination Interface Address**.

8. Select other security policy options as required.
9. Select **OK**.

CLI configuration: adding persistence for a specific domain

Load balancing is configured from the CLI using the `config firewall vip` command and by setting `type` to `server-load-balance`.

For the CLI configuration, both virtual servers include setting `http-cookie-domain` to `.example.org` because HTTP cookie persistence is just required for the `example.org` domain.

First, the configuration for the HTTP virtual IP:

```
config firewall vip
   edit HTTP_Load_Balance
      set type server-load-balance
      set server-type http
      set extport 8080
      set extintf port2
      set extip 192.168.20.20
      set persistence http-cookie
      set http-cookie-domain .example.org
         config realservers
            edit 1
               set ip 10.10.10.1
            next
            edit 2
               set ip 10.10.10.2
            next
            edit 3
               set ip 10.10.10.3
            end
   end
```

Second, the configuration for the HTTPS virtual IP. In this configuration you don't have to set `extport` to `443` because `extport` is automatically set to `443` when `server-type` is set to `https`.

```
config firewall vip
   edit HTTPS_Load_Balance
      set type server-load-balance
      set server-type https
      set extport 443
      set extintf port2
      set extip 192.168.20.20
      set persistence http-cookie
      set http-cookie-domain .example.org
         config realservers
            edit 1
               set ip 10.10.10.1
```

```
            next
            edit 2
               set ip 10.10.10.2
            next
            edit 3
               set ip 10.10.10.3
            end
      end
```

Chapter 28 - SSL VPN

The following chapters are included in this document:

SSL VPN Overview provides useful general information about VPN and SSL, how the FortiGate unit implements them, and gives guidance on how to choose between SSL and IPsec.

Basic configuration explains how to configure the FortiGate unit and the web portal. Along with these configuration details, this chapter also explains how to grant unique access permissions, how to configure the SSL encryption key algorithm, and describes the SSL VPN OS Patch Check feature that allows a client with a specific OS patch to access SSL VPN services.

The SSL VPN client provides an overview of the FortiClient software required for tunnel mode, where to obtain the software, how to install it, and the configuration information required for remote users to connect to the internal network.

The SSL VPN web portal provides an overview of the SSL VPN web portal, with explanations of how to use and configure the web portal features.

Setup examples explores several configuration scenarios with step-by-step instructions. While the information provided is enough to set up the described SSL VPN configurations, these scenarios are not the only possible SSL VPN setups.

Troubleshooting provides some general maintenance and troubleshooting procedures for SSL VPNs.

What's new in FortiOS 5.4

This chapter describes new SSL VPN features added to FortiOS 5.4.0 and FortiOS 5.4.1.

FortiOS 5.4.1

These features first appeared in FortiOS 5.4.1.

Control the cipher suites that can be used by an SSL VPN (304741)

Administrators can now ban the use of specific cipher suites in the CLI for SSL VPN, so PCI-DSS (Payment Card Industry Data Security Standard) certification can be met.

CLI syntax

```
config vpn ssl settings
   set banned-cipher [RSA | DH | DHE | ECDH | ECDHE | DSS | ECDSA | AES | AESGCM |
       CAMELLIA | 3DES | SHA1 | SHA256 | SHA384]
```

SSL VPN monitor enhancements (258700)

SSL VPN monitor GUI page is updated, with additional usability improvements.

Change to SSL VPN authentication (306982)

SSL VPN authentication has been refined to fix an issue regarding authentication policies being ignored.

Local and remote users with multiple groups and policies will authenticate with the first matched policy (user in policy has higher priority), and traffic will go through all matched policies.

FortiOS 5.4.0

These features first appeared in FortiOS 5.4.0.

Significant SSL VPN web portal improvements (287328, 292726, 299319)

Significant updates and improvements have been made to the SSL VPN web portal in preparation for future browser updates, and in order to support all browsers:

- SSL VPN web portal redesigned.
- SSL VPN tunnel mode widget no longer works in the web portal. The tunnel mode widget used a deprecated NPAPI plugin mechanism to send the tunnel client to the browser for local system execution—this is a popular exploitation vector. FortiClient is now required for tunnel mode SSL VPN.
- SSL VPN Web mode RDP Native java applet removed.
- Removed unnecessary options from RDP bookmark and changed to HTML5 RDP.
- Cache cleaning function has been removed.
- If updating to 5.4.1, see above (258700).

Implement post-authentication CSRF protection in SSL VPN web mode (287180)

This attribute can enable/disable verification of a referrer in the HTTP request header in order to prevent a Cross-Site Request Forgery attack.

Syntax:

```
config vpn ssl settings
   set check-referer [enable|disable]
end
```

Group-based SSL VPN bookmarks (292125)

This CLI-only feature allows administrators to add bookmarks for groups of users. SSL VPN will only output the matched group-name entry to the client.

Syntax:

```
config vpn ssl web portal
   edit "portal-name"
      set user-group-bookmark enable*/disable
   next
end
config vpn ssl web user-group-bookmark
   edit "group-name"
      config bookmark
         edit "bookmark1"
         ....
         next
      end
   next
end
```

DTLS support (227138)

The Datagram Transport Layer Security (DTLS) protocol is supported for SSL VPN connections. DTLS support can be enabled in the CLI as described below.

Syntax

```
config vpn ssl settings
   set dtls-tunnel [enable | disable] (default: enabled)
end
```

Added options to allow firewall addresses to be used in routing table for SSL VPN (265430)

If destination **Named Address** is set in **Network > Static Routes** and **Address Range** is set to **Automatically assign addresses** in **VPN > SSL-VPN Settings**, SSL VPN should refresh the routing table automatically.

HTTP to HTTPS redirect support (278728)

The admin HTTP port can now be redirected to the admin HTTPS port. This is enabled in **VPN > SSL-VPN Settings** using the option **Redirect port 80 to this login port**.

There are two likely scenarios for this:

- SSL VPN is not in use, in which case the admin GUI runs on port 443 or 10443, and port 80 is redirected.
- SSL VPN runs on port 443, in which case port 80 is redirected to 443 and the admin port runs on 10443.

If the administrator chooses to run SSL VPN on port 80, the redirect option is invalid.

This can also be configured in the CLI as described below.

Syntax:

```
config vpn ssl settings
   set https-redirect [enable | disable] (default: disabled)
end
```

Removed guest group and SSO group (303041)

Guest group and SSO group have been removed from `config user group` and `config vpn ssl web user-group-bookmark`.

CLI changes (299319)

Removed the following obsolete/unnecessary portal options from the CLI:

```
config vpn ssl web portal
   edit <name>
      set auto-prompt-mobile-user-download   REMOVED
      set display-forticlient-download   REMOVED
      set display-history-limit   REMOVED
      set page-layout   REMOVED
      set cache-cleaner   REMOVED
   end
```

Removed the following unnecessary RDP bookmark options from the CLI in preparation for HTML5 RDP:

```
config vpn ssl web <user-bookmark|user-group-bookmark>
   edit <group/user name>
      config bookmarks
         edit <bookmark>
            set full-screen-mode   REMOVED
            set screen-height   REMOVED
            set screen-width   REMOVED
            set keyboard-layout   REMOVED
         end
      end
```

SSL VPN Overview

As organizations have grown and become more complex, secure remote access to network resources has become critical for day-to-day operations. In addition, businesses are expected to provide clients with efficient, convenient services including knowledge bases and customer portals. Employees traveling across the country or around the world require timely and comprehensive access to network resources. As a result of the growing need for providing remote/mobile clients with easy, cost-effective and secure access to a multitude of resources, the concept of a Virtual Private Network (VPN) was developed.

SSL VPNs establish connectivity using SSL, which functions at Levels 4 - 5 (Transport and Session layers). Information is encapsulated at Levels 6 - 7 (Presentation and Application layers), and SSL VPNs communicate at the highest levels in the OSI model. SSL is not strictly a Virtual Private Network (VPN) technology that allows clients to connect to remote networks in a secure way. A VPN is a secure logical network created from physically separate networks. VPNs use encryption and other security methods to ensure that only authorized users can access the network. VPNs also ensure that the data transmitted between computers cannot be intercepted by unauthorized users. When data is encoded and transmitted over the Internet, the data is said to be sent through a “VPN tunnel”. A VPN tunnel is a non-application oriented tunnel that allows the users and networks to exchange a wide range of traffic regardless of application or protocol.

The advantages of a VPN over an actual physical private network are two-fold. Rather than utilizing expensive leased lines or other infrastructure, you use the relatively inexpensive, high-bandwidth Internet. Perhaps more important though is the universal availability of the Internet. In most areas, access to the Internet is readily obtainable without any special arrangements or long wait times.

SSL (Secure Sockets Layer) as HTTPS is supported by most web browsers for exchanging sensitive information securely between a web server and a client. SSL establishes an encrypted link, ensuring that all data passed between the web server and the browser remains private and secure. SSL protection is initiated automatically when a user (client) connects to a web server that is SSL-enabled. Once the successful connection is established, the browser encrypts all the information before it leaves the computer. When the information reaches its destination, it is decrypted using a secret (private) key. Any data sent back is first encrypted, and is decrypted when it reaches the client.

FortiOS supports the SSL and TLS versions defined below:

SSL and TLS version support table

Version	RFC
SSL 2.0	RFC 6176
SSL 3.0	RFC 6101
TLS 1.0	RFC 2246
TLS 1.1	RFC 4346
TLS 1.2	RFC 5246

SSL VPN modes of operation

When a remote client connects to the FortiGate unit, the FortiGate unit authenticates the user based on username, password, and authentication domain. A successful login determines the access rights of remote users according to user group. The user group settings specify whether the connection will operate in web-only mode or tunnel mode.

Web-only mode

Web-only mode provides remote users with a fast and efficient way to access server applications from any thin client computer equipped with a web browser. Web-only mode offers true clientless network access using any web browser that has built-in SSL encryption and the Sun Java Runtime Environment (note that there is no minimum Java/JRE version requirement—any version of Java/JRE currently supported by the supplier of the Java/JRE for the operating system should work).

Support for SSL VPN web-only mode is built into FortiOS. The feature comprises of an SSL daemon running on the FortiGate unit, and a web portal, which provides users with access to network services and resources including HTTP/HTTPS, Telnet, FTP, SMB/CIFS, VNC, RDP, and SSH.

In web-only mode, the FortiGate unit acts as a secure HTTP/HTTPS gateway and authenticates remote users as members of a user group. After successful authentication, the FortiGate unit redirects the web browser to the web portal home page and the user can access the server applications behind the FortiGate unit.

When the FortiGate unit provides services in web-only mode, a secure connection between the remote client and the FortiGate unit is established through the SSL VPN security in the FortiGate unit and the SSL security in the web browser. After the connection has been established, the FortiGate unit provides access to selected services and network resources through a web portal.

FortiGate SSL VPN web portals have a 1- or 2-column page layout and portal functionality is provided through small applets called widgets. Widget windows can be moved or minimized. The controls within each widget depend on its function. There are predefined web portals and the administrator can create additional portals.

Configuring the FortiGate unit involves selecting the appropriate web portal configuration in the user group settings. These configuration settings determine which server applications can be accessed. SSL encryption is used to ensure traffic confidentiality.

The following table lists the operating systems and web browsers supported by SSL VPN web-only mode.

VPN Web-only Mode, supported operating systems and web browsers

Operating System	Web Browser
Microsoft Windows 7 SP1 (32-bit/64-bit)	• Microsoft Internet Explorer version 11 • Mozilla Firefox version 46
Microsoft Windows 8/8.1 (32-bit/64-bit)	• Microsoft Internet Explorer version 11 • Mozilla Firefox version 46
Mac OS 10.9	• Safari 7
Linux CentOS version 6.5	• Mozilla Firefox version 46

Other operating systems and web browsers may function correctly, but are not supported by Fortinet.

Tunnel mode

In Tunnel mode, remote clients connect to a FortiGate unit that acts as a secure HTTP/HTTPS gateway and authenticates remote users as members of a user group.

The SSL VPN client encrypts all traffic from the remote client computer and sends it to the FortiGate unit through an SSL VPN tunnel over the HTTPS link between the user and the FortiGate unit. Another option is split tunneling, which ensures that only the traffic for the private network is sent to the SSL VPN gateway. Internet traffic is sent through the usual unencrypted route. This conserves bandwidth and alleviates bottlenecks.

When the user initiates a VPN connection with the FortiGate unit through the SSL VPN client, the FortiGate unit establishes a tunnel with the client and assigns the client a virtual IP address from a range of reserved addresses. The client uses the assigned IP address as its source address for the duration of the connection. After the tunnel has been established, the user can access the network behind the FortiGate unit.

SSL VPN conserve mode

FortiGate units perform all security profile processing in physical RAM. Since each model has a limited amount of memory, Kernel conserve mode is activated when the remaining free memory is nearly exhausted or the AV proxy has reached the maximum number of sessions it can service.

SSL VPN also has its own conserve mode. The FortiGate enters the SSL VPN conserve mode before the Kernel conserve mode in an attempt to prevent the Kernel conserve mode from triggering. During the SSL VPN conserve mode, no new SSL connections are allowed. It starts when free memory is <25% of the total memory (when the memory on the FortiGate is less than 512Mb) or <10% of the total memory (when the FortiGate has more than 512Mb built in).

To determine if the FortiGate has entered SSL VPN conserve mode - CLI

Run the following command in the CLI Console:

```
diagnose vpn ssl statistics
```

Result (showing conserve mode state in red):

```
SSLVPN statistics:
------------------
Memory unit:                    1
System total memory:            2118737920
System free memory:             218537984
SSLVPN memory margin:           314572800
SSLVPN state:                   conserve

Port forwarding mode

While tunnel mode provides a Layer 3 tunnel that users can run any application over, the user needs to install the tunnel client, and have the required administrative rights to do so. In some situations, this may not be desirable, yet the simple web mode does not provide enough flexibility for application support (for example, if you wish to use an email client that communicates with a POP3 server). The port forward mode, or proxy mode, provides this middle ground between web mode and tunnel mode.

SSL VPN port forwarding listens on local ports on the user's computer. When it receives data from a client application, the port forward module encrypts and sends the data to the FortiGate unit, which then forwards the traffic to the application server.

The port forward module is implemented with a Java applet, which is downloaded and runs on the user's computer. The applet provides the up-to-date status information such as addressing and bytes sent and received.

On the user end, the user logs into the FortiGate SSL VPN portal, and selects a port forward bookmark configured for a specific application. The bookmark defines the server address and port as well as which port to listen to on the user's computer.

The user must configure the application on the PC to point to the local proxy instead of the application server. For information on this configuration change, see the application documentation.

This mode only supports client/server applications that are using a static TCP port. It will not support client/server applications using dynamic ports or traffic over UDP.

Application support

With Citrix application servers, the server downloads an ICA configuration file to the user's PC. The client application uses this information to connect to the Citrix server. The FortiGate unit will read this file and append a SOCKS entry to set the SOCKS proxy to 'localhost'. The Citrix client will then be able to connect to the SSL VPN port forward module to provide the connection. When configuring the port forwarding module, a selection is available for Citrix servers.

For Windows Remote Desktop Connections, when selecting the RDP option, the tunnel will launch the RDP client and connect to the local loopback address after the port forward module has been initiated.

Note that the RDP/VNC web portals are **not** supported for the following platforms:

Platform	Model
FortiGate	80D, 92D, 200D, 200D-POE, 240D, 240D-POE, 600C, 800C, 1000C, 3240C, 3600C, and 5001C
FortiGate-Rugged	90D
FortiWiFi	92D

Antivirus and firewall host compatibility

The following tables list the antivirus and firewall client software packages that are supported in FortiOS.

Supported Windows XP antivirus and firewall software

Product supported	Antivirus	Firewall
Symantec Endpoint Protection V11	•	•
Kaspersky Antivirus 2009	•	
McAfee Security Center v8.1	•	•
Trend Micro Internet Security Pro	•	•
F-Secure Internet Security 2009	•	•

Supported Windows 7 32-bit and 64-bit antivirus and firewall software

Product supported	Antivirus	Firewall
CA Internet Security 2011	•	•
AVG Internet Security 2011		
F-Secure Internet Security 2011	•	•
Kaspersky Internet Security 2011	•	•
McAfee Internet Security 2011	•	•
Norton 360TM Version 4.0	•	•
NortonTM Internet Security 2011	•	•
Panda Internet Security 2011	•	•
Sophos Security Suite	•	•
Trend Micro Titanium Internet Security	•	•
ZoneAlarm Security Suite	•	•
Symantec Endpoint Protection Small Business Edition 12.0	•	•

Traveling and security

Because SSL VPN provides a means for “on-the-go” users to dial in to the network while away from the office, you need to ensure that wherever and however they choose to dial in is secure, and not potentially compromising the corporate network.

Host check

To reinforce security, you can enable a host integrity checker to scan the remote client. The integrity checker probes the remote client computer to verify that it is safe before access is granted. Security attributes recorded on the client computer (for example, in the Windows registry, in specific files, or held in memory due to running processes) are examined and uploaded to the FortiGate unit. For more information, see Host check on page 2911.

Host Check is applicable for both SSL VPN Web Mode and SSL VPN Tunnel mode.

SSL VPN and IPv6

FortiOS supports SSL VPN with IPv6 addressing, and is available for all the java applets (Telnet, VNC, RDP, and so on). IPv6 configurations for security policies and addressing include:

- Policy matching for IPv6 addresses
- Support for DNS resolving in SSL VPN
- Support IPv6 for ping
- FTP applications
- SMB

In essentially any of the following instructions, replace **IPv4** with **IPv6** to achieve the same desired results, but for IPv6 addresses and configurations.

Basic configuration

Configuring SSL VPN involves a number of configurations within FortiOS that you need to complete to make it all come together. This chapter describes the components required, and how and where to configure them to set up the FortiGate unit as an SSL VPN server. The configurations and steps are high level, to show you the procedures needed, and where to locate the options in FortiOS. For real-world examples, see Setup examples on page 2933.

There are three or four key steps to configuring an SSL VPN tunnel. The first three in the points below are mandatory, while the others are optional. This chapter outlines these key steps as well as additional configurations for tighter security and monitoring.

The key steps are:

- Create user accounts and user groups for the remote clients.
  (User accounts and groups on page 2892)
- Create a web portal to define user access to network resources.
  (Configuring SSL VPN web portals on page 2896)
- Configure the security policies.
  (Configuring security policies on page 2902)
- For tunnel-mode operation, add routing to ensure that client tunnel-mode packets reach the SSL VPN interface.
  (Routing in tunnel mode on page 2909)
- Setup logging of SSL VPN activities.
  (SSL VPN logs on page 2915)

This section contains the following information:

User accounts and groups

The first step for an SSL VPN tunnel is to add the users and user groups that will access the tunnel. You may already have users defined for other authentication-based security policies.

The user group is associated with the web portal that the user sees after logging in. You can use one policy for multiple groups, or multiple policies to handle differences between the groups such as access to different services, or different schedules.

To create a user account:

- In the web-based manager, go to **User & Device > User Definition**, and select **Create New.**
- In the CLI, use the commands in `config user local`.

All users accessing the SSL tunnel must be in a firewall user group. User names can be up to 64 characters long.

To create user groups:

- In the web-based manager, go to **User & Device > User Groups** and select **Create New**.
- In the CLI, use the commands in `config user group`.

Guest group and SSO group have been removed from `config user group` and `config vpn ssl web user-group-bookmark`.

Authentication

Remote users must be authenticated before they can request services and/or access network resources through the web portal. The authentication process can use a password defined on the FortiGate unit or optionally use established external authentication mechanisms such as RADIUS or LDAP.

To authenticate users, you can use a plain text password on the local FortiGate unit, forward authentication requests to an external RADIUS, LDAP or TACACS+ server, or utilize PKI certificates.

For information about how to create RADIUS, LDAP, TACACS+ or PKI user accounts and certificates, see the Authentication Guide.

FortiOS supports LDAP password renewal notification and updates through SSL VPN. Configuration is enabled using the CLI commands:

```
config user ldap
   edit <username>
       set server <domain>
       set password-expiry-warning enable
       set password-renewal enable
end
```

For more information, see the Authentication Guide.

MAC host check

When a remote client attempts to log in to the portal, you can have the FortiGate unit check against the client's MAC address to ensure that only a specific computer or device is connecting to the tunnel. This can ensure better security should a password be compromised.

MAC addresses can be tied to specific portals and can be either the entire MAC address or a subset of the address. MAC host checking is configured in the CLI using the folowing commands:

```
conf vpn ssl web portal
   edit portal
      set mac-addr-check enable
      set mac-addr-action allow
         config mac-addr-check-rule
            edit "rule1"
               set mac-addr-list 01:01:01:01:01:01 08:00:27:d4:06:5d
               set mac-addr-mask 48
         end
   end
```

IP addresses for users

After the FortiGate unit authenticates a request for a tunnel-mode connection, the FortiGate unit assigns the SSL VPN client an IP address for the session. The address is assigned from an IP Pool, which is a firewall address

defining an IP address range.

Take care to prevent overlapping IP addresses. Do not assign to clients any IP addresses that are already in use on the private network. As a precaution, consider assigning IP addresses from a network that is not commonly used (for example, 10.254.254.0/24).

To set tunnel-mode client IP address range - web-based manager:

1. Go to **Policy & Objects > Addresses** and select **Create New**.
2. Enter an **Name**, for example, `SSL_VPN_tunnel_range`.
3. Select a **Type** of **IP Range**.
4. In the **Subnet/IP Range** field, enter the starting and ending IP addresses that you want to assign to SSL VPN clients, for example `10.254.254.[80-100]`.
5. In **Interface**, select **Any**.
6. Select **OK**.

To set tunnel-mode client IP address range - CLI:

If your SSL VPN tunnel range is for example 10.254.254.80 - 10.254.254.100, you could enter

```
config firewall address
   edit SSL_tunnel_users
      set type iprange
      set end-ip 10.254.254.100
      set start-ip 10.254.254.80
   end
```

Authentication of remote users

When remote users connect to the SSL VPN tunnel, they must perform authentication before being able to use the internal network resources. This can be as simple as assigning users with their own passwords, connecting to an LDAP server or using more secure options. FortiOS provides a number of options for authentication as well as security option for those connected users.

The web portal can include bookmarks to connect to internal network resources. A web (HTTP/HTTPS) bookmark can include login credentials so that the FortiGate unit automatically logs the user into the website. This means that the user logs into the SSL VPN and then does not have to enter any more credentials to visit preconfigured web sites.

Both the administrator and the end user can configure bookmarks, including SSO bookmarks. To add bookmarks as a web portal user, see Using the Bookmarks widget on page 2925.

Setting the client authentication timeout

The client authentication timeout controls how long an authenticated user will remain connected. When this time expires, the system forces the remote client to authenticate again. As with the idle timeout, a shorter period of time is more secure. The default value is 28800 seconds (8 hours). You can only modify this timeout value in the CLI.

For example, to change the authentication timeout to 18 000 seconds, enter the following commands in the CLI:

```
config vpn ssl settings
   set auth-timeout 18000
```

```
end
```

You can also set the idle timeout for the client, to define how long the user does not access the remote resources before they are logged out.

Allow one-time login per user

You can set the SSL VPN tunnel such that each user can only log into the tunnel one time concurrently per user per login. That is, once logged into the portal, they cannot go to another system and log in with the same credentials again.

To allow one-time login per user - web-based manager:

Go to **VPN > SSL-VPN Portals**, select a portal, and enable **Limit Users to One SSL-VPN Connection at a Time.** It is disabled by default.

To allow one-time login per user - CLI:

```
config vpn ssl web portal
   edit <portal_name>
      set limit-user-logins enable
end
```

Strong authentication with security certificates

The FortiGate unit supports strong (two-factor) authentication through X.509 security certificates (version 1 or 3). The FortiGate unit can require clients to authenticate using a certificate, and the client can require the FortiGate unit to authenticate using a certificate.

For information about obtaining and installing certificates, see the Authentication Guide.

You can select the **Require Client Certificate** option so that clients must authenticate using certificates. The client browser must have a local certificate installed, and the FortiGate unit must have the corresponding CA certificate installed.

When the remote client initiates a connection, the FortiGate unit prompts the client browser for its client-side certificate as part of the authentication process.

To require client authentication by security certificates - web-based manager:

1. Go to **VPN > SSL-VPN Settings**.
2. Select **Require Client Certificate**.
3. Select **Apply**.

To require client authentication by security certificates - CLI:

```
config vpn ssl settings
   set reqclientcert enable
end
```

If your SSL VPN clients require strong authentication, the FortiGate unit must offer a CA certificate that the client browser has installed.

In the FortiGate unit SSL VPN settings, you can select which certificate the FortiGate offers to authenticate itself. By default, the FortiGate unit offers its factory installed (Fortinet_CA_SSLProxy) certificate from Fortinet to remote clients when they connect. If you leave the default setting, a warning appears that recommends you purchase a certificate for your domain and upload it for use.

To enable FortiGate unit authentication by certificate - web-based manager:

1. Go to **VPN > SSL-VPN Settings**.
2. From the **Server Certificate** list, select the certificate that the FortiGate unit uses to identify itself to SSL VPN clients.
3. Select **Apply**.

To enable FortiGate unit authentication by certificate - CLI:

For example, to use the `example_cert` certificate

```
config vpn ssl settings
   set servercert example_cert
end
```

FortiOS will check the server certificate to verify that the certificate is valid. Only valid server certificates should be used.

NSA Suite B cryptography support

FortiOS supports the use of ECDSA Local Certificates for SSL VPN Suite B. The National Security Agency (NSA) developed Suite B algorithms in 2005 to serve as a cryptographic base for both classified and unclassified information at an interoperable level.

FortiOS allows you to import, generate, and use ECDSA certificates defined by the Suite B cryptography set. To generate ECDSA certificates, use the following command in the CLI:

```
exec vpn certificate local generate ec <certificate-name_str> <elliptic-curve-name>
    <subject_str> [<optional_information>]
```

Configuring SSL VPN web portals

The SSL VPN portal enables remote users to access internal network resources through a secure channel using a web browser. FortiGate administrators can configure login privileges for system users as well as the network resources that are available to the users.

FortiOS supports LDAP password renewal notification and updates through SSL VPN. Configuration is enabled using the CLI commands:

```
config user ldap
   edit <username>
        set server <domain>
        set password-expiry-warning enable
        set password-renewal enable
end
```

For more information, see the Authentication Guide.

This step in the configuration of the SSL VPN tunnel sets up the infrastructure; the addressing, encryption, and certificates needed to make the initial connection to the FortiGate unit. This step is also where you configure what the remote user sees with a successful connection. The portal view defines the resources available to the remote users and the functionality they have on the network.

SSL connection configuration

To configure the basic SSL VPN settings for encryption and login options, go to **VPN > SSL-VPN Settings.**

Listen on Interface(s)	Define the interface which the FortiGate will use to listen for SSL VPN tunnel requests. This is generally your external interface.
Listen on Port	Enter the port number for HTTPS access.

Redirect port 80 to this login port	Enable to redirect the admin HTTP port to the admin HTTPS port.
	There are two likely scenarios for this:
	• SSL VPN is not in use, in which case the admin GUI runs on port 443 or 10443, and port 80 is redirected.
	• SSL VPN runs on port 443, in which case port 80 is redirected to 443 and the admin port runs on 10443.
	If the administrator chooses to run SSL VPN on port 80, the redirect option is invalid.
	This can also be configured in the CLI as shown below (note that HTTPS-redirect is disabled by default):
	Syntax:
	`config vpn ssl settings`
	`  set https-redirect [enable | disable]`
	`end`

Restrict Access	Restrict accessibility to either **Allow access from any host** or to **Limit access to specific hosts** as desired. If selecting the latter, you must specify the hosts.

Idle Logout	Type the period of time (in seconds) that the connection can remain inactive before the user must log in again. The range is from 10 to 28800 seconds. Setting the value to 0 will disable the idle connection timeout. This setting applies to the SSL VPN session. The interface does not time out when web application sessions or tunnels are up.
Server Certificate	Select the signed server certificate to use for authentication. If you leave the default setting (Fortinet_CA_SSLProxy), the FortiGate unit offers its built-in certificate from Fortinet to remote clients when they connect. A warning appears that recommends you purchase a certificate for your domain and upload it for use.
Require Client Certificate	Select to use group certificates for authenticating remote clients. When the remote client initiates a connection, the FortiGate unit prompts the client for its client-side certificate as part of the authentication process. For information on using PKI to provide client certificate authentication, see the Authentication Guide.
Address Range	Select **Automatically assign addresses** or **Specify custom IP ranges**. The latter will allow you to select the range or subnet firewall addresses that represent IP address ranges reserved for tunnel-mode SSL VPN clients.
DNS Server	If you select **Specify**, you may enter up to two DNS servers (IPv4 or IPv6) to be provided for the use of clients.
Specify WINS Servers	Enable to access options for entering up to two WINS servers (IPv4 or IPv6) to be provided for the use of clients.
Allow Endpoint Registration	Select so that FortiClient registers with the FortiGate unit when connecting. If you configured a registration key by going to **System > Config > Advanced**, the remote user is prompted to enter the key. This only occurs on the first connection to the FortiGate unit.

Portal configuration

The portal configuration determines what the remote user sees when they log in to the portal. Both the system administrator and the user have the ability to customize the SSL VPN portal.

To view the portals settings page, go to **VPN > SSL-VPN Portals**.

There are three pre-defined default portal configurations available:

- *full-access*
- *tunnel-access*
- *web-access*

Each portal type includes similar configuration options. Select between the different portals by double-clicking one of the default portals in the list. You can also create a custom portal by selecting the **Create New** option at the top.

Portal Setting	Description
Name	The name for the portal.
Limit Users to One SSL-VPN Connection at a Time	You can set the SSL VPN tunnel such that each user can only log into the tunnel one time concurrently per user per login. That is, once logged into the portal, they cannot go to another system and log in with the same credentials again. This option is disabled by default.
Tunnel Mode	These settings determine how tunnel mode clients are assigned IPv4 addresses.
Enable Split Tunneling	Select so that the VPN carries only the traffic for the networks behind the FortiGate unit. The user's other traffic follows its normal route. If you enable split tunneling, you are required to set the **Routing Address**, which is the address that your corporate network is using. Traffic intended for the Routing Address will not be split from the tunnel.
Source IP Pools	Select an IP Pool for users to acquire an IP address when connecting to the portal. There is always a default pool available if you do not create your own.
Tunnel Mode Client Options	These options affect how the FortiClient application behaves when connected to the FortiGate VPN tunnel. When enabled, a check box for the corresponding option appears on the VPN login screen in FortiClient, and is not enabled by default. • **Allow client to save password** - When enabled, if the user selects this option, their password is stored on the user's computer and will automatically populate each time they connect to the VPN. • **Allow client to connect automatically** - When enabled, if the user selects this option, when the FortiClient application is launched, for example after a reboot or system startup, FortiClient will automatically attempt to connect to the VPN tunnel. • **Allow client to keep connections alive** - When enabled, if the user selects this option, the FortiClient should try to reconnect once it detects the VPN connection is down unexpectedly (not manually disconnected by user).
Enable Web Mode	Select to enable web mode access.
Portal Message	This is a text header that appears on the top of the web portal.

Portal Setting	Description
Theme	Select a color styling specifically for the web portal.
Show Session Information	The **Show Session Information** widget displays the login name of the user, the amount of time the user has been logged in and the inbound and outbound traffic statistics.
Show Connection Launcher	Displays the **Connection Launcher** widget in the web portal.
Show Login History	Select to include user login history on the web portal.
User Bookmarks	Enable to allow users to add their own bookmarks in the web portal.
Predefined Bookmarks	Select to include bookmarks on the web portal. Bookmarks are used as links to internal network resources. When a bookmark is selected from a bookmark list, a pop-up window appears with the web page. Telnet, VNC, and RDP require a browser plugin. FTP and Samba replace the bookmarks page with an HTML file-browser.

Options to allow firewall address to be used in routing table for SSL VPN

If destination **Named Address** is set in **Network > Static Routes** and **Address Range** is set to **Automatically assign addresses** in **VPN > SSL-VPN Settings**, SSL VPN should refresh the routing table automatically.

If your network configuration does not contain a default SSL VPN portal, you might receive the error message “Input value is invalid” when you attempt to access **VPN > SSL-VPN Portals**.

To enable a default portal - CLI:

```
config vpn ssl settings
   set default-portal <full-access | tunnel-access |
    web-access>
end
```

Adding bookmarks

A web bookmark can include login credentials to automatically log the SSL VPN user into the website. When the administrator configures bookmarks, the website credentials must be the same as the user’s SSL VPN credentials. Users configuring their own bookmarks can specify alternative credentials for the website.

To add a bookmark - web-based manager:

1. On the **VPN > SSL-VPN Portals** page, ensure **Enable User Bookmarks** is enabled.
2. Select **Create New** and enter the following information:

Category	Select a category, or group, to include the bookmark. If this is the first bookmark added, you will be prompted to add a category. Otherwise, select **Create** from the drop-down list.
Name	Enter a name for the bookmark.
Type	Select the type of link from the drop-down list. Telnet, VNC, and RDP require a browser plugin. FTP and Samba replace the bookmarks page with an HTML file-browser.
URL	Enter the IP address source.
Description	Enter a brief description of the link.
Single Sign-On	Enable if you wish to use Single Sign-On (SSO) for any links that require authentication. When including a link using SSO, be sure to use the entire URL. For example, http://10.10.1.0/login, rather than just the IP address.

3. Select **OK**.

For more configuration options, see Configuring SSL VPN web portals on page 2896.

Personal bookmarks

The administrator has be ability to view bookmarks the remote client has added to their SSL VPN login in the bookmarks widget. This enables the administrator to monitor and, if needed, remove unwanted bookmarks that do not meet with corporate policy.

To view and maintain remote client bookmarks, go to **VPN > SSL-VPN Personal Bookmarks**.

For more information about available bookmark applications, see Applications available in the web portal on page 2924

To enable personal bookmarks:

1. Go to **System > Feature Select**.
2. Enable **SSL-VPN Personal Bookmark Management**.
3. Select **Apply**.

SSL VPN Realms

You can go to **VPN > SSL-VPN Realms** and create custom login pages for your SSL VPN users. You can use this feature to customize the SSL VPN login page for your users and also to create multiple SSL VPN logins for different user groups.

In order to create a custom login page using the web-based manager, this feature must be enabled using **Feature Select**.

Before you begin, copy the default login page text to a separate text file for safe-keeping. Afterward, if needed, you can restore the text to the original version.

To configure SSL VPN Realms - web-based manager:

1. Configure a custom SSL VPN login by going to **VPN > SSL-VPN Realms** and selecting **Create New**. Users access different portals depending on the URL they enter.
2. The first option in the custom login page is to enter the path of the custom URL.
   This path is appended to the address of the FortiGate unit interface to which SSL VPN users connect. The actual path for the custom login page appears beside the URL path field.
3. You can also limit the number of users that can access the custom login at any given time.
4. You can use HTML code to customize the appearance of the login page.
5. After adding the custom login, you must associate it with the users that will access the custom login. Do this by going to **VPN > SSL-VPN Settings** and adding a rule to the **Authentication/Portal Mapping** section.
6. Under **Authentication/Portal Mapping**, click **Create New** and select the user group(s) and the associated Realm.

To configure SSL VPN Realms - CLI:

```
config vpn ssl web realm
   edit <url-path>
      set login-page <content_str>
      set max-concurrent-user <int>
      set virtual-host <hostname_str>
   end
```

Where the following variables are set:

Variable	Description	Default
`edit <url-path>`	Enter the URL path to access the SSL-VPN login page. Do not include “http://”.	No default.
`login-page <content_str>`	Enter replacement HTML for SSL-VPN login page.	No default.
`max-concurrent-user <int>`	Enter the maximum number of concurrent users allowed. Range 0-65 535. 0 means unlimited.	0
`virtual-host <hostname_str>`	Enter the virtual host name for this realm. Optional. Maximum length 255 characters.	No default.

Configuring security policies

You will need at least one SSL VPN security policy. This is an identity-based policy that authenticates users and enables them to access the SSL VPN web portal. The SSL VPN user groups named in the policy determine who can authenticate and which web portal they will use. From the web portal, users can access protected resources or download the SSL VPN tunnel client application.

This section contains the procedures needed to configure security policies for web-only mode operation and tunnel-mode operation. These procedures assume that you have already completed the procedures outlined in Configuring security policies on page 2902.

If you will provide tunnel mode access, you will need a second security policy—an ACCEPT tunnel mode policy to permit traffic to flow between the SSL VPN tunnel and the protected networks.

Firewall addresses

Before you can create security policies, you need to define the firewall addresses you will use in those policies. For both web-only and tunnel mode operation, you need to create firewall addresses for all of the destination networks and servers to which the SSL VPN client will be able to connect.

For tunnel mode, you will already have defined firewall addresses for the IP address ranges that the FortiGate unit will assign to SSL VPN clients.

The source address for your SSL VPN security policies will be the predefined “all” address. Both the address and the netmask are `0.0.0.0`. The “all” address is used because VPN clients will be connecting from various addresses, not just one or two known networks. For improved security, if clients will be connecting from one or two known locations you should configure firewall addresses for those locations, instead of using the “all” address.

To create a firewall address, in the web-based manager, go to **Policy & Objects > Objects > Addresses**, and select **Create New.**

Create an SSL VPN security policy

At minimum, you need one SSL VPN security policy to authenticate users and provide access to the protected networks. You will need additional security policies only if you have multiple web portals that provide access to different resources. You can use one policy for multiple groups, or multiple policies to handle differences between the groups such as access to different services, or different schedules.

The SSL VPN security policy specifies:

- The incoming interface that corresponds to the ssl.root interface.
- The SSL VPN user groups that can use the security policy.
- The times (schedule) and types of services that users can access.
- The UTM features and logging that are applied to the connection.

Do not use ALL as the destination address. If you do, you will see the “Destination address of Split Tunneling policy is invalid” error when you enable Split Tunneling.

To create an SSL-VPN security policy - web-based manager:

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New.**
2. Enter the following information:

Incoming Interface	Select the virtual SSL VPN interface, such as **ssl.root.**
Outgoing Interface	Select the FortiGate network interface that connects to the protected network.

Source	Select to allow access only to holders of a (shared) group certificate. The holders of the group certificate must be members of an SSL VPN user group, and the name of that user group must be present in the Allowed field. See Configuring security policies on page 2902.
Destination Address	Select the firewall address you created that represents the networks and servers to which the SSL VPN clients will connect. If you want to associate multiple firewall addresses or address groups with the **Destination Interface/Zone**, from **Destination Address**, select the plus symbol. In the dialog box, move the firewall addresses or address groups from the **Available Addresses** section to the **Members** section, then select **OK**.
Schedule	Select **always**.
Service	Select services from the list. Select the ALL service to allow the user group access to all services.
Action	Select **Accept**.

Your identity-based policies are listed in the security policy table. The FortiGate unit searches the table from the top down to find a policy to match the client's user group. Using the move icon in each row, you can change the order of the policies in the table to ensure the best policy will be matched first. You can also use the icons to edit or delete policies. Furthermore, you can drag and drop policies in the policy list to rearrange their order.

To create an SSL VPN security policy - CLI:

Create the SSL VPN security policy by entering the following CLI commands.

```
config firewall policy
   edit <id>
      set srcintf ssl.root(sslvpn tunnel interface)
      set dstintf port2
      set srcaddr all
      set dstaddr OfficeLAN
      set nat enable
   end
```

Create a tunnel mode security policy

If your SSL VPN will provide tunnel mode operation, you need to create a security policy to enable traffic to pass between the SSL VPN virtual interface and the protected networks. This is in addition to the SSL VPN security policy that you created in the preceding section.

The SSL VPN virtual interface is the FortiGate unit end of the SSL tunnel that connects to the remote client. It is named `ssl.<vdom_name>`. In the root VDOM, for example, it is named `ssl.root`. If VDOMs are not enabled on your FortiGate unit, the SSL VPN virtual interface is also named ssl.root.

To configure the tunnel mode security policy - web-based manager:

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information and select **OK**.

Incoming Interface	Select the virtual SSL VPN interface, such as **ssl.root.**
Outgoing Interface	Select the FortiGate network interface that connects to the protected network.
Source Address	Select the firewall address you created that represents the IP address range assigned to SSL VPN clients, such as SSL_VPN_tunnel_users.
Source User(s)	Select to allow access only to holders of a (shared) group certificate. The holders of the group certificate must be members of an SSL VPN user group, and the name of that user group must be present in the Allowed field. See Configuring security policies on page 2902.
Destination Address	Select the firewall address that represents the networks and servers to which the SSL VPN clients will connect. To select multiple firewall addresses or address groups, select the plus sign next to the drop-down list.
Schedule	Select **always**.
Service	Select services from the list. Select the ALL service to allow the user group access to all services.
Action	Select **Accept**.
Enable NAT	Select **Enable NAT. (Optional)**

To configure the tunnel mode security policy - CLI:

```
config firewall policy
   edit <id>
      set srcintf ssl.root(sslvpn tunnel interface)
      set dstintf <dst_interface_name>
      set srcaddr <tunnel_ip_address>
      set dstaddr <protected_network_address_name>
      set schedule always
      set service ALL
      set nat enable
   end
```

This policy enables the SSL VPN client to initiate communication with hosts on the protected network. If you want to enable hosts on the protected network to initiate communication with the SSL VPN client, you should create another Accept policy like the preceding one but with the source and destination settings reversed.

You must also add a static route for tunnel mode operation.

Routing for tunnel mode

If your SSL VPN operates in tunnel mode, you must add a static route so that replies from the protected network can reach the remote SSL VPN client.

To add the tunnel mode route - web-based manager:

1. Go to **Network > Static Routes** and select **Create New**.

For low-end FortiGate units, go to **System > Network > Routing** and select **Create New**.

2. Enter the **Destination IP/Mask** of the tunnel IP address that you assigned to the users of the web portal.
3. Select the SSL VPN virtual interface for the **Device**.
4. Select **OK**.

To add the tunnel mode route - CLI:

If you assigned 10.11.254.0/24 as the tunnel IP range, you would enter:

```
config router static
   edit <id>
      set device ssl.root
      set dst 10.11.254.0/24
end
```

Split tunnel Internet browsing policy

With split tunneling disabled, all of the SSL VPN client's requests are sent through the SSL VPN tunnel. But the tunnel mode security policy provides access only to the protected networks behind the FortiGate unit. Clients will receive no response if they attempt to access Internet resources. You can enable clients to connect to the Internet through the FortiGate unit using a split tunnel Internet browsing policy.

To add an Internet browsing policy:

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information and select **OK**.

Incoming Interface	Select the virtual SSL VPN interface (**ssl.root**, for example).
Outgoing Interface	Select the FortiGate network interface that connects to the Internet.
Source	Select the firewall address you created that represents the IP address range assigned to SSL VPN clients.
Destination Address	Select **All**.
Action	Select **Accept**.
Enable NAT	Select **Enable**.

To configure the Internet browsing security policy - CLI:

To enable browsing the Internet through port1, you would enter:

```
config firewall policy
   edit 0
      set srcintf ssl.root
      set dstintf port1
      set srcaddr SSL_tunne_users
      set dstaddr all
      set schedule always
      set service ALL
      set nat enable
end
```

Enabling a connection to an IPsec VPN

You might want to provide your SSL VPN clients access to another network, such as a branch office, that is connected by an IPsec VPN. To do this, you need only to add the appropriate security policy. For information about route-based and policy-based IPsec VPNs, see the IPsec VPN Guide.

Route-based connection

To configure interconnection with a route-based IPsec VPN - web-based manager:

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information and select **OK**.

Incoming Interface	Select the virtual SSL VPN interface (**ssl.root**, for example).
Outgoing Interface	Select the virtual IPsec interface for your IPsec VPN.
Source	Select the firewall address that represents the IP address range assigned to SSL VPN clients.
Destination Address	Select the address of the IPsec VPN remote protected subnet.
Action	Select **ACCEPT**.
Enable NAT	Enable.

To configure interconnection with a route-based IPsec VPN - CLI:

If, for example, you want to enable SSL VPN users to connect to the private network (address name OfficeAnet) through the toOfficeA IPsec VPN, you would enter:

```
config firewall policy
   edit 0
      set srcintf ssl.root
      set dstintf toOfficeA
      set srcaddr SSL_tunnel_users
      set dstaddr OfficeAnet
      set action accept
      set nat enable
      set schedule always
      set service ALL
end
```

Policy-based connection

To configure interconnection with a policy-based IPsec VPN - web-based manager:

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information and select **OK**.

Incoming Interface	Select the virtual SSL VPN interface (**ssl.root**, for example).
Outgoing Interface	Select the FortiGate network interface that connects to the Internet.

Source	Select the firewall address that represents the IP address range assigned to SSL VPN clients.
Destination Address	Select the address of the IPsec VPN remote protected subnet.

3. Configure inbound NAT from the CLI:

```
config firewall policy
   edit 0
      set natinbound enable
   end
```

To configure interconnection with a policy-based IPsec VPN - CLI:

If, for example, you want to enable SSL VPN users to connect to the private network (address name OfficeAnet) through the OfficeA IPsec VPN, you would enter:

```
config firewall policy
   edit 0
      set srcintf ssl.root
      set dstintf port1
      set srcaddr SSL_tunnel_users
      set dstaddr OfficeAnet
      set action ipsec
      set schedule always
      set service ALL
      set inbound enable
      set outbound enable
      set natinbound enable
      set vpntunnel OfficeA
end
```

In this example, port1 is connected to the Internet.

Configuring encryption key algorithms

The FortiGate unit supports a range of cryptographic cipher suites to match the capabilities of various web browsers. The web browser and the FortiGate unit negotiate a cipher suite before any information (for example, a user name and password) is transmitted over the SSL link. You can only configure encryption key algorithms for SSL VPN in the CLI.

To configure encryption key algorithms - CLI:

Use the following CLI command,

```
config vpn ssl settings
   set algorithm <cipher_suite>
end
```

where one of the following variables replaces <*cipher_suite*>:

Variable	Description
`low`	Use any cipher suite; AES, 3DES, RC4, or DES.

Variable	Description
`medium`	Use a 128-bit or greater cipher suite; AES, 3DES, or RC4.
`high`	Use a ciper suite grather than 128 bits; AES or 3DES.

Note that the `algorithm <cipher_suite>` syntax is only available when the `sslvpn-enable` attribute is set to **enable**.

Additional configuration options

Beyond the basics of setting up the SSL VPN, you can configure a number of other options that can help to ensure your internal network is secure and can limit the possibility of attacks and viruses entering the network from an outside source.

Routing in tunnel mode

If you are creating a SSL VPN connection in tunnel mode, you need to add a static route so that replies from the protected network can reach the remote SSL VPN client.

To add the tunnel mode route - web-based manager:

1. Go to **Network > Static Routes** and select **Create New**.
2. Enter the **Destination IP/Mask** of the tunnel IP address that you assigned to the users of the web portal.
3. Select the SSL VPN virtual interface for the **Device**.
4. Select **OK**.

To add the tunnel mode route - CLI:

If you assigned 10.11.254.0/24 as the tunnel IP range, you would enter:

```
config router static
   edit <id>
      set device ssl.root
      set dst 10.11.254.0/24
end
```

DTLS tunneling to improve upload/download speed

The Datagram Transport Layer Security (DTLS) protocol is supported for SSL VPN connections. DTLS tunneling implementation avoids TCP over TCP issues and can improve throughput. DTLS support can be enabled in the CLI as described below:

To configure DTLS tunneling - CLI:

```
config vpn ssl settings
   set dtls-tunnel [enable | disable] (default: enabled)
end
```

Changing the port number for web portal connections

You can specify a different TCP port number for users to access the web portal login page through the HTTPS link. By default, the port number is 443 and users can access the web portal login page using the following default URL:

`https://<FortiGate_IP_address>:443/remote/login`

where `<FortiGate_IP_address>` is the IP address of the FortiGate interface that accepts connections from remote users.

To change the SSL VPN port - web-based manager:

1. If **Current VDOM** appears at the bottom left of the screen, select **Global** from the list of VDOMs.
2. Go to **VPN > SSL-VPN Settings**.
3. Type an unused port number in the **Listen on Port** field and select **Apply**.

To change the SSL VPN port - CLI:

This is a global setting. For example, to set the SSL VPN port to 10443, enter the following:

```
config vpn ssl settings
   set port 10443
end
```

HTTP to HTTPS redirect support

The admin HTTP port can be redirected to the admin HTTPS port. This is enabled in **VPN > SSL-VPN Settings** using the option **Redirect port 80 to this login port**.

There are two likely scenarios for this:

- SSL VPN is not in use, in which case the admin GUI runs on port 443 or 10443, and port 80 is redirected.
- SSL VPN runs on port 443, in which case port 80 is redirected to 443 and the admin port runs on 10443.

If the administrator chooses to run SSL VPN on port 80, the redirect option is invalid.

This can also be configured in the CLI as described below:

To redirect HTTP to HTTPS port - CLI:

```
config vpn ssl settings
   set https-redirect [enable | disable] (default: disabled)
end
```

SSL offloading

To configure SSL offloading, which allows or denies client renegotiation, you must use the CLI. This helps to resolve the issues that affect all SSL and TLS servers that support renegotiation, identified by the Common Vulnerabilities and Exposures system in CVE-2009-3555. The SSL offloading renegotiation feature is considered a workaround until the IETF permanently resolves the issue.

The CLI command is `ssl-client-renegotiation` and is found under the `config firewall vip` syntax.

Host check

When you enable AV, FW, or AV-FW host checking in the web portal Security Control settings, each client is checked for security software that is recognized by the Windows Security Center. As an alternative, you can create a custom host check that looks for security software selected from the Host Check list. For more information, see Additional configuration options on page 2909.

The Host Check list includes default entries for many security software products.

Host integrity checking is only possible with client computers running Microsoft Windows platforms.

To configure host checking - CLI:

To configure the full-access portal to check for AV and firewall software on client Windows computers, you would enter the following:

```
config vpn ssl web portal
   edit full-access
      set host-check av-fw
end
```

To configure the full-access portal to perform a custom host check for FortiClient Host Security AV and firewall software, you would enter the following:

```
config vpn ssl web portal
   edit full-access
      set host-check custom
      set host-check-policy FortiClient-AV FortiClient-FW
end
```

Replacing the host check error message

You can add your own host security check error message using either the web-based manager or the CLI. The default message reads: “Your PC does not meet the host checking requirements set by the firewall. Please check that your OS version or antivirus and firewall applications are installed and running properly or you have the right network interface.”

To replace the host check error message - web-based manager:

1. Navigate to **System > Replacement Messages** and select **Extended View** in the upper right corner.
2. Scroll down to **SSL VPN** and select **Hostcheck Error Message**.
3. Edit the text in the right-hand column below and select **Save**.
   If you are unhappy with the new message, you can restore the message to its default by selecting **Restore Default** instead of **Save**.

To replace the host check error message - CLI:

Configure the host check error message using the following command.

```
config system replacemsg sslvpn hostcheck-error
```

Creating a custom host check list

You can add your own software requirements to the host check list using the CLI. Host integrity checking is only possible with client computers running Microsoft Windows platforms. Enter the following commands:

```
config vpn ssl web host-check-software
   edit <software_name>
      set guid <guid_value>
      set type <av | fw>
      set version <version_number>
end
```

If known, enter the Globally Unique Identifier (GUID) for the host check application. Windows uses GUIDs to identify applications in the Windows Registry. The GUID can be found in the Windows registry in the HKEY_ CLASSES_ROOT section.

To obtain the exact versioning, in Windows, right-click on the .EXE file of the application and select **Properties**, then select the **Version** tab.

Host Check is applicable for both SSLVPN Web Mode and SSLVPN Tunnel mode.

Windows OS check

The Windows patch check enables you to define the minimum Windows version and patch level allowed when connecting to the SSL VPN portal. When the user attempts to connect to the web portal, FortiOS performs a query on the version of Windows the user has installed. If it does not match the minimum requirement, the connection is denied. The Windows patch check is configured in the CLI.

The following example shows you how to add an OS check to the 'g1portal' web portal. This OS check accepts all Windows XP users and Windows 2000 users running patch level 3.

To specify the acceptable patch level, you set the `latest-patch-level` and the `tolerance`. The lowest acceptable patch level is `latest-patch-level` minus `tolerance`. In this case, `latest-patch-level` is 3 and `tolerance` is 1, so 2 is the lowest acceptable patch level.

```
config vpn ssl web portal
   edit g1portal
      set os-check enable
      config os-check-list windows-2000
         set action check-up-to-date
         set latest-patch-level 3
         set tolerance 1
      end
      config os-check-list windows-xp
         set action allow
      end
   end
```

Host check for Windows firewall

The Windows built-in firewall does not have a GUID in root\securitycenter or root\securitycenter2, but you can use a registry value to detect the firewall status.

If Windows firewall is on, the following registry value will be set to 1:

- **KeyName:** HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\SharedAccess\Parameters\FirewallPolicy\StandardProfile
- **ValueName:** EnableFirewall

In FortiOS, use the registry-value-check feature to define the Windows Firewall software by entering the following in the CLI:

```
config vpn ssl web host-check-software
   edit "Microsoft-Windows-Firewall"
      config check-item-list
         edit 1
            set target
                "HKLM\\SYSTEM\\CurrentControlSet\\Services\\SharedAccess\\Parameters\\Firew
                allPolicy\\StandardProfile:EnableFirewall==1"
            set type registry
         next
         edit 2
            set target
                "HKLM\\SYSTEM\\CurrentControlSet\\Services\\SharedAccess\\Parameters\\Firew
                allPolicy\\PublicProfile:EnableFirewall==1"
            set type registry
         next
         edit 3
            set target
                "HKLM\\SYSTEM\\CurrentControlSet\\Services\\SharedAccess\\Parameters\\Firew
                allPolicy\\DomainProfile:EnableFirewall==1"
            set type registry
         next
      end
   set type fw
next
set host-check custom
set host-check-policy Microsoft-Windows-Firewall
```

Configuring virtual desktop

Available for 32-bit Windows XP, Windows Vista, and Windows 7 client PCs, the virtual desktop feature completely isolates the SSL VPN session from the client computer's desktop environment. All data is encrypted, including cached user credentials, browser history, cookies, temporary files, and user files created during the session. When the SSL VPN session ends normally, the files are deleted. If the session ends due to a malfunction, files might remain, but they are encrypted so that the information is protected.

When the user starts an SSL VPN session that has virtual desktop enabled, the virtual desktop replaces the user's normal desktop. When the virtual desktop exits, the user's normal desktop is restored.

Virtual desktop requires the Fortinet cache cleaner plugin. If the plugin is not present, it automatically downloads to the client computer.

To enable virtual desktop :

To enable virtual desktop on the full-access portal and apply the application control list 'List1', for example, you would enter:

```
config vpn ssl web portal
   edit full-access
      set virtual-desktop enable
      set virtual-desktop-app-list List1
   end
```

Configuring virtual desktop application control

You can control which applications users can run on their virtual desktop. To do this, you create an Application Control List of either allowed or blocked applications. When you configure the web portal, you select the list to use.

Configure the application control list in the CLI.

To create an Application Control List - CLI:

If you want to add 'BannedApp' to 'List1', a list of blocked applications, you would enter:

```
config vpn ssl web virtual-desktop-app-list
   edit "List1"
      set action block
      config apps
         edit "BannedApp"
            set md5s "06321103A343B04DF9283B80D1E00F6B"
         end
   end
```

Configuring client OS Check

The SSLVPN client OS Check feature can determine if clients are running the Windows 2000, Windows XP, Windows Vista or Windows 7 operating system. You can configure the OS Check to do any of the following:

- Allow the client access.
- Allow the client access only if the operating system has been updated to a specified patch (service pack) version.
- Deny the client access.

The OS Check has no effect on clients running other operating systems.

To configure OS Check:

OS Check is configurable only in the CLI.

```
config vpn ssl web portal
   edit <portal_name>
      set os-check enable
      config os-check-list {windows-2000 | windows-xp | windows-vista | windows-7}
         set action {allow | check-up-to-date | deny}
         set latest-patch-level {disable | 0 - 255}
         set tolerance {tolerance_num}
      end
   end
```

Adding WINS and DNS services for clients

You can specify the WINS or DNS servers that are made available to SSL-VPN clients.

DNS servers provide the IP addresses that browsers need to access web sites. For Internet sites, you can specify the DNS server that your FortiGate unit uses. If SSL VPN users will access intranet sites using URLs, you need to provide them access to the intranet's DNS server. You specify a primary and a secondary DNS server.

A WINS server provides IP addresses for named servers in a Windows domain. If SSL VPN users will access a Windows network, you need to provide them access to the domain WINS server. You specify a primary and a secondary WINS server.

To specify WINS and DNS services for clients - web-based manager:

1. Go to **VPN > SSL-VPN Settings**.
2. Next to **DNS Server** select **Specify**.
3. Enter the IP addresses of DNS servers in the **DNS Server** fields as needed. Fields are available for both IPv4 and IPv6 addresses.
4. Select **Specify WINS Servers**, and enter the IP addresses of WINS servers in the **WINS Server** fields as needed. Fields are available for both IPv4 and IPv6 addresses.
5. Select **Apply**.

To specify WINS and DNS services for clients - CLI:

```
config vpn ssl settings
   set dns-server1 <address_ipv4>
   set dns-server2 <address_ipv4>
   set wins-server1 <address_ipv4>
   set wins-server2 <address_ipv4>
end
```

Setting the idle timeout setting

The idle timeout setting controls how long the connection can remain idle before the system forces the remote user to log in again. For security, keep the default value of 5000 seconds or less. Set the timeout value to 0 to disable idle timeouts.

To set the idle timeout - web-based manager:

1. Go to **VPN > SSL-VPN Settings** and enable **Idle Logout**.
2. In the **Inactive For** field, enter the timeout value.
   The valid range is from 10 to 28800 seconds.
3. Select **Apply**.

To set the idle timeout - CLI:

```
config vpn ssl settings
   set idle-timeout <seconds_int>
end
```

SSL VPN logs

Logging is available for SSL VPN traffic so you can monitor users connected to the FortiGate unit and their activity. For more information on configuring logs on the FortiGate unit, see the Logging and Reporting Guide.

To enable logging of SSL VPN events - web-based manager:

1. Go to **Log & Report > Log Settings**.
2. Enable **Event Logging**, and select **VPN activity event**.
3. Select **Apply**.

To view the SSL VPN log data, in the web-based manager, go to **Log & Report** and select either the **Event Log** or **Traffic Log**.

In event log entries, look for the sub-types “sslvpn-session” and “sslvpn-user”.

For information about how to interpret log messages, see the FortiGate Log Message Reference.

Monitoring active SSL VPN sessions

You can go to **User & Device > Monitor** to view a list of active SSL VPN sessions. The list displays the user name of the remote user, the IP address of the remote client, and the time the connection was made. You can also see which services are being provided, and delete an active web session from the FortiGate unit.

To monitor SSL VPNs - web-based manager:

To view the list of active SSL VPN sessions, go to **Monitor > SSL-VPN Monitor**.

When a tunnel-mode user is connected, the **Description** field displays the IP address that the FortiGate unit assigned to the remote host.

If required, you can end a session/connection by selecting its checkbox and then clicking the **Delete** icon.

Importing and using a CA-signed SSL certificate

Use the following set of instructions to import a CA-signed SSL certificate and configure an SSL VPN using that certificate.

Import the signed certificate into your FortiGate device

1. Unzip the file downloaded from the CA.
   There should be two .CRT files: a CA certificate with bundle in the file name, and a local certificate.
2. Log in to your FortiGate unit and browse to **System > Certificates**.
3. Select **Create New > Local Certificate** to import the local certificate.
   The status of the certificate will change from PENDING to OK.
4. Import the CA certificate by selecting **Import > CA Certificate**.
   It will be listed in the CA Certificates section of the certificates list. You can now configure SSL VPN using the signed certificate.

Configure your FortiGate device to use the signed certificate

1. Log in to your FortiGate unit and browse to **VPN > SSL-VPN Settings**.
2. In the **Connection Settings** section, locate the **Server Certificate** field.
3. Select the new certificate from the drop-down menu.
4. Select **Apply** to configure SSL VPN to use the new certificate.

Implement post-authentication CSRF protection in SSL VPN web mode

This attribute can enable/disable verification of a referrer in the HTTP request header in order to prevent a Cross-Site Request Forgery attack.

Syntax:

```
config vpn ssl settings
   set check-referer [enable|disable]
```

```
end
```

DTLS support

The Datagram Transport Layer Security (DTLS) protocol is now supported for SSL VPN connections. DTLS allows datagram-based applications to communicate in a way that prevents eavesdropping, tampering, or message forgery. It is similar to the Transport Layer Security (TLS) protocol. DTLS support can be enabled in the CLI as described below.

Syntax

```
config vpn ssl settings
   set dtls-tunnel [enable | disable] (default: enabled)
end
```

Allow firewall address to be used in routing table for SSL VPN

If destination **Named Address** is set in **Network > Static Routes** and **Address Range is set to Automatically assign addresses** is enabled in **VPN > SSL-VPN Settings**, SSL VPN should refresh the routing table automatically.

To view the routes in the routing table, go to **Monitor > Routing Monitor**.

The SSL VPN client

The remote client connects to the SSL VPN tunnel in various ways, depending on the VPN configuration.

- Tunnel mode establishes a connection to the remote protected network that any application can use. If the client computer runs Microsoft Windows, they can download the tunnel mode client from the web portal.
  If the client computer runs Linux or Mac OS X, the user needs to download the tunnel mode client application from the Fortinet Support web site. See the Release Notes for your FortiOS firmware for the specific operating system versions that are supported.
- The virtual desktop application creates a virtual desktop on a user's PC and monitors the data read/write activity of the web browser running inside the virtual desktop. When the application starts, it presents a 'virtual desktop' to the user. The user starts the web browser from within the virtual desktop and connects to the SSL VPN web portal. The browser file/directory operation is redirected to a new location, and the data is encrypted before it is written to the local disk. When the virtual desktop application exits normally, all the data written to the disk is removed. If the session terminates abnormally (power loss, system failure, etc.), the data left behind is encrypted and unusable to the user. The next time you start the virtual desktop, the encrypted data is removed.

The SSL VPN standalone client installer for Windows is no longer supported in FortiOS 5.4. Users should use the FortiClient installer with the "VPN Only" option instead.

FortiClient

Remote users can use the FortiClient software to initiate an SSL VPN tunnel to connect to the internal network. FortiClient uses local port TCP 1024 to initiate an SSL encrypted connection to the FortiGate unit, on port TCP 443. When connecting using FortiClient, the FortiGate unit authenticates the FortiClient SSL VPN request based on the user group options. The FortiGate unit establishes a tunnel with the client and assigns a virtual IP address to the client PC. Once the tunnel has been established, the user can access the network behind the FortiGate unit.

FortiClient software is available for download at www.forticlient.com and is available for Windows, Mac OS X, Apple iOS, and Android.

Tunnel mode client configuration

The FortiClient SSL VPN tunnel client requires basic configuration by the remote user to connect to the SSL VPN tunnel. When distributing the FortiClient software, provide the following information for the remote user to enter once the client software has been started. Once entered, they can select **Connect** to begin an SSL VPN session.

Connection Name	If you have pre-configured the connection settings, select the connection from the list and then select **Connect**. Otherwise, enter the settings in the fields below.
Remote Gateway	Enter the IP address or FQDN of the FortiGate unit that hosts the SSL VPN.

Username	Enter your username.
Client Certificate	Use this field if the SSL VPN requires a certificate for authentication. Select the required certificate from the drop-down list. The certificate must be installed in the Internet Explorer certificate store.

The SSL VPN web portal

This chapter explains how to use and configure the web portal features. This chapter is written for end users as well as administrators.

The following topics are included:

Connecting to the FortiGate unit

You can connect to the FortiGate unit using a web browser. The URL of the FortiGate interface may vary from one installation to the next. If required, ask your FortiGate administrator for the URL of the FortiGate unit, and obtain a user name and password. You can connect to the web portal using an Android phone, iPhone, or iPad. The FortiGate unit will display the content of the portal to fit the device's screen.

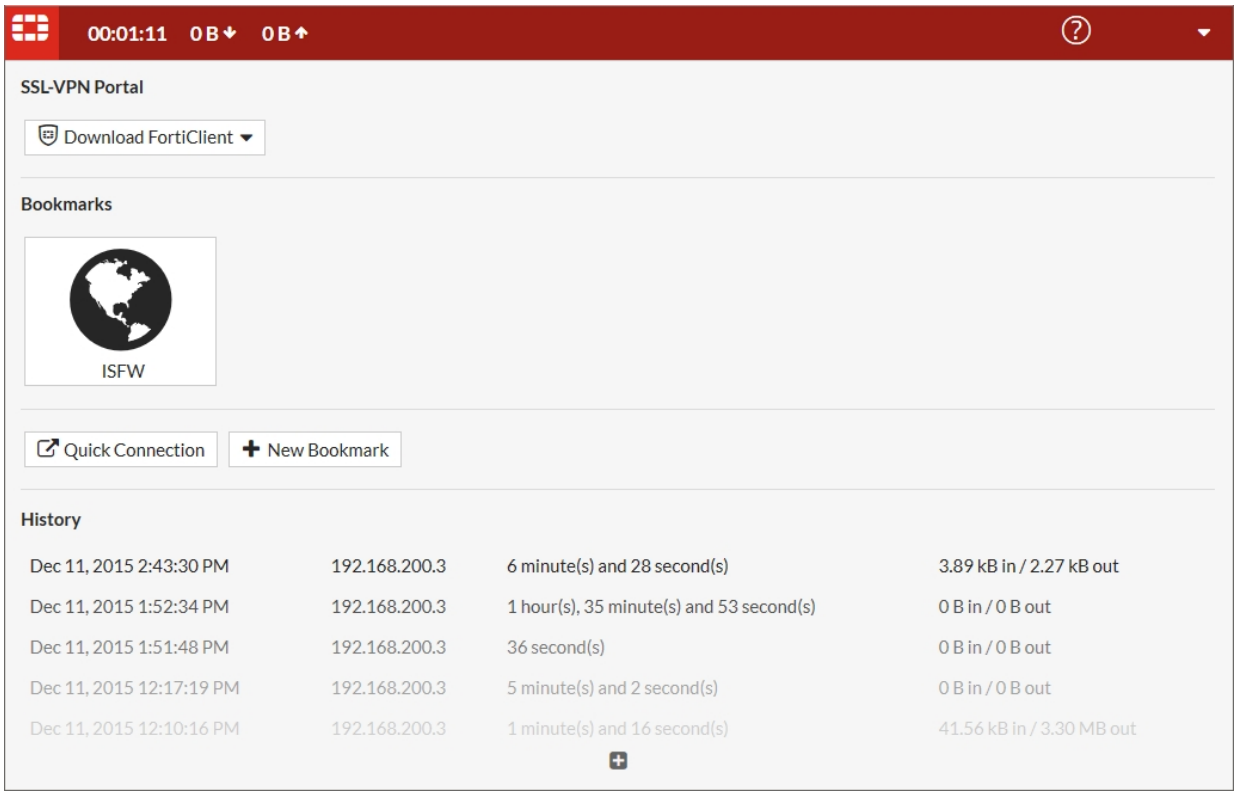
In addition, if you will be using a personal or group security (X.509) certificate to connect to the FortiGate unit, your web browser may prompt you for the name of the certificate. Your FortiGate administrator can tell you which certificate to select.

To log into the secure FortiGate HTTP gateway

1. Using the web browser on your computer, browse to the URL of the FortiGate unit (for example, `https://`<FortiGate_IP_address>`:443/remote/login`). The FortiGate unit may offer you a self-signed security certificate. If you are prompted to proceed, select **Yes**.
   A second message may be displayed to inform you that the FortiGate certificate distinguished name differs from the original request. This message is displayed because the FortiGate unit is attempting to redirect your web browser connection. You can ignore the message.
2. When you are prompted for your user name and password:
   - In the **Name** field, type your user name.
   - In the **Password** field, type your password.
3. Select **Login**.
   The FortiGate unit will redirect your web browser to the FortiGate SSL VPN web portal home page automatically.

Web portal overview

After logging in to the web portal, the remote user is presented with a web portal page similar to the following:



Various widgets provide the web portal's features:

- **Session Information** displays the elapsed time since login and the volume of HTTP and HTTPS traffic, both inbound and outbound.
- **Quick Connection** enables you to connect to network resources without using or creating a bookmark.
- **Download Forticlient** provides access to the FortiClient tunnel application for various operating systems.
- **Bookmarks** provides links to network resources. You can use the administrator-defined bookmarks and you can add your own bookmarks.

While using the web portal, you can select the **Help** button to get information to assist you in using the portal features. This information displays in a separate browser window.

When you have finished using the web portal, select the **Logout** button in the top right corner of the portal window.

After making any changes to the web portal configuration, be sure to select **Apply**.

Portal configuration

The SSL VPN web portal enables users to access network resources through a secure channel using a web browser. Fortinet administrators can configure log in privileges for system users and which network resources are available to the users.

The portal configuration determines what the user sees when they log in to the portal. Both the system administrator and the user have the ability to customize the SSL VPN portal.

There are three pre-defined default web portal configurations available:

- **full-access**: Includes all widgets available to the user - **Session Information**, **Tunnel Mode** options, **Connection Launcher**, **Remote Desktop**, and **Predefined Bookmarks**.
- **tunnel-access**: Includes **Session Information** and **Tunnel Mode** options.
- **web-access**: Includes **Session Information** and **Predefined Bookmarks** widgets.

You can also create your own web portal to meet your corporate requirements.

Portal page	
Create New	Creates a new web portal.
Edit	Select a portal from the list to enable the Edit option, and modify the portal configuration.
Delete	Removes a portal configuration. To remove multiple portals from the list, select the check box beside the portal names, then select **Delete**.
Name	The name of the web portal.
Ref.	Displays the number of times the object is referenced in other configurations on the FortiGate unit, such as security policies. To view the location of the referenced object, select the number in **Ref.** column. To view more information about how the object is used, select one of: **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. **Edit this object** – modifies settings within that particular setting that the object is referenced with. **View the details for this object** – similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with.

Portal settings

A web portal defines SSL VPN user access to network resources. The portal configuration determines what SSL VPN users see when they log in to the unit. Both the Fortinet administrator and the SSL VPN user have the ability to customize the web portal settings. Portal settings are configured in **VPN > SSL-VPN Portals**.

The following settings are available, allow you to configure general and security console options for your web portal.

Portal Setting	Description
Name	The name for the portal.
Limit Users to One SSL-VPN Connection at a Time	You can set the SSL VPN tunnel such that each user can only log into the tunnel one time concurrently per user per login. That is, once logged into the portal, they cannot go to another system and log in with the same credentials again. This option is disabled by default.
Tunnel Mode	These settings determine how tunnel mode clients are assigned IPv4 addresses.
Enable Split Tunneling	Select so that the VPN carries only the traffic for the networks behind the FortiGate unit. The user's other traffic follows its normal route. If you enable split tunneling, you are required to set the **Routing Address**, which is the address that your corporate network is using. Traffic intended for the Routing Address will not be split from the tunnel.
Source IP Pools	Select an IP Pool for users to acquire an IP address when connecting to the portal. There is always a default pool available if you do not create your own.
Tunnel Mode Client Options	These options affect how the FortiClient application behaves when connected to the FortiGate VPN tunnel. When enabled, a check box for the corresponding option appears on the VPN login screen in FortiClient, and is not enabled by default. • **Allow client to save password** - When enabled, if the user selects this option, their password is stored on the user's computer and will automatically populate each time they connect to the VPN. • **Allow client to connect automatically** - When enabled, if the user selects this option, when the FortiClient application is launched, for example after a reboot or system startup, FortiClient will automatically attempt to connect to the VPN tunnel. • **Allow client to keep connections alive** - When enabled, if the user selects this option, the FortiClient should try to reconnect once it detects the VPN connection is down unexpectedly (not manually disconnected by user).
Enable Web Mode	Select to enable web mode access.
Portal Message	This is a text header that appears on the top of the web portal.

Portal Setting	Description
Theme	Select a color styling specifically for the web portal.
Show Session Information	The **Show Session Information** widget displays the login name of the user, the amount of time the user has been logged in and the inbound and outbound traffic statistics.
Show Connection Launcher	Displays the **Connection Launcher** widget in the web portal.
Show Login History	Select to include user login history on the web portal.
User Bookmarks	Enable to allow users to add their own bookmarks in the web portal.
Predefined Bookmarks	Select to include bookmarks on the web portal. Bookmarks are used as links to internal network resources. When a bookmark is selected from a bookmark list, a pop-up window appears with the web page. Telnet, VNC, and RDP require a browser plugin. FTP and Samba replace the bookmarks page with an HTML file-browser.

Predefined Bookmarks

Bookmarks are used as links to specific resources on the network. When a bookmark is selected from a bookmark list, a pop-up window appears with the requested web page. Telnet, RDP, and VNC pop up a window that requires a browser plug-in. FTP and Samba replace the bookmarks page with an HTML file-browser.

Note that the RDP/VNC web portals are **not** supported for the following platforms:

Platform	Model
FortiGate	80D, 92D, 200D, 200D-POE, 240D, 240D-POE, 600C, 800C, 1000C, 3240C, 3600C, and 5001C
FortiGate-Rugged	90D
FortiWiFi	92D

A web bookmark can include login credentials to automatically log the SSL VPN user into the web site. When the administrator configures bookmarks, the web site credentials must be the same as the user's SSL VPN credentials. Users configuring their own bookmarks can specify alternative credentials for the web site.

Applications available in the web portal

Depending on the web portal configuration and user group settings, one or more of the following server applications are available to you through **Predefined Bookmarks**, as well as the **Quick Connection** widget:

- Citrix makes use of SOCKS so that the Citrix client can connect to the SSL VPN port forward module to provide the connection.
- FTP (File Transfer Protocol) enables you to transfer files between your computer and a remote host.

- HTTP/HTTPS accesses web pages.
- Port Forward provides the middle ground between web mode and tunnel mode. When the SSL VPN receives data from a client application, the data is encrypted and sent to the FortiGate unit, which then forwards the traffic to the application server.
- RDP (Remote Desktop Protocol), similar to VNC, enables you to remotely control a computer running Microsoft Terminal Services.
- SMB/CIFS implements the Server Message Block (SMB) protocol to support file sharing between your computer and a remote server host.
- SSH (Secure Shell) enables you to exchange data between two computers using a secure channel.
- TELNET (Teletype Network emulation) enables you to use your computer as a virtual text-only terminal to log in to a remote host.
- VNC (Virtual Network Computing) enables you to remotely control another computer, for example, accessing your work computer from your home computer.

Some server applications may prompt you for a user name and password. You must have a user account created by the server administrator so that you can log in.

Windows file sharing through SMB/CIFS is supported through shared directories.

Implementing post-authentication CSRF protection in SSL VPN web mode

This attribute can enable/disable verification of a referer in the HTTP request header in order to prevent a Cross-Site Request Forgery (CSRF) attack.

Syntax:

```
config vpn ssl settings
   set check-referer [enable|disable]
end
```

Using the Bookmarks widget

The Bookmarks widget shows both administrator-configured and user-configured bookmarks. Administrator bookmarks cannot be altered but you can add, edit or delete user bookmarks.

The FortiGate unit forwards client requests to servers on the Internet or internal network. To use the web-portal applications, you add the URL, IP address, or name of the server application to the My Bookmarks list. For more information, see Adding bookmarks on page 2925.

If you want to access a web server or telnet server without first adding a bookmark to the My Bookmarks list, use the Connection Tool instead. For more information, see Using the Bookmarks widget on page 2925.

Adding bookmarks

You can add frequently used connections as bookmarks. Afterward, select any hyperlink from the Bookmarks list to initiate a session.

To add a bookmark

1. In the web portal, select **New Bookmark**.
2. Enter the following information:

Name	Enter the name to display in the Bookmarks list.
Type	Select the abbreviated name of the server application or network service from the drop-down list.
Location	Enter the IP address or FQDN of the server application or network service. For RDP connections, you can append some parameters to control screen size and keyboard layout. See Using the Bookmarks widget on page 2925.
Description	Optionally enter a short description. The description displays when you pause the mouse pointer over the hyperlink.
SSO	Single Sign On (SSO) is available for HTTP/HTTPS bookmarks only. **Disabled** — This is not an SSO bookmark. **Automatic** — Use your SSL VPN credentials or an alternate set. See the **SSO Credentials** field. **Static** — Supply credentials and other required information (such as an account number) to a web site that uses an HTML form for authentication. You provide a list of the form field names and the values to enter into them. This method does not work for sites that use HTTP authentication, in which the browser opens a pop-up dialog box requesting credentials.
SSO fields	
SSO Credentials	**SSL VPN Login** — Use your SSL VPN login credentials. **Alternative** — Enter **Username** and **Password** below.
Username	Alternative username. Available if **SSO Credentials** is **Alternative**.
Password	Alternative password. Available if **SSO Credentials** is **Alternative**.
Static SSO fields	These fields are available if **SSO** is **Static**.
Field Name	Enter the field name, as it appears in the HTML form.
Value	Enter the field value. To use the values from **SSO Credentials**, enter `%passwd%` for password or `%username%` for username.
Add	Add another **Field Name / Value** pair.

3. Select **OK** and then select **Done**.

Group-based SSL VPN bookmarks

This CLI-only feature allows administrators to add bookmarks for groups of users. SSL VPN will only output the matched group-name entry to the client.

Syntax:

```
config vpn ssl web portal
   edit "portal-name"
      set user-group-bookmark enable*/disable
   next
end
conf vpn ssl web user-group-bookmark
   edit "group-name"
      conf bookmark
         edit "bookmark1"
         ....
         next
      end
   next
end
```

Group-based SSL VPN bookmarks

This CLI-only feature allows administrators to add bookmarks for groups of users. SSL VPN will only output the matched group-name entry to the client.

Syntax:

```
config vpn ssl web portal
   edit <portal-name>
      set user-group-bookmark [enable | disable]
   next
end
config vpn ssl web user-group-bookmark
   edit <group-name>
      config bookmark
         edit <bookmark1>
         ....
         next
      end
   next
end
```

Using the Quick Connection Tool

The **Quick Connection Tool** widget enables a user to connect to a resource when it isn't a predefined bookmark.

You can connect to any type of server without adding a bookmark to the **Bookmarks** list. The fields in the **Quick Connection Tool** enable you to specify the type of server and the URL or IP address of the host computer.

See the following procedures:

- To connect to a web server on page 2928
- To ping a host or server behind the FortiGate unit on page 2928
- To start a Telnet session on page 2928
- To start an FTP session on page 2929
- To start an SMB/CIFS session on page 2929
- To start an SSH session on page 2929
- To start an RDP session on page 2930
- To start a VNC session on page 2931

Except for ping, these services require that you have an account on the server to which you connect.

When you use **Quick Connection Tool**, the FortiGate unit may offer you its self-signed security certificate. Select **Yes** to proceed. A second message may be displayed to inform you of a host name mismatch. This message is displayed because the FortiGate unit is attempting to redirect your web browser connection. Select **Yes** to proceed.

To connect to a web server

1. In **Type**, select **HTTP/HTTPS**.
2. In the **Host** field, type the URL of the web server.
   For example: `http://www.mywebexample.com` or `https://172.20.120.101`
3. Select **Launch**.
4. To end the session, close the browser window.

To ping a host or server behind the FortiGate unit

1. In **Type**, select **Ping**.
2. In the **Host** field, enter the IP address of the host or server that you want to reach.
   For example: `10.11.101.22`
3. Select **Launch**.
   A message stating whether the IP address can be reached or not is displayed.

To start a Telnet session

1. In **Type**, select **Telnet**.
2. In the **Host** field, type the IP address of the telnet host.
   For example: `10.11.101.12`
3. Select **Launch**.
   A Telnet window opens.
4. Select **Connect**.
5. A telnet session starts and you are prompted to log in to the remote host.
   After you log in, you may enter any series of valid telnet commands at the system prompt.
6. To end the session, select **Disconnect** (or type `exit`) and then close the TELNET connection window.

To start an FTP session

1. In **Type**, select **FTP**.
2. In the **Host** field, type the IP address of the FTP server.
   For example: `10.11.101.12`
3. Select **Launch**.
   A login window opens.
4. Enter your user name and password and then select **Login**.
   You must have a user account on the remote host to log in.
5. Manipulate the files in any of the following ways:
   - To download a file, select the file link in the **Name** column.
   - To access a subdirectory (**Type** is **Folder**), select the link in the **Name** column.
   - To create a subdirectory in the current directory, select **New directory**.
   - To delete a file or subdirectory from the current directory, select its **Delete** icon.
   - To rename a file in the current directory, select its **Rename** icon.
   - To upload a file to the current directory from your client computer, select **Upload**.
   - When the current directory is a subdirectory, you can select **Up** to access the parent directory.
6. To end the FTP session, select **Logout**.

To start an SMB/CIFS session

1. In **Type**, select **SMB/CIFS**.
2. In the **Host** field, type the IP address of the SMB or CIFS server.
   For example: `10.11.101.12`
3. Select **Launch**.
4. Enter your user name and password and then select **Login**.
   You must have a user account on the remote host to log in.
5. Manipulate the files in any of the following ways:
   - To download a file, select the file link in the **Name** column.
   - To access a subdirectory (**Type** is **Folder**), select the file link in the **Name** column.
   - To create a subdirectory in the current directory, select **New Directory**.
   - To delete a file or subdirectory from the current directory, select its **Delete** icon.
   - To rename a file, select its **Rename** icon.
   - To upload a file from your client computer to the current directory, select **Upload**.
   - When the current directory is a subdirectory, you can select **Up** to access the parent directory.
6. To end the SMB/CIFS session, select **Logout** and then close the SMB/CIFS window.

To start an SSH session

1. In **Type**, select **SSH**.
2. In the **Host** field, type the IP address of the SSH host.
   For example: `10.11.101.12`
3. Select **Launch**.
   A login window opens.

4. Select **Connect**.
   A SSH session starts and you are prompted to log in to the remote host. You must have a user account to log in. After you log in, you may enter any series of valid commands at the system prompt.
5. To end the session, select **Disconnect** (or type `exit`) and then close the SSH connection window.

To start an RDP session

1. In **Type**, select **RDP**.
2. In the **Host** field, type the IP address of the RDP host.
   For example: `10.11.101.12`
3. Optionally, you can specify additional options for RDP by adding them to the **Host** field following the host address. See RDP options on page 2930 for information about the available options.
   For example, to use a French language keyboard layout you would add the `-m` parameter:
   `10.11.101.12 -m fr`
4. To log in to the remote host, type your user name and password. You must have a user account on the remote host to log in. Note that the user name should be entered in User Principal Name (UPN) format.
5. Select **Launch**.
   A login window opens.
6. When you see a screen configuration dialog, click **OK**.
   The screen configuration dialog does not appear if you specified the screen resolution with the host address.
7. Select **Login**.
   If you need to send Ctrl-Alt-Delete in your session, use Ctrl-Alt-End.
8. To end the RDP session, Log out of Windows or select **Cancel** from the Logon window.

Some Windows servers require a specific Security to be set for RDP sessions, such as Network Level Authentication (NLA) or Transport Layer Security (TLS), not the standard RDP encryption security. For example, Windows 10 requires the use of TLS.

RDP options

Locale/Keyboard Use this option if the remote computer might not use the same keyboard layout as your computer. Select the locale code that matches your computer.	-m <locale> The supported values of `<locale>` are:

ar	Arabic	it	Italian
da	Danish	ja	Japanese
de	German	lt	Lithuanian
de-ch	Swiss German	lv	Latvian
en-gb	British English	mk	Macedonian
en-uk	UK English	no	Norwegian
en-us	US English	pl	Polish
es	Spanish	pt	Portuguese
fi	Finnish	pt-br	Brazilian Portuguese
fr	French	ru	Russian
fr-be	Belgian French	sl	Slovenian
fr-ca	Canadian French	sv	Sudanese
fr-ch	Swiss French	tk	Turkmen
hr	Croatian	tr	Turkish
hu	Hungarian		

To start a VNC session

1. In **Type**, select **VNC**.
2. In the **Host** field, type the IP address of the VNC host.
   For example: `10.11.101.12`
3. Select **Launch**.
   A login window opens.
4. Type your user name and password when prompted to log in to the remote host.
   You must have a user account on the remote host to log in.
5. Select **OK**.
   If you need to send Ctrl-Alt-Delete in your session, press F8, then select **Send Ctrl-Alt-Delete** from the pop-up menu.
6. To end the VNC session, close the VNC window.

Note that the RDP/VNC web portals are **not** supported for the following platforms:

Platform	Model
FortiGate	80D, 92D, 200D, 200D-POE, 240D, 240D-POE, 600C, 800C, 1000C, 3240C, 3600C, and 5001C
FortiGate-Rugged	90D
FortiWiFi	92D

Using the SSL VPN virtual desktop

The virtual desktop feature is available for Windows only. When you start an SSL VPN session, the virtual desktop replaces your normal desktop. When the virtual desktop exits, your regular desktop is restored. Virtual desktop information is encrypted so that no information from it remains available after your session ends.

To use the SSL VPN virtual desktop, simply log in to an SSL VPN that requires the use of the virtual desktop. Wait for the virtual desktop to initialize and replace your desktop with the SSL VPN desktop, which has a Fortinet SSL VPN logo as wallpaper. Your web browser will open to the web portal page.

You can use the virtual desktop just as you use your regular desktop, subject to the limitations that virtual desktop application control imposes. If it is enabled in the web portal virtual desktop settings, you can switch between the virtual desktop and your regular desktop. Right-click the **SSL VPN Virtual Desktop** icon in the taskbar and select **Switch Desktop**.

To see the web portal virtual desktop settings, right-click the **SSL VPN Virtual Desktop** icon in the taskbar and select **Virtual Desktop Option**.

When you have finished working with the virtual desktop, right-click the SSL VPN Virtual Desktop icon in the taskbar and select **Exit**. Select **Yes** to confirm. The virtual desktop closes and your regular desktop is restored.

Using FortiClient

Remote users can use FortiClient Endpoint Security to initiate an SSL VPN tunnel to connect to the internal network. FortiClient uses local port TCP 1024 to initiate an SSL encrypted connection to the FortiGate unit, on port TCP 10443. When connecting using FortiClient, the FortiGate unit authenticates the FortiClient SSL VPN

request based on the user group options. the FortiGate unit establishes a tunnel with the client and assigns a virtual IP address to the client PC. Once the tunnel has been established, the user can access the network behind the FortiGate unit.

For information on configuring the FortiGate unit for SSL VPN connectivity, see Basic configuration on page 2892. For details on configuring FortiClient for SSL VPN connections, see the FortiClient documentation.

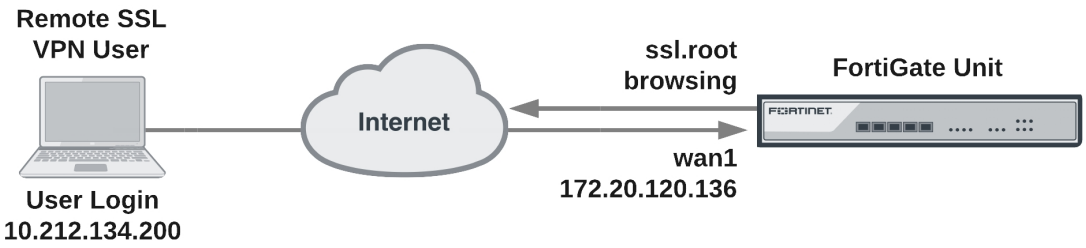
Setup examples

The examples in this chapter demonstrate the basic configurations needed for common connections to the SSL VPN tunnel and portals, applying the steps outlined in Basic configuration on page 2892.

The following examples are included:

Secure Internet browsing

This example sets up an SSL VPN tunnel that provides remote users the ability to access the Internet while traveling, and ensures that they are not subject to malware and other dangers, by using the corporate firewall to filter all of their Internet traffic. Essentially, the remote user will connect to the corporate FortiGate unit to surf the Internet.



Using SSL VPN and FortiClient SSL VPN software, you create a means to use the corporate FortiGate to browse the Internet safely.

Creating an SSL VPN IP pool and SSL VPN web portal

1. Go to **VPN > SSL-VPN Portals** and select *tunnel-access*.
2. For **Source IP Pools** select **SSLVPN_TUNNEL_ADDR1**.
3. Select **OK**.

Creating the SSL VPN user and user group

1. Create the SSL VPN user and add the user to a user group configured for SSL VPN use.
2. Go to **User & Device > User Definition** and select **Create New** to add the user:

User Name	twhite
Password	password

3. Select **OK**.
4. Go to **User & Device > User Groups** and select **Create New** to add `twhite` to a group called `SSL VPN`:

Name	SSL VPN
Type	Firewall

5. Move **twhite** to the **Members** list.
6. Select **OK**.

Creating a static route for the remote SSL VPN user

Create a static route to direct traffic destined for tunnel users to the SSL VPN tunnel.

1. Go to **Network > Static Routes** and select **Create New** to add the static route.

Destination IP/Mask	10.212.134.0/255.255.255.0
Device	ssl.root

The **Destination IP/Mask** matches the network address of the remote SSL VPN user.

2. Select **OK**.

Creating security policies

Create an SSL VPN security policy with SSL VPN user authentication to allow SSL VPN traffic to enter the FortiGate unit. Create a normal security policy from ssl.root to wan1 to allow SSL VPN traffic to connect to the Internet.

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Add an SSL VPN security policy as below, and click *OK*.

Incoming Interface	wan1
Source Address	all
Source User(s)	SSL VPN
Outgoing Interface	ssl.root

3. Select **Create New** to add a security policy that allows remote SSL VPN users to connect to the Internet:

Incoming Interface	ssl.root
Source Address	all
Source User(s)	SSL VPN
Outgoing Interface	wan1

Destination Address	all
Schedule	always
Service	ALL
Action	ACCEPT

4. Select **OK**.

Configuring authentication rules

1. Go to **VPN > SSL-VPN Settings** and select **Create New** under **Authentication/Portal Mapping**.
2. Add an authentication rule for the remote user:

Users/Groups	Tunnel
Portal	tunnel-access

3. Select **OK** and **Apply**.

Results

Using the FortiClient SSLVPN application, access the VPN using the address `https://172.20.120.136:443/` and log in as `twhite`. Once connected, you can browse the Internet.

From the FortiGate web-based manager, go to **Monitor > SSL-VPN Monitor** to view the list of users connected using SSL VPN. The **Subsession** entry indicates the split tunnel which redirects to the Internet.

Split Tunnel

In this configuration, remote users are able to securely access the head office internal network through the head office firewall, yet browse the Internet without going through the head office FortiGate. Split tunneling is enabled by default for SSL VPN on FortiGate units.

The solution below describes how to configure FortiGate SSL VPN split tunneling using the FortiClient SSL VPN software, available from the Fortinet Support site.

Without split tunneling, all communication from remote SSL VPN users to the head office internal network and to the Internet uses an SSL VPN tunnel between the user's PC and the head office FortiGate unit. Connections to the Internet are routed back out the head office FortiGate unit to the Internet. Replies come back into the head office FortiGate unit before being routed back through the SSL VPN tunnel to the remote user.

In short, enabling split tunneling protects the head office from potentially harmful access and external threats that may occur as a result of the end user's indiscretion while browsing the Internet. By contrast, disabling split tunneling protects the end user by forcing all their Internet traffic to pass through the FortiGate firewall.

Creating a firewall address for the head office server

1. Go to **Policy & Objects > Addresses** and select **Create New** and add the head office server address:

Category	Address
Name	Head office server
Type	Subnet
Subnet / IP Range	192.168.1.12
Interface	Internal

2. Select **OK**.

Creating an SSL VPN IP pool and SSL VPN web portal

1. Go to **VPN > SSL-VPN Portals** and select **tunnel-access**.
2. Enter the following:

Name	Connect to head office server
Enable Tunnel Mode	Enable
Enable Split Tunneling	Enable
Routing Address	Internal
Source IP Pools	SSLVPN_TUNNEL_ADDR1

3. Select **OK**.

Creating the SSL VPN user and user group

Create the SSL VPN user and add the user to a user group.

1. Go to **User & Device > User Definition**, select **Create New** and add the user:

User Name	twhite
Password	password

2. Select **OK**.
3. Go to **User & Device > User Groups** and select **Create New** to add the new user to the SSL VPN user group:

Name	Tunnel
Type	Firewall

4. Move **twhite** to the **Members** list.
5. Select **OK**.

Creating a static route for the remote SSL VPN user

Create a static route to direct traffic destined for tunnel users to the SSL VPN tunnel.

1. Go to **Network > Static Routes** and select **Create New**

Destination IP/Mask	10.212.134.0/255.255.255.0
Device	ssl.root

2. Select **OK**.

Creating security policies

Create an SSL VPN security policy with SSL VPN user authentication to allow SSL VPN traffic to enter the FortiGate unit. Create a normal security policy from ssl.root to wan1 to allow SSL VPN traffic to connect to the Internet.

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Complete the following:

Incoming Interface	ssl.root
Source Address	all
Source User(s)	Tunnel
Outgoing Interface	internal
Destination Address	Head office server

3. Select **OK**.
4. Add a security policy that allows remote SSL VPN users to connect to the Internet.
5. Select **Create New**.
6. Complete the following and select **OK**:

Incoming Interface	ssl.root
Source Address	all
Source User(s)	Tunnel
Outgoing Interface	wan1
Destination Address	all
Schedule	always
Service	ALL
Action	ACCEPT

Configuring authentication rules

1. Go to **VPN > SSL-VPN Settings** and select **Create New** under **Authentication/Portal Mapping**.
2. Add an authentication rule for the remote user:

Users/Groups	Tunnel
Portal	tunnel-access

3. Select **OK** and **Apply**.

Results

Using the FortiClient SSL VPN application on the remote PC, connect to the VPN using the address `https://172.20.120.136:443/` and log in with the `twhite` user account. Once connected, you can connect to the head office server or browse to web sites on the Internet.

From the web-based manager, go to **Monitor > SSL-VPN Monitor** to view the list of users connected using SSL VPN. The **Subsession** entry indicates the split tunnel which redirects SSL VPN sessions to the Internet.

Multiple user groups with different access permissions

You might need to provide access to several user groups with different access permissions. Consider the following example topology in which users on the Internet have controlled access to servers and workstations on private networks behind a FortiGate unit.

In this example configuration, there are two users:

- User1 can access the servers on Subnet_1.
- User2 can access the workstation PCs on Subnet_2.

You could easily add more users to either user group to provide them access to the user group's assigned web portal.

General configuration steps

1. Create firewall addresses for:
   - The destination networks.
   - Two non-overlapping tunnel IP address ranges that the FortiGate unit will assign to tunnel clients in the two user groups.
2. Create two web portals.
3. Create two user accounts, User1 and User2.
4. Create two user groups. For each group, add a user as a member and select a web portal. In this example, User1 will belong to Group1, which will be assigned to Portal1 (similar configuration for User2).
5. Create security policies:
   - Two SSL VPN security policies, one to each destination.
   - Two tunnel-mode policies to allow each group of users to reach its permitted destination network.
6. Create the static route to direct packets for the users to the tunnel.

Creating the firewall addresses

Security policies do not accept direct entry of IP addresses and address ranges. You must define firewall addresses in advance.

Creating the destination addresses

SSL VPN users in this example can access either Subnet_1 or Subnet_2.

To define destination addresses - web-based manager:

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**, enter the following information, and select **OK**:

Name	Subnet_1
Type	Subnet
Subnet/IP Range	10.11.101.0/24
Interface	port2

3. Select **Create New**, enter the following information, and select **OK**:

Name	Subnet_2
Type	Subnet
Subnet/IP Range	10.11.201.0/24
Interface	port3

Creating the tunnel client range addresses

To accommodate the two groups of users, split an otherwise unused subnet into two ranges. The tunnel client addresses must not conflict with each other or with other addresses.

To define tunnel client addresses - web-based manager:

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**, enter the following information, and select **OK**:

Name	Tunnel_group1
Type	IP Range
Subnet/IP Range	10.11.254.1-10.11.254.50
Interface	Any

3. Select **Create New**, enter the following information, and select **OK**.

Name	Tunnel_group2
Type	IP Range

Subnet/IP Range	10.11.254.51-10.11.254.100
Interface	Any

Creating the web portals

To accommodate two different sets of access permissions, you need to create two web portals, portal1 and portal2, for example. Later, you will create two SSL VPN user groups, one to assign to portal1 and the other to assign to portal2.

To create the portal1 web portal:

1. Go to **VPN > SSL-VPN Portals** and select **Create New**.
2. Enter `portal1` in the **Name** field.
3. In **Source IP Pools**, select **Tunnel_ group1**.
4. Select **OK**.

To create the portal2 web portal:

1. Go to **VPN > SSL-VPN Portals** and select **Create New**.
2. Enter `portal2` in the **Name** field and select **OK**.
3. In **IP Pools**, select **Tunnel_ group2**
4. Select **OK**.

Later, you can configure these portals with bookmarks and enable connection tool capabilities for the convenience of your users.

Creating the user accounts and user groups

After enabling SSL VPN and creating the web portals that you need, you need to create the user accounts and then the user groups that require SSL VPN access.

Go to **User & Device > User Definition** and create user1 and user2 with password authentication. After you create the users, create the SSL VPN user groups.

To create the user groups - web-based manager:

1. Go to **User & Device > User Groups**.
2. Select **Create New** and enter the following information:

Name	Group1
Type	Firewall

3. From the **Available** list, select **User1** and move it to the **Members** list by selecting the right arrow button.
4. Select **OK**.
5. Repeat steps 2 through 4 to create Group2, assigned to Portal2, with User2 as its only member.

Creating the security policies

You need to define security policies to permit your SSL VPN clients, web-mode or tunnel-mode, to connect to the protected networks behind the FortiGate unit. Before you create the security policies, you must define the source and destination addresses to include in the policy. See Creating the firewall addresses on page 2938.

Two types of security policy are required:

- An SSL VPN policy enables clients to authenticate and permits a web-mode connection to the destination network. In this example, there are two destination networks, so there will be two SSL VPN policies. The authentication ensures that only authorized users can access the destination network.
- A tunnel-mode policy is a regular ACCEPT security policy that enables traffic to flow between the SSL VPN tunnel interface and the protected network. Tunnel-mode policies are required if you want to provide tunnel-mode connections for your clients. In this example, there are two destination networks, so there will be two tunnel-mode policies.

To create the SSL VPN security policies - web-based manager:

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New.**
2. Enter the following information and click **OK**:

Incoming Interface	ssl.root (sslvpn tunnel interface)
Source Address	All
Source User(s)	Group1
Outgoing Interface	port2
Destination Address	Subnet_1
Service	All

3. Select **Create New.**
4. Enter the following information:

Incoming Interface	ssl.root (sslvpn tunnel interface)
Source Address	All
Source User(s)	Group2
Outgoing Interface	port3
Destination Address	Subnet_2
Service	All

5. Click **OK**.

Configuring authentication rules

1. Go to **VPN > SSL-VPN Settings** and select **Create New** under **Authentication/Portal Mapping**.
2. Add an authentication rule for the first remote group:

Users/Groups	Group1
Portal	Portal1

3. Select **OK** and **Apply**.
4. Select **Create New** and add an authentication rule for the second remote group:

Users/Groups	Group2
Portal	Portal2

5. Select **OK** and **Apply**.

To create the tunnel-mode security policies - web-based manager:

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information, and select **OK**:

Incoming Interface	ssl.root (sslvpn tunnel interface)
Source Address	Tunnel_group1
Source User(s)	Group1
Outgoing Interface	port2
Destination Address	Subnet_1
Service	All
Action	ACCEPT
Enable NAT	Enable

3. Select **Create New.**
4. Enter the following information, and select **OK**:

Incoming Interface	ssl.root (sslvpn tunnel interface)
Source Address	Tunnel_group2
Source User(s)	Group2
Outgoing Interface	port3
Destination Address	Subnet_2
Service	All
Action	ACCEPT
Enable NAT	Enable

Create the static route to tunnel mode clients

Reply packets destined for tunnel mode clients must pass through the SSL VPN tunnel. You need to define a static route to allow this.

To add a route to SSL VPN tunnel mode clients - web-based manager:

1. Go to **Network > Static Routes** and select **Create New**.
2. Enter the following information and select **OK**.

Destination IP/Mask	`10.11.254.0/24` This IP address range covers both ranges that you assigned to SSL VPN tunnel-mode users. See Creating the tunnel client range addresses on page 2939.
Device	Select the SSL VPN virtual interface, **ssl.root** for example.

In this example, the **IP Pools** field on the **VPN > SSL-VPN Settings** page is not used because each web portal specifies its own tunnel IP address range.

Troubleshooting

This section contains tips to help you with some common challenges of SSL VPNs.

- Enter the following to display debug messages for SSL VPN:

  ```
  diagnose debug application sslvpn -1
  ```

  This command enables debugging of SSL VPN with a debug level of -1. The -1 debug level produces detailed results.

- Enter the following command to verify the debug configuration:

  ```
  diagnose debug info
  debug output: disable
  console timestamp: disable
  console no user log message: disable
  sslvpn debug level: -1 (0xffffffff)
  CLI debug level: 3
  ```

  This output verifies that SSL VPN debugging is enabled with a debug level of -1, and shows what filters are in place. The output above indicates that debug output is disabled, so debug messages are not displayed. The output also indicates that debugging has not been enabled for any software systems.

- Enter the following to enable displaying debug messages:

  ```
  diagnose debug enable
  ```

  To view the debug messages, log into the SSL VPN portal. The CLI displays debug output similar to the following:

  ```
  FGT60C3G10002814 # [282:root]SSL state:before/accept initialization (172.20.120.12)
  [282:root]SSL state:SSLv3 read client hello A (172.20.120.12)
  [282:root]SSL state:SSLv3 write server hello A (172.20.120.12)
  [282:root]SSL state:SSLv3 write change cipher spec A (172.20.120.12)
  [282:root]SSL state:SSLv3 write finished B (172.20.120.12)
  [282:root]SSL state:SSLv3 flush data (172.20.120.12)
  [282:root]SSL state:SSLv3 read finished A:system lib(172.20.120.12)
  [282:root]SSL state:SSLv3 read finished A (172.20.120.12)
  [282:root]SSL state:SSL negotiation finished successfully (172.20.120.12)
  [282:root]SSL established: DHE-RSA-AES256-SHA SSLv3 Kx=DH Au=RSA Enc=AES(256) Mac=SHA1
  ```

- Enter the following to stop displaying debug messages:

  ```
  diagnose debug disable
  ```

The following is a list of potential issues. The suggestions below are not exhaustive, and may not reflect your network topology.

There is no response from the SSL VPN URL.

- Go to **VPN > SSL-VPN Settings** and check the SSL VPN port assignment. Also, verify that the SSL VPN policy is configured correctly.
- Check the URL you are attempting to connect to. It should follow this pattern:

  ```
  https://<FortiGate IP>:<Port>/remote/login
  ```

- Ensure that you are using the correct port number in the URL.

FortiClient cannot connect.

Read the Release Notes to ensure that the version of FortiClient you are using is compatible with your version of FortiOS.

Tunnel-mode connection shuts down after a few seconds.

This issue can occur when there are multiple interfaces connected to the Internet (for example, a dual WAN). Upgrade to the latest firmware then use the following CLI command:

```
config vpn ssl settings
   set route-source-interface enable
end
```

When you attempt to connect using FortiClient or in Web mode, you are returned to the login page, or you receive the following error message: "*Unable to logon to the server. Your user name or password may not be configured properly for this connection. (-12).*"

- Ensure that cookies are enabled in your browser.
- If you are using a remote authentication server, ensure that the FortiGate is able to communicate with it.
- Access to the web portal or tunnel will fail if Internet Explorer has the privacy Internet Options set to High. If set to High, Internet Explorer will block cookies that do not have a compact privacy policy, and that use personally identifiable information without your explicit consent.

You receive an error message stating: "*Destination address of Split Tunneling policy is invalid.*"

The SSL VPN security policy uses the **ALL** address as its destination. Change the address to that of the protected network instead.

The tunnel connects but there is no communication.

Go to **Network > Static Routes** and ensure that there is a static route to direct packets destined for the tunnel users to the SSL VPN interface.

You can connect remotely to the VPN tunnel but are unable to access the network resources.

Go to **Policy & Objects > IPv4 Policy** and examine the policy allowing VPN access to the local network. If the destination address is set to all, create a firewall address for the internal network. Change the destination address and attempt to connect remotely again.

Users are unable to download the SSL VPN plugin.

Go to **VPN > SSL-VPN Portals** to make sure that the option to **Limit Users to One SSL-VPN Connection at a Time** is disabled. This allows users to connect to the resources on the portal page while also connecting to the VPN through FortiClient.

Users are being assigned to the wrong IP range.

Ensure that the same IP Pool is used in VPN Portal and VPN Settings to avoid conflicts. If there is a conflict, the portal settings will be used.

Sending tunnel statistics to FortiAnalyzer

By default, logged events include tunnel-up and tunnel-down status events. Other events, by default, will appear in the FortiAnalyzer report as "No Data Available". More accurate results require logs with `action=tunnel-stats`, which is used in generating reports on the FortiAnalyzer (rather than the tunnel-up and tunnel-down event logs). The FortiGate does not, by default, send `tunnel-stats` information.

To allow VPN `tunnel-stats` to be sent to FortiAnalyzer, configure the FortiGate unit as follows using the CLI:

```
config system settings
   set vpn-stats-log ipsec ssl
   set vpn-stats-period 300
end
```

Chapter 29 - System Administration

This guide contains the following sections:

What's New in FortiOS 5.4 informs you about new system features in FortiOS 5.4.x.

Administrators describes the tasks that can be done to add and secure administrative access to a FortiGate.

Central management describes how to configure the FortiGate unit to use FortiManager as a method of maintaining the device and other features that FortiManager has to facilitate the administration of multiple devices.

Monitoring discusses the various methods of monitoring both the FortiGate unit and the network traffic through a range of different tools available within FortiOS.

Replacement messages explains how to view and customize various replacement messages on the FortiGate.

Administration for schools shares basic practices administrators in school systems can employ to meet the challenges of maintaining a network and access to the Internet

PPTP and L2TP contains information on configuring PPTP and L2TP VPNs as well as PPTP passthrough.

Session helpers explains how to use session helpers to analyze the data in the packet bodies of some protocols and adjust the firewall to allow those protocols to send packets through the firewall.

Advanced concepts describes more involved administrative topics to enhance network security and traffic efficiency.

What's New in FortiOS 5.4

This section describes new system administration features added to FortiOS 5.4.0, FortiOS 5.4.1, and FortiOS 5.4.2.

FortiOS 5.4.2

Incorrect access group for backup and restore config (389328)

FortiOS no longer allows lower level administrator profiles to backup and restore the FortiOS configuration (because this would allow them to acquire hashes for administrator passwords, including super-admin).

Enhancements to IPS Signatures page (285543)

The IPS signatures list page now shows which IPS package is currently deployed. Users can also change their IPS package by linking directly to the FortiGate's **System > FortiGuard** page from the IPS Signatures list page.

Combine multiple commands into a CLI alias (308921)

Multiple commands can be supported under a single command alias defined in the CLI by users.

Configure alias command

```
config system alias
   edit "alias-name" -- Alias command name
      set command "get system status" -- Command list to execute
   next
end
```

Basic config examples (simple command substitution)

```
config sys alias
   edit 1
      set alias "sh ver"
      set cmd "get system status"
   next
   edit 2
      set alias "sh ip route"
      set cmd "get router info routing-table all"
   next
   edit 3
      set alias "sh bgp sum"
      set cmd "get router info bgp summary"
   next
   edit 11
      set alias "debug1"
      set cmd "diag debug enable;diag debug flow show console enable"
   next
   edit 12
      set alias "debug2"
      set cmd "diag debug flow filter saddr"
```

```
      set noenter enable
   next
   edit 13
      set alias "debug3"
      set cmd "diag debug flow trace start"
      set noenter enable
   next
   edit 14
      set "alias debugstop"
      set "cmd diag debug flow trace stop"
   next
end
```

Advanced config examples (parameter substitution)

```
config sys alias
   edit 4
      set alias "sniff (\d+\.\d+\.\d+\.\d+)"
      set cmd "diag sniffer packet any 'host $1' 4"
   next
   edit 5
      set alias "sniff6 (\d+\.\d+\.\d+\.\d+)"
      set cmd "diag sniffer packet any 'host $1' 6"
   next
   edit 6
      set alias "sniff (\S+) (.*)"
      set cmd "diag sniffer packet $1 '$2' 4"
   next
   edit 7
      set alias "trace (\d+\.\d+\.\d+\.\d+) (\d+)"
      set cmd "diag debug enable;diag debug flow show console enable;diag debug flow
          filter saddr $1;diag debug flow trace start $2"
   next
end
```

The `noenter` setting specifies whether the alias substitution should contain a new line or not.

These examples are placed in numerical order.

.

New SNMP trap for bypass events (307329)

When bypass mode is enabled or disabled on FortiGate units that are equipped with bypass interfaces and support AMC modules, a new SNMP trap is generated and logs bypass events.

FortiOS 5.4.1

Maintainer password recovery enhancements (356944)

For information about recovering a lost password and enhancements to the process, see: Resetting a lost Admin password on the Fortinet Cookbook site.

SSH support updated to 7.1p1 (290889)

The OpenSSH daemon has been upgraded from version 3.7.1p2 to version 7.1p1 to support new security algorithms.

The central management FortiGuard server list can include FQDNs (354449)

This new feature implements support of FQDN, to make it an option for central-management server-list. This feature can be set through the GUI and the CLI.

GUI Changes

On **System > FortiGuard > Override FortiGuard Servers > Create New / Edit**, a new option, **FQDN** is added for **Address Type**.

CLI Changes

```
config server-list
   edit 1
      set server-type {update|rating}
      set addr-type {ipv4|ipv6|fqdn} <== added fqdn
      set server-address ipv4
      set server-address6 ipv6
      set fqdn FQDN <== added
   end
```

Features removed from the FortiGate 80C (356154)

Features have been changed on the FortiGate / FortiWifi 80C so as to increase available memory and decrease the image size on flash.

Changes made include:

- removal of web application firewall (WAF)
- removal of WAN optimization
- removal of network vulnerability scan (netscan)
- compression of the Intrusion Prevention System and AntiVirus library files and storing them in a gzip file
- compression of certain WiFi data files
- addition of virtual switch function for 80c (applicable to 5.4 only)

FortiOS 5.4.0

New role property on interfaces (294385)

Interfaces now have a property called 'role' which affects visibility and suggests different default options depending on it's value.

- WAN - this interface is used to connect to the internet.
- LAN - this interface is used to connect to local network of endpoints.
- DMZ - this interface is used to connect to servers.
- Undefined - This interface has a custom role which isn't one of the above.

Interface roles affect visibility of properties and features (295736)

Depending on an interfaces role, some properties may set to a default value and the visibility of others may be set to show or hide in the GUI.

Toggle automatic authorization of extension devices (294966)

When an interface is configured to be dedicated to an extension device, a new option appears to auto-authorize extension devices.

Support for new modem added (293598)

Support for the Linktop LW273 modem has been added.

IPS packet capture files can be backed up (276489)

Use the command `execute backup disk ipsarchives` and the option of `tftp`, `ftp`, or `usb`.

Change between NAT and Transparent modes removed from the GUI (278289)

The feature in the GUI initiating the change between NAT and Transparent modes has been removed. It can still be done, but only through the CLI. The configuration setting that is used is:

```
config system settings
   set opmode [nat | transparent]
   end
```

Switch mode changes (286447)

Hub mode is no longer available. The old switch mode, usually called 'LAN' will no longer be available. The interface mode is still available and on all models, and instead of the old switch mode, most of the lower end units will come configured, by default, with a hardware switch called 'LAN', which has the function of the old switch mode but is more flexible. Most models with 40 ports or more will come by default in vlan switch mode.

New start attribute as been added to scheduled scripts (285206)

The start attribute has the options manual and auto. Manual means a schedule script needs to be manually started after a reboot. Auto automatically restarts the script after a reboot.

Use the following command to set a script to automatically run after the FortiGate starts up:

```
config system auto-script
   edit <script-name>
      set start auto
   end
```

Toggle displaying the hostname on the GUI login page (272572)

Use the following command:

```
config sys settings
   set gui-display-hostname {disable | enable}
end
```

PPTP and L2TP address pool ranges expanded (275709)

PPTP and L2TP address pool ranges are allowed to use a subnet mask of up to 255.255.0.0 (B-class), increasing the maximum range size from 254 to 65,534

Pop up notification of impending timeout of Administrator GUI sessions (266413)

A convenience feature to let administrators know that their session is about to expire. This is especially convenient for units that have a timeout setting of just a few minutes.

SNMP can generate traps based on detecting a device's online/offline status (273107)

This setting is related to the device detection feature. It allows SNMP traps to detect when a new device comes online. Within SNMP configurations there is a configurable timeout setting that periodically checks for the device. When a check determines that the device is present a trap is sent.

In the GUI, when configuring an SNMP object, one of the settings is a checkbox, under **SNMP Events** for **Device detected**.

To configure the SNMP object in the CLI use the following syntax:

```
config system snmp community
   edit <community ID number>
      set name <string>
      set events device-new
      end
```

In order to configure the idle timeout for the device, use the following syntax in the CLI:

```
config system global
   set device-idel-timeout <integer of time in seconds>
   end
```

The time value for the field can be set from 30 to 31536000.

SNMP improvements for dynamic routing (168927)

SNMP improvements for dynamic routing include support for RFC 4750 OSPF Version 2 Management Information Base and RFC 5643 Management Information Base for OSPFv3. These changes add the capability of logging dynamic routing activity. Examples include sending OSPF routing events or changes to a syslog server or FortiAnalyzer or changes in neighborhood status.

Network Mobility Extensions for Mobile IPv4 (NEMO)

This is an implementation of RFC 5177 that includes the following CLI command.

```
config system mobile-tunnel
   set status enable/disable //Enable/disable this mobile tunnel.
   set roaming-interface port1 //Roaming interface name.
   set home-agent xxx.xxx.xxx.xxx //IP address of the NEMO HA.
   set home-address xxx.xxx.xxx.xxx // Home IP address.
   set n-mhae-spi 256 //NEMO authentication spi.
   set n-mhae-key-type ascii/base64 //NEMO authentication key type.
   set n-mhae-key vWZZxx //NEMO authentication key.
   set hash-algorithm hmac-md5 //Hash Algorithm.
   set tunnel-mode gre //NEMO tunnnel mode.
   set renew-interval 60 //Time before lifetime expiraton to send NMMO HA re-registration.
   set lifetime 180 //NEMO HA registration request lifetime.
   set reg-interval 5 //NEMO HA registration interval.
   set reg-retry 3 //NEMO HA registration maximal retries.
end
```

Restoring configuration file without rebooting the FortiGate (237786)

A setting has been added in the CLI that when set to enable, will allow the FortiGate to start using the newly uploaded configuration file without going through a full reboot process.

The syntax for the setting is:

```
config system global
   set reboot-upon-config-restore {enable | disable}
end
```

Auto repeat of CLI commands(160023 259531)

Occasionally there is a need to repeatedly run a diagnose command over a long period of time (like checking CPU or memory usage, or checking proxy health), Previously, this could only be done with external console connections. Now this can be done in a script using the `interval` and `repeat` commands.

Scripts can be uploaded as a file from the CLI or GUI. To upload scripts from the GUI go to **System > Advanced > Configuration Scripts** and upload and run the script.

To configure the schedule and scripts, use the following syntax:

```
config system auto-script
   edit <ScriptName>
      set interval
      set repeat
      set script
   end
end
```

`interval` the interval time in seconds between instances of the script running.

`repeat` the number of times to repeat the running of the script. The value 0 is used to set an infinite number of repetitions.

`start` select `manual` to start the script manually or `auto` to start the script automatically

`script` the contents of the script.

This feature may not be available on all models as a hard drive is necessary to make use of it.

Proxy-arp function extension (250651)

A new attribute `end-ip` is added to proxy-arp. If `end-ip` is not set, then the ip has the same meaning as before. If `end-ip` is set, then the ip becomes the start-ip, and the `end-ip` should be larger than ip and the ip range should less than 256.

```
config system proxy-arp
   edit 1
      set interface internal
      set ip xxx.xxx.xxx.xxx
      set end-ip xxx.xxx.xxx.xxx
   next
end
```

Changes to the FortiGuard Distribution Network GUI page (219862)

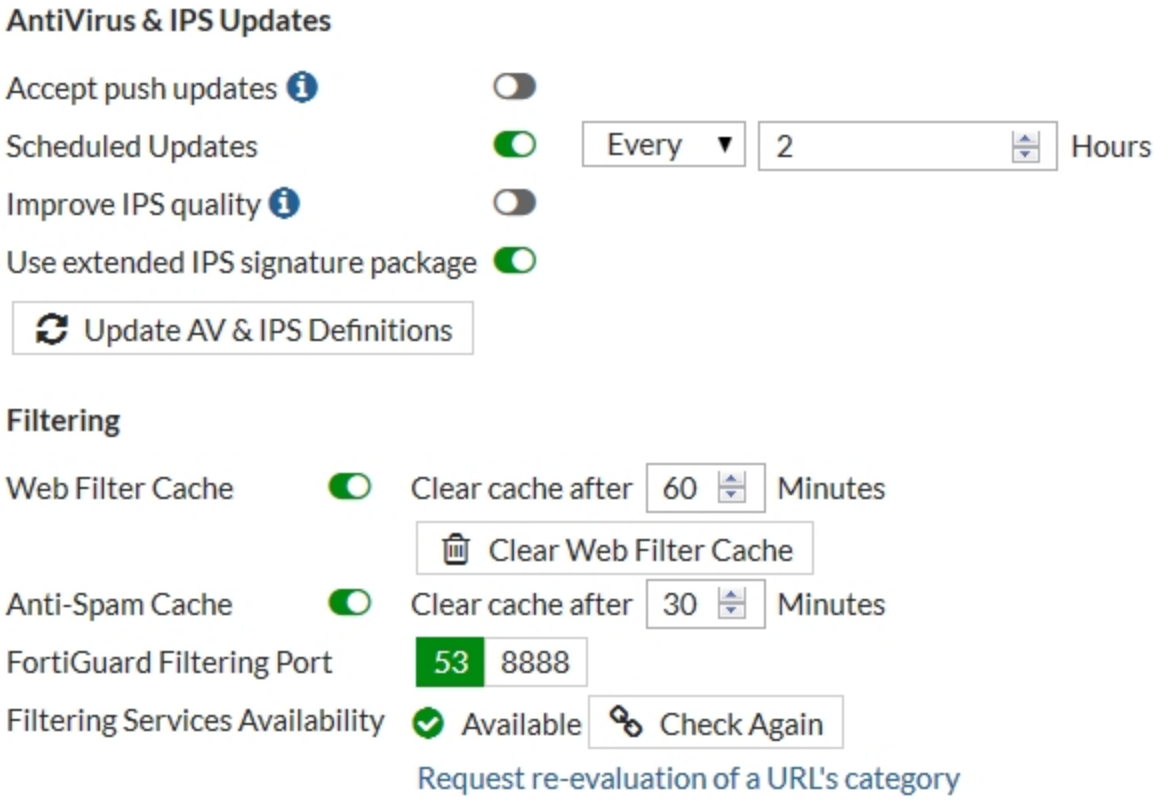
The **System > FortiGuard** page has been updated to include new FortiGuard features including Mobile Malware Definitions, Botnet Definitions and so on. From this page you can also upload packages, and view the list of Botnet Definitions.

FortiGuard Distribution Network

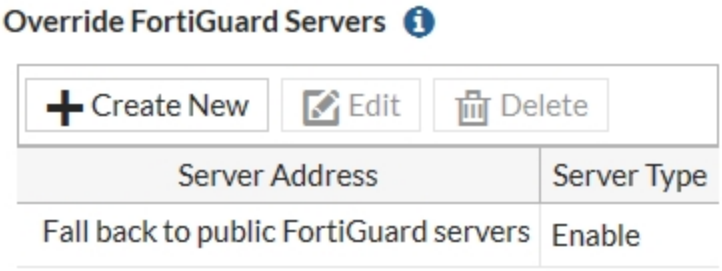
License Information

Contract	Status	
FortiCare Support	Registered (kleroux@fortinet.com)	Launch Portal
Hardware Version	8 x 5 support (Expires on 2016-09-29)	
Comprehensive Support	24 x 7 support (Expires on 2016-09-29)	
Firmware	8 x 5 support (Expires on 2016-09-29)	
Enhanced Support	24 x 7 support (Expires on 2016-09-29)	
IPS & Application Control	Licensed (Expires on 2016-09-29)	Upload Package
IPS Definitions	Version 6.00755	
IPS Engine	Version 3.00156	
AntiVirus	Licensed (Expires on 2016-09-29)	Upload Package
AV Definitions	Version 31.00354	
AV Engine	Version 5.00227	
Mobile Malware Definitions	Version 0.00000	
Botnet Definitions	Version 2.00684	View List
SSL-VPN Package	Unreachable	Upload Package
Web Filtering	Licensed (Expires on 2016-09-29)	
Anti-Spam Filtering	Licensed (Expires on 2016-09-29)	

From this page you can also access new functionality for AntiVirus and IPS updates and Web Filtering and Spam filtering.



You can also use this page to override FortiGuard servers.



Changes to firmware upgrade GUI page (248866)

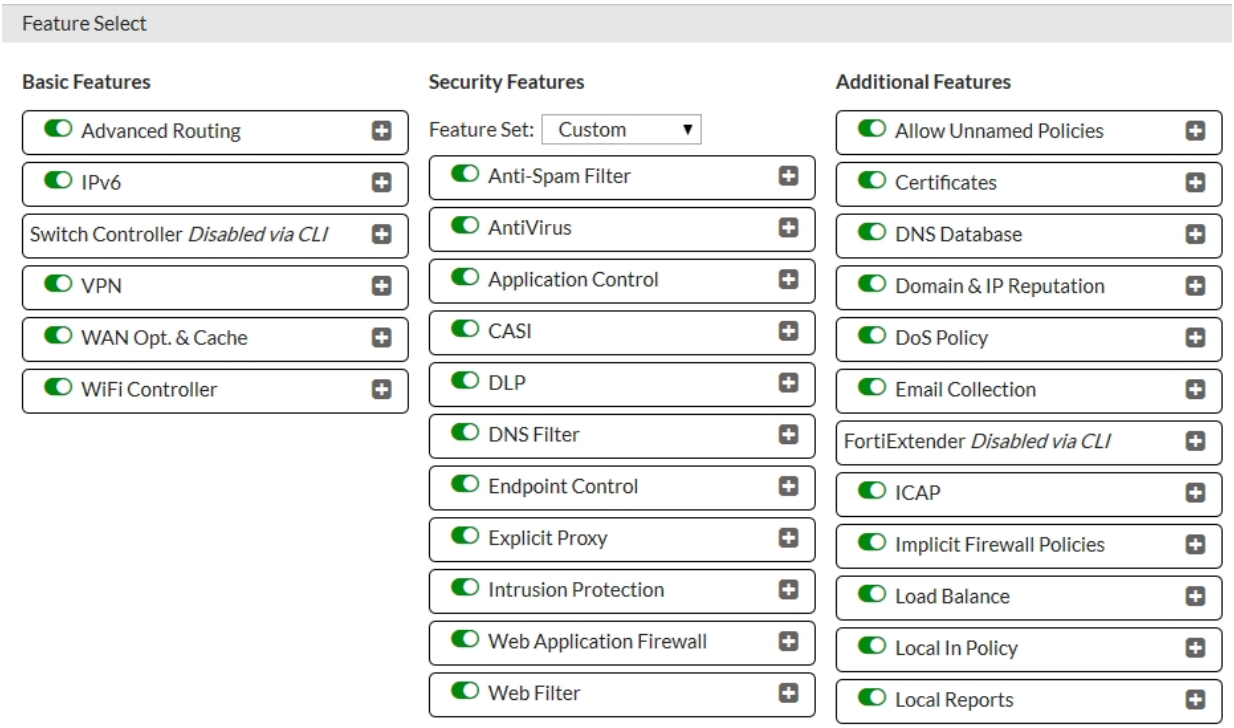
The following changes have been made to the GUI as it relates to the firmware upgrade process:

- The interface now provides an upgrade recommendations that is based on FortiGuard's list of supported upgrade paths
- Allows user to easily select and upgrade to one of the recommended versions
- There is a graphic representation of the progress of downloading the image and the upgrade process.

GUI features can now be enabled and disabled per VDOM (263708 273799)

When VDOMs are enabled, most of the items in the Features section of the menu are moved to a similar menu section within the VDOM menu and are now customizable on a per VDOM basis. Some items such as IPv6 and Certificates are still configured on a global basis.

From the GUI, you can enable or disable GUI features from **System > Feature Select**.

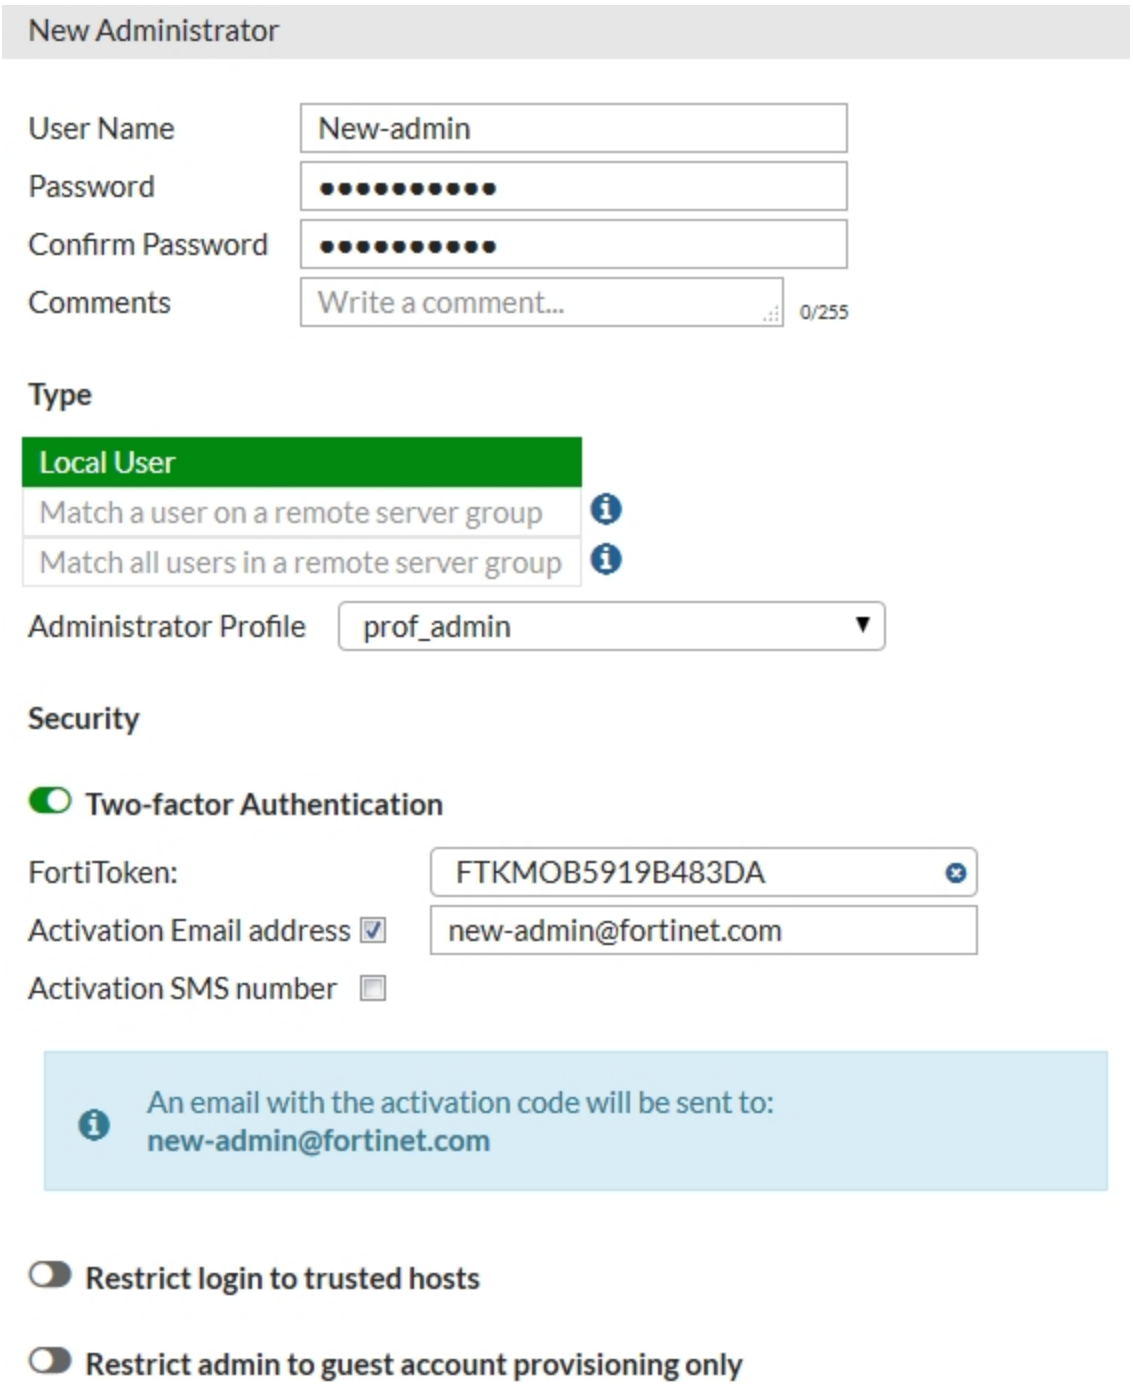


From the CLI, GUI items that are enabled or disabled per-VDOM are configured from the `config system settings` command. GUI items that are enabled globally are enabled or disabled from the `config system global` command.

Turning these features on or off does not enable or disable the feature but determines whether or not that option is displayed on the GUI.

Improvements to system admin GUI pages (205280)

Several items relating to system administration, and the configuration of the system administrator accounts and profiles in particular, have been updated so that the layout is clearer and more efficient. One of the things improve is that it is now easier to set up two factor authentication.



The TFTP session helper supports (263127)

The TFTP session helper supports TFTP for NAT66 and NAT46.

Support for IPv6 addressing when configuring central management (297144)

Previously, the configuration of an IP address for a server for ratings and updates, such as a FortiManager, could only use IPv4 addresses. Now, as shown below IPv6 addressing can be used as well.

```
config system central-management
   set type fortimanager
   set fmg "2000:172:16:200::207"
   set vdom "vdom1"
      config server-list
         edit 1
         set server-type rating update
         set addr-type ipv6
         set server-address6 2000:172:16:200::207
         next
      end
   end
```

New execute traceroute command options (272169)

Different query options can be configured for the `execute traceroute` command. These settings can also be saved using the `execute traceroute-options` command as follows:

```
execute traceroute-options device [Auto | <interface name>]
execute traceroute-options queries <integer>
execute traceroute-options source [Auto | <source interface IP address>]
```

The `queries` setting is to determine the number of queries per hop. Use execute traceroute-options to view the traceroute settings:

```
execute traceroute-options view-settings
Traceroute Options:
       Number of probes per hop: 3
       Source Address: auto
       Device: auto
```

Administrator password updates (292858)

To set a minimum level of security for the administrative accounts, minimum levels of complexity can be set on guest admin accounts.

```
config system password-policy-guest-admin
   set status [enable | disable]
   set min-lower-case-letter <integer>
   set min-upper-case-letter <integer>
   set min-non-alphanumeric <integer>
   set min-number <integer>
   end
```

If the required level of complexity is not met, an error message will appear explaining that the password must conform to the system password policy.

Certificate validation added to FortiGate email server configuration (299506)

When configuring the email server on a FortiGate to send out alert emails that use SMTPS, the FortiGate can validate the email chain, thus reducing the possibility of compromise.

In the CLI the configuration of the email is set up with the following syntax:

```
config system email-server
   set type custom
   set reply-to <email address>
   set server <SMTP server IP address or hostname>
   set port <integer for SMTP server port>
```

```
set source-ip <SMTP server source address - IPv4 format>
set source-ip6 <SMTP server source address - IPv6 format>
set authenticate [enable| disable]
set validate-server [enable| disable]
security Connection security.
set security [none | starttls |smtps|
end
```

The `set validate-server` option is the new setting that enables the verification.

Changes to backing up and restoring configuration files (298176)

When you insert a USB drive into a FortiGate USB port options to save the configuration to USB and restore configuration from a USB appear on the configureation save and restore pages.

You can also use the command `execute backup usb` command to backup the configuration to the USB drive.

Administrators

By default, the FortiGate has a super administrator account, called `admin`, which cannot be deleted. Additional administrators can be added for various functions, each with a unique user name, password, and set of access privileges.

The following tasks can be done to add and secure administrative access to a FortiGate:

- Administrator profiles
- Adding a local administrator
- LDAP authentication for administrators
- Other methods of authentication
- Monitoring administrators
- Management access
- Security precautions

Administrator profiles

Administrator profiles define what the administrator can do when logged into the FortiGate. When you set up an administrator account, you also assign an administrator profile dictating what the administrator will see. Depending on the nature of the administrator's work, access level or seniority, you can allow them to view and configure as much, or as little, as required.

super_admin profile

This profile has access to all components of FortiOS, including the ability to add and remove other system administrators. For some administrative functions, such as backing up and restoring the configuration, super_admin access is required. The super_admin profile cannot be deleted or modified, to ensure that there is always a method to administer the FortiGate.

Lower level administrator profiles cannot backup or restore the FortiOS configuration.

The super_admin profile is used by the default `admin` account. It is recommended to add a password and rename this account once you have set up your FortiGate. In order to rename the default account, a second admin account is required. For more information, see "Administrators" on page 2961.

Creating profiles

To configure administrator profiles go to **System > Admin Profiles** and select **Create New**.

On the **New Administrator Profile** page, you define the components of FortiOS that will be available to view and/or edit. For example, you can configure a profile so that the administrator can only access the **Firewall Configuration**, which includes firewall policies, addresses, services, schedules, packet capture, and some other parts of the FortiGate configuration. Any other aspects of the FortiGate configuration, including VPNs and security profiles, will be hidden from this administrator.

Adding a local administrator

Only administrators with read-write for **Administrator Users** can create a new administrator account.

To add an administrator - GUI

1. Go to **System > Administrators**.
2. Select **Create New**.
3. Add a **Name** for the administrator.

The name of the administrator should not contain the characters `<>()#"'`. Using these characters in the administrator account name can result in a cross site scripting (XSS) vulnerability.

4. Enter the **Password** for the user. This may be a temporary password that the administrator can change later. Passwords can be up to 256 characters in length. For more information on passwords, see the Passwords discussion in the Getting Started chapter.
5. Set **Type** to **Local User**.
6. Set the **Administrator Profile** and **Security**
7. Select **OK**.

To add an administrator - CLI

```
config system admin
   edit <admin_name>
      set password <password>
      set accprofile <profile_name>
end
```

LDAP authentication for administrators

Administrators can use remote authentication, such as LDAP, to connect to the FortiGate.

To do this, requires three steps:

- configure the LDAP server
- add the LDAP server to a user group

- configure the administrator account

Configure the LDAP server

First set up the LDAP server as you normally would, and include a group to bind to.

To configure the LDAP server - GUI

1. Go to **User & Device > LDAP Servers** and select **Create New**.
2. Enter a **Name** for the server.
3. Enter the **Server IP** address or name.
4. Enter the **Common Name Identifier** and **Distinguished Name**.
5. Set the **Bind Type to Regular** and enter the **User DN** and **Password**.
6. Select **OK**.

To configure the LDAP server - CLI

```
config user ldap
   edit <ldap_server_name>
      set server <server_ip>
      set cnid cn
      set dn DC=XYZ,DC=COM
      set type regular
      set user name CN=Administrator,CN=Users,DC=XYZ,DC=COM
      set password <password>
      set member-attr <group_binding>
end
```

Add the LDAP server to a user group

Next, create a user group that will include the LDAP server that was created above.

To create a user group - GUI

1. Go to **User & Device > User Groups** and select **Create New**.
2. Enter a **Name** for the group.
3. In the section labeled **Remote groups**, select **Create New**.
4. Select the **Remote Server** from the drop-down list.
5. Select **OK**.

To create a user group - CLI

```
config user group
   edit <group_name>
      config match
         edit 1
            set server-name <LDAP_server>
            set group-name <group_name>
      end
   end
```

Configure the administrator account

Now you can create a new administrator, where rather than entering a password, you will use the new user group and the wildcard option for authentication.

To create an administrator - GUI

1. Go to **System > Administrators** and select **Create New**.
2. In the **Administrator** field, enter the name for the administrator.
3. For **Type**, select **Match a user on a remote server group**.
4. Select the **User Group** created above from the drop-down list.
5. Select **Wildcard**. The Wildcard option allows for LDAP users to connect as this administrator.
6. Select an **Admin Profile**.
7. Select **OK**.

To create an administrator - CLI

```
config system admin
   edit <admin_name>
      set remote-auth enable
      set accprofile super_admin
      set wild card enable
      set remote-group ldap
   end
```

Other methods of authentication

Admin accounts can use a variety of methods for authentication, including RADIUS, TACACS+, and PKI.

RADIUS authentication for administrators

If you want to use a RADIUS server to authenticate administrators, you must:

- configure the FortiGate to access the RADIUS server
- create the RADIUS user group
- configure an administrator to authenticate with a RADIUS server.

TACACS+ authentication for administrators

If you want to use a TACACS+ server to authenticate administrators, you must:

- configure the FortiGate to access the TACACS+ server
- create a TACACS+ user group
- configure an administrator to authenticate with a TACACS+ server.

PKI certificate authentication for administrators

To use PKI authentication for an administrator, you must:

- configure a PKI user
- create a PKI user group

- configure an administrator to authenticate with a PKI certificate.

Monitoring administrators

You can view the administrators logged in using the **System Information** widget on the Dashboard. The **Current Administrator** row that shows the administrator logged in and the total number of administrators logged in. Selecting **Details** displays the administrators, where they are logging in from and how (CLI, GUI) and when they logged in.

You are also able to monitor the activities the administrators perform on the FortiGate using the event logging. Event logs include a number of options to track configuration changes.

To set logging - GUI

1. Go to **Log & Report > Log Settings**.
2. Under **Event Logging**, select **Customize** and ensure **System activity event** is selected.
3. Select **Apply**.

To set logging - CLI

```
config log eventfilter
   set event enable
   set system enable
end
```

To view the logs go to **Log & Report > System Events**.

Management access

Management access defines how administrators are able to log on to the FortiGate. In NAT mode, access is configured for each of the FortiGate's interfaces, using the interface's IP to connect. In Transparent mode, a single management IP address is configured to allow access.

Management access can be via HTTP, HTTPS, Telnet, or SSH sessions. HTTPS and SSH are preferred as they are more secure. The management computer must connect to an interface that permits management access and its IP address must be on the same network. If you are using VDOMs, an administrator who is restricted to a specific VDOM must use a computer that connects to an interface on that VDOM.

You can allow remote administration of the FortiGate; however, it is not recommended, since it could compromise the security of the FortiGate. If you require remote administration, the following precautions can be taken to improve the security of a FortiGate:

- Use secure administrator passwords.
- Change these passwords regularly.
- Enable two-factor authentication for administrators.
- Enable secure administrative access to this interface using only HTTPS or SSH.
- Use Trusted Hosts to limit where the remote access can originate from.
- Do not change the system idle timeout from the default value of 5 minutes.

Security precautions

One potential point of a security breach is at the management computer. Administrators who leave their workstations for a prolonged amount of time while staying logged into the GUI or CLI leave the firewall open to

malicious intent.

Preventing unwanted log in attempts

Setting trusted hosts for an administrator limits what computers an administrator can log in from, causing the FortiGate to only accept the administrator's log in from the configured IP address. Any attempt to log in with the same credentials from any other IP address will be dropped.

Trusted hosts are configured when adding a new administrator by going to **System > Administrators** in the GUI or `config system admin` in the CLI.

To ensure the administrator has access from different locations, you can enter up to ten IP addresses, though ideally this should be kept to a minimum. For higher security, use an IP address with a net mask of 255.255.255.255, and enter an IP address (non-zero) in each of the three default trusted host fields. Also ensure all entries contain actual IP addresses, not the default 0.0.0.0.

The trusted hosts apply to the GUI, ping, SNMP, and the CLI when accessed through Telnet or SSH. CLI access through the console port is not affected.

Prevent concurrent administrator sessions

Concurrent administrator sessions occur when multiple people concurrently access the FortiGate using the same administrator account. This is allowed by default. If you wish to prevent this behavior, use the following CLI command:.

```
config system global
   set admin-concurrent disable
end
```

Note, if you disable concurrent sessions for an administrator, you will be allowed only one session with the same username even if it is from the same IP.

On 2U FortiGates, this option is also available in the GUI by going to **System > Settings** and disable **Allow multiple concurrent sessions for each administrator**.

Segregated administrative roles

To minimize the effect of an administrator causing errors to the FortiGate configuration and possibly jeopardizing the network, create individual administrative roles where none of the administrators have super_admin permissions. For example, one account is used solely to create security policies, another for users and groups, another for VPN, and so on.

SSH log in time out

You can take up to 120 seconds to log into the FortiGate when using SSH. You can use the following CLI command to reduce this time to enhance security:

```
config system global
   set admin-ssh-grace-time <number_of_seconds>
end
```

The range can be between 10 and 3600 seconds.

HTTPS redirect

You can redirect an administrator's traffic from HTTP to HTTPS for a more secure connection.

To redirect HTTP to HTTPS - GUI

1. Go to **System > Settings**.
2. Under **Administration Settings**, enable **Redirect to HTTPS**.
3. Select **Apply**.

To redirect HTTP to HTTPS - CLI

```
config system global
   set admin-https-redirect enable
end
```

This command is not available on low-crypto FortiGates. The default is `disable`.

Log in/out warning message

For administrators logging in and out of the FortiGate, you can include a log in disclaimer. This disclaimer provides a statement that must be accepted or declined where corporations are governed by strict usage policies for forensics and legal reasons.

This disclaimer can appear either before the log in screen loads (`pre-login banner`) or after an administrator enters their credentials (`post-login-banner`). The disclaimer is enabled through the CLI:

```
config system global
   set pre-login-banner enable
   set post-login-banner enable
end
```

The banner is a default message that you can customize by going to **System > Replacement Messages**. Select **Extended View** to see the **Administrator** category and messages.

Disable the console interface

You can disable your FortiGate's console interface to prevent any unwanted login attempts:

```
config system console
   set login disable
end
```

Disable other interfaces

If any of the interfaces on the FortiGate are not being used, disable traffic on that interface. This avoids someone plugging in network cables and potentially causing network bypass or loop issues.

To disable an interface - GUI

1. Go to **Network > Interfaces**.
2. Select the interface from the list and select **Edit**.
3. For **Administrative Access**, select **Down**.
4. Select **OK**.

To disable an interface - CLI

```
config system interface
```

```
    edit <inerface_name>
      set status down
end
```

Central management

Administering one or two FortiGate units is fairly simple enough, especially when they are in the same room or building. However, if you are administering many FortiGate units that may be located in locations in a large geographical area, or in the world, you will need a more efficient method of maintaining firmware upgrades, configuration changes, and updates.

The FortiManager family of appliances supply the tools needed to effectively manage any size Fortinet security infrastructure, from a few devices to thousands of appliances. FortiManager appliances provide centralized policy-based provisioning, configuration, and update management, as well as end-to-end network monitoring for added control. Managers can control administrative access and simplify policy deployment using role-based administration to define user privileges for specific management domains and functions by aggregating collections of Fortinet appliances and agents into independent management domains. By locally hosting security content updates for managed devices and agents, FortiManager appliances minimize web filtering rating request response time and maximize network protection.

This chapter describes the basics of using FortiManager as an administration tool for multiple FortiGate units. It describes the basics of setting up a FortiGate unit in FortiManager and some key management features you can use within FortiManager to manage the FortiGate unit. For full details and instructions on FortiManager, see the FortiManager Administration Guide.

This section includes the topics:

In order for the FortiGate unit and FortiManager unit to properly connect, both units must have compatible firmware. To find out if your firmware is compatible, refer to the FortiManager Release Notes or the FortiManager support table for FortiOS.

Adding a FortiGate to FortiManager

Before you can maintain a FortiGate unit using a FortiManager unit, you need to add it to the FortiManager. This requires configuration on both the FortiGate and FortiManager. This section describes the basics to configure management using a FortiManager device. For more information on the interaction of FortiManager with the FortiGate unit, see the FortiManager documentation.

FortiGate configuration

These steps ensure that the FortiGate unit will be able to receive updated antivirus and IPS updates and allow remote management through the FortiManager system or FortiCloud service. You can add a FortiGate unit whether it is running in either NAT mode or transparent mode. The FortiManager appliance provides remote management of a FortiGate unit over TCP port 541.

If you have not already done so, register the FortiGate unit by visiting http://support.fortinet.com and select **Product Registration**. By registering your unit, you will receive updates to the FortiGuard services and will also ensure your access to technical support.

You must enable the FortiGate management option so the FortiGate unit can accept management updates to firmware and FortiGuard services.

To configure the FortiGate unit - GUI

1. Log in to the FortiGate unit.
2. Go to **System > Settings**.
3. Under **Central Management**, select FortiManager.
4. Enter the IP address of the FortiManager unit.
5. Select **Apply**.

The FortiManager ID now appears in the Trusted FortiManager table.

As an additional security measure, you can also select **Registration Password** and enter a password to connect to the FortiManager.

To configure the FortiGate unit - CLI

```
config system central-management
   set type fortimanager
   set fmg <ip_address>
end
```

To use the registration password, enter:

```
execute central-mgmt register-device <fmg-serial-no><fmg-register-password><fgt-
    usrname><fgt-password>
```

Configuring an SSL connection

An SSL connection can be configured between the two devices and an encryption level selected. Use the following CLI commands in the FortiGate CLI to configure the connection:

```
config system central-management
   set status enable
   set enc-algorithm {default* | high | low}
end
```

The default encryption automatically sets high and medium encryption algorithms. Algorithms used for high, medium, and low follows openssl definitions:

- **High** - Key lengths larger than 128 bits, and some cipher suites with 128-bit keys.

Algorithms are: DHE-RSA-AES256-SHA:AES256-SHA: EDH-RSA-DES-CBC3-SHA: DES-CBC3-SHA:DES-CBC3-MD5:DHE-RSA-AES128-SHA:AES128-SHA

- **Medium** - Key strengths of 128 bit encryption.

Algorithms are: RC4-SHA:RC4-MD5:RC4-MD

- **Low** - Key strengths of 64 or 56 bit encryption algorithms but excluding export cipher suites

Algorithms are: EDH-RSA-DES-CDBC-SHA; DES-CBC-SHA; DES-CBC-MD5.

FortiManager configuration

Once the connection between the FortiGate unit and the FortiManager unit has been configured, you can add the FortiGate to the Device Manager in the FortiManager unit's web-based manager. For details on completing the configuration, see the FortiManager Administration Guide.

Configuration updates through FortiManager

With the FortiManager system, you can monitor and configure multiple FortiGate units from one location. Using the FortiManager's Device Manager, you can view the FortiGate units and make the usual configuration updates and changes, without having to log in and out of multiple FortiGate units.

FortiManager enables you to complete the configuration, by going to the Device Manager, selecting the FortiGate unit and using the same menu structure and pages as you would see in the FortiGate web-based manager. All changes to the FortiGate configuration are stored locally on the FortiManager unit until you synchronize with the FortiGate unit.

When a FortiGate unit is under control of a FortiManager system, administrators will not be able to change the configuration using the FortiGate. When trying to change options, the unit displays a message that it is configured through FortiManager, and any changes may be reverted.

Global objects

If you are maintaining a number of FortiGate units within a network, many of the policies and configuration elements will be the same across the corporation. In these instances, the adding and editing of many of the same policies will be come a tedious and error-prone activity. With FortiManager global objects, this level of configuration is simplified.

A global object is an object that is not associated specifically with one device or group. Global objects include security policies, a DNS server, VPN, and IP pools.

The Global Objects window is where you can configure global objects and copy the configurations to the FortiManager device database for a selected device or a group of devices. You can also import configurations from the FortiManager device database for a selected device and modify the configuration as required.

When configuring or creating a global policy object the interface, prompts, and fields are the same as creating the same object on a FortiGate unit using the FortiGate web-based manager.

Locking the FortiGate web-based manager

When you use the FortiManager to manager multiple FortiGate units, a local FortiGate unit becomes locked from any configuration changes using the web-based manager for most administrators. The super_admin will still be able to make changes to the configuration; however, this is not recommended as it may cause conflicts with the FortiManager.

FortiGuard

FortiManager can also connect to the FortiGuard Distribution Network (FDN) to receive push updates for IPS signatures and antivirus definitions. These updates can then be used to update multiple FortiGate units throughout an organization. By using the FortiManager as the host for updates, bandwidth use is minimized as updates are downloaded to one source instead of many.

To receive IPS and antivirus updates from FortiManager, indicate an alternate IP address on the FortiGate unit.

To configure updates from FortiManager

1. Go to **System > FortiGuard**.
2. Under **AntiVirus and IPS Updates**, enable both **Accept push updates** and **Use override push**.
3. Enter the IP address of the FortiManager unit.
4. Select **Apply**.

The central management FortiGuard server list can include FQDNs (354449)

This feature, introduced in FortiOS 5.4.0, implements support of FQDN, to make it an option for central-management server-list. This feature can be set through the GUI and the CLI.

GUI Changes

On **System > FortiGuard > Override FortiGuard Servers > Create New / Edit**, a new option, **FQDN** is added for **Address Type**.

CLI Changes

```
config server-list
   edit 1
      set server-type {update|rating}
      set addr-type {ipv4|ipv6|fqdn} <== added fqdn
      set server-address ipv4
      set server-address6 ipv6
      set fqdn FQDN <== added
   end
end
```

Sending malware statistics to FortiGuard

To support following Malware trends and making zero-day discoveries, FortiGate units send encrypted statistics to FortiGuard about IPS, Application Control, and AntiVirus events detected by the FortiGuard services running on your FortiGate. FortiGuard uses the statistics collected to achieve a balance between performance and security effectiveness by moving inactive signatures to an extended signature database.

The statistics include some non-personal information that identifies your FortiGate and its country. The information is never shared with external parties. You can choose to disable the sharing of this information by entering the following CLI command.

```
config system global
   set fds-statistics disable
end
```

Firmware updates

A FortiManager unit can also perform firmware updates for multiple FortiGate units, saving time rather than upgrading each FortiGate unit individually.

The FortiManager unit stores local copies of firmware images, either by downloading images from the Fortinet Distribution Network (FDN) or by accepting firmware images that are uploaded from the management computer.

If you are using the FortiManager unit to download firmware images, the FDN first validates device licenses and support contracts and then provides a list of currently available firmware images. For devices with valid Fortinet Technical Support contracts, you can download new firmware images from the FDN and the firmware release notes.

After firmware images have been either downloaded from the FDN or imported to the firmware list, you can either schedule or immediately upgrade/downgrade a device or group of device's firmware.

See the FortiManager Administration Guide for more information on updating the FortiGate firmware using the FortiManager central management.

Administrative domains

FortiManager administrative domains enable the super_admin to create groupings of devices for configured administrators to monitor and manage. FortiManager can manage a large number of Fortinet appliances. This enables administrators to maintain managed devices specific to their geographic location or business division. This also includes FortiGate units with multiple configured VDOMs.

Each administrator is tied to an administrative domain (ADOM). When that particular administrator logs in, they see only those devices or VDOMs configured for that administrator and ADOM. The one exception is the super_admin account that can see and maintain all administrative domains and the devices within those domains.

Administrative domains are not enabled by default and enabling and configuring the domains can only be performed by the super_admin.

The maximum number of administrative domains you can add depends on the FortiManager system model. See the FortiManager Administration Guide for information on the maximums for each model.

Backup and restore configurations

A FortiManager unit stores configuration files for backup and restore purposes. A FortiManager also enables you to save revisions of configuration files. Configuration backups occur automatically when the administrator logs out or the administrator login session expires.

FortiManager also enables you to view differences between different configurations to identify where changes have been made.

Monitoring

With network administration, the first step is installing and configuring the FortiGate unit to be the protector of the internal network. Once the system is running efficiently, the next step is to monitor the system and network traffic, making configuration changes as necessary when a threat or vulnerability is discovered.

This chapter discusses the various methods of monitoring both the FortiGate unit and the network traffic through a range of different tools available within FortiOS.

This section includes the topics:

- Dashboard
- sFlow
- Monitor menus
- Logging

- Alert email
- SNMP
- SNMP get command syntax

Dashboard

The FortiOS dashboard provides a location to view real-time system information. By default, the dashboard displays the key statistics of the FortiGate unit itself, providing the memory and CPU status, as well as the health of the ports, whether they are up or down and their throughput.

Widgets

Within the Dashboard is a number of smaller windows, called widgets, that provide this status information. Beyond what is visible by default, you can add a number of other widgets that display other key traffic information including application use, traffic per IP address, top attacks, traffic history and logging statistics.

You can add multiple dashboards to reflect what data you want to monitor, and add the widgets accordingly. Dashboard configuration is only available through the GUI. Administrators must have read and write privileges to customize and add widgets when in either menu. Administrators must have read privileges if they want to view the information.

To add a dashboard and widgets

1. Go to **Dashboard**.
2. Select the **Dashboard** menu at the top of the window and select **Add Dashboard**.
3. Enter a name.
4. Select the **Widget** menu at the top of the window.
5. From the screen, select the type of information you want to add.
6. When done, select the X in the top right of the widget.

Dashboard widgets provide an excellent method to view real-time data about the events occurring on the FortiGate unit and the network. For example, by adding the Network Protocol Usage widget, you can monitor the activity of various protocols over a selected span of time. Based on that information you can add or adjust traffic shaping and/or security policies to control traffic.

License Information

The **License Information** widget displays summary information for your:

- Support Contract
- FortiGuard services
- FortiCloud account
- FortiSandbox license
- FortiClient connections
- FortiToken Mobile tokens assigned

The FortiClient connections section displays the number of FortiClient connections allowed and the number of users connecting. By selecting the **Details** link for the number of connections, you can view more information about the connecting user, including IP address, user name, and the user's operating system type. Included with this information is a link for Mac and Windows. Selecting these links automatically downloads the FortiClient install file (.dmg or .exe) to the management computer.

sFlow

sFlow is a method of monitoring the traffic on your network to identify areas on the network that may impact performance and throughput. FortiOS implements sFlow version 5.

sFlow uses packet sampling to monitor network traffic. The sFlow Agent captures packet information at defined intervals and sends them to an sFlow Collector for analysis, providing real-time data analysis. The information sent is only a sampling of the data for minimal impact on network throughput and performance.

The sFlow Agent is embedded in the FortiGate unit. Once configured, the FortiGate unit sends sFlow datagrams of the sampled traffic to the sFlow Collector, also called an sFlow Analyzer. The sFlow Collector receives the datagrams, and provides real-time analysis and graphing to indicate where potential traffic issues are occurring. sFlow Collector software is available from a number of third party software vendors.

sFlow data captures only a sampling of network traffic, not all traffic like the traffic logs on the FortiGate unit. Sampling works by the sFlow Agent looking at traffic packets when they arrive on an interface. A decision is made whether the packet is dropped and allowed to be to its destination or if a copy is forwarded to the sFlow Collector. The sample used and its frequency are determined during configuration.

sFlow is not supported on virtual interfaces such as vdom link, ipsec, ssl.root or gre.

The sFlow datagram sent to the Collector contains the information:

- Packet header (e.g. MAC,IPv4,IPv6,IPX,AppleTalk,TCP,UDP, ICMP)
- Sample process parameters (rate, pool etc.)
- Input/output ports
- Priority (802.1p and TOS)
- VLAN (802.1Q)
- Source/destination prefix
- Next hop address
- Source AS, Source Peer AS
- Destination AS Path
- Communities, local preference
- User IDs (TACACS/RADIUS) for source/destination
- URL associated with source/destination
- Interface statistics (RFC 1573, RFC 2233, and RFC 2358)

sFlow agents can be added to any type of FortiGate interface. sFlow isn't supported on some virtual interfaces such as VDOM link, IPsec, gre, and ssl.root.

For more information on sFlow, Collector software and sFlow MIBs, visit www.sflow.org.

Configuration

sFlow configuration is available only from the CLI. Configuration requires two steps: enabling the sFlow Agent and configuring the interface for the sampling information.

Enable sFlow

```
config system sflow
   set collector-ip <ip_address>
   set collector-port <port_number>
   set source-ip <ip_address>
```

```
end
```

The default port for sFlow is UDP 6343. To configure in VDOM, use the commands:

```
config system vdom-sflow
   set vdom-sflow enable
   set collector-ip <ip_address>
   set collector-port <port_number>
   set source-ip <ip_address>
end
```

Configure sFlow agents per interface.

```
config system interface
   edit <interface_name>
      set sflow-sampler enable
      set sample-rate <every_n_packets>
      set sample-direction [tx | rx | both]
      set polling-interval <seconds>
   end
```

Monitor menus

The **Monitor** menus enable you to view session and policy information and other activity occurring on your FortiGate unit. The monitors provide the details of user activity, traffic and policy usage to show live activity. Monitors are available for DHCP, routing, security policies, traffic shaping, load balancing, security features, VPN, users, and WiFi.

Logging

FortiOS provides a robust logging environment that enables you to monitor, store, and report traffic information and FortiGate events, including attempted log ins and hardware status. Depending on your requirements, you can log to a number of different hosts.

To configure logging in the web-based manager, go to **Log & Report > Log Settings**.

To configure logging in the CLI use the commands `config log <log_location>`.

For details on configuring logging see the Logging and Reporting Guide.

If you will be using several FortiGate units, you can also use a FortiAnalyzer unit for logging. For more information, see the FortiAnalyzer Administration Guide.

Syslog server

An industry standard for collecting log messages, for off-site storage. In the web-based manager, you are able to send logs to a single syslog server, however in the CLI you can configure up to three syslog servers where you can also use multiple configuration options. For example, send traffic logs to one server, antivirus logs to another. The FortiGate unit sends Syslog traffic over UDP port 514. Note that if a secure tunnel is configured for communication to a FortiAnalyzer unit, then Syslog traffic will be sent over an IPsec connection, using UPD 500/4500, Protocol IP/50.

To configure a Syslog server in the web-based manager, go to **Log & Report > Log Settings**. In the CLI use the commands:

```
config log syslogd setting
   set status enable
```

```
    set server <IP address or FQDN of syslog server>
end
```

Further options are available when enabled to configure a different port, facility and server IP address.

For Syslog traffic, you can identify a specific port/IP address for logging traffic. Configuration of these services is performed in the CLI, using the command `set source-ip`. When configured, this becomes the dedicated port to send this traffic over.

For example, to set the source IP of a Syslog server to be on the DMZ1 port with an IP of 192.168.4.5, the commands are:

```
config log syslogd setting
   set status enable
   set source-ip 192.168.4.5
end
```

You must configure the secure tunnel on **both** ends of the tunnel, the FortiGate unit and the FortiAnalyzer unit.

Alert email

As an administrator, you want to be certain you can respond quickly to issues occurring on your network or on the FortiGate unit. Alert emails provide an efficient and direct method of notifying an administrator of events. By configuring alert messages, you can define the threshold when a problem becomes critical and needs attention. When this threshold is reached, the FortiGate unit will send an email to one or more individuals, notifying them of the issue.

In the following example, the FortiGate unit is configured to send email to two administrators (admin1 and admin2) when multiple intrusions are detected every two minutes. The FortiGate unit has its own email address on the mail server.

To configure the email service

1. Go to **System > Config > Advanced**.
2. In the **Email Service**, complete the following and select **Apply**:

SMTP Server	Enter the address or name of the email server. For example, `smtp.example.com`.
Default Reply To	Enter an email address to associate with the alert email. This field is optional. If you enter an email address here, it overrides the email address entered when configuring alert email in **Log & Report > Alert E-mail**.
Authentication	Enable authentication if required by the email server.
Security mode	Choose between *None*, *SMTPS* or *STARTTLS*
Port	25

To configure alert email - web-based manager

1. Go to **Log & Report > Log Config > Alert E-mail**.
2. Enter the information:

Email from	fortigate@example.com
Email to	admin1@example.com admin2@example.com

3. For the **Interval Time**, enter `2`.
4. Select **Intrusion Detected**.
5. Select **Apply**.

To configure alert email - CLI

```
config system email-server
   set port 25
   set server smtp.example.com
   set authenticate enable
   set username FortiGate
   set password *************
end
config alertemail setting
   set username fortigate@example.com
   set mailto1 admin1@example.com
   set mailto2 admin2@example.com
   set filter category
   set IPS-logs enable
end
```

SNMP

Simple Network Management Protocol (SNMP) enables you to monitor hardware on your network. You can configure the hardware, such as the FortiGate SNMP agent, to report system information and send traps (alarms or event messages) to SNMP managers. An SNMP manager, or host, is a typically a computer running an application that can read the incoming trap and event messages from the agent and send out SNMP queries to the SNMP agents. A FortiManager unit can act as an SNMP manager to one or more FortiGate units. FortiOS supports SNMP using IPv4 and IPv6 addressing.

By using an SNMP manager, you can access SNMP traps and data from any FortiGate interface or VLAN subinterface configured for SNMP management access. Part of configuring an SNMP manager is to list it as a host in a community on the FortiGate unit it will be monitoring. Otherwise, the SNMP monitor will not receive any traps from that FortiGate unit or be able to query that unit.

The FortiGate SNMP implementation is read-only. SNMP v1, v2c, and v3 compliant SNMP managers have read-only access to FortiGate system information through queries and can receive trap messages from the FortiGate unit.

To monitor FortiGate system information and receive FortiGate traps, you must first compile the Fortinet and FortiGate Management Information Base (MIB) files. A MIB is a text file that describes a list of SNMP data

objects that are used by the SNMP manager. These MIBs provide information the SNMP manager needs to interpret the SNMP trap, event, and query messages sent by the FortiGate unit SNMP agent.

FortiGate core MIB files are available for download by going to **System > SNMP** and selecting the download link on the page.

The Fortinet implementation of SNMP includes support for most of RFC 2665 (Ethernet-like MIB) and most of RFC 1213 (MIB II). For more information, see "Fortinet MIBs". RFC support for SNMP v3 includes Architecture for SNMP Frameworks (RFC 3411), and partial support of User-based Security Model (RFC 3414).

SNMP traps alert you to events that occur such as a full log disk or a virus detected.

SNMP fields contain information about the FortiGate unit, such as CPU usage percentage or the number of sessions. This information is useful for monitoring the condition of the unit on an ongoing basis and to provide more information when a trap occurs.

The FortiGate SNMP v3 implementation includes support for queries, traps, authentication, and privacy. Authentication and encryption are configured in the CLI. See the `system snmp user` command in the FortiGate CLI Reference.

SNMP configuration settings

Before a remote SNMP manager can connect to the FortiGate agent, you must configure one or more FortiGate interfaces to accept SNMP connections by going to **Network > Interfaces**. Select the interface and, in the **Administrative Access**, select **SNMP**.

For VDOMS, SNMP traps can only be sent on interfaces in the management VDOM. Traps cannot be sent over other interfaces outside the management VDOM.

To configure SNMP settings, go to **System > SNMP**.

SNMP Agent	Select to enable SNMP communication.
Description	Enter descriptive information about the FortiGate unit. The description can be up to 35 characters.
Location	Enter the physical location of the FortiGate unit. The system location description can be up to 35 characters long.
Contact	Enter the contact information for the person responsible for this FortiGate unit. The contact information can be up to 35 characters.
SNMP v1/v2c section To create a new SNMP community, see SNMP Community.	
Community Name	The name to identify the community.
Queries	Indicates whether queries protocols (v1 and v2c) are enabled or disabled. A green check mark indicates queries are enabled; a gray x indicates queries are disabled. If one query is disabled and another one enabled, there will still be a green check mark.

Traps	Indicates whether trap protocols (v1 and v2c) are enabled or disabled. A green check mark indicates traps are enabled; a gray x indicates traps are disabled. If one query is disabled and another one enabled, there will still be a green check mark.
Enable	Select the check box to enable or disable the community.
SNMP v3 section To create a new SNMP community, see SNMP Community page.	
User Name	The name of the SNMPv3 user.
Security Level	The security level of the user.
Notification Host	The IP address or addresses of the host.
Queries	Indicates whether queries are enabled or disabled. A green check mark indicates queries are enabled; a gray x indicates queries are disabled
New SNMP Community page	
Community Name	Enter a name to identify the SNMP community
Hosts (section)	
IP Address	Enter the IP address and Identify the SNMP managers that can use the settings in this SNMP community to monitor the FortiGate unit. You can also set the IP address to 0.0.0.0 to so that any SNMP manager can use this SNMP community.
Delete	Removes an SNMP manager from the list within the **Hosts** section.
Add	Select to add a blank line to the Hosts list. You can add up to eight SNMP managers to a single community.
Queries (section)	
Protocol	The SNMP protocol. In the v1 row, this means that the settings are for SNMP v1. In the v2c row, this means that the settings are for SNMP v2c.
Port	Enter the port number (161 by default) that the SNMP managers in this community use for SNMP v1 and SNMP v2c queries to receive configuration information from the FortiGate unit. Select the **Enable** check box to activate queries for each SNMP version. **Note:** The SNMP client software and the FortiGate unit must use the same port for queries.
Enable	Select to enable that SNMP protocol.

Traps (section)	
Protocol	The SNMP protocol. In the v1 row, this means that the settings are for SNMP v1. In the v2c row, this means that the settings are for SNMP v2c.
Local	Enter the remote port numbers (port 162 for each by default) that the FortiGate unit uses to send SNMP v1 or SNMP v2c traps to the SNMP managers in this community. Select the **Enable** check box to activate traps for each SNMP version. **Note:** The SNMP client software and the FortiGate unit must use the same port for traps.
Remote	Enter the remote port number (port 162 is default) that the FortiGate unit uses to send SNMP v1 or v2c traps to the SNMP managers in this community. **Note:** The SNMP client software and the FortiGate unit must use the same port for queries.
Enable	Select to activate traps for each SNMP version.
SNMP Event	Enable each SNMP event for which the FortiGate unit should send traps to the SNMP managers in this community. **CPU Over usage** traps sensitivity is slightly reduced, by spreading values out over 8 polling cycles. This prevents sharp spikes due to CPU intensive short-term events such as changing a policy. **Power Supply Failure** event trap is available only on some models. **AMC interfaces enter bypass mode** event trap is available only on models that support AMC modules.
Enable	Select to enable the SNMP event.
Create New SNMP V3 User	
User Name	Enter the name of the user.
Security Level	Select the type of security level the user will have.
Notification Host	Enter the IP address of the notification host. If you want to add more than one host, after entering the IP address of the first host, select the plus sign to add another host.
Enable Query	Select to enable or disable the query. By default, the query is enabled.
Port	Enter the port number in the field.
Events	Select the SNMP events that will be associated with that user.

Gigabit interfaces

When determining the interface speed of a FortiGate unit with a 10G interface, the IF-MIB.ifSpeed may not return the correct value. IF-MIB.ifSpeed is a 32-bit gauge used to report interface speeds in bits/second and cannot convert to a 64-bit value. The 32-bit counter wrap the output too fast to be accurate.

In this case, you can use the value ifHighSpeed. It reports interface speeds in megabits/second. This ensures that 10Gb interfaces report the correct value.

SNMP agent

You need to first enter information and enable the FortiGate SNMP Agent. Enter information about the FortiGate unit to identify it so that when your SNMP manager receives traps from the FortiGate unit, you will know which unit sent the information.

To configure the SNMP agent - GUI

1. Go to **System > SNMP**.
2. Select **Enable** for the **SNMP Agent**.
3. Enter a descriptive name for the agent.
4. Enter the location of the FortiGate unit.
5. Enter a contact or administrator for the SNMP Agent or FortiGate unit.
6. Select **Apply**.

To configure SNMP agent - CLI

```
config system snmp sysinfo
   set status enable
   set contact-info <contact_information>
   set description <description_of_FortiGate>
   set location <FortiGate_location>
end
```

SNMP community

An SNMP community is a grouping of devices for network administration purposes. Within that SNMP community, devices can communicate by sending and receiving traps and other information. One device can belong to multiple communities, such as one administrator terminal monitoring both a firewall SNMP and a printer SNMP community.

Add SNMP communities to your FortiGate unit so that SNMP managers can connect to view system information and receive SNMP traps.

You can add up to three SNMP communities. Each community can have a different configuration for SNMP queries and traps. Each community can be configured to monitor the FortiGate unit for a different set of events. You can also add the IP addresses of up to 8 SNMP managers to each community.

When the FortiGate unit is in virtual domain mode, SNMP traps can only be sent on interfaces in the management virtual domain. Traps cannot be sent over other interfaces.

To add an SNMP v1/v2c community - GUI

1. Go to **System > SNMP**.
2. In the **SNMP v1/v2c** area, select **Create New**.

3. Enter a **Community Name**.
4. Enter the IP address and Identify the SNMP managers that can use the settings in this SNMP community to monitor the FortiGate unit.
5. Select the interface if the SNMP manager is not on the same subnet as the FortiGate unit.
6. Enter the **Port** number that the SNMP managers in this community use for SNMP v1 and SNMP v2c queries to receive configuration information from the FortiGate unit. Select the **Enable** check box to activate queries for each SNMP version.
7. Enter the Local and Remote port numbers that the FortiGate unit uses to send SNMP v1 and SNMP v2c traps to the SNMP managers in this community.
8. Select the **Enable** check box to activate traps for each SNMP version.
9. Select **OK**.

To add an SNMP v1/v2c community - CLI

```
config system snmp community
   edit <index_number>
      set events <events_list>
      set name <community_name>
      set query-v1-port <port_number>
      set query-v1-status {enable | disable}
      set query-v2c-port <port_number>
      set query-v2c-status {enable | disable}
      set status {enable | disable}
      set trap-v1-lport <port_number>
      set trap-v1-rport <port_number>
      set trap-v1-status {enable | disable}
      set trap-v2c-lport <port_number>
      set trap-v2c-rport <port_number>
      set trap-v2c-status {enable | disable}
end
```

To add an SNMP v3 community - GUI

1. Go to **System > SNMP**.
2. In the **SNMP v3** area, select **Create New**.
3. Enter a **User Name**.
4. Select a **Security Level** and associated authorization algorithms.
5. Enter the IP address of the **Notification Host** SNMP managers that can use the settings in this SNMP community to monitor the FortiGate unit.
6. Enter the **Port** number that the SNMP managers in this community use to receive configuration information from the FortiGate unit. Select the **Enable** check box to activate queries for each SNMP version.
7. Select the **Enable** check box to activate traps.
8. Select **OK**.

To add an SNMP v3 community - CLI

```
config system snmp user
   edit <index_number>
      set security-level [auth-priv | auth-no-priv | no-auth-no-priv}
      set queries enable
      set query-port <port_number>
      set notify-hosts <ip_address>
```

```
      set events <event_selections>
end
```

Enabling on the interface

Before a remote SNMP manager can connect to the FortiGate agent, you must configure one or more FortiGate interfaces to accept SNMP connections.

To configure SNMP access - GUI

1. Go to **Network > Interfaces**.
2. Choose an interface that an SNMP manager connects to and select **Edit**.
3. In **Administrative Access**, select **SNMP**.
4. Select **OK**.

To configure SNMP access - CLI

```
config system interface
   edit <interface_name>
      set allowaccess snmp
end
```

If the interface you are configuring already has protocols that are allowed access, use the command `append allowaccess snmp` instead, or else the other protocols will be replaced. For more information, see Adding and removing options from lists.

Fortinet MIBs

The FortiGate SNMP agent supports Fortinet proprietary MIBs as well as standard RFC 1213 and RFC 2665 MIBs. RFC support includes support for the parts of RFC 2665 (Ethernet-like MIB) and the parts of RFC 1213 (MIB II) that apply to FortiGate unit configuration.

There are two MIB files for FortiGate units - the Fortinet MIB, and the FortiGate MIB. The Fortinet MIB contains traps, fields and information that is common to all Fortinet products. The FortiGate MIB contains traps, fields and information that is specific to FortiGate units. Each Fortinet product has its own MIB. If you use other Fortinet products you will need to download their MIB files as well. Both MIB files are used for FortiOS and FortiOS Carrier; there are no additional traps for the Carrier version of the operating system.

The Fortinet MIB and FortiGate MIB along with the two RFC MIBs are listed in tables in this section. You can download the two FortiGate MIB files from Fortinet Customer Support. The Fortinet MIB contains information for Fortinet products in general. the Fortinet FortiGate MIB includes the system information for The FortiGate unit and version of FortiOS. Both files are required for proper SNMP data collection.

To download the MIB files, go to **System > SNMP** and select a MIB link in the **FortiGate SNMP MIB** section.

Your SNMP manager may already include standard and private MIBs in a compiled database that is ready to use. You must add the Fortinet proprietary MIB to this database to have access to the Fortinet specific information.

There were major changes to the MIB files between FortiOS Carrier v3.0 and v4.0. You need to use the new MIBs for FortiOS Carrier v4.0 or you may mistakenly access the wrong traps and fields.

MIB files are updated for each version of FortiOS. When upgrading the firmware ensure that you updated the Fortinet FortiGate MIB file as well.

Fortinet MIBs

MIB file name or RFC	Description
FORTINET-CORE-MIB.mib	The Fortinet MIB includes all system configuration information and trap information that is common to all Fortinet products. Your SNMP manager requires this information to monitor FortiGate unit configuration settings and receive traps from the FortiGate SNMP agent.
FORTINET-FORTIGATE-MIB.mib	The FortiGate MIB includes all system configuration information and trap information that is specific to FortiGate units. Your SNMP manager requires this information to monitor FortiGate configuration settings and receive traps from the FortiGate SNMP agent. FortiManager systems require this MIB to monitor FortiGate units.
RFC-1213 (MIB II)	The FortiGate SNMP agent supports MIB II groups with these exceptions. • No support for the EGP group from MIB II (RFC 1213, section 3.11 and 6.10). • Protocol statistics returned for MIB II groups (IP/ICMP/TCP/UDP/etc.) do not accurately capture all FortiGate traffic activity. More accurate information can be obtained from the information reported by the Fortinet MIB.
RFC-2665 (Ethernet-like MIB)	The FortiGate SNMP agent supports Ethernet-like MIB information. FortiGate SNMP does not support for the dot3Tests and dot3Errors groups.

SNMP improvements for dynamic routing include support for RFC 4750 OSPF Version 2 Management Information Base and RFC 5643 Management Information Base for OSPFv3. These changes add the capability of logging dynamic routing activity. Examples include sending OSPF routing events or changes to a syslog server or FortiAnalyzer or changes in neighborhood status.

Device Detection for SNMP Traps in FortiOS 5.4.0

This setting is related to the device detection feature. It allows SNMP traps to detect when a new device comes online. Within SNMP configurations there is a configurable timeout setting that periodically checks for the device. When a check determines that the device is present a trap is sent.

In the GUI, when configuring an SNMP object, one of the settings is a checkbox, under **SNMP Events** for **Device detected**.

To configure the SNMP object in the CLI use the following syntax:

```
config system snmp community
   edit <community ID number>
      set name <string>
      set events device-new
      end
```

In order to configure the idle timeout for the device, use the following syntax in the CLI:

```
config system global
   set device-idel-timeout <integer of time in seconds>
   end
```

The time value for the field can be set from 30 to 31536000.

SNMP get command syntax

Normally, to get configuration and status information for a FortiGate unit, an SNMP manager would use an SNMP get commands to get the information in a MIB field. The SNMP get command syntax would be similar to:

```
snmpget -v2c -c <community_name> <address_ipv4> {<OID> | <MIB_field>}
```

…where…

`<community_name>` is an SNMP community name added to the FortiGate configuration. You can add more than one community name to a FortiGate SNMP configuration. The most commonly used community name is `public`.

`<address_ipv4>` is the IP address of the FortiGate interface that the SNMP manager connects to.

`{<OID> | <MIB_field>}` is the object identifier (OID) for the MIB field or the MIB field name itself.

The SNMP `get` command gets firmware version running on the FortiGate unit. The community name is `public`. The IP address of the interface configured for SNMP management access is `10.10.10.1`. The firmware version MIB field is `fgSysVersion` and the OID for this MIB field is `1.3.6.1.4.1.12356.101.4.1.1` The first command uses the MIB field name and the second uses the OID:

```
snmpget -v2c -c public 10.10.10.1 fgSysVersion.0
snmpget -v2c -c public 10.10.10.1 1.3.6.1.4.1.12356.101.4.1.1.0
```

The OIDs and object names used in these examples are dependent on the version of MIB and are subject to change.

Replacement messages

The replacement message list in **System > Replacement Messages**.

The replacement messages list enables you to view and customize replacement messages. Highlight the e replacement messages you wish to edit and customize the message content to your requirements. Hit **Save** when done.

Should you make a major error to the code, you can select the **Restore Default** to return to the original message and code base.

For connections requiring authentication, the FortiGate unit uses HTTP to send an authentication disclaimer page for the user to accept before a security policy is in effect. Therefore, the user must initiate HTTP traffic first in order to trigger the authentication disclaimer page. Once the disclaimer is accepted, the user can send whatever traffic is allowed by the security policy.

Replacement message images

You can add images to replacement messages to:

- Disclaimer pages
- Login pages
- Declined disclaimer pages
- Login failed page
- Login challenge pages
- Keepalive pages

Image embedding is also available to the endpoint NAC download portal and recommendation portal replacement messages, as well as HTTP replacement messages.

Supported image formats are GIF, JPEG, TIFF and PNG. The maximum file size supported is 6000 bytes.

Adding images to replacement messages

To upload an image for use in a message

1. Go to **System > Replacement Messages**.
2. Select **Manage Images** at the top of the page.
3. Select **Create New**.
4. Enter a **Name** for the image.
5. Select the **Content Type**.
6. Select **Browse** to locate the file and select **OK**.

The image that you include in a replacement message, must have the following html:

```
<img src=%%IMAGE: <config_image_name>%% size=<bytes> >
```

For example:

```
<img src=%%IMAGE: logo_hq%% size=4272>
```

Modifying replacement messages

Replacement messages can be modified to include a message or content that suits your organization.

Use the expand arrows to view the replacement message list for a given category. Messages are in HTML format. To change a replacement message, go to **System > Replacement Messages** select the replacement message that you want to modify. At the bottom pane of the window, you can see the message on one side and the HTML code on the other side. The message view changes in real-time as you change the content.

A list of common replacement messages appears in the main window. To see the entire list and all categories of replacement messages, in the upper-right corner of the window, select **Extended View**.

Replacement message categories

Alert Email replacement messages

The FortiGate unit adds the replacement messages listed in this category to alert email messages sent to administrators. If you enable the option **Send alert email for logs based on severity** in **Log & Report**, you control whether or not replacement messages are sent by alert email based on how you set the **Minimum log level**.

For more information on Alert emails, see the Monitoring chapter.

Authentication replacement messages

The FortiGate unit uses the text of the authentication replacement messages for various user authentication HTML pages that are displayed when a user is required to authenticate because a security policy includes at least one identity-based policy that requires firewall users to authenticate.

These replacement message pages are for authentication using HTTP and HTTPS. You cannot customize the firewall authentication messages for FTP and Telnet.

The authentication login page and the authentication disclaimer include replacement tags and controls not found on other replacement messages.

Users see the authentication login page when they use a VPN or a security policy that requires authentication. You can customize this page in the same way as you modify other replacement messages.

There are some unique requirements for these replacement messages:

- The login page must be an HTML page containing a form with `ACTION="/"` and `METHOD="POST"`
- The form must contain the following hidden controls:
  - `<INPUT TYPE="hidden" NAME="%%MAGICID%%" VALUE="%%MAGICVAL%%">`
  - `<INPUT TYPE="hidden" NAME="%%STATEID%%" VALUE="%%STATEVAL%%">`
  - `<INPUT TYPE="hidden" NAME="%%REDIRID%%" VALUE="%%PROTURI%%">`
- The form must contain the following visible controls:
  - `<INPUT TYPE="text" NAME="%%USERNAMEID%%" size=25>`
  - `<INPUT TYPE="password" NAME="%%PASSWORDID%%" size=25>`

Example

The following is an example of a simple authentication page that meets the requirements listed above.

```
<HTML><HEAD><TITLE>Firewall Authentication</TITLE></HEAD>
      <BODY><H4>You must authenticate to use this service.</H4>
<FORM ACTION="/" method="post">
      <INPUT NAME="%%MAGICID%%" VALUE="%%MAGICVAL%%" TYPE="hidden">
<TABLE ALIGN="center" BGCOLOR="#00cccc" BORDER="0"
      CELLPADDING="15" CELLSPACING="0" WIDTH="320"><TBODY>
<TR><TH>Username:</TH>
      <TD><INPUT NAME="%%USERNAMEID%%" SIZE="25" TYPE="text"> </TD></TR>
<TR><TH>Password:</TH>
      <TD><INPUT NAME="%%PASSWORDID%%" SIZE="25" TYPE="password"> </TD></TR>
<TR><TD COLSPAN="2" ALIGN="center" BGCOLOR="#00cccc">
      <INPUT NAME="%%STATEID%%" VALUE="%%STATEVAL%%" TYPE="hidden">
          <INPUT NAME="%%REDIRID%%" VALUE="%%PROTURI%%" TYPE="hidden">
          <INPUT VALUE="Continue" TYPE="submit"> </TD></TR>
```

```
</TBODY></TABLE></FORM></BODY></HTML>
```

Captive Portal Default replacement messages

The Captive Portal Default replacement messages are used for wireless authentication only. You must have a VAP interface with the security set as captive portal to trigger these replacement messages.

Device Detection Portal replacement message

The FortiGate unit displays the replacement message when the FortiGate unit cannot determine the type of BYOD or handheld device is used to connect the network.

Email replacement messages

The FortiGate unit sends the mail replacement messages to email clients using IMAP, POP3, or SMTP when an event occurs such as antivirus blocking a file attached to an email that contains a virus. Email replacement messages are text messages.

If the FortiGate unit supports SSL content scanning and inspection these replacement messages can also be added to IMAPS, POP3S, and SMTPS email messages.

Endpoint Control replacement message

The FortiGate unit displays the replacement message when the FortiClient Endpoint Security software is not installed or registered correctly with the FortiGate unit.

FortiGuard Web Filtering replacement messages

The FortiGate unit sends the FortiGuard Web Filtering replacement messages to web browsers using the HTTP protocol when FortiGuard web filtering blocks a URL, provides details about blocked HTTP 4xx and 5xx errors, and for FortiGuard overrides. FortiGuard Web Filtering replacement messages are HTTP pages.

If the FortiGate unit supports SSL content scanning and inspection and if **Protocol Recognition > HTTPS Content Filtering Mode** is set to Deep Scan in the antivirus profile, these replacement messages can also replace web pages downloaded using the HTTPS protocol.

FTP replacement messages

The FortiGate unit sends the FTP replacement messages listed in the table below to FTP clients when an event occurs such as antivirus blocking a file that contains a virus in an FTP session. FTP replacement messages are text messages.

HTTP replacement messages

The FortiGate unit sends the HTTP replacement messages listed in the following table to web browsers using the HTTP protocol when an event occurs such as antivirus blocking a file that contains a virus in an HTTP session. HTTP replacement messages are HTML pages.

If the FortiGate unit supports SSL content scanning and inspection, and if under HTTPS in the protocol option list has Enable Deep Scan enabled, these replacement messages can also replace web pages downloaded using the HTTPS protocol.

IM replacement messages

The FortiGate unit sends the IM replacement messages to IM clients using AIM, ICQ, MSN, or Yahoo! Messenger when an event occurs such as antivirus blocking a file attached to an email that contains a virus. IM replacement messages are text messages.

NNTP replacement messages

The FortiGate unit sends the NNTP replacement messages NNTP clients when an event occurs such as antivirus blocking a file attached to an NNTP message that contains a virus. NNTP replacement messages are text messages.

Spam replacement messages

The FortiGate unit adds the Spam replacement messages to SMTP server responses if the email message is identified as spam and the spam action is discard. If the FortiGate unit supports SSL content scanning and inspection these replacement messages can also be added to SMTPS server responses.

NAC quarantine replacement messages

The page that is displayed for the user depends on whether NAC quarantine blocked the user because a virus was found, a DoS sensor detected an attack, an IPS sensor detected an attack, or a DLP rule with action set to **Quarantine IP address** or **Quarantine Interface** matched a session from the user.

The default messages inform the user of why they are seeing this page and recommend they contact the system administrator. You can customize the pages as required, for example to include an email address or other contact information or if applicable a note about how long the user can expect to be blocked.

SSL VPN replacement messages

The SSL VPN login replacement message is an HTML replacement message that formats the FortiGate SSL VPN portal login page. You can customize this replacement message according to your organization's needs. The page is linked to FortiGate functionality and you must construct it according to the following guidelines to ensure that it will work.

- The login page must be an HTML page containing a form with `ACTION="%%SSL_ACT%%"` and `METHOD="%%SSL_METHOD%%"`
- The form must contain the `%%SSL_LOGIN%%` tag to provide the login form.
- The form must contain the `%%SSL_HIDDEN%%` tag.

Web Proxy replacement messages

The FortiGate unit sends Web Proxy replacement messages when a web proxy event occurs that is detected and matches the web proxy configuration. These replacement messages are web pages that appear within your web browser.

The following web proxy replacement messages require an identity-based security policy so that the web proxy is successful. You can also enable FTP-over-HTTP by selecting the **FTP** option in **System > Network > Explicit Proxy**.

Traffic quota control replacement messages

When user traffic is going through the FortiGate unit and it is blocked by traffic shaping quota controls, users see the **Traffic shaper block message** or the **Per IP traffic shaper block message** when they attempt to connect through the FortiGate unit using HTTP.

The traffic quota HTTP pages should contain the `%%QUOTA_INFO%%` tag to display information about the traffic shaping quota setting that is blocking the user.

MM1 replacement messages

MM1 replacement messages are sent when, during MMS content scanning, FortiOS Carrier detects, for example a virus, using the MMS profile.

You must have **Remove Blocked** selected within the MMS profile if you want to remove the content that is intercepted during MMS scanning on the FortiGate unit.

MM3 replacement messages

MM3 replacement messages are sent when, during MMS content scanning, FortiOS Carrier detects, for example a virus, using the MMS profile.

You must have **Remove Blocked** selected within the MMS profile if you want to remove the content that is intercepted during MMS scanning on the unit.

MM4 replacement messages

MM4 replacement messages are sent when, during MMS content scanning, FortiOS Carrier detects, for example a virus, using the MMS profile.

MM7 replacement messages

MM7 replacement messages are sent when, during MMS content scanning, FortiOS Carrier detects, for example a virus, using the MMS profile.

MMS replacement messages

The MMS replacement message is sent when a section of an MMS message has been replaced because it contains a blocked file. This replacement message is in HTML format.

The message text is:

```
<HTML><BODY>This section of the message has been replaced because it contained a blocked
    file</BODY></HTML>
```

Replacement message groups

Replacement message groups enable you to view common messages in groups for large carriers. Message groups can be configured by going to **Config > Replacement Message Group**.

Using the defined groups, you can manage specific replacement messages from a single location, rather than searching through the entire replacement message list.

If you enable virtual domains (VDOMs) on the FortiGate unit, replacement message groups are configured separately for each virtual domain. Each virtual domain has its own default replacement message group, configured from **System > Replacement Messages Group**.

When you modify a message in a replacement message group, a Reset icon appears beside the message in the group. You can select this Reset icon to reset the message in the replacement message group to the default version.

All MM1/4/7 notification messages for FortiOS Carrier (and MM1 retrieve-conf messages) can contain a SMIL layer and all MM4 notification messages can contain an HTML layer in the message. These layers can be used to brand messages by using logos uploaded to the FortiGate unit via the 'Manage Images' link found on the replacement message group configuration page.

Administration for schools

For system administrator in the school system it is particularly difficult to maintain a network and access to the Internet. There are potential legal liabilities if content is not properly filtered and children are allowed to view pornography and other non-productive and potentially dangerous content. For a school, too much filtering is better than too little. This section describes some basic practices administrators can employ to help maintain control without being too draconian for access to the internet.

Security policies

The default security policies in FortiOS allow all traffic on all ports and all IP addresses. Not the most secure. While applying UTM profiles can help to block viruses, detect attacks and prevent spam, this doesn't provide a solid overall security option. The best approach is a layered approach; the first layer being the security policy.

When creating outbound security policies, you need to know the answer to the question "What are the students allowed to do?" The answer is surf the web, connect to FTP sites, send/receive email, and so on.

Once you know what the students need to do, you can research the software used and determine the ports the applications use. For example, if the students only require web surfing, then there are only two ports (80 - HTTP and 443 - HTTPS) needed to complete their tasks. Setting the security policies to only allow traffic through two ports (rather than all 65,000), this will significantly lower any possible exploits. By restricting the ports to known services, means stopping the use of proxy servers, as many of them operate on a non-standard port to hide their traffic from URL filtering or HTTP inspection.

DNS

Students should not be allowed to use whatever DNS they want. this opens another port for them to use and potentially smuggle traffic on. The best approach is to point to an internal DNS server and only allow those devices out on port 53. Its the same approach one would use for SMTP. Only allow the mail server to use port 25 since nothing else should be sending email.

If there is no internal DNS server, then the list of allowed DNS servers they can use should be restrictive. One possible exploit would be for them to set up their own DNS server at home that serves different IPs for known hosts, such as having Google.com sent back the IP for playboy.com.

Encrypted traffic (HTTPS)

Generally speaking, students should not be allowed to access encrypted web sites. Encrypted traffic cannot be sniffed, and therefore, cannot be monitored. HTTPS traffic should only be allowed when necessary. Most web sites a student needs to access are HTTP, not HTTPS. Due to the nature of HTTPS protocol, and the fact that encryption is an inherent security risk to your network, its use should be restricted.

Adding a security policy that encompasses a list of allowed secure sites will ensure that any HTTPS sites that are required are the only sites a student can go to.

FTP

For the most part, students should not be using FTP. FTP is not HTTP or HTTPS so you cannot use URL filtering to restrict where they go. This can be controlled with destination IPs in the security policy. With a policy that specifically outlines which FTP addresses are allowed, all other will be blocked.

Example security policies

Given these requirements, an example set of security policies could look like the following illustration. In a large setup, all the IPs for the students are treated by one of these four policies.

Simple security policy setup

	Seq. No.	ID	Source	Destination	Schedule	Service	Action	Status
☐	1	2	Student PCs	Allowed Websites	always	HTTPS	✓	☑
☐	2	3	Student PCs	all	always	HTTP	✓	☑
☐	3	4	Student PCs	Allowed DNS	always	DNS	✓	☑
☐	4	5	Student PCs	Allowed FTP	always	FTP	✓	☑
☐	5		all	all	always	ANY	⊘	Implicit

The last policy in the list, included by default, is a deny policy. This adds to the potential of error that could end up allowing unwanted traffic to pass. The deny policy ensures that an y traffic making it to this point is stopped. It can also help in further troubleshooting by viewing the logs for denied traffic.

With these policies in place, even before packet inspection occurs, the FortiGate, and the network are fairly secure. Should any of the UTM profiles fail, there is still a basic level of security.

UTM security profiles

AntiVirus profiles

Antivirus screening should be enabled for any service you have enabled in the security policies. In the case above, HTTP, FTP, as well as POP3 and SMTP (assuming there is email access for students). There is not a virus scan option for HTTPS, because the content is encrypted. Generally speaking, most of the network traffic will be students surfing the web.

To configure antivirus profiles in the web-based manager, go to **Security Profiles > AntiVirus**, or use the CLI commands under `config antivirus profile`.

Web filtering

The actual filtering of URLs, sites and content, should be performed by FortiGuard. It is easier for the network administrator. Web sites are constantly being monitored, and new ones reviewed and added to the FortiGuard databases every day. The FortiGuard categories provide an extensive list of offensive and non-productive sites.

As well, there are additional settings to include in a web filtering profile to best contain a student's web browsing.

- Web URL filtering should be enabled to set up exemptions for web sites that are blocked or reasons other than category filtering. It also prevents the use of IP addresses to get around web filtering.

- Block invalid URLs - HTTPS only. This option inspects the HTTPS certificate and looks at the URL to ensure it's valid. It is common for proxy sites to create an HTTPS certificate with a garbage URL. If the site is legitimate, it should be set up correctly. If the site approach to security is to ignore it, then their security policy puts your network at risk and the site should be blocked.
- Enable **Block malicious URLs discovered by FortiSandbox**. If the FortiSandbox discovers a threat, the source URL will be added to the list of URLs to be blocked by the FortiGate.

Web filtering options are configured in the GUI by going to **Security Profiles > Web Filter**, or in the CLI under `config webfilter profile`.

Categories and Classifications

For the selection of what FortiGuard categories and classifications that should be blocked, that is purely based on the school system and its Internet information policy.

Email Filtering

Other than specific teacher-led email inboxes, there is no reason why a student should be able to access, read or send personal email. Ports for POP3, SMTP and IMAP should not be opened in a security policies.

IPS

The intrusion protection profiles should be used to ensure the student PCs are not vulnerable to attacks, nor do you want students making attacks. As well, IPS can do more than simple vulnerability scans. With a FortiGuard subscription, IPS signatures are pushed to the FortiGate unit. New signatures are released constantly for various intrusions as they are discovered.

FortiOS includes a number of predefined IPS sensors that you can enable by default. Selecting the all_default signature is a good place to start as it includes the major signatures.

To configure IPS sensors in the GUI, go to **Security Profiles > Intrusion Protection**, on the CLI use commands under `config ips sensor`.

Application control

Application control uses IPS signatures to limit the use of instant messaging and peer-to-peer applications which can lead to possible infections on a student's PC. FortiOS includes a number of pre-defined application categories. To configure and maintain application control profiles in the GUI, go to **Security Profiles > Application Control**. In the CLI use commands under `config application list`.

Some applications to consider include proxies, botnets, toolbars and P2P applications.

Logging

Turn on all logging. Every option in this section should be enabled. This is not where you decide what you are going to log. It is simply defining what the UTM profiles can log.

Logging everything is a way to monitor traffic on the network, see what student's are utilizing the most, and locate any potential holes in your security plan. As well, keeping this information may help to prove negligence later in necessary.

PPTP and L2TP

A virtual private network (VPN) is a way to use a public network, such as the Internet, as a vehicle to provide remote offices or individual users with secure access to private networks. FortiOS supports the Point-to-Point Tunneling Protocol (PPTP), which enables interoperability between FortiGate units and Windows or Linux PPTP clients. Because FortiGate units support industry standard PPTP VPN technologies, you can configure a PPTP VPN between a FortiGate unit and most third-party PPTP VPN peers.

This section describes how to configure PPTP and L2TP VPNs as well as PPTP passthrough.

This section includes the topics:

- How PPTP VPNs work
- FortiGate unit as a PPTP server
- Configuring the FortiGate unit for PPTP VPN
- Configuring the FortiGate unit for PPTP pass through
- Testing PPTP VPN connections
- Logging VPN events
- Configuring L2TP VPNs
- L2TP configuration overview

How PPTP VPNs work

The Point-to-Point Tunneling Protocol enables you to create a VPN between a remote client and your internal network. Because it is a Microsoft Windows standard, PPTP does not require third-party software on the client computer. As long as the ISP supports PPTP on its servers, you can create a secure connection by making relatively simple configuration changes to the client computer and the FortiGate unit.

PPTP uses Point-to-Point protocol (PPP) authentication protocols so that standard PPP software can operate on tunneled PPP links. PPTP packages data in PPP packets and then encapsulates the PPP packets within IP packets for transmission through a VPN tunnel.

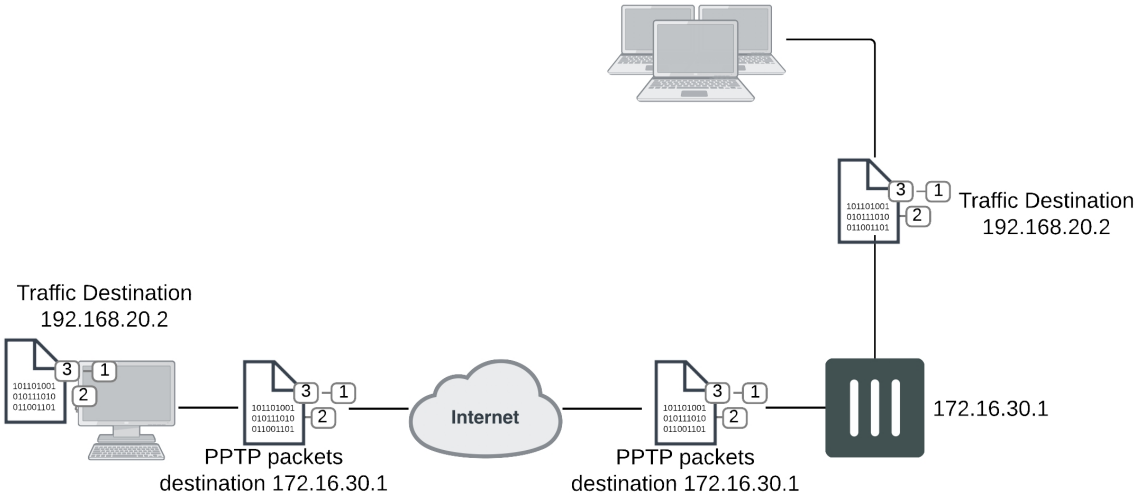
When the FortiGate unit acts as a PPTP server, a PPTP session and tunnel is created as soon as the PPTP client connects to the FortiGate unit. More than one PPTP session can be supported on the same tunnel. FortiGate units support PAP, CHAP, and plain text authentication. PPTP clients are authenticated as members of a user group.

Traffic from one PPTP peer is encrypted using PPP before it is encapsulated using Generic Routing Encapsulation (GRE) and routed to the other PPTP peer through an ISP network. PPP packets from the remote client are addressed to a computer on the private network behind the FortiGate unit. PPTP packets from the remote client are addressed to the public interface of the FortiGate unit. Seethe figure below.

PPTP control channel messages are not authenticated, and their integrity is not protected. Furthermore, encapsulated PPP packets are not cryptographically protected and may be read or modified unless appropriate encryption software such as Secure Shell (SSH) or Secure File Transfer Protocol (SFTP) is used to transfer data after the tunnel has been established.

As an alternative, you can use encryption software such as Microsoft Point-to-Point Encryption (MPPE) to secure the channel. MPPE is built into Microsoft Windows clients and can be installed on Linux clients. FortiGate units support MPPE.

Packet encapsulation



Shown above, traffic from the remote client is addressed to a computer on the network behind the FortiGate unit. When the PPTP tunnel is established, packets from the remote client are encapsulated and addressed to the FortiGate unit. The FortiGate unit forwards disassembled packets to the computer on the internal network.

When the remote PPTP client connects, the FortiGate unit assigns an IP address from a reserved range of IP addresses to the client PPTP interface. The PPTP client uses the assigned IP address as its source address for the duration of the connection.

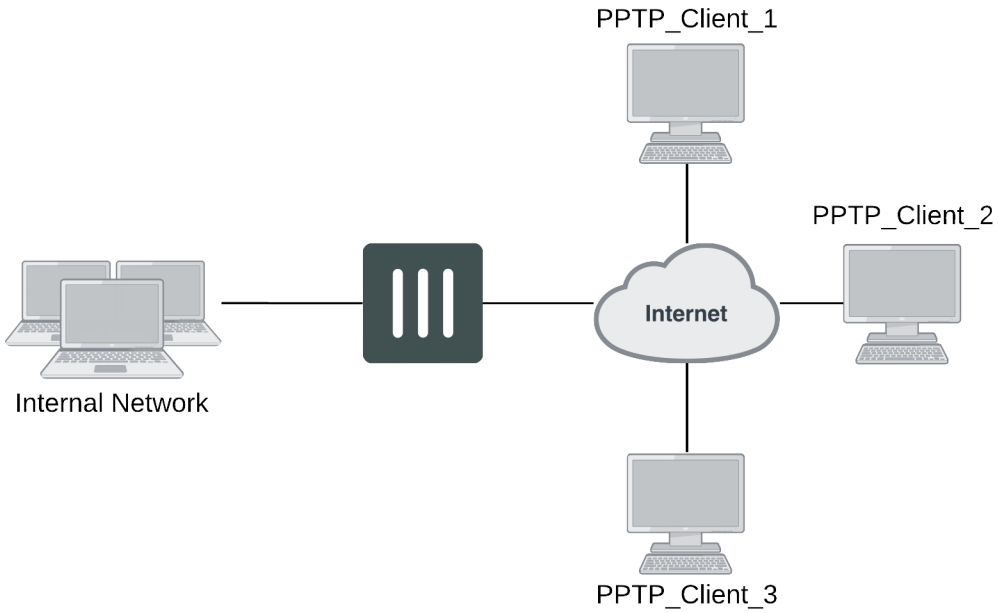
When the FortiGate unit receives a PPTP packet, the unit disassembles the PPTP packet and forwards the packet to the correct computer on the internal network. The security policy and protection profiles on the FortiGate unit ensure that inbound traffic is screened and processed securely.

PPTP clients must be authenticated before a tunnel is established. The authentication process relies on FortiGate user group definitions, which can optionally use established authentication mechanisms such as RADIUS or LDAP to authenticate PPTP clients. All PPTP clients are challenged when a connection attempt is made.

FortiGate unit as a PPTP server

In the most common Internet scenario, the PPTP client connects to an ISP that offers PPP connections with dynamically-assigned IP addresses. The ISP forwards PPTP packets to the Internet, where they are routed to the FortiGate unit.

FortiGate unit as a PPTP server



If the FortiGate unit will act as a PPTP server, there are a number of steps to complete:

- Configure user authentication for PPTP clients.
- Enable PPTP.
- Specify the range of addresses that are assigned to PPTP clients when connecting
- Configure the security policy.

Configuring user authentication for PPTP clients

To enable authentication for PPTP clients, you must create user accounts and a user group to identify the PPTP clients that need access to the network behind the FortiGate unit. Within the user group, you must add a user for each PPTP client.

You can choose to use a plain text password for authentication or forward authentication requests to an external RADIUS, LDAP, or TACACS+ server. If password protection will be provided through a RADIUS, LDAP, or TACACS+ server, you must configure the FortiGate unit to forward authentication requests to the authentication server.

This example creates a basic user/password combination.

Configuring a user account

To add a local user - GUI

1. Go to **User & Device > User Definition** and select **Create New.**
2. Select **Local User**
3. Enter a **User Name**.
4. Enter a **Password** for the user. The password should be at least six characters.
5. Select **OK**.

To add a local user - CLI

```
config user local
   edit <username>
      set type password
      set passwd <password>
end
```

Configuring a user group

To ease configuration, create user groups that contain users in similar categories or departments.

To create a user group - GUI

1. Go to **User & Device > User Group** and select **Create New**.
2. Enter a **Name** for the group.
3. Select the **Type** of **Firewall**.
4. From the **Available Users** list, select the required users and select the right-facing arrow to add them to the **Members** list.
5. Select **OK**.

To create a user group - CLI

```
config user group
   edit <group_name>
      set group-type firewall
      set member <user_names>
end
```

Enabling PPTP and specifying the PPTP IP address range

The PPTP address range specifies the range of addresses reserved for remote PPTP clients. When a PPTP client connects to the FortiGate unit, the client is assigned an IP address from this range. Afterward, the FortiGate unit uses the assigned address to communicate with the PPTP client.

The address range that you reserve can be associated with private or routable IP addresses. If you specify a private address range that matches a network behind the FortiGate unit, the assigned address will make the PPTP client appear to be part of the internal network.

PPTP requires two IP addresses, one for each end of the tunnel. The PPTP address range is the range of addresses reserved for remote PPTP clients. When the remote PPTP client establishes a connection, the FortiGate unit assigns an IP address from the reserved range of IP addresses to the client PPTP interface or

retrieves the assigned IP address from the PPTP user group. If you use the PPTP user group, you must also define the FortiGate end of the tunnel by entering the IP address of the unit in **Local IP** (web-based manager) ***or*** `local-ip` (CLI). The PPTP client uses the assigned IP address as its source address for the duration of the connection.

PPTP configuration is only available through the CLI. In the example below, PPTP is enabled with the use of an IP range of `192.168.1.1` to `192.168.1.10` for addressing and the user group is hr_staff.

FortiOS 5.4.0 and later versions allow the start and end IPs in the PPTP address range to be in the same 16-bit subnet. Earlier versions require that the start and end IPs in the PPTP address range be in the same 24-bit subnet, for example, 192.168.1.1 - 192.168.1.254. .

```
config vpn pptp
   set status enable
   set ip-mode range
   set eip 192.168.1.10
   set sip 192.168.1.1
   set usrgrp hr_staff
end
```

In this example, PPTP is enabled with the use of a user group for addressing, where the IP address of the PPTP server is `192.168.1.2` and the user group is `hr_admin`.

```
config vpn pptp
   set status enable
   set ip-mode range
   set local-ip 192.168.2.1
   set usrgrp hr_admin
end
```

Adding the security policy

The security policy specifies the source and destination addresses that can generate traffic inside the PPTP tunnel and defines the scope of services permitted through the tunnel. If a selection of services are required, define a service group.

To configure the firewall for the PPTP tunnel - GUI

1. Go to **Policy & Objects > IPv4** or **Policy & Objects > IPv6** and select **Create New**.
2. Complete the following and select **OK**:

Incoming Interface	The FortiGate interface connected to the Internet.
Source Address	Select the name that corresponds to the range of addresses that you reserved for PPTP clients.
Outgoing Interface	The FortiGate interface connected to the internal network.
Destination Address	Select the name that corresponds to the IP addresses behind the FortiGate unit.
Schedule	always

Service	ALL
Action	ACCEPT

To configure the firewall for the PPTP tunnel - CLI

```
config firewall policy or config firewall policy6
   edit 1
      set srcintf <interface to internet>
      set dstintf <interface to internal network>
      set srcaddr <reserved_range>
      set dstaddr <internal_addresses>
      set action accept
      set schedule always
      set service ALL
end
```

Configuring the FortiGate unit for PPTP VPN

To arrange for PPTP packets to pass through the FortiGate unit to an external PPTP server, perform the following tasks in the order given:

- Configure user authentication for PPTP clients.
- Enable PPTP on the FortiGate unit and specify the range of addresses that can be assigned to PPTP clients when they connect.
- Configure PPTP pass through on the FortiGate unit.

Configuring the FortiGate unit for PPTP passthrough

To forward PPTP packets to a PPTP server on the network behind the FortiGate unit, you need to perform the following configuration tasks on the FortiGate unit:

- Define a virtual IP address that points to the PPTP server.
- Create a security policy that allows incoming PPTP packets to pass through to the PPTP server.

The address range is the external (public) ip address range which requires access to the internal PPTP server through the FortiGate virtual port-forwarding firewall.

IP addresses used in this document are fictional and follow the technical documentation guidelines specific to Fortinet. Real external IP addresses are not used.

Configuring a virtual IP address

The virtual IP address will be the address of the PPTP server host.

To define a virtual IP for PPTP passthrough - GUI

1. Go to **Policy & Objects > Virtual IPs**.
2. Select **Create New**.
3. Choose the **VIP Type**.
4. Enter the name of the VIP, for example, `PPTP_Server`.

5. Select the **External Interface** where the packets will be received for the PPTP server.
6. Enter the **External IP Address** for the VIP.
7. Select **Port Forwarding**.
8. Set the **Protocol to TCP**.
9. Enter the **External Service Port** of `1723`, the default for PPTP.
10. Enter the **Map to Port** to `1723`.
11. Select **OK**.

To define a virtual IP for PPTP passthrough - CLI

```
config firewall vip or config firewall vip6
   edit PPTP_Server
      set extintf <interface>
      set extip <ip_address>
      set portforward enable
      set protocol tcp
      set extport 1723
      set mappedport 1723
      set mappedip <destination IP address range>
      end
```

You can also use `config firewall vip46` to define a virtual IP from an IPv4 address to an IPv6 address or `config firewall vip64` to define a virtual IP from an IPv6 address to an IPv4 address.

Configuring a port-forwarding security policy

To create a port-forwarding security policy for PPTP passthrough you must first create an address range reserved for the PPTP clients.

To create an address range - GUI

1. Go to **Policy & Objects > Addresses** and select **Create New**.
2. Select a **Category**.
3. Enter a **Name** for the range, for example, `External_PPTP`.
4. Select a **Type** of **Subnet/IP Range**.
5. Enter the IP address range.
6. Select the **Interface** to the Internet.
7. Select **OK**.

To create an address range - CLI

```
config firewall address OR config firewall address6
   edit External_PPTP
      set type ip_range
      set start-ip <ip_address>
      set end-ip <ip_address>
      set associated-interface <internet_interface>
end
```

With the address set, you can add the security policy.

To add the security policy - GUI

1. Go to **Policy & Objects > IPv4** or **Policy & Objects > IPv6** and select **Create New**.
2. Complete the following and select **OK**:

Incoming Interface	The FortiGate interface connected to the Internet.
Source Address	Select the address range created in the previous step.
Outgoing Interface	The FortiGate interface connected to the PPTP server.
Destination Address	Select the VIP address created in the previous steps.
Schedule	always
Service	PPTP
Action	ACCEPT

To add the security policy - CLI

```
config firewall policy or config firewall policy6
   edit <policy_number>
      set srcintf <interface to internet>
      set dstintf <interface to PPTP server>
      set srcaddr <address_range>
      set dstaddr <PPTP_server_address>
      set action accept
      set schedule always
      set service PPTP
end
```

Testing PPTP VPN connections

To confirm that a PPTP VPN between a local network and a dialup client has been configured correctly, at the dialup client, issue a ping command to test the connection to the local network. The PPTP VPN tunnel initializes when the dialup client attempts to connect.

Logging VPN events

PPTP VPN, activity is logged when enabling VPN logging. The FortiGate unit connection events and tunnel status (up/down) are logged.

To log VPN events

1. Go to **Log & Report > Log Settings**.
2. Enable **Event Logging**.
3. Select **VPN activity event**.
4. Select **Apply**.

To view event logs

1. Go to **Log & Report > VPN Events**.
2. If the option is available to set the log location list, select disk or memory.
3. Select a log event and select **Details**.

Configuring L2TP VPNs

This section describes how to configure a FortiGate unit to establish a Layer Two Tunneling Protocol (L2TP) tunnel with a remote dialup client. The FortiGate implementation of L2TP enables a remote dialup client to establish an L2TP tunnel with the FortiGate unit directly.

According to RFC 2661, an Access Concentrator (LAC) can establish an L2TP tunnel with an L2TP Network Server (LNS). In a typical scenario, the LAC is managed by an ISP and located on the ISP premises; the LNS is the gateway to a private network. When a remote dialup client connects to the Internet through the ISP, the ISP uses a local database to establish the identity of the caller and determine whether the caller needs access to an LNS through an L2TP tunnel. If the services registered to the caller indicate that an L2TP connection to the LNS is required, the ISP LAC attempts to establish an L2TP tunnel with the LNS.

A FortiGate unit can be configured to act as an LNS. The FortiGate implementation of L2TP enables a remote dialup client to establish an L2TP tunnel with the FortiGate unit directly, bypassing any LAC managed by an ISP. The ISP must configure its network access server to forward L2TP traffic from the remote client to the FortiGate unit directly whenever the remote client requires an L2TP connection to the FortiGate unit.

When the FortiGate unit acts as an LNS, an L2TP session and tunnel is created as soon as the remote client connects to the FortiGate unit. The FortiGate unit assigns an IP address to the client from a reserved range of IP addresses. The remote client uses the assigned IP address as its source address for the duration of the connection.

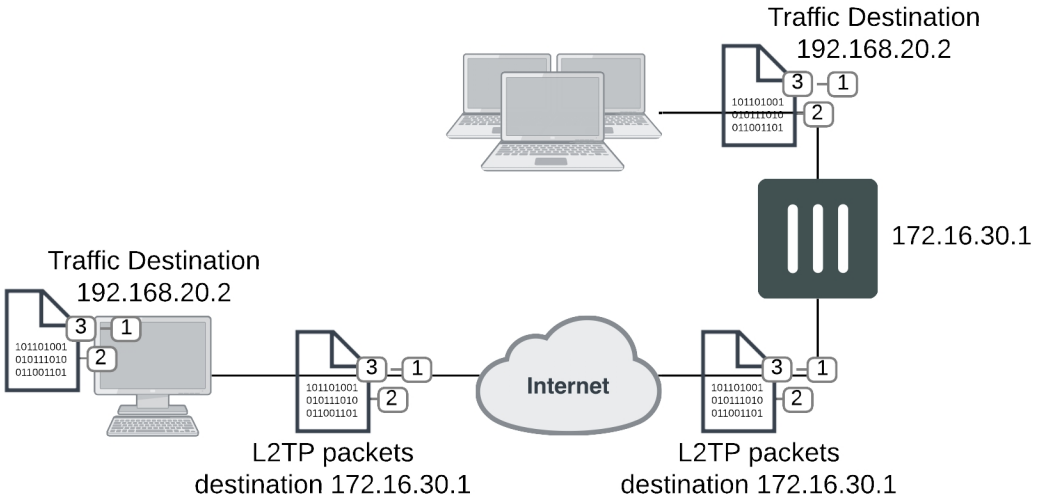
More than one L2TP session can be supported on the same tunnel. FortiGate units can be configured to authenticate remote clients using a plain text user name and password, or authentication can be forwarded to an external RADIUS or LDAP server. L2TP clients are authenticated as members of a user group.

For site-to-site connections, Windows servers use IPsec encryption when you configure the VPN to connect to an L2TP server.

Traffic from the remote client must be encrypted using IPsec before it is encapsulated and routed to the FortiGate unit. Packets originating at the remote client are addressed to a computer on the private network behind the FortiGate unit. Encapsulated packets are addressed to the public interface of the FortiGate unit. See the figure below.

When the FortiGate unit receives an L2TP packet, the unit disassembles the packet and forwards the packet to the correct computer on the internal network. The security policy and protection profiles on the FortiGate unit ensure that inbound traffic is screened and processed securely.

L2TP encapsulation

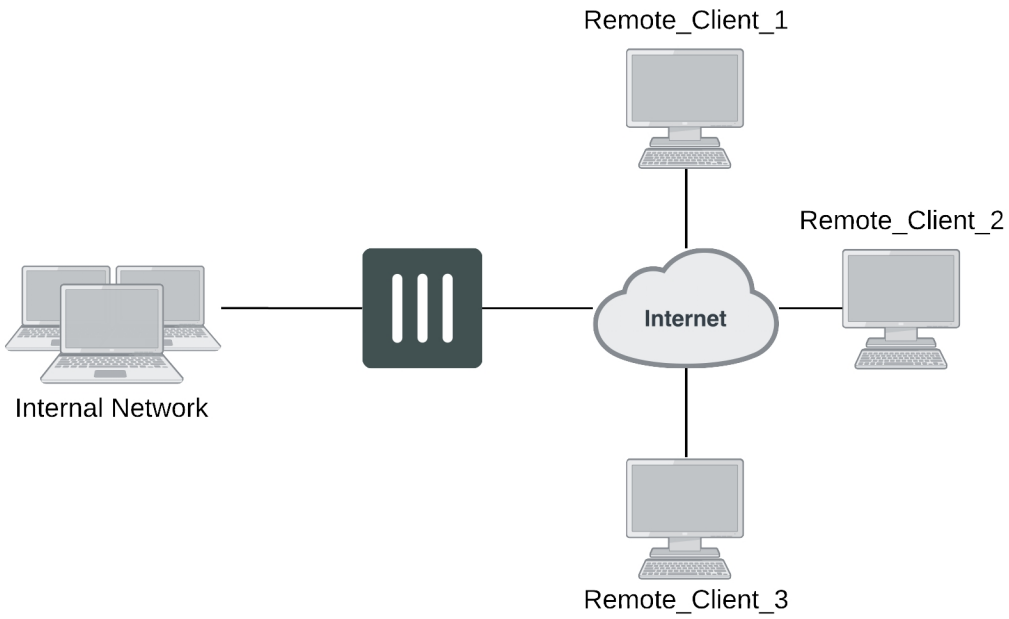


FortiGate units cannot deliver non-IP traffic such as Frame Relay or ATM frames encapsulated in L2TP packets — FortiGate units support the IPv4 and IPv6 addressing schemes only

Network topology

The remote client connects to an ISP that determines whether the client requires an L2TP connection to the FortiGate unit. If an L2TP connection is required, the connection request is forwarded to the FortiGate unit directly.

Example L2TP configuration



L2TP infrastructure requirements

- The FortiGate unit must be operating in NAT mode and have a static public IP address.
- The ISP must configure its network access server to forward L2TP traffic from remote clients to the FortiGate unit directly.
- The remote client must not generate non-IP traffic (Frame Relay or ATM frames).

L2TP configuration overview

To configure a FortiGate unit to act as an LNS, you perform the following tasks:

- Create an L2TP user group containing one user for each remote client.
- Enable L2TP on the FortiGate unit and specify the range of addresses that can be assigned to remote clients when they connect.
- Define firewall source and destination addresses to indicate where packets transported through the L2TP tunnel will originate and be delivered.
- Create the security policy and define the scope of permitted services between the source and destination addresses.
- Configure the remote clients.

Authenticating L2TP clients

L2TP clients must be authenticated before a tunnel is established. The authentication process relies on FortiGate user group definitions, which can optionally use established authentication mechanisms such as RADIUS or LDAP to authenticate L2TP clients. All L2TP clients are challenged when a connection attempt is made.

To enable authentication, you must create user accounts and a user group to identify the L2TP clients that need access to the network behind the FortiGate unit.

You can choose to use a plain text password for authentication or forward authentication requests to an external RADIUS or LDAP server. If password protection will be provided through a RADIUS or LDAP server, you must configure the FortiGate unit to forward authentication requests to the authentication server.

Enabling L2TP and specifying an address range

The L2TP address range specifies the range of addresses reserved for remote clients. When a remote client connects to the FortiGate unit, the client is assigned an IP address from this range. Afterward, the FortiGate unit uses the assigned address to communicate with the remote client.

The address range that you reserve can be associated with private or routable IP addresses. If you specify a private address range that matches a network behind the FortiGate unit, the assigned address will make the remote client appear to be part of the internal network.

To enable L2TP and specify the L2TP address range, use the `config vpn l2tp` CLI command.

The following example shows how to enable L2TP and set the L2TP address range using a starting address of `192.168.10.80` and an ending address of `192.168.10.100` for an existing group of L2TP users named `L2TP_users`:

```
config vpn l2tp
   set sip 192.168.10.80
   set eip 192.168.10.100
   set status enable
   set usrgrp L2TP_users
end
```

Defining firewall source and destination addresses

Before you define the security policy, you must define the source and destination addresses of packets that are to be transported through the L2TP tunnel:

- For the source address, enter the range of addresses that you reserved for remote L2TP clients (for example `192.168.10.[80-100]`).
- For the destination address, enter the IP addresses of the computers that the L2TP clients need to access on the private network behind the FortiGate unit (for example, `172.16.5.0/24` for a subnet, or `172.16.5.1` for a server or host, or `192.168.10.[10-15]` for an IP address range).

To define the firewall source address

1. Go to **Policy & Objects > Addresses** and select **Create New**.
2. Select **Address**.
3. In the **Name** field, type a name that represents the range of addresses that you reserved for remote clients (for example, `Ext_L2TPrange`).
4. In **Type**, select **IP Range**.
5. In the **Subnet / IP Range** field, type the corresponding IP address range.
6. In **Interface**, select the FortiGate interface that connects to the clients.
7. This is usually the interface that connects to the Internet.
8. Select **OK**.

To define the firewall destination address

1. Go to **Policy & Objects > Addresses** and select **Create New**.
2. In the **Address Name** field, type a name that represents a range of IP addresses on the network behind the FortiGate unit (for example, `Int_L2TPaccess`).
3. In **Type**, select **IP Range**.
4. In the **IP Range** field, type the corresponding IP address range.
5. In **Interface**, select the FortiGate interface that connects to the network behind the FortiGate unit.
6. Select **OK**.

Adding the security policy

The security policy specifies the source and destination addresses that can generate traffic inside the L2TP tunnel and defines the scope of services permitted through the tunnel. If a selection of services are required, define a service group.

To define the traffic and services permitted inside the L2TP tunnel

1. Go to **Policy & Objects > IPv4** or **Policy & Objects > IPv6** and select **Create New**.
2. Enter these settings:

Name	Input a name for the policy.
Incoming Interface	Select the FortiGate interface to the Internet.
Outgoing Interface	Select the FortiGate interface to the internal (private) network.
Source Address	Select the name that corresponds to the address range that reserved for L2TP clients (for example, `Ext_L2TPrange`).
Destination Address	Select the name that corresponds to the IP addresses behind the FortiGate unit (for example, `Int_L2TPaccess`).
Schedule	Select ALWAYS, or if a select schedule is required instead, select a schedule that you defined previously.
Service	Select ALL, or if selected services are required instead, select the service group that you defined previously.
Action	ACCEPT

3. Select **OK**.

Configuring a Linux client

This procedure outlines how to install L2TP client software and run an L2TP tunnel on a Linux computer. Obtain an L2TP client package that meets your requirements (for example, `rp-l2tp`). If needed to encrypt traffic, obtain L2TP client software that supports encryption using IPsec.

To establish an L2TP tunnel with a FortiGate unit that has been set up to accept L2TP connections, you can obtain and install the client software following these guidelines:

1. If encryption is required, you will need to verify the IPsec configuration.
2. Download and install the L2TP client package.

3. Configure an L2TP connection to run the L2TP program.
4. Configure routes to determine whether all or some of your network traffic will be sent through the tunnel. You must define a route to the remote network over the L2TP link and a host route to the FortiGate unit.
5. Run `l2tpd` to start the tunnel.

Follow the software supplier's documentation to complete the steps.

To configure the system, you need to know the public IP address of the FortiGate unit, and the user name and password that has been set up on the FortiGate unit to authenticate L2TP clients. Contact the FortiGate administrator if required to obtain this information.

Monitoring L2TP sessions

You can display a list of all active sessions and view activity by port number. By default, port 1701 is used for L2TP VPN-related communications. If required, active sessions can be stopped from this view. Use **FortiView > All Sessions**.

Testing L2TP VPN connections

To confirm that a VPN between a local network and a dialup client has been configured correctly, at the dialup client, issue a ping command to test the connection to the local network. The VPN tunnel initializes when the dialup client attempts to connect.

Logging L2TP VPN events

You can configure the FortiGate unit to log VPN events. For L2TP VPNs, connection events and tunnel status (up/down) are logged.

To log VPN events - GUI

1. Go to **Log & Report > Log Settings**.
2. Enable the storage of log messages to one or more locations.
3. Select **Enable**, and then select **VPN activity event**.
4. Select **Apply**.

To log VPN events - CLI

```
config log memory setting
   set diskfull overwrite
   set status enable
end
config log eventfilter
   set vpn enable
end
```

Session helpers

The FortiOS firewall can analyze most TCP/IP protocol traffic by comparing packet header information to security policies. This comparison determines whether to accept or deny the packet and the session that the packet belongs to.

Some protocols include information in the packet body (or payload) that must be analyzed to successfully process sessions for this protocol. For example, the SIP VoIP protocol uses TCP control packets with a standard destination port to set up SIP calls. But the packets that carry the actual conversation can use a variety of UDP protocols with a variety of source and destination port numbers. The information about the protocols and port numbers used for a SIP call is contained in the body of the SIP TCP control packets. To successfully process SIP VoIP calls, FortiOS must be able to extract information from the body of the SIP packet and use this information to allow the voice-carrying packets through the firewall.

FortiOS uses session helpers to analyze the data in the packet bodies of some protocols and adjust the firewall to allow those protocols to send packets through the firewall.

This section includes the topics:

- Viewing the session helper configuration
- Changing the session helper configuration
- DCE-RPC session helper (dcerpc)
- DNS session helpers (dns-tcp and dns-udp)
- File transfer protocol (FTP) session helper (ftp)
- H.245 session helpers (h245I and h245O)
- H.323 and RAS session helpers (h323 and ras)
- Media Gateway Controller Protocol (MGCP) session helper (mgcp)
- ONC-RPC portmapper session helper (pmap)
- PPTP session helper for PPTP traffic (pptp)
- Remote shell session helper (rsh)
- Real-Time Streaming Protocol (RTSP) session helper (rtsp)
- Session Initiation Protocol (SIP) session helper (sip)
- Trivial File Transfer Protocol (TFTP) session helper (tftp)
- Oracle TNS listener session helper (tns)

Viewing the session helper configuration

You can view the session helpers enabled on your FortiGate unit in the CLI using the commands below. The following output shows the first two session helpers. The number of session helpers can vary to around 20.

```
show system session-helper
   config system session-helper
      edit 1
         set name pptp
         set port 1723
         set protocol 6
      next
         set name h323
         set port 1720
         set protocol 6
      end
      .
      .
```

The configuration for each session helper includes the name of the session helper and the port and protocol number on which the session helper listens for sessions. Session helpers listed on protocol number 6 (TCP) or 17 (UDP). For a complete list of protocol numbers see Assigned Internet Protocol Numbers.

For example, the output above shows that FortiOS listens for PPTP packets on TCP port 1723 and H.323 packets on port TCP port 1720.

If a session helper listens on more than one port or protocol the more than one entry for the session helper appears in the `config system session-helper` list. For example, the pmap session helper appears twice because it listens on TCP port 111 and UDP port 111. The rsh session helper appears twice because it listens on TCP ports 514 and 512.

Changing the session helper configuration

Normally you will not need to change the configuration of the session helpers. However in some cases you may need to change the protocol or port the session helper listens on.

Changing the protocol or port that a session helper listens on

Most session helpers are configured to listen for their sessions on the port and protocol that they typically use. If your FortiGate unit receives sessions that should be handled by a session helper on a non-standard port or protocol you can use the following procedure to change the port and protocol used by a session helper. The following example shows how to change the port that the pmap session helper listens on for Sun RPC portmapper TCP sessions. By default pmap listens on TCP port 111.

To change the port that the pmap session helper listens on to TCP port 112

1. Confirm that the TCP pmap session helper entry is 11 in the session-helper list:

```
show system session-helper 11
   config system session-helper
      edit 11
         set name pmap
         set port 111
         set protocol 6
      next
   end
```

2. Enter the following command to change the TCP port to 112.

```
config system session-helper
   edit 11
      set port 112
   end
```

3. The pmap session helper also listens on UDP port 111. Confirm that the UDP pmap session helper entry is 12 in the session-helper list:

```
show system session-helper 12
   config system session-helper
      edit 12
         set name pmap
         set port 111
         set protocol 17
      next
   end
```

4. Enter the following command to change the UDP port to 112.

```
config system session-helper
   edit 12
      set port 112
      end
```

Use the following command to set the h323 session helper to listen for ports on the UDP protocol.

To change the protocol that the h323 session helper listens on

1. Confirm that the h323 session helper entry is 2 in the session-helper list:

```
show system session-helper 2
   config system session-helper
      edit 2
         set name h323
         set port 1720
         set protocol 6
      next
   end
```

2. Enter the following command to change the protocol to UDP.

```
config system session-helper
   edit 2
      set protocol 17
      end
```

If a session helper listens on more than one port or protocol, then multiple entries for the session helper must be added to the session helper list, one for each port and protocol combination. For example, the rtsp session helper listens on TCP ports 554, 7070, and 8554 so there are three rtsp entries in the session-helper list. If your FortiGate unit receives rtsp packets on a different TCP port (for example, 6677) you can use the following command to configure the rtsp session helper to listen on TCP port 6677.

To configure a session helper to listen on a new port and protocol

```
config system session-helper
   edit 0
      set name rtsp
      set port 6677
      set protocol 6
      end
```

Disabling a session helper

In some cases you may need to disable a session helper. Disabling a session helper just means removing it from the session-helper list so that the session helper is not listening on a port. You can completely disable a session helper by deleting all of its entries from the session helper list. If there are multiple entries for a session helper on the list you can delete one of the entries to prevent the session helper from listening on that port.

To disable the mgcp session helper from listening on UDP port 2427

1. Enter the following command to find the mgcp session helper entry that listens on UDP port 2427:

```
show system session-helper
   .
   .
   .
```

```
edit 19
   set name mgcp
   set port 2427
   set protocol 17
next
   .
   .
   .
```

2. Enter the following command to delete session-helper list entry number 19 to disable the mgcp session helper from listening on UDP port 2427:

```
config system session-helper
   delete 19
```

By default the mgcp session helper listens on UDP ports 2427 and 2727. The previous procedure shows how to disable the mgcp protocol from listening on port 2427. The following procedure completely disables the mgcp session helper by also disabling it from listening on UDP port 2727.

To completely disable the mgcp session helper

1. Enter the following command to find the mgcp session helper entry that listens on UDP port 2727:

```
show system session-helper
   .
   .
   .
edit 20
   set name mgcp
   set port 2727
   set protocol 17
next
   .
   .
   .
```

2. Enter the following command to delete session-helper list entry number 20 to disable the mgcp session helper from listening on UDP port 2727:

```
config system session-helper
   delete 20
```

DCE-RPC session helper (dcerpc)

Distributed Computing Environment Remote Procedure Call (DCE-RPC) provides a way for a program running on one host to call procedures in a program running on another host. DCE-RPC (also called MS RPC for Microsoft RPC) is similar to ONC-RPC. Because of the large number of RPC services, for example, MAPI, the transport address of an RPC service is dynamically negotiated based on the service program's universal unique identifier (UUID). The Endpoint Mapper (EPM) binding protocol in FortiOS maps the specific UUID to a transport address.

To accept DCE-RPC sessions you must add a security policy with service set to any or to the DEC-RPC pre-defined service (which listens on TCP and UDP ports 135). The dcerpc session helper also listens on TCP and UDP ports 135.

The session allows FortiOS to handle DCE-RPC dynamic transport address negotiation and to ensure UUID-based security policy enforcement. You can define a security policy to permit all RPC requests or to permit by specific UUID number.

In addition, because a TCP segment in a DCE-RPC stream might be fragmented, it might not include an intact RPC PDU. This fragmentation occurs in the RPC layer; so FortiOS does not support parsing fragmented packets.

The DCE-RPC session helper does not support destination NAT (DNAT) or Firewall VIPs unless you are using the OXID Resolver service (also called IOXIDResolver).

DNS session helpers (dns-tcp and dns-udp)

FortiOS includes two DNS session helpers, dns-tcp, a session helper for DNS over TCP, and dns-udp, a session helper for DNS over UDP.

To accept DNS sessions you must add a security policy with service set to any or to the DNS pre-defined service (which listens on TCP and UDP ports 53). The dns-udp session helper also listens on UDP port 53. By default the dns-tcp session helper is disabled. If needed you can use the following command to enable the dns-tcp session helper to listen for DNS sessions on TCP port 53:

```
config system session-helper
   edit 0
      set name dns-tcp
      set port 53
      set protocol 6
end
```

File transfer protocol (FTP) session helper (ftp)

The FTP session helper monitors PORT, PASV and 227 commands and NATs the IP addresses and port numbers in the body of the FTP packets and opens ports on the FortiGate unit as required.

To accept FTP sessions you must add a security policy with service set to any or to the FTP, FTP_Put, and FTP_GET pre-defined services (which all listen on TCP port 21).

H.245 session helpers (h245I and h245O)

H.245 is a control channel protocol used for H.323 and other similar communication sessions. H.245 sessions transmit non-telephone signals. H.245 sessions carry information needed for multimedia communication, such as encryption, flow control jitter management and others.

FortiOS includes two H.245 sessions helpers, h245I which is for H.245 call in and h245O which is for H.245 call out sessions. There is no standard port for H.245. By default the H.245 sessions helpers are disabled. You can enable them as you would any other session helper. When you enable them, you should specify the port and protocol on which the FortiGate unit receives H.245 sessions.

H.323 and RAS session helpers (h323 and ras)

The H.323 session helper supports secure H.323 voice over IP (VoIP) sessions between terminal endpoints such as IP phones and multimedia devices. In H.323 VoIP networks, gatekeeper devices manage call registration, admission, and call status for VoIP calls. The FortiOS h323 session helper supports gatekeepers installed on two different networks or on the same network.

To accept H.323 sessions you must add a security policy with service set to any or to the H323 pre-defined service (which listens on TCP port numbers 1720 and 1503 and on UDP port number 1719). The h323 session helper listens on TCP port 1720.

The ras session helper is used with the h323 session helper for H.323 Registration, Admission, and Status (RAS) services. The ras session helper listens on UDP port 1719.

Alternate H.323 gatekeepers

The h323 session helper supports using H.323 alternate gatekeepers. All the H.323 end points must register with a gatekeeper through the Registration, Admission, and Status (RAS) protocol before they make calls. During the registration process, the primary gatekeeper sends Gatekeeper Confirm (GCF) and Registration Confirm (RCF) messages to the H.323 end points that contain the list of available alternate gatekeepers.

The alternate gatekeeper provides redundancy and scalability for the H.323 end points. If the primary gatekeeper fails the H.323 end points that have registered with that gatekeeper are automatically registered with the alternate gatekeeper. To use the H.323 alternate gatekeeper, you need to configure security policies that allow H.323 end points to reach the alternate gatekeeper.

Media Gateway Controller Protocol (MGCP) session helper (mgcp)

The Media Gateway Control Protocol (MGCP) is a text-based application layer protocol used for VoIP call setup and control. MGCP uses a master-slave call control architecture in which the media gateway controller uses a call agent to maintain call control intelligence, while the media gateways perform the instructions of the call agent.

To accept MGCP sessions you must add a security policy with service set to any or to the MGCP predefined service (which listens on UDP port numbers 2427 and 2727). The h323 session helper also listens on UDP port numbers 2427 and 2727.

The MGCP session helper does the following:

- VoIP signaling payload inspection. The payload of the incoming VoIP signaling packet is inspected and malformed packets are blocked.
- Signaling packet body inspection. The payload of the incoming MGCP signaling packet is inspected according to RFC 3435. Malformed packets are blocked.
- Stateful processing of MGCP sessions. State machines are invoked to process the parsed information. Any out-of-state or out-of-transaction packet is identified and properly handled.
- MGCP Network Address Translation (NAT). Embedded IP addresses and ports in packet bodies is properly translated based on current routing information and network topology, and is replaced with the translated IP address and port number, if necessary.
- Manages pinholes for VoIP traffic. To keep the VoIP network secure, the IP address and port information used for media or signaling is identified by the session helper, and pinholes are dynamically created and closed during call setup.

ONC-RPC portmapper session helper (pmap)

Open Network Computing Remote Procedure Call (ONC-RPC) is a widely deployed remote procedure call system. Also called Sun RPC, ONC-RPC allows a program running on one host to call a program running on another. The transport address of an ONC-RPC service is dynamically negotiated based on the service's program number and version number. Several binding protocols are defined for mapping the RPC program number and version number to a transport address.

To accept ONC-RPC sessions you must add a security policy with service set to any or to the ONC-RPC pre-defined service (which listens on TCP and UDP port number 111). The RPC portmapper session helper (called pmap) handles the dynamic transport address negotiation mechanisms of ONC-RPC.

PPTP session helper for PPTP traffic (pptp)

The PPTP session help supports port address translation (PAT) for PPTP traffic. PPTP provides IP security at the Network Layer. PPTP consists of a control session and a data tunnel. The control session runs over TCP and helps in establishing and disconnecting the data tunnel. The data tunnel handles encapsulated Point-to-Point Protocol (PPP) packets carried over IP.

To accept PPTP sessions that pass through the FortiGate unit you must add a security policy with service set to any or to the PPTP pre-defined service (which listens on IP port 47 and TCP port 1723). The pptp session helper listens on TCP port 1723.

PPTP uses TCP port 1723 for control sessions and Generic Routing Encapsulation (GRE) (IP protocol 47) for tunneling the encapsulated PPP data. The GRE traffic carries no port number, making it difficult to distinguish between two clients with the same public IP address. PPTP uses the source IP address and the Call ID field in the GRE header to identify a tunnel. When multiple clients sharing the same IP address establish tunnels with the same PPTP server, they may get the same Call ID. The call ID value can be translated in both the control message and the data traffic, but only when the client is in a private network and the server is in a public network.

PPTP clients can either directly connect to the Internet or dial into a network access server to reach the Internet. A FortiGate unit that protects PPTP clients can translate the clients' private IP addresses to a pool of public IP addresses using NAT port translation (NAT-PT). Because the GRE traffic carries no port number for address translation, the pptp session helper treats the Call ID field as a port number as a way of distinguishing multiple clients.

After the PPTP establishing a TCP connection with the PPTP server, the client sends a start control connection request message to establish a control connection. The server replies with a start control connection reply message. The client then sends a request to establish a call and sends an outgoing call request message. FortiOS assigns a Call ID (bytes 12-13 of the control message) that is unique to each PPTP tunnel. The server replies with an outgoing call reply message that carries its own Call ID in bytes 12-13 and the client's call ID in bytes 14-15. The pptp session helper parses the control connection messages for the Call ID to identify the call to which a specific PPP packet belongs. The session helper also identifies an outgoing call request message using the control message type field (bytes 8-9) with the value 7. When the session helper receives this message, it parses the control message for the call ID field (bytes 12-13). FortiOS translates the call ID so that it is unique across multiple calls from the same translated client IP. After receiving outgoing call response message, the session helper holds this message and opens a port that accepts GRE traffic that the PPTP server sends. An outgoing call request message contains the following parts:

- The protocol used for the outgoing call request message (usually GRE)
- Source IP address (PPTP server IP)
- Destination IP address (translated client IP)
- Destination port number (translated client call ID)

The session helper identifies an outgoing call reply message using the control message type field (bytes 8-9) with the value 8. The session helper parses these control messages for the call ID field (bytes 12-13) and the client's call ID (bytes 14-15). The session helper then uses the client's call ID value to find the mapping created for the other direction, and then opens a pinhole to accept the GRE traffic that the client sends.

An outgoing call reply message contains the following parts:

- Protocol used for the outgoing call reply message (usually GRE)
- Source IP address (PPTP client IP)
- Destination IP address (PPTP server IP)
- Destination port number (PPTP server Call ID)

Each port that the session opens creates a session for data traffic arriving in that direction. The session helper opens the following two data sessions for each tunnel:

- Traffic from the PPTP client to the server, using the server's call ID as the destination port
- Traffic from the PPTP server to the client, using the client's translated call ID as the destination port

The default timeout value of the control connection is 30 minutes. The session helper closes the pinhole when the data session exceeds the timeout value or is idle for an extended period.

Remote shell session helper (rsh)

Using the remote shell program (RSH), authenticated users can run shell commands on remote hosts. RSH sessions most often use TCP port 514. To accept RSH sessions you must add a security policy with service set to any or to the RSH pre-defined service (which listens on TCP port number 514).

FortiOS automatically invokes the rsh session helper to process all RSH sessions on TCP port 514. The rsh session helper opens ports required for the RSH service to operate through a FortiGate unit running NAT or transparent and supports port translation of RSH traffic.

Real-Time Streaming Protocol (RTSP) session helper (rtsp)

The Real-Time Streaming Protocol (RTSP) is an application layer protocol often used by SIP to control the delivery of multiple synchronized multimedia streams, for example, related audio and video streams. Although RTSP is capable of delivering the data streams itself it is usually used like a network remote control for multimedia servers. The protocol is intended for selecting delivery channels (like UDP, multicast UDP, and TCP) and for selecting a delivery mechanism based on the Real-Time Protocol (RTP). RTSP may also use the SIP Session Description Protocol (SDP) as a means of providing information to clients for aggregate control of a presentation consisting of streams from one or more servers, and non-aggregate control of a presentation consisting of multiple streams from a single server.

To accept RTSP sessions you must add a security policy with service set to any or to the RTSP pre-defined service (which listens on TCP ports 554, 770, and 8554 and on UDP port 554). The rtsp session helper listens on TCP ports 554, 770, and 8554.

The rtsp session help is required because RTSP uses dynamically assigned port numbers that are communicated in the packet body when end points establish a control connection. The session helper keeps track of the port numbers and opens pinholes as required. In Network Address Translation (NAT) mode, the session helper translates IP addresses and port numbers as necessary.

In a typical RTSP session the client starts the session (for example, when the user selects the Play button on a media player application) and establishes a TCP connection to the RTSP server on port 554. The client then sends an OPTIONS message to find out what audio and video features the server supports. The server responds to the OPTIONS message by specifying the name and version of the server, and a session identifier, for example, 24256-1.

The client then sends the DESCRIBE message with the URL of the actual media file the client wants to play. The server responds to the DESCRIBE message with a description of the media in the form of SDP code. The client

then sends the SETUP message, which specifies the transport mechanisms acceptable to the client for streamed media, for example RTP/RTCP or RDT, and the ports on which it receives the media.

In a NAT configuration the rtsp session helper keeps track of these ports and addresses translates them as necessary. The server responds to the SETUP message and selects one of the transport protocols. When both client and server agree on a mechanism for media transport the client sends the PLAY message, and the server begins streaming the media.

Session Initiation Protocol (SIP) session helper (sip)

The sip session helper is described in the VoIP Solutions: SIP Guide.

Trivial File Transfer Protocol (TFTP) session helper (tftp)

To accept TFTP sessions you must add a security policy with service set to any or to the TFTP pre-defined service (which listens on UDP port number 69). The TFTP session helper also listens on UTP port number 69.

TFTP initiates transfers on UDP port 69, but the actual data transfer ports are selected by the server and client during initialization of the connection. The tftp session helper reads the transfer ports selected by the TFTP client and server during negotiation and opens these ports on the firewall so that the TFTP data transfer can be completed. When the transfer is complete the tftp session helper closes the open ports.

Oracle TNS listener session helper (tns)

The Oracle Transparent Network Substrate (TNS) listener listens on port TCP port 1521 for network requests to be passed to a database instance. The Oracle TNS listener session helper (tns) listens for TNS sessions on TCP port 1521. TNS is a foundation technology built into the Oracle Net foundation layer and used by SQLNET.

Advanced concepts

This section provides configuration concepts and techniques to enhance your network security and includes the topics:

- Single firewall vs. multiple virtual domains
- Modem
- FortiExtender
- Assigning IP address by MAC address
- IP addresses for self-originated traffic
- Disk
- CLI Scripts
- Rejecting PING requests
- Opening TCP 113
- Obfuscate HTTP responses

You can also find a collection of practical articles on Fortinet's Cookbook site under **Resources > SysAdmin Notes**.

Single firewall vs. multiple virtual domains

A typical FortiGate setup, with a small to mid-range appliance, enables you to include a number of subnets on your network using the available ports and switch interfaces. This can potentially provide a means of having three or more mini networks for the various groups in a company. Within this infrastructure, multiple network administrators have access to the FortiGate to maintain security policies.

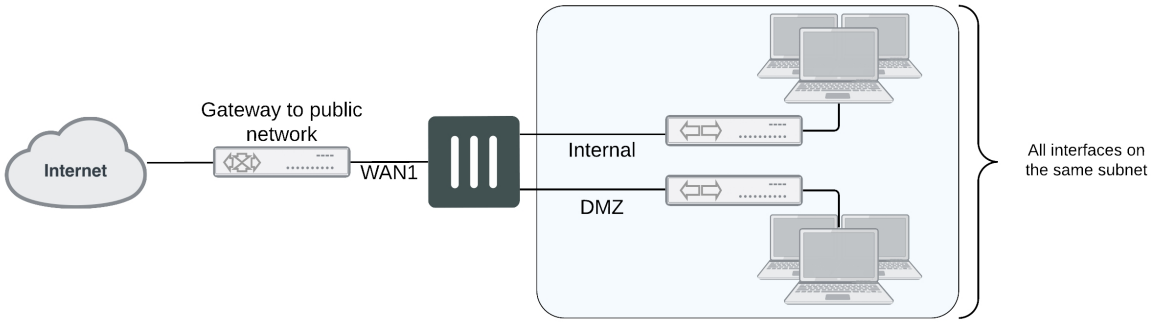
However, the FortiGate unit may not have enough interfaces to match the number of departments in the organization. If the FortiGate unit it running in transparent mode however, there is only one interface, and multiple network branches through the FortiGate are not possible.

A FortiGate unit with Virtual Domains (VDOMs) enabled, provides a means to provide the same functionality in transparent mode as a FortiGate in NAT mode. VDOMs are a method of dividing a FortiGate unit into two or more virtual units that function as multiple independent units. VDOMs can provide separate security policies and, in NAT mode, completely separate configurations for routing and VPN services for each connected network. For administration, an administrator can be assigned to each VDOM, minimizing the possibility of error or fouling network communications.

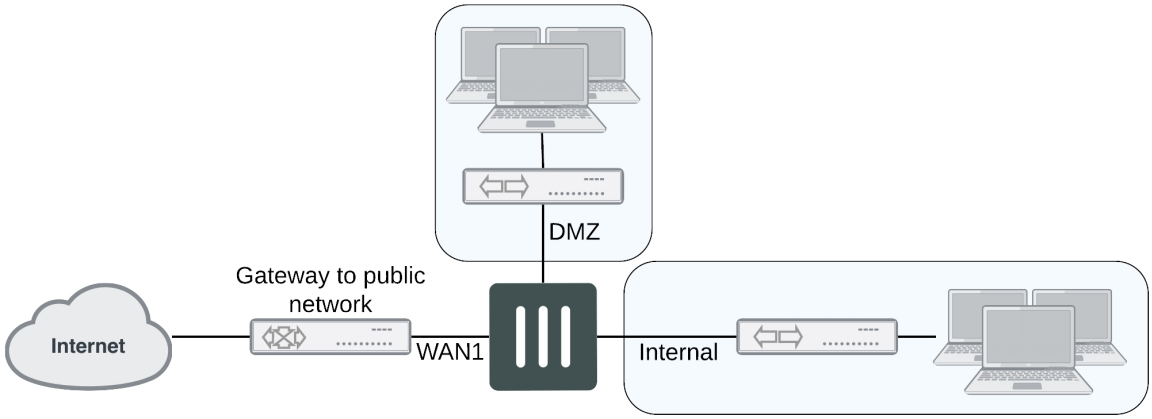
By default, most FortiGate units support 10 VDOMs. Many FortiGate models support purchasing a license key to increase the maximum number.

Single firewall vs. vdoms

When VDOMs are not enabled, and the FortiGate unit is in transparent mode, all the interfaces on your unit become broadcast interfaces. The problem is there are no interfaces free for additional network segments.



A FortiGate with three interfaces means only limited network segments are possible without purchasing more FortiGate devices.



With multiple VDOMs you can have one of them configured in transparent mode, and the rest in NAT mode. In this configuration, you have an available transparent mode FortiGate unit you can drop into your network for troubleshooting, and you also have the standard.

This example shows how to enable VDOMs on the FortiGate unit and the basic and create a VDOM accounting on the DMZ2 port and assign an administrator to maintain the VDOM. First enable Virtual Domains on the FortiGate unit.

To enable VDOMs - web-based manager

1. Go to **System > Dashboard > Status**.
2. In the **System Information** widget, select **Enable** for **Virtual Domain**.

Note that on FortiGate-60 series and lower models, you need to enable VDOMs in the CLI only.

The FortiGate unit logs you out. Once you log back in, you will notice that the menu structure has changed. This reflects the global settings for all Virtual Domains.

To enable VDOMs - CLI

```
config system global
   set vdom-admin enable
end
```

Next, add the VDOM called accounting.

To add a VDOM - web-based manager

1. Go to **Global > VDOM > VDOM**, and select **Create New**.
2. Enter the VDOM name `accounting`.
3. Select **OK**.

To add a VDOM - CLI

```
config vdom
   edit <new_vdom_name>
end
```

With the Virtual Domain created, you can assign a physical interface to it, and assign it an IP address.

To assign physical interface to the accounting Virtual Domain - web-based manager

1. Go to **Global > Network > Interface**.
2. Select the DMZ2 port row and select **Edit**.
3. For the **Virtual Domain** drop-down list, select **accounting**.
4. Select the **Addressing Mode** of **Manual**.
5. Enter the IP address for the port of 10.13.101.100/24.
6. Set the **Administrative Access** to **HTTPS** and **SSH**.
7. Select **OK**.

To assign physical interface to the accounting Virtual Domain - CLI

```
config global
   config system interface
      edit dmz2
      set vdom accounting
      set ip 10.13.101.100/24
      set allowaccess https ssh
   next
end
```

Modem

FortiGate units support the use of wireless, 3G and 4G modems connected using the USB port or, if available, the express card slot. Modem access provides either primary or secondary (redundant) access to the Internet. For FortiGate units that do not include an internal modem (those units with an “M” designation), the modem interface will not appear in the web-based manager until enabled in the CLI. To enable the modem interface enter the CLI commands:

```
config system modem
   set status enable
end
```

You will need to log out of the FortiGate and log back in to see the modem configuration page at **Network > Modem**. Once enabled, modem options become available by going to **Network > Interfaces**.

Note that the modem interface is only available when the FortiGate unit is in NAT mode.

To configure modem settings, go to **> Network > Modem**.

Configuring the modem settings is a matter of entering the ISP phone number, user name and password. Depending on the modem, additional information may need to be supplied such as product identifiers, and initialization strings.

The FortiGate unit includes a number of common modems within its internal database. You can view these by selecting the **Configure Modem** link on the **Modem Settings** page. If your modem is not on the list, select **Create New** to add the information. This information is stored on the device, and will remain after a reboot.

Fortinet has an online database of modem models and configuration settings through FortiGuard. A subscription to the FortiGuard services is not required to access the information. As models are added, you can select the **Configure Modem** link and select **Update Now** to download new configurations.

USB modem port

Each USB modem has a specific dial-out port. This will be indicated with the documentation for your modem. To enable the correct USB port, use the CLI commands:

```
config system modem
   set wireless-port {0 | 1 | 2}
end
```

To test the port, use the diagnose command:

```
diagnose sys modem com /1
```

The 1 will be the value of your USB port selected. The response will be:

```
Serial port: /dev/1
Press Ctrl+W to exit.
```

If the port does not respond the output will be:

```
Can not open modem device '/dev/1' : Broken pipe
```

Modes

The FortiGate unit allows for two modes of operation for the modem; stand alone and redundant. In stand alone mode, the modem connects to a dialup ISP account to provide the connection to the Internet. In redundant mode, the modem acts as a backup method of connecting to the Internet, should the primary port for this function fails.

Configuring either stand alone or redundant modes are very similar. The primary difference is the selection of the interface that the modem will replace in the event of it failing, and the configuration of a PING server to monitor the chosen interface.

Configuring stand alone mode

Configuring stand alone mode is a matter of configuring the modem information and the dialing mode. The dial mode is either **Always Connect** or **Dial on demand**. Selecting **Always Connect** ensures that once the modem has connected, it remains connected to the ISP. Selecting **Dial on Demand**, the modem only calls the ISP if packets are routed to the modem interface. Once sent, the modem will disconnect after a specified amount of time.

To configure standalone mode as needed - GUI

1. Go to **Network > Modem**.
2. Select the **Mode** of **Standalone**.
3. Select the **Dial Mode** of **Dial on Demand**.
4. Select the number of redials the modem attempts if connection fails to 5.
5. Select **Apply**.

To configure standalone mode as needed- CLI

```
config system modem
   set status enable
   set mode standalone
   set auto-dial enable
   set redial 5
end
```

Configuring redundant mode

Redundant mode provides a backup to an interface, typically to the Internet. If that interface fails or disconnects, the modem automatically dials the configured phone number(s). Once connected, the FortiGate unit routes all traffic to the modem interface until the monitored interface is up again. The FortiGate unit pings the connection to determine when it is back online.

For the FortiGate to verify when the interface is back up, you need to configure a Ping server for that interface. You will also need to configure security policies between the modem interface and the other interfaces of the FortiGate unit to ensure traffic flow.

To configure redundant mode as needed - GUI

1. Go to **Network > Modem**.
2. Select the **Mode** of **Redundant**.
3. Select the interface the modem takes over from if it fails.
4. Select the **Dial Mode** of **Dial on Demand**.
5. Select the number of redials the modem attempts if connection fails to 5.
6. Select **Apply**.

To configure standalone mode as needed- CLI

```
config system modem
   set status enable
   set mode redundant
   set interface wan1
   set auto-dial enable
   set redial 5
end
```

Link Health Monitor

Adding a link health monitor is required for routing fail over traffic. A link health monitor will confirm the connectivity of the device's interface

To add a link health monitor

```
config system link-monitor
   edit "Example1"
      set srcint <Interface_sending_probe>
      set server <ISP_IP_address>
      set protocol <Ping or http>
      set gateway-ip <the_gateway_IP_to_reach_the_server_if_required>
      set failtime <failure_count>
      set interval <seconds>
      set update-cascade-interface enable
      set update-static-route enable
      set status enable
end
```

Additional modem configuration

The CLI provides additional configuration options when setting up the modem options including adding multiple ISP dialing and initialization options and routing. For more information, see the CLI Reference.

Modem interface routing

The modem interface can be used in FortiOS as a dedicated interface. Once enabled and configured, you can use it in security policies and define static and dynamic routing. Within the CLI commands for the modem, you can configure the distance and priority of routes involving the modem interface. The CLI commands are:

```
config system modem
   set distance <route_distance>
   set priority <priority_value>
end
```

For more information on the routing configuration in the CLI, see the CLI Reference. For more information on routing and configuring routing, see the Advanced Routing Guide.

Assigning IP address by MAC address

To prevent users in the from changing their IP addresses and causing IP address conflicts or unauthorized use of IP addresses, you can bind an IP address to a specific MAC address using DHCP.

Use the CLI to reserve an IP address for a particular client identified by its device MAC address and type of connection. The DHCP server then always assigns the reserved IP address to the client. The number of reserved addresses that you can define ranges from 10 to 200 depending on the FortiGate model.

After setting up a DHCP server on an interface by going to **Network > Interfaces**, select the blue arrow next to **Advanced** to expand the options. If you know the MAC address of the system select **Create New** to add it, or if the system has already connected, locate it in the list, select the check box and select **Add from DHCP Client List**.

You can also match an address to a MAC address in the CLI. In the example below, the IP address 10.10.10.55 for User1 is assigned to MAC address 00:09:0F:30:CA:4F.

```
config system dhcp reserved-address
   edit User1
      set ip 10.10.10.55
      set mac 00:09:0F:30:CA:4F
      set type regular
   end
```

IP addresses for self-originated traffic

On the FortiGate unit, there are a number of protocols and traffic that is specific to the internal workings of FortiOS. For many of these traffic sources, you can identify a specific port/IP address for this self-originating traffic. The following traffic can be configured to a specific port/IP address:

- SNMP
- Syslog
- alert email
- FortiManager connection IP
- FortiGuard services
- FortiAnalyzer logging
- NTP
- DNS
- Authorization requests such as RADIUS
- FSSO

Configuration of these services is performed in the CLI. In each instance, there is a command set `source-ip`. For example, to set the source IP of NTP to be on the DMZ1 port with an IP of 192.168.4.5, the commands are:

```
config system ntp
   set ntpsync enable
   set syncinterval 5
   set source-ip 192.168.4.5
end
```

To see which services are configured with source-ip settings, use the get command:

```
get system source-ip status
```

The output will appear similar to the sample below:

```
NTP: x.x.x.x
DNS: x.x.x.x
SNMP: x.x.x.x
Central Management: x.x.x.x
FortiGuard Updates (AV/IPS): x.x.x.x
FortiGuard Queries (WebFilter/SpamFilter): x.x.x.x
```

Disk

To view the status and storage information of the local disk on your FortiGate unit, go to **System > Advanced**. The **DiskSettings** menu appears only on FortiGate units with an internal hard or flash disk.

Formatting the disk

The internal disk of the FortiGate unit (if available) can be formatted by going to **System > Advanced** and selecting **Disk Settings**.

Formatting the disk will erase all data on it, including databases for antivirus and IPS; logs, quarantine files, and WAN optimization caches. The FortiGate unit requires a reboot once the disk has been formatted.

Setting space quotas

If the FortiGate unit has an internal hard or flash disk, you can allocate the space on the disk for specific logging and archiving, and WAN optimization. By default, the space is used on an as required basis. As such, a disk can fill up with basic disk logging, leaving less potential space for quarantine.

By going to **System > Advanced**, you can select the **Edit** icon for **Logging and Archiving** and **WAN Optimization & Web Cache** and define the amount of space each log, archive and WAN optimization has on the disk.

CLI Scripts

To upload bulk CLI commands and scripts, go to **System > Advanced**.

Scripts are text files containing CLI command sequences. Scripts can be used to deploy identical configurations to many devices. For example, if all of your devices use identical security policies, you can enter the commands required to create the security policies in a script, and then deploy the script to all the devices which should use those same settings.

Use a text editor such as Notepad or other application that creates simple text files. Enter the commands in sequence, with each line as one command, similar to examples throughout the FortiOS documentation set.

If you are using a FortiGate unit that is not remotely managed by a FortiManager unit or the FortiGuard Analysis and Management Service, the scripts you upload are executed and discarded. If you want to execute a script more than once, you must keep a copy on your management PC.

If your FortiGate unit is configured to use a FortiManager unit, you can upload your scripts to the FortiManager unit, and run them from any FortiGate unit configured to use the FortiManager unit. If you upload a script directly to a FortiGate unit, it is executed and discarded.

If your FortiGate unit is configured to use FortiGuard Analysis and Management Service, scripts you upload are executed and stored. You can run uploaded scripts from any FortiGate unit configured with your FortiGuard Analysis and Management Service account. The uploaded script files appear on the FortiGuard Analysis and Management Service portal web site.

Uploading script files

After you have created a script file, you can then upload it through **System > Advanced**. When a script is uploaded, it is automatically executed.

Commands that require the FortiGate unit to reboot when entered in the command line will also force a reboot if included in a script.

To execute a script

1. Go to **System > Advanced**.
2. Enable **Configuration Scripts**.
3. Select **Upload and Run a New Script** to locate the script file.
4. Select **Apply**.

If the FortiGate unit is not configured for remote management, or if it is configured to use a FortiManager unit, uploaded scripts are discarded after execution. Save script files to your management PC if you want to execute them again later.

If the FortiGate unit is configured to use the FortiGuard Analysis and Management Service, the script file is saved to the remote server for later reuse. You can view the script or run it from the FortiGuard Analysis and Management Service portal web site.

Auto repeat of CLI commands

Occasionally there is a need to repeatedly run a diagnose command over a long period of time (like checking CPU or memory usage, or checking proxy health), Previously, this could only be done with external console connections. With FortiOS 5.4.0, this can be done in a script using the `interval` and `repeat` commands.

Scripts can be uploaded as a file from the CLI or GUI. To upload scripts from the GUI go to **System > Advanced > Configuration Scripts** and upload and run the script.

To configure the schedule and scripts, use the following syntax:

```
config system auto-script
   edit <ScriptName>
      set interval
      set repeat
      set script
   end
end
```

`interval` the interval time in seconds between instances of the script running.

`repeat` the number of times to repeat the running of the script. The value 0 is used to set an infinite number of repetitions.

`start` select `manual` to start the script manually or `auto` to start the script automatically

`script` the contents of the script.

This feature may not be available on all models as a hard drive is necessary to make use of it.

Rejecting PING requests

The factory default configuration of your FortiGate unit allows the default external interface to respond to ping requests. Depending on the model of your FortiGate unit the actual name of this interface will vary. For the most secure operation, you should change the configuration of the external interface so that it does not respond to ping requests. Not responding to ping requests makes it more difficult for a potential attacker to detect your FortiGate unit from the Internet. One such potential threat are Denial of Service (DoS) attacks.

A FortiGate unit responds to ping requests if ping administrative access is enabled for that interface.

To disable ping administrative access - web-based manager

1. Go to **System > Network > Interface**.
2. Choose the external interface and select **Edit**.
3. Clear the **Ping Administrative Access** check box.
4. Select **OK**.

In the CLI, when setting the allowaccess settings, by selecting the access types and not including the PING option, that option is then not selected. In this example, only HTTPS is selected.

To disable ping administrative access - CLI

```
config system interface
```

```
   edit external
      set allowaccess https
end
```

Opening TCP 113

Although seemingly contrary to conventional wisdom of closing ports from hackers, this port, which is used for ident requests, should be opened.

Port 113 initially was used as an authentication port, and later defined as an identification port (see RFC 1413). Some servers may still use this port to help in identifying users or other servers and establish a connection. Because port 113 receives a lot of unsolicited traffic, many routers, including on the FortiGate unit, close this port.

The issue arises in that unsolicited requests are stopped by the FortiGate unit, which will send a response saying that the port is closed. In doing so, it also lets the requesting server know there is a device at the given address, and thus announcing its presence. By enabling traffic on port 113, requests will travel to this port, and will most likely, be ignored and never responded to.

By default, the ident port is closed. To open it, use the following CLI commands:

```
config system interface
   edit <port_name>
      set ident_accept enable
end
```

You could also further use port forwarding to send the traffic to a non-existent IP address and thus never have a response packet sent.

Obfuscate HTTP responses

The FortiGate unit can obfuscate the HTTP responses from the FortiGate admin GUI and SSL VPN servers. By default this option is not enabled. To obfuscate HTTP headers, use the following CLI command:

```
config vpn ssl settings
   set url-obscuration {enable | disable}
```

Chapter 30 - Traffic Shaping

With the ever-increasing demands on network systems for a number of protocols, including email, HTTP traffic both internally and externally to the internet, voice over IP, FTP, and more, slow traffic is becoming a reality. Important traffic may even be dropped or slowed to an unusable speed. Web traffic delays can result in a loss of revenue for businesses.

Traffic shaping attempts to normalize traffic peaks and bursts to prioritize certain flows over others. There is a physical limitation to the amount of data which can be buffered and to the length of time it can be buffered.

FortiGate units provide Quality of Service (QoS) by applying bandwidth limits and prioritization. Using traffic shaping, you can adjust how your FortiGate unit allocates resources to different traffic types to improve performance and stability of latency sensitive or bandwidth intensive network applications.

This chapter describes Quality of Service (QoS), traffic shaping, FortiGate traffic shaping algorithms, and includes configuration procedures for traffic shaping on FortiGate units.

This guide contains the following sections:

The purpose of traffic shaping describes traffic shaping theories and quality of service.

Traffic shaping methods lists different methods of applying traffic shaping within FortiOS, and explains how to use ToS and Differentiated Services.

Examples provides basic application scenarios for shapers.

Troubleshooting traffic shaping lists diagnose commands to use for determining if traffic shapers are working correctly.

What's new in FortiOS 5.4

This chapter describes new traffic shaping features added to FortiOS 5.4.0 and FortiOS 5.4.1.

FortiOS 5.4.1

These features first appeared in FortiOS 5.4.1.

Traffic shaping policy IDs added to traffic logs (303802)

As of build 1013, traffic shaping policy IDs are now displayed in traffic logs and IP sessions. This allows you to easily identify which shaping policy is applied to traffic, even with multiple shaping policies configured. Look at the example below to see a sample log with the `shapingpolicyid`:

```
date=2016-01-29 time=15:35:25 logid=0000000013 type=traffic subtype=forward
level=notice vd=vdom1 srcip=192.0.2.2 srcname="A" srcport=43041
srcintf="port3" dstip=203.0.113.55 dstport=80 dstintf="port11"
poluuid=bcd3b008-c6bd-51e5-0e2c-2002e7a5774d sessionid=18364 proto=6
action=close policyid=2 policytype=policy dstcountry="Reserved"
srccountry="Reserved" trandisp=snat transip=192.0.2.2 transport=43041
service="HTTP" duration=205 sentbyte=747285 rcvdbyte=26382426 sentpkt=12887
```

```
rcvdpkt=17592 shapingpolicyid=1 shapersentname="shaper400"
shaperdropsentbyte=0 shaperrcvdname="shaper200" shaperdroprcvdbyte=14065762
appcat="unscanned" devtype="Fortinet Device" osname="Fortinet OS"
mastersrcmac=33:5b:0e:ca:dd:dc srcmac=33:5b:0e:ca:dd:dc
```

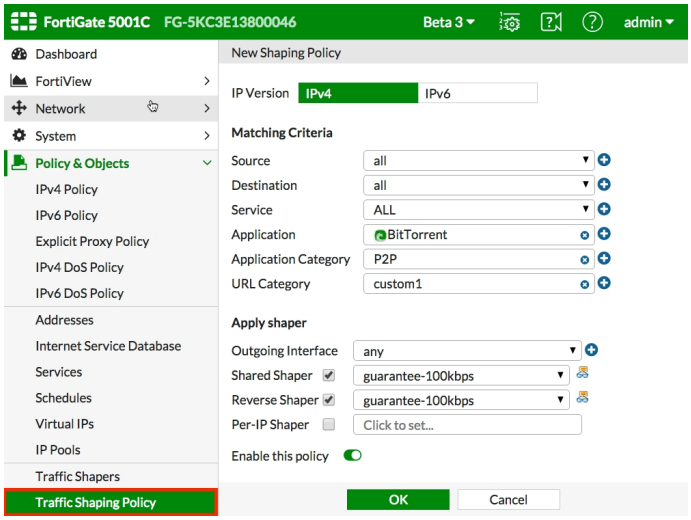
FortiOS 5.4.0

These features first appeared in FortiOS 5.4.0.

New Traffic Shaper Policy Configuration Method (269943)

Previously, traffic shapers were configured in **Policy & Objects > Objects > Traffic Shapers** and then applied in security policies under **Policy & Objects > Policy > IPv4** . In FortiOS 5.4, traffic shapers are now configured in a new traffic shaping section in **Policy & Objects > Traffic Shapers**.

The way that traffic shapers are applied to policies has changed significantly in 5.4., because there is now a specific section for traffic shaping policies in **Policy & Objects > Traffic Shaping Policy**. In the new traffic shaping policies, you must ensure that the **Matching Criteria** is the **same** as the security policy or policies you want to apply shaping to. The screen shot below shows the new 5.4 GUI interface:



There is also added Traffic Shaper support based on the following:

- Source (Address, Local Users, Groups)
- Destination (Address, FQDN, URL or category)
- Service (General, Web Access, File Access, Email and Network services, Authentication, Remote Access, Tunneling, VoIP, Messaging and other Applications, Web Proxy)
- Application
- Application Category
- URL Category

Creating Application Control Shapers

Application Control Shapers were previously configured in the **Security Profiles > Application Control** section, but for simplicity they are now consolidated in the same section as the other two types of traffic shapers: Shared and Per-IP.

To create an Application Control Shaper, you must first enable application control at the policy level, in **Policy & Objects > Policy > [IPv4 or IPv6]**. Then, you can create a matching application-based traffic shaping policy that will apply to it, in the new Traffic Shaping section under **Policy & Objects > Traffic Shaping Policy**.

New attributes added to "firewall shaping-policy" (277030) (275431)

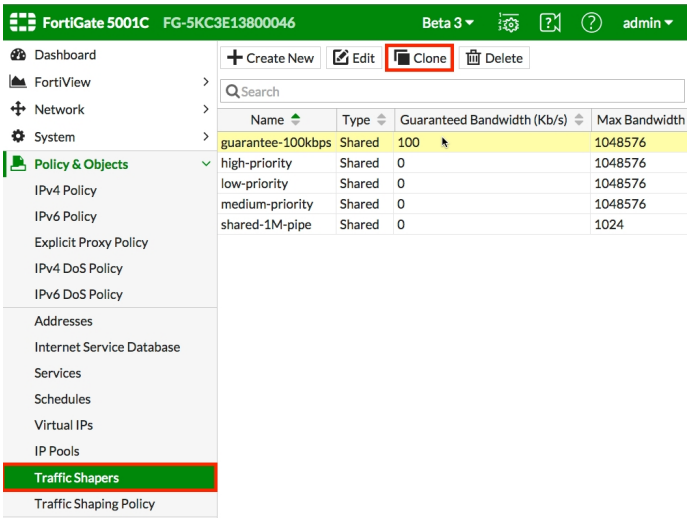
The two new attributes are `status` and `url-category`. The `status` attribute verifies whether the policy is set to enabled or disabled. The `url-category` attribute applies the shaping-policy to sessions without a URL rating when set to 0, and no web filtering is applied.

Syntax:

```
config firewall shaping-policy
   edit 1
      set status enable
      set url-category [category ID number]
```

New button added to "Clone" Shapers

You can now easily create a copy of an existing shaper by selecting the shaper and clicking the **Clone** button.



The purpose of traffic shaping

Traffic shaping, or traffic management, controls the bandwidth available and sets the priority of traffic processed by the policy to control the volume of traffic for a specific period (bandwidth throttling) or rate the traffic is sent (rate limiting).

Traffic shaping attempts to normalize traffic peaks and bursts to prioritize certain flows over others. But there is a physical limitation to the amount of data which can be buffered and to the length of time. Once these thresholds have been surpassed, frames and packets will be dropped, and sessions will be affected in other ways.

A basic traffic shaping approach is to prioritize certain traffic flows over other traffic whose potential loss is less disadvantageous. This would mean that you accept certain sacrifices in performance and stability on low-priority traffic, to increase or guarantee performance and stability to high-priority traffic.

If, for example, you are applying bandwidth limitations to certain flows, you must accept the fact that these sessions can be limited and therefore negatively impacted.

Note that traffic shaping is effective for normal IP traffic at normal traffic rates. Traffic shaping is not effective during periods when traffic exceeds the capacity of the FortiGate unit. Because packets must be received by the FortiGate unit before they are subject to traffic shaping, if the FortiGate unit cannot process all of the traffic it receives, then dropped packets, delays, and latency are likely to occur.

To ensure that traffic shaping is working at its best, make sure that the interface Ethernet statistics show no errors, collisions or buffer overruns.

Accelerated interfaces (NPx network processors and CE) affect traffic shaping. For more information, see the FortiOS Whats New in Hardware Acceleration for FortiOS 5.4 guide.

Quality of Service

Quality of Service (QoS) is the capability to adjust some quality aspects of your overall network traffic. This can include such techniques as priority-based queuing and traffic policing. Because bandwidth is finite and because some types of traffic are slow, jitter or packet loss sensitive, bandwidth intensive, or operation critical, QoS can be a useful tool for optimizing the performance of the various applications on your network.

Before implementing QoS, organizations should first identify the types of traffic that are important to the organization, the types of traffic that use high amounts of bandwidth, and the types of traffic that are sensitive to latency or packet loss.

For example, a company might want to guarantee sufficient bandwidth for revenue producing e-commerce traffic. They need to ensure that transactions can be completed and that clients do not experience service delays and interruptions. At the same time, the company may need to ensure low latency for voice over IP (VoIP) traffic used by sales and customer support, while traffic latency and bursts may be less critical to the success of other network applications such as long term, resumable file transfers. Many organizations discover that QoS is especially important for managing their voice and streaming multi-media traffic. These types of traffic can rapidly consume bandwidth and are sensitive to latency.

Discovering the needs and relative importance of each traffic type on your network will help you to design an appropriate overall approach, including how you will configure each available QoS component technique. Some organizations discover that they only need to configure bandwidth limits for some services. Other organizations

determine that they need to fully configure interface and security policy bandwidth limits for all services, and prioritize queuing of critical services relative to traffic rate.

You can implement QoS on FortiGate units using the following techniques:

Traffic policing	Drops packets that do not conform to bandwidth limitations.
Traffic shaping	Ensures that the traffic may consume bandwidth at least at the guaranteed rate by assigning a greater priority queue if the guarantee is not being met. Also ensures that the traffic cannot consume bandwidth greater than the maximum at any given instance in time. Flows greater than the maximum rate are subject to traffic policing.
Queuing	Transmits packets in order of their assigned priority queue for that physical interface. All traffic in a higher priority traffic queue must be completely transmitted before traffic in lower priority queues will be transmitted.

When deciding how to configure QoS techniques, it can be helpful to know when FortiGate units employ each technique in the overall traffic processing flow, and the considerations that arise from those mechanisms.

Traffic policing

The FortiGate unit begins to process traffic as it arrives (ingress) and departs (egress) on an interface. In later phases of the network processing, such as enforcing maximum bandwidth use on sessions handled by a security policy, if the current rate for the destination interface or traffic regulated by that security policy is too high, the FortiGate unit may drop the packet. Time spent on prior processing, such as web filtering, decryption or IPS, is often wasted on packets that are not forwarded. This applies to VLAN interfaces and physical interfaces.

You can prevent this wasted effort on ingress by configuring the FortiGate unit to preemptively drop excess packets when they are received at the source interface, before most other traffic processing is performed:

```
config system interface
   edit <interface_name>
      set inbandwidth <rate_int>
   next
end
```

where `<rate_int>` is the bandwidth limit in Kb/s. Excess packets will be dropped. If `inbandwidth` is `0`, the rate is not limited.

A similar command is available that can be performed on egress as well using the CLI commands:

```
config system interface
   edit <interface_name>
      set outbandwidth <rate_int>
   next
end
```

As with ingress, setting the rate to 0 (zero) sets the rate to unlimited.

Rate limiting traffic accepted by the interface enables you to restrict incoming traffic to rates that, while no longer the full capacity of the interface, at the traffic shaping point in the processing are more likely to result in acceptable rates of outgoing traffic per destination interface or all security policies. This conserves FortiGate processing resources for those packets that are more likely to be viable completely to the point of egress.

Excessive traffic policing can degrade network performance rather than improve it. For more details on factors that affect traffic policing, see Important considerations on page 3037.

Bandwidth guarantee, limit, and priority interactions

After packet acceptance, the FortiGate unit classifies traffic and may apply traffic policing at additional points during processing. It may also apply QoS techniques, such as prioritization and traffic shaping. Traffic shaping consists of a mixture of traffic policing to enforce bandwidth limits, and priority queue adjustment to assist packets in achieving the guaranteed rate.

If you have configured prioritization, the FortiGate unit prioritizes egressing packets by distributing them among FIFO (first in, first out) queues associated with each possible priority number. Each physical interface has six priority queues. Virtual interfaces do not have their own queues, and instead use the priority queues of the physical interface to which they are bound.

Each physical interface's six queues are queue 0 to queue 5, where queue 0 is the highest priority queue. However, for the reasons described below, you may observe that your traffic uses only a subset of those six queues. Some traffic may always use a certain queue number. Some queuing may vary by the packet rate or mixture of services. Some queue numbers may be used only by through traffic for which you have configured traffic shaping in the security policy that applies to that traffic session. For example:

- Administrative access traffic will always use queue 0.
- Traffic matching security policies ***without*** traffic shaping may use queue 0, queue 1, or queue 2. Which queue will be used depends on the priority value you have configured for packets with that ToS (type of service) bit value, if you have configured ToS-based priorities.
- Traffic matching security policies ***with*** traffic shaping may use any queue. Which queue will be used depends on whether the packet rate is currently below the guaranteed bandwidth (queue 0), or above the guaranteed bandwidth. Packets at rates greater than the maximum bandwidth limit are dropped.
- If the global tos-based-priority is low (3), the priority in a traffic-shaper is medium (2) and a packet flows though a policy that refers to the shaper, the packet will be assigned the priority defined by the shaper, in this case medium (2).

Prioritization and traffic shaping behavior varies by your configuration, the service types and traffic volumes, and by whether the traffic is through traffic, or the traffic originates from or terminates at the FortiGate unit itself.

FortiGate traffic

Security Policies do not apply to Administrative access to the FortiGate through HTTPS or SSH, or IPsec tunnel negotiations, and therefore FortiGate units do not apply traffic shaping. Such traffic also uses the highest priority queue, queue 0. In other words:

packet priority = 0

Exceptions to this rule include traffic types that are connections related to a session governed by a security policy.

For example, if you have enabled scanning by FortiGuard antivirus, traffic from the sender technically terminates at the FortiGate proxy that scans that traffic type; the FortiGate unit initiates a second connection that transmits scanned content to its destination. Because the second connection's traffic is technically originating from the FortiGate proxy and therefore the FortiGate unit itself, it uses the highest priority queue, queue 0. However, this connection is logically associated with through traffic, and is therefore subject to possible bandwidth enforcement and guarantees in its governing security policy. In this way, it behaves partly like other through traffic.

Through traffic

For traffic passing through the FortiGate unit, the method a FortiGate unit uses to determine the priority queue varies by whether Traffic Shaping is enabled or not. Packets may or may not use a priority queue directly or indirectly derived from the type of service (ToS) bit — sometimes used instead with differentiated services — in the packet's IP header.

If Traffic Shaping is not applied to a security policy, the FortiGate unit neither limits nor guarantees bandwidth, and traffic for that session uses the priority queue determined directly by matching the ToS bit in its header with your configured values:

```
config system global
set traffic-priority tos
set traffic-priority-level {high | low | medium}
end
```

or, if you have configured a priority specifically for that ToS bit value:

```
config system tos-based-priority
   edit <id_int>
      set tos [0-15]
      set priority {high | low | medium}
end
```

where `tos` is the value of the ToS bit in the packcet's IP header, and `high` has a priority value of 0 and `low` is 2. Priority values configured in the second location will override the global ToS-based priority. In other words:

packet priority = ToS-based priority

For example, you might specify that packets with a ToS bit value of 2 should use queue 0, the highest priority queue:

```
config system tos-based-priority
   edit 15
      set tos 2
      set priority high
   next
end
```

If traffic shaping is applied to a security policy using a shared shaper, the FortiGate unit may subject packets to traffic policing or priority queue increases in an effort to meet bandwidth guarantees configured in the shaper.

For example, you might create a Shared Shaper, where `high` has a priority value of 1 and `low` is 3, and `<rate>` is the bandwidth limit in kilobits per second:

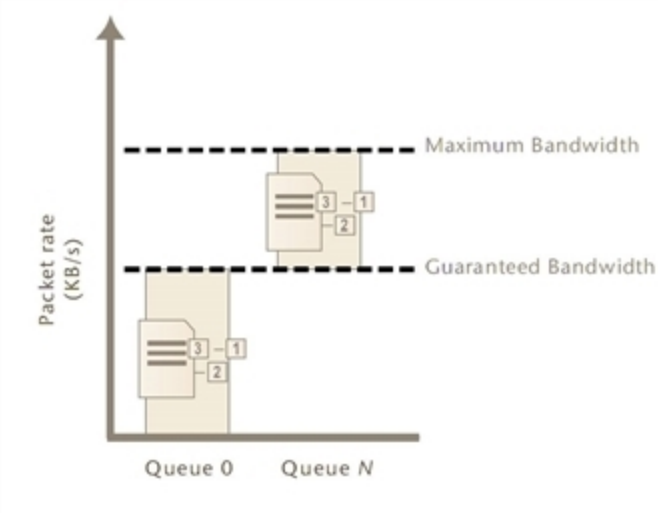
```
config firewall shaper traffic-shaper
   edit <shaper_name>
      ...
      set priority {high | medium | low}
      set maximum-bandwidth <rate>
      set guaranteed-bandwidth <rate>
end
```

Note that it is also necessary to create a traffic shaping policy and set it to use the shared shaper:

```
config firewall shaping-policy
   edit <policy ID>
   ...
      set srcaddr <source address>
      set dstaddr <destination address>
      set service <service name>
      set dstintf <destination interface list>
      set traffic-shaper <shaper_name>
end
```

The diagram below illustrates traffic queuing as the packet rate increases.

Traffic queuing as the packet rate increases



- If the current packet rate is less than Guaranteed Bandwidth, packets use priority queue 0:

  packet priority = 0

- If the current packet rate is greater than Guaranteed Bandwidth but less than Maximum Bandwidth, the FortiGate unit assigns a priority queue by adding the numerical value of the security policy-based priority, where the value of `High` is 1, and `Low` is 3, with the numerical value of the ToS-based priority, where `high` has a priority value of 0 and `low` is 2. Because the two values are added, depending on the configured ToS-based priorities, packets in this category could use queues from queue 1 to queue 5. In other words:

  packet priority = ToS-based priority + security policy-based priority

- If you have enabled Traffic Shaping in the security policy, and the security policy's Traffic Priority is Low (value 3), and the priority normally applied to packets with that ToS bit is `medium` (value 1), then packets have a total packet priority of 4, and use priority queue 4.
- If the current packet rate exceeds Maximum Bandwidth, excess packets are dropped.

Calculation and regulation of packet rates

Packet rates specified for Maximum Bandwidth or Guaranteed Bandwidth are:

```
rate = amount / time
```

where rate is expressed in kilobits per second (Kb/s).

Burst size at any given instant cannot exceed the amount configured in Maximum Bandwidth. Packets in excess are dropped. Packets deduct from the amount of bandwidth available to subsequent packets and available bandwidth regenerates at a fixed rate. As a result, bandwidth available to a given packet may be less than the configured rate, down to a minimum of 0 Kb/s.

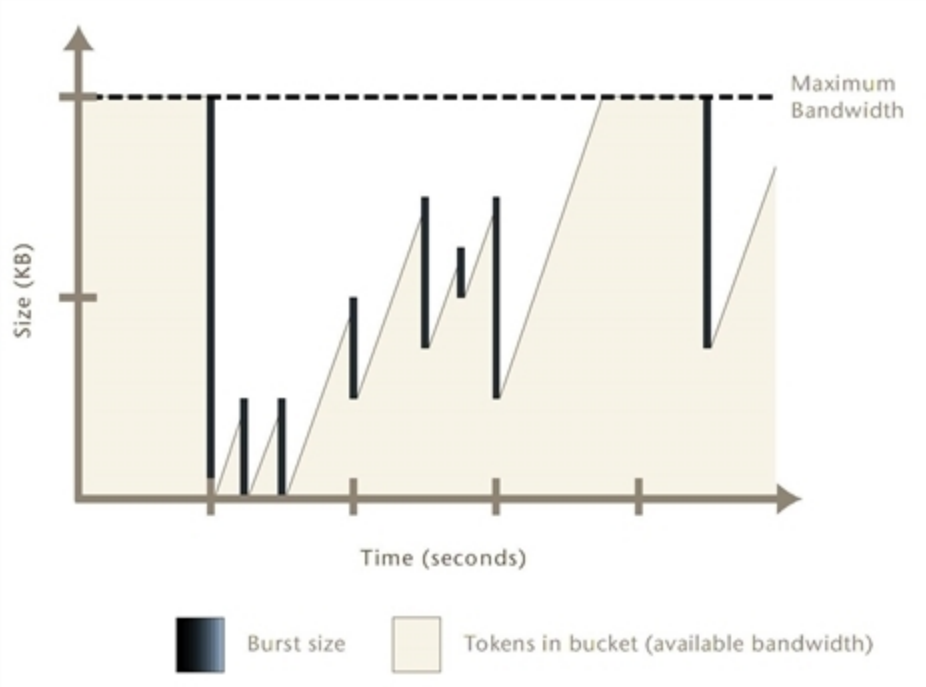
Rate calculation and behavior can alternatively be described using the token bucket metaphor, where:

- A traffic flow has an associated bucket, which represents burst size bounds, and is the size of your configured bandwidth limit.
- The bucket receives tokens, which represent available bandwidth, at the fixed configured rate.
- As time passes, tokens are added to the bucket, up to the capacity of the bucket; excess tokens are discarded.
- When a packet arrives, the packet must deduct bandwidth tokens from the bucket equal to its packet size in order to egress.
- Packets cannot egress if there are insufficient tokens to pay for its egress; these nonconforming packets are dropped.

Bursts are not redistributed over a longer interval, so bursts are propagated rather than smoothed, although their peak size is limited.

Maximum burst size is the capacity of the bucket (the configured bandwidth limit); actual size varies by the current number of tokens in the bucket, which may be less than bucket capacity, due to deductions from previous packets and the fixed rate at which tokens accumulate. A depleted bucket refills at the rate of your configured bandwidth limit. Bursts cannot borrow tokens from other time intervals. This behavior is illustrated in the graph below.

Bursts and bandwidth limits over time



By limiting traffic peaks and token regeneration in this way, the available bandwidth at any given moment may be less than bucket capacity, but your limit on the total amount per time interval is ensured. Total bandwidth use during each interval of 1 second is at most the integral of your configured rate.

You may observe that external clients, such as FTP or BitTorrent clients, initially report rates between Maximum Bandwidth and twice that of Maximum Bandwidth, depending on the size of their initial burst. This is notably so when a connection is initiated following a period of no network activity.The apparent discrepancy in rates is caused by a difference in perspective when delimiting time intervals. A burst from the client may initially consume all tokens in the bucket, and before the end of 1 second, as the bucket regenerates, be allowed to consume almost another bucket's worth of bandwidth. From the perspective of the client, this constitutes one time interval. From the perspective of the FortiGate unit, however, the bucket cannot accumulate tokens while full; therefore, the time interval for token regeneration begins **after** the initial burst, and does not contain the burst. These different points of reference result in an initial discrepancy equal to the size of the burst — the client's rate contains it, but the FortiGate unit's rate does not. If the connection is sustained to its limit and time progresses over an increasing number of intervals, however, this discrepancy decreases in importance relative to the bandwidth total, and the client's reported rate will eventually approach that of the FortiGate unit's configured rate limit.

For example, your Maximum Bandwidth might be 50 Kb/s and there has been no network activity for one or more seconds. The bucket is full. A burst from an FTP client immediately consumes 50 Kb. Because the bucket completely regenerates over 1 second, by the time almost another 1 second has elapsed from the initial burst, traffic can consume another 49.999 Kb, for a total of 99.999 Kb between the two points in time. From the vantage point of an external FTP client regulated by this bandwidth limit, it therefore initially appears that the bandwidth limit is 99.999 Kb/s, almost twice the configured limit of 50 Kb/s. However, bucket capacity only regenerates at your configured rate of 50 Kb/s, and so the connection can only consume a maximum of 50 Kb during each second thereafter. The result is that as bandwidth consumption is averaged over an increasing number of time intervals, each of which are limited to 50 Kb/s, the effects of the first interval's doubled bandwidth size diminishes proportionately, and the client's reported rate eventually approaches your configured rate limit. The effects are shown in the table below.

Effects of a 50 Kb/s limit on client reported rates

Total size transferred (Kb)	Time (s)	Rate reported by client (Kb/s)
99.999 (50 + 49.999)	1	99.999
149.999	2	74.999
199.999	3	66.666
249.999	4	62.499
299.999	5	59.998
349.999	6	58.333
...	...	...

Guaranteed Bandwidth can also be described using a token bucket metaphor. However, because this feature attempts to achieve or exceed a rate rather than limit it, the FortiGate unit does not discard non-conforming

packets, as it does for Maximum Bandwidth; instead, when the flow does not achieve the rate, the FortiGate unit increases the packets' priority queue, in an effort to increase the rate.

Guaranteed and maximum bandwidth rates apply to the bidirectional total for all sessions controlled by the security policy. For example, an FTP connection may entail two separate connections for the data and control portion of the session; some packets may be reply traffic rather than initiating traffic. All packets for both connections are counted when calculating the packet rate for comparison with the guaranteed and maximum bandwidth rate.

Important considerations

By implementing QoS, you trade some performance and/or stability from traffic X by discarding packets or introducing latency in order to improve performance and stability of traffic Y. The best traffic shaping configuration for your network will balance the needs of each traffic flow by considering not only the needs of your particular organization, but also the resiliency and other characteristics of each particular service.

For example, you may find that web browsing traffic is both more resistant to interruptions or latency and less business critical than UDP or VoIP traffic, and so you might implement less restrictive QoS measures on UDP or VoIP traffic than on HTTP traffic.

An appropriate QoS configuration will also take into account the physical limits of your network devices, and the interactions of the aforementioned QoS mechanisms, described in Bandwidth guarantee, limit, and priority interactions on page 3032.

You may choose to configure QoS differently based upon the hardware limits of your network and FortiGate unit. Traffic shaping may be less beneficial in extremely high-volume situations where traffic exceeds a network interface's or your FortiGate model's overall physical capacity. A FortiGate unit must have enough resources, such as memory and processing power, to process all traffic it receives, and to process it at the required rate; if it does not have this capacity, then dropped packets and increased latency are likely to occur. For example, if the total amount of memory available for queuing on a physical interface is frequently exceeded by your network's typical packet rates, frames and packets must be dropped. In such a situation, you might choose to implement QoS using a higher model FortiGate unit, or to configure an incoming bandwidth limit on each interface.

Incorrect traffic shaping configurations can actually further degrade certain network flows, because excessive discarding of packets or increased latency beyond points that can be gracefully handled by that protocol can create additional overhead at upper layers of the network, which may be attempting to recover from these errors. For example, a configuration might be too restrictive on the bandwidth accepted by an interface, and may therefore drop too many packets, resulting in the inability to complete or maintain a SIP call.

To optimize traffic shaping performance, first ensure that the network interface's Ethernet statistics are clean of errors, collisions, or buffer overruns. To check the interface, enter the following diagnose command to see the traffic statistics:

```
diagnose hardware deviceinfo nic <port_name>
```

If these are not clean, adjust FortiGate unit and settings of routers or other network devices that are connected to the FortiGate unit. For more information, see Troubleshooting traffic shaping on page 3072.

Once Ethernet statistics are clean, you may want to use only some of the available FortiGate QoS techniques, or configure them differently, based upon the nature of FortiGate QoS mechanisms described in Bandwidth guarantee, limit, and priority interactions on page 3032.

Configuration considerations include:

- For maximum bandwidth limits, ensuring that bandwidth limits at the source interface and/or the security policy are not too low, which can cause the FortiGate unit to discard an excessive number of packets.
- For prioritization, considering the ratios of how packets are distributed between available queues, and which queue is used by which types of services. If you assign most packets to the same priority queue, it negates the effects of configuring prioritization. If you assign many high bandwidth services to high priority queues, lower priority queues may be starved for bandwidth and experience increased or indefinite latency. For example, you may want to prioritize a latency-sensitive service such as SIP over a bandwidth-intensive service such as FTP. Consider also that bandwidth guarantees can affect the queue distribution, assigning packets to queue 0 instead of their typical queue in high-volume situations.
- You may or may not want to guarantee bandwidth, because it causes the FortiGate unit to assign packets to queue 0 if the guaranteed packet rate is not currently being met. Comparing queuing behavior for lower-bandwidth and higher-bandwidth situations, this would mean that effects of prioritization only become visible as traffic volumes rise and exceed their guarantees. Because of this, you might want only some services to use bandwidth guarantees, to avoid the possibility that in high-volume situations all traffic uses the same queue, thereby negating the effects of configuring prioritization.
- For prioritization, configure prioritization for all through traffic. You may want to configure prioritization by either ToS-based priority or security policy priority, but not both. This simplifies analysis and troubleshooting.

  Traffic subject to both security policy and ToS-based priorities will use a combined priority from both of those parts of the configuration, while traffic subject to only one of the prioritization methods will use only that priority. If you configure both methods, or if you configure either method for only a subset of your traffic, packets for which a combined priority applies will frequently receive a lower priority queue than packets for which you have only configured one priority method, or for which you have not configured prioritization.

  For example, if both ToS-based priority and security policy priority both dictate that a packet should receive a “medium” priority, in the absence of bandwidth guarantees, a packet will use queue 3, while if only ToS-based priority had been configured, the packet would have used queue 1, and if only security policy-based priority had been configured, the packet would have used queue 2. If no prioritization had been configured at all, the packet would have used queue 0.

For example alternative QoS implementations that illustrate these considerations, see Examples on page 3061.

Traffic shaping methods

In FortiOS, there are three types of traffic shaping configurations. Each has a specific function, and all can be used together in varying configurations. Policy shaping enables you to define the maximum bandwidth and the guaranteed bandwidth set for a security policy. Per-IP shaping enables you to define traffic control on a more granular level. Application traffic shaping goes further, enabling traffic controls on specific applications or application groupings.

This chapter describes the types of traffic shapers and how to configure them in the web-based manager and the CLI.

To configure traffic shaping in the web-based manager, you must enable the **Traffic Shaping** feature under System > Feature Select.

Traffic shaping options

When configuring traffic shaping for your network, there are three different methods to control the flow of network traffic to ensure that the desired traffic gets through while also limiting bandwidth for less important or bandwidth consuming traffic. The three methods are the following:

- **Shared policy shaping** - bandwidth management by security policies
- **Per-IP shaping** - bandwidth management by user IP addresses
- **Application control shaping** - bandwidth management by application

Shapers allow you to define how traffic will flow by setting the traffic priority, bandwidth and DSCP options. Shared policy shapers and Per-IP shapers are created under Policy & Objects > Traffic Shapers.

Traffic Shapers are then enabled within the traffic shaping policy, under Policy & Objects > Traffic Shaping Policy.

Application control shaping can be applied to any traffic shaping policy, under Policy & Objects > Traffic Shaping Policy. You can control traffic by application category, application, and/or URL category.

To apply application control shaping, you must first enable application control at the policy level, under Policy & Objects > IPv4 Policy.

Traffic shaping policies allow you to apply traffic shaping measures to any traffic matching your criteria. The criteria must specify a source, a destination, a service, and the outgoing interface. Also, at least one type of shaper must be enabled to create a traffic shaping policy.

The three different traffic shaping options offered by the FortiGate unit can be enabled at the same time within a single traffic shaping policy. Generally, the hierarchy for traffic shapers in FortiOS is:

- Application control shaper
- Shared policy shaper
- Per-IP shaper

Within this hierarchy, if an application control list has a traffic shaper defined, it will always have precedence over any other policy shaper. For example, the Facebook application control example shown in Application control shaping on page 3048 will supersede any security policy enabled traffic shapers. While the Facebook application may reach its maximum bandwidth, the user can still have the bandwidth room available from the Shared Shaper and, if enabled, the Per-IP shaper.

Equally, any security policy shared shaper will have precedence over any per-IP shaper. However, traffic that exceeds any of these shapers will be dropped. For example, the policy shaper will take effect first, however, if the per-IP shaper limit is reached first, then traffic for that user will be dropped even if the shared shaper limit for the policy has not been exceeded.

Shared policy shaping

Traffic shaping by security policy enables you to control the maximum and/or guaranteed throughput for any security policies specified in the Traffic Shaping Policy.

When configuring a shaper, you can select to apply the bandwidth shaping per policy or for all policies. Depending on your selection, the FortiGate unit will apply the shaping rules differently.

By default shared shapers apply shaping evenly to all policies using it. For **Per policy** and **All policies using this shaper** options to appear in the web-based interface, you must first enable it in the CLI. Go to Policy & Objects > Traffic Shapers and right-click on the shaper to edit it in the CLI. Enter:

```
    set per-policy enable
end
```

Per policy

When selecting a shared shaper to be **per policy**, the FortiGate unit will apply the shaping rules defined to each security policy individually.

For example, if a shaper is set to per policy with a maximum bandwidth of 1000 Kb/s and applied to four security policies, each policy has the same maximum bandwidth of 1000 Kb/s.

Per policy traffic shaping is compatible with client/server (active-passive) transparent mode WAN optimization rules. Traffic shaping is ignored for peer-to-peer WAN optimization and for client/server WAN optimization not operating in transparent mode.

For all policies using a shaper

When selecting a shared shaper to be for all policies -**All Policies using this shaper** - the FortiGate unit applies the shaping rules to all policies using the same shaper. For example, the shaper is set to be per policy with a maximum bandwidth of 1000 Kb/s. There are four security policies monitoring traffic through the FortiGate unit. All four have the shaper enabled. Each security policy must share the defined 1000 Kb/s, and is set on a first come, first served basis. For example, if policy 1 uses 800 Kb/s, the remaining three must share 200 Kb/s. As policy 1 uses less bandwidth, it is opened up to the other policies to use as required. Once used, any other policies will encounter latency until free bandwidth opens from a policy currently in use.

Maximum and guaranteed bandwidth

The maximum bandwidth instructs the security policy what the largest amount of traffic allowed using the policy. Depending on the service or the users included for the security policy, this number can provide a larger or smaller throughput depending on the priority you set for the shaper.

The **Maximum Bandwidth** can be set to a value of between 1 and 16776000 kbit/s. The Web-Based Manager gives an error if any value outside of this range is used, but in the CLI a value of 0 can be entered. Setting `maximum-bandwidth` to 0 (zero) prevents any traffic from going through the policy.

The guaranteed bandwidth ensures there is a consistent reserved bandwidth available for a given service or user. When setting the guaranteed bandwidth, ensure that the value is significantly less than the bandwidth capacity of the interface, otherwise no other traffic will pass through the interface or very little an potentially causing unwanted latency.

Traffic priority

Select a Traffic Priority of high, medium or low, so the FortiGate unit manages the relative priorities of different types of traffic. For example, a policy for connecting to a secure web server that needed to support e-commerce traffic should be assigned a high traffic priority. Less important services should be assigned a low priority. The firewall provides bandwidth to low-priority connections only when bandwidth is not needed for high-priority connections.

Be sure to enable traffic shaping on all security policies. If you do not apply any traffic shaping rule to a policy, the policy is set to high priority by default. Distribute security policies over all three priority queues.

Traffic shaping policy order

The traffic shaping policies must also be placed in the correct order in the traffic shaping policy list page to get the desired results. It is necessary to arrange your traffic shaping policies into a sequence that places your more granular policies above general internet access policies. For example, you would place any policies with application control shaping at the top of the traffic shaping policy list. More general traffic shaping policies with shared policy shapers and/or Per-IP shapers would follow.

The policy list page is located under Policy & Objects > Traffic Shaping Policy. You can change the order of your policies by selecting the far left column to move the policy up or down. Make sure that the **Seq.#** column is shown on your menu to easily verify a policy's position in the sequence.

The following example illustrates how to order your policies. The high priority VoIP traffic shaping policy is placed at the top of the list, followed by restrictive policies to control streaming media, and your general internet access policy is placed last.

Seq.#	Source Address	Destination	Outgoing Interface	Shared Shaper	Reverse Shaper	Service	Application	Application Category
IPv4 (1 - 4)								
1	• all	• all	• wan1	guarantee-100kbps	guarantee-100kbps	• ALL	• SIP	• VoIP
2	• all	• all	• wan1	limited_bandwidth	limited_bandwidth	• ALL	• Vimeo • YouTube	• Video/Audio
3	• all	• all	• wan1	high-priority	high-priority	• ALL		

Traffic Shaping Policy Configuration Settings

To configure a traffic shaping policy go to Policy & Objects > Traffic Shaping Policy and select the **Create New** "Plus" sign to create a new traffic shaping policy.

Set the "**Matching Criteria**" to the default options shown below or specify the criteria so that it matches a specific security policy.

Source	***all** (default)
Destination	***all** (default)
Service	***ALL** (default)
Application Category	**-** Choose an application category to apply shaping to a specific category of applications. For example, P2P, Social.Media,or VoIP.
Application	**-** Choose an application to specify which applications you wish to apply traffic shaping to. For example, YouTube, Vimeo, or Facebook.
URL Category	**-** Choose a URL category to block a subset of applications. For example, potentially liable websites, security risks, or bandwidth consuming services.

Set **Apply shaper** to the following:

Outgoing Interface	***any** (Set this to the external interface you wish to apply shaping to. For example, wan1 is often used.)
Shared Shaper	Choose one of the default shared shapers: guarantee-100kbps, high-priority, medium-priority, low-priority, shared-1M-pipe or create your own under Policy & Objects > Traffic Shapers. Shared Shapers share the alloted bandwidth with any security policies using them (unless they are set to per-policy in the CLI). This affects uploads or outbound traffic.
Reverse Shaper	Choose one of the default shared shapers: guarantee-100kbps, high-priority, medium-priority, low-priority, shared-1M-pipe, or create your own under Policy & Objects > Traffic Shapers. This affects downloads or inbound traffic.
Per-IP Shaper	Enable a Per-IP Shaper if you want to apply shaping by bandwidth management by user IP addresses. Shapers are created under Policy & Objects > Traffic Shapers. Per-IP shapers affect downloads and uploads.
Enable this policy	Policies are enabled by default, but if you wish to disable a traffic shaping policy de-select it here.

To create the traffic shaping policy - CLI:

```
config firewall shaping-policy
   edit <shaping policy ID>
      set srcaddr <source address>
```

```
    set dstaddr <destination address>
    set service <service name>
    application <application name>
    app-category <application category ID list>
    url-category <URL category ID list>
    dstintf <destination interface list>
    traffic-shaper <shared shaper name>
    traffic-shaper-reverse <reverse traffic shaper name>
    per-ip-shaper <per IP shaper name>
end
```

VLAN, VDOM and virtual interfaces

Policy-based traffic shaping does not use queues directly. It shapes the traffic and if the packet is allowed by the security policy, then a priority is assigned. That priority controls what queue the packet will be put in upon egress. VLANs, VDOMs, aggregate ports and other virtual devices do not have queues and as such, traffic is sent directly to the underlying physical device where it is queued and affected by the physical ports. This is also the case with IPsec connections.

Shared traffic shaper configuration settings

To configure a shared traffic shaper go to **Policy & Objects > Traffic Shapers** and select the **Create New** "Plus" sign to create a new traffic shaper.

Type	Select **Shared**.
Name	Enter a name for the traffic shaper.
Apply Shaper	When selecting a shaper to be **Per Policy**, the FortiGate unit will apply the shaping rules defined to each security policy individually. For example, if a shaper is set to per policy, with a maximum bandwidth of 1000 Kb/s, any security policies that have that shaper enabled will get 1000 Kb/s of bandwidth each. When selecting a shaper to be for all policies - **For All Policies Using This Shaper** - the FortiGate unit applies the shaping rules to all policies using the same shaper. For example, the shaper is set to be per policy with a maximum bandwidth of 1000 Kb/s. There are four security policies monitoring traffic through the FortiGate unit. All four have the shaper enabled. Each security policy must share the defined 1000 Kb/s, and is set on a first come, first served basis. For example, if policy 1 uses 800 Kb/s, the remaining three must share 200 Kb/s. As policy 1 uses less bandwidth, that open bandwidth becomes available to the other policies to use as required. Once used, any other policies will encounter latency until free bandwidth opens from a policy currently in use.

Traffic Priority	Select level of importance **Priority** so the FortiGate unit manages the relative priorities of different types of traffic. For example, a policy for connecting to a secure web server needed to support e-commerce traffic should be assigned a high traffic priority. Less important services should be assigned a low priority. If you do not apply any traffic shaping priority, the priority is set to high priority by default.
Maximum Bandwidth	The maximum bandwidth instructs the security policy what the largest amount of traffic allowed using the policy. Depending on the service or the users included for the security policy, this number can provide a larger or smaller throughput depending on the priority you set for the shaper. Setting **Maximum Bandwidth** to 0 (zero) provides unlimited bandwidth.
Guaranteed Bandwidth	The guaranteed bandwidth ensures that a consistent reserved bandwidth is available for a given service or user. Ensure that you set the bandwidth to a value that is significantly less than the bandwidth capacity of the interface. Otherwise little to no traffic will pass through the interface and potentially cause unwanted latency. Setting **Guaranteed Bandwidth** to 0 (zero) provides unlimited bandwidth.
DSCP	Enter the number for the DSCP value. You can use the FortiGate Differentiated Services feature to change the DSCP (Differentiated Services Code Point) value for all packets accepted by a policy. The network can use these DSCP values to classify, mark, shape, and police traffic, and to perform intelligent queuing. DSCP features are applied to traffic by configuring the routers on your network to apply different service levels to packets depending on the DSCP value of the packet. For more information, see Traffic shaping methods.

Shared Shaper Per Policy Example

The following steps creates a Per Policy traffic shaper called “Throughput” with a maximum traffic amount of 720,000 Kb/s, and a guaranteed traffic of 150,000 Kb/s with a high traffic priority.

To create the shared shaper - web-based manager:

1. Go to **Policy & Objects > Traffic Shapers** and select the **Create New** “Plus” sign.
2. Set the **Type** to **Shared**.
3. Enter the **Name** `Throughput`.
4. Set the **Apply shaper** field to **Per Policy**.

By default shared shapers apply shaping evenly to all policies using it. For **Per policy** and **All policies using this shaper** options to appear in the web-based interface, you must first enable it in the CLI. Go to Policy & Objects > Traffic Shapers and right-click on the shaper to edit it in the CLI. Enter:

```
    set per-policy enable
end
```

5. Set the **Traffic Priority** to **High**.
6. Select the **Maximum Bandwidth** check box and enter the value `150000`.
7. Select the **Guaranteed Bandwidth** check box and enter the value `120000`.
8. Select **OK**.

To create the shared shaper - CLI:

```
config firewall shaper traffic-shaper
   edit Throughput
      set per-policy enable
      set maximum-bandwidth 150000
      set guaranteed-bandwidth 120000
      set priority high
   end
```

Per-IP shaping

Traffic shaping by IP enables you to apply traffic shaping to all source IP addresses in the security policy. As well as controlling the maximum bandwidth users of a selected policy, you can also define the maximum number of concurrent sessions.

Per-IP traffic shaping enables you limit the behavior of every member of a policy to avoid one user from using all the available bandwidth - it now is shared within a group equally. Using a per-IP shaper avoids having to create multiple policies for every user you want to apply a shaper. Per-IP traffic shaping is not supported over NP2 interfaces.

Per-IP traffic shaping configuration settings

To configure per-IP traffic shaping go to **Policy & Objects > Traffic Shapers > Per-IP** and select the **Create New** “Plus” sign.

Type	Select **Per-IP**.
Name	Enter a name for the per-IP traffic shaper.

Maximum Bandwidth	The maximum bandwidth instructs the security policy what the largest amount of traffic allowed using the policy. Depending on the service or the users included for the security policy, this number can provide a larger or smaller throughput depending on the priority you set for the shaper. Setting **Maximum Bandwidth** to 0 (zero) provides unlimited bandwidth.
Maximum Concurrent Connections	Enter the maximum allowed concurrent connection.
Forward DSCP **Reverse DSCP**	Enter the number for the DSCP value. You can use the FortiGate Differentiated Services feature to change the DSCP (Differentiated Services Code Point) value for all packets accepted by a policy. The network can use these DSCP values to classify, mark, shape, and police traffic, and to perform intelligent queuing. DSCP features are applied to traffic by configuring the routers on your network to apply different service levels to packets depending on the DSCP value of the packet. For more information, see Traffic shaping methods.

Example

The following steps create a Per-IP traffic shaper called “Accounting” with a maximum traffic amount of 720,000 Kb/s, and the number of concurrent sessions of 200.

To create the shared shaper - web-based manager:

1. Go to **Policy & Objects > Traffic Shapers** and select the **Create New** “Plus” Icon.
2. Set the **Type** to **Per-IP**.
3. Enter the **Name** `Accounting`.
4. Enable the **Maximum Bandwidth** and enter the value `720000`.
5. Enable the **Maximum Concurrent Sessions** and enter the value `200`.
6. Select **OK**.

To create the shared shaper - CLI:

```
config firewall shaper per-ip-shaper
   edit Accounting
      set max100-bandwidth 720000
      set max-concurrent-session 200
   end
```

Adding a Per-IP traffic shaper to a traffic shaping policy

Per-IP traffic shaping is supported by IPv6 security policies. You can add any Per-IP traffic shaper to an IPv6 security policy in the CLI.

Example

The following steps show you how to add an existing Per-IP traffic shaper to an IPv6 security policy. Make sure that you have already created a Per-IP traffic shaper under Policy & Objects > Traffic Shapers.

To add a Per-IP traffic shaper to an IPv6 security policy - web-based manager:

1. Go to **Policy & Objects > IPv6 Policy** and click the **Create New** "Plus" icon to create an internet access policy.
2. Set the following:

Name	Enter a descriptive name.
Incoming Interface	Internal
Source address	All
Outgoing interface	wan1
Destination address	all
Schedule	Always
Service	Any
Action	Accept

3. Select **OK**.
4. Go to Policy & Objects > Traffic Shaping Policy and the **Create New** "Plus" icon to create a new traffic shaping policy.
5. To apply your traffic shaping policy to the security policy you created earlier set the **Matching Criteria** to the following:

Source	all
Destination address	all
Service	ALL
Application Category	-
Application	-
URL Category	-

6. Under **Apply shaper**, set the following:

Outgoing interface	any (The outgoing interface should match the outgoing interface of the security policy you wish to apply shaping to.)
Shared Shaper	-
Reverse Shaper	-
Per-IP Shaper	Enable **Per-IP Shaper** and select your shaper from the dropdown menu.
Enable this policy	Enable this policy.

7. Select **OK**.
8. On the policy list page, move the Per-IP Shaper to the top of the list by clicking on the far left column to drag and drop it.

There are two methods to configure traffic shaping in the CLI. You can add a Per-IP shaper directly to an IPv6 security policy, or you can add a Per-IP shaper to a traffic shaping policy. The second method will allow you to apply traffic shaping based on the interface and can therefore affect multiple security policies easily. The first method requires that you enable traffic shaping individually in ALL policies using the same two interfaces.

To add a Per-IP traffic shaper to an IPv6 security policy- CLI:

```
config firewall policy6
   edit <security policy ID number>
      set per-ip-shaper <per IP shaper name>
   end
```

To add a Per-IP traffic shaper to an IPv6 traffic shaping policy -CLI:

```
config firewall shaping-policy
   edit 1 <security policy ID number>
      set ip-version 6
      set srcaddr <source address>
      set dstaddr <destination address>
      set service <service name>
      set dstintf <outgoing interface>
      set per-ip-shaper <per IP shaper name>
   end
```

Application control shaping

Traffic shaping is also possible for specific applications, too. Application control shaping works in conjunction with a Shared Shaper or Per-IP Shaper. You must create a shaper with the bandwidth settings you would like to enforce or edit one of the predefined shapers in the Policy & Objects > Traffic Shapers menu.

Traffic shaping policies allow you to enable these shapers and configure application control options. In the traffic shaping policy, you can set an **Application Category**, **Application**, and **URL Category**. You must also specify which security policies to apply your shaper to by setting the **Matching Criteria**.You can create a traffic shaping policy in the Policy & Objects > Traffic Shaping Policy section.

For application control shaping to work, application control must be enabled in a security policy, through Policy & Objects > IPv4 Policy or Policy & Objects > IPv6 Policy under **Security Profiles.**

Also, application control shaping will only affect applications that are set to pass in the Security Profiles > Application Control menu.

For more information on application control, see the FortiOS Chapter 26 - Security Profiles Guide.

Example

This example sets the traffic shaping definition for Facebook to a medium priority, a default traffic shaper.

To add traffic shaping for Facebook - web-based manager:

1. Go to Policy & Objects > IPv4 Policy to create a general Internet access security policy.
2. Select the **Create New** "Plus" icon in the upper right corner of the screen to create a new security policy (or edit an existing Internet access policy).
3. Set the following to enable application control within a security policy:

Name	<Enter a descriptive name.>
Incoming Interface	Internal
Source address	All
Outgoing interface	wan1
Destination address	all
Schedule	Always
Service	Any
Action	Accept
Application Control	Under Security Profiles, enable **Application Control** and select the default application control profile.

4. Select **OK**.
5. Go to Policy & Objects > Traffic Shaping Policy and the **Create New** "Plus" icon to create a new traffic shaping policy.
6. To apply your traffic shaping policy to the security policy you created earlier set the **Matching Criteria** to the following:

Source	all
Destination address	all
Service	ALL
Application Category	Social.Media
Application	Facebook
URL Category	Social Networking

7. Under **Apply shaper**, set the following:

Outgoing interface	any (The outgoing interface should match the outgoing interface of the security policy you wish to apply shaping to.)

Shared Shaper	Enable **Shared Shaper** and select **medium-priority** from the drop down menu.
Reverse Shaper	Enable **Shared Shaper** and select **medium-priority** from the drop down menu.
Enable this policy	Enable this policy.

8. Select **OK**.
9. On the policy list page, move the facebook traffic shaping policy to the top of the list by clicking on the far left column to drag and drop it.

To create a traffic shaping policy for Facebook - CLI:

```
config firewall shaping-policy
   edit 1 <shaping policy ID number>
      set srcaddr all
      set dstaddr all
      set service ALL
      set application 15832
      set app-category 23 <Social.Media>
      set url-category 37 <Social Networking>
      set dstintf wan1 <outgoing interface>
      set traffic-shaper medium-priority
      set reverse-traffic-shaper medium-priority
   end
```

Reverse direction traffic shaping

The shaper you select in the traffic shaping policy (shared shaper) will affect the traffic in the direction defined in the policy. For example, if the source port is lan and the destination is wan1, the shaping affects the flow in this direction only — affecting the upload speed of the outbound traffic. By selecting **Shared Traffic Shaper Reverse Direction**, you can define the traffic shaper for the policy in the opposite direction to affect the download speed of the inbound traffic. In this example, from wan 1 to lan.

To add a reverse shaper

1. Go to Policy & Objects > Traffic Shaping Policy.
2. Click **Create New** or select an existing policy and click **Edit**.
3. Set the **Matching Criteria** to match the interfaces of any security policies you wish to affect.
4. Navigate to the **Apply shaper** section, enable the **Shared Shaper**, and select a shaper from the dropdown menu.
5. Enable the **Reverse Shaper** and select a shaper from the dropdown menu.
6. Select **OK**.

Setting the reverse direction only

There may be instances where you only need traffic shaping for incoming connections, which is in the “reverse” direction of typical traffic shapers.

To add a reverse shaper - web-based manager:

1. Go to Policy & Objects > Traffic Shaping Policy.
2. Click **Create New** or select an existing policy and click **Edit**.
3. Set the **Matching Criteria** to match the interfaces of any security policies you wish to affect.
4. Navigate to the **Apply shaper** section, enable the **Reverse Shaper** and select a shaper from the dropdown menu.
5. Select **OK**.

To configure a reverse-only shaper in a traffic shaping policy - CLI:

```
config firewall shaping-policy
   edit <policy_number>
      set reverse-traffic-shaper medium-priority
   end
```

To configure a reverse-only shaper within a security policy- CLI:

```
config firewall policy
   edit <policy_number>
      ...
      set traffic-shaper-reverse <shaper_name>
   end
```

Enabling traffic shaping in the security policy

Historically, FortiOS traffic shapers have always been enabled within a security policy.This is no longer the easiest way to apply shapers, since in FortiOS 5.4 traffic shaping is now configured in the traffic shaping policy section, under Policy & Objects > Traffic Shaping Policy. However, you can still enable traffic shapers within a security policy using CLI commands and it will then appear in the web-based manager afterwards. The shapers always go into effect after any DoS detection policies, and before any routing or packet scanning occurs.

Traffic shaping is also supported for IPv6 policies.

This is not the recommended method, as it is easier to keep track of and order your traffic shaping policies if you configure them within a traffic shaping policy.

To enable traffic shaping within a security policy- CLI:

```
config firewall policy
   edit <policy number>
      ...
      set traffic-shaper <shaper name>
      set reverse-traffic-shaper <shaper name>
      set per-ip-shaper <per IP shaper name>
   end
```

Shared shapers affect outbound traffic heading to a destination. To affect inbound traffic , or downloads, enable the **Reverse Shaper**, too. For more information, see Reverse direction traffic shaping on page 3050.

Type of Service priority

Type of service (ToS) is an 8-bit field in the IP header that enables you to determine how the IP datagram should be delivered, using criteria of Delay, Throughput, Priority, Reliability, and Cost. Each quality helps gateways determine the best way to route datagrams. A router maintains a ToS value for each route in its routing table. The lowest priority ToS is 0; the highest is 7 when bits 3, 4, and 5 are all set to 1. There are other seldom used or reserved bits that are not listed here.

Together these bits are the ToS variable of the `tos-based-priority` command. The router tries to match the ToS of the datagram to the ToS on one of the possible routes to the destination. If there is no match, the datagram is sent over a zero ToS route. Using increased quality may increase the cost of delivery because better performance may consume limited network resources.

Each bit represents the priority as per RFC 1349:

- 1000 - minimize delay
- 0100 - maximize throughput
- 0010 - maximize reliability
- 0001 - minimize monetary cost

The ToS value is set in the CLI using the commands:

```
config system tos-based-priority
   edit <sequence-number>
      set tos [0-15]
      set priority [high | medium | low]
end
```

Where `tos` is the value of the type of service bit in the IP datagram header with a value between 0 and 15, and `priority` is the priority of this type of service priority. These priority levels conform to the firewall traffic shaping priorities, as defined in RFC 1349.

For example, if you want to configure the FortiGate unit so that reliability is the first priority, set the tos value to 4.

```
config system tos-based-priority
   edit 1
      set tos 4
      set priority high
end
```

For a list of ToS values and their DSCP equivalents see Traffic shaping methods on page 3039.

Example

```
config system tos-based-priority
   edit 1
      set tos 1
      set priority low
   next
   edit 4
      set tos 4
      set priority medium
   next
   edit 6
      set tos 6
```

```
      set priority high
   next
end
```

ToS in FortiOS

Traffic shaping and ToS follow the following sequence:

- The CLI command `tos-based-priority` acts as a `tos-to-priority` mapping. FortiOS maps the ToS to a priority when it receives a packet.
- Traffic shaping settings adjust the packet's priority according the traffic.
- Deliver the packet based on its priority.

Traffic Shaping Units of Measurement

Bandwidth speeds are measured in Kilobits per second (Kb/s), and Bytes that are sent/received are measured in megabytes (MB). Occasionally this can cause confusion depending on whether your ISP uses kilobits (kbps), kilobytes (KB), megabits per second (mbps), or gigabits per second (gbps).

Download Speeds

- 1 kilobit per second (kbps) = 8 kilobytes per second (KB/s)
- 1 megabit per second (mbps) = 1,000,000 bits per second (bps)
- 1 gigabit per second (gbps) = 1,000 (mbps)

File Sizes

- 1 megabyte (MB) = 1,024 kilobytes (KB)
- 1 gigabyte (GB) = 1,024 megabytes (MB) or 1,048,576 kilobytes (KB)

To change a shaper's unit of measurement - CLI

```
config firewall shaper traffic-shaper
   edit <shaper name>
      set bandwidth-unit {kbps | mbps | gbps}
end
```

Differentiated Services

Differentiated Services describes a set of end-to-end Quality of Service (QoS) capabilities. End-to-end QoS is the ability of a network to deliver service required by specific network traffic from one end of the network to another. By configuring differentiated services, you configure your network to deliver particular levels of service for different packets based on the QoS specified by each packet.

Differentiated Services (also called DiffServ) is defined by RFC 2474 and 2475 as enhancements to IP networking to enable scalable service discrimination in the IP network without the need for per-flow state and signaling at every hop. Routers that can understand differentiated services sort IP traffic into classes by inspecting the DS field in IPv4 header or the Traffic Class field in the IPv6 header.

You can use the FortiGate Differentiated Services feature to change the DSCP (Differentiated Services Code Point) value for all packets accepted by a policy. The network can use these DSCP values to classify, mark, shape, and police traffic, and to perform intelligent queuing. DSCP features are applied to traffic by configuring the routers on your network to apply different service levels to packets depending on the DSCP value of the packet.

If the differentiated services feature is not enabled, the FortiGate unit treats traffic as if the DSCP value is set to the default (00), and will not change IP packets' DSCP field. DSCP values are also not applied to traffic if the traffic originates from a FortiGate unit itself.

The FortiGate unit applies the DSCP value and IPsec encryption to the differentiated services (formerly ToS) field in the first word of the IP header. The typical first word of an IP header, with the default DSCP value, is 4500:

- 4 for IPv4
- 5 for a length of five words
- 00 for the default DSCP value

You can change the packet's DSCP field for traffic initiating a session (forward) or for reply traffic (reverse) and enable each direction separately and configure it in the security policy.

Changes to DSCP values in a security policy effect new sessions. If traffic must use the new DSCP values immediately, clear all existing sessions.

DSCP is enabled using the CLI command:

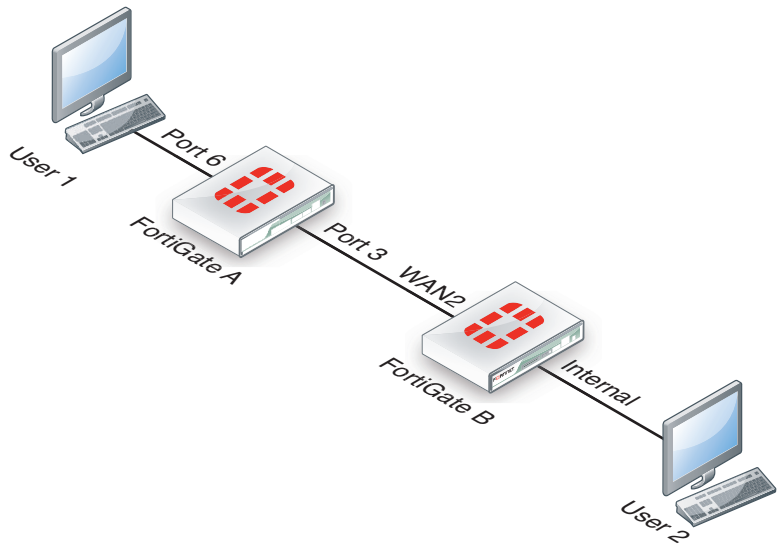
```
config firewall policy
   edit <policy_number>
      ...
      set diffserv-forward enable
      set diffservcode-forward <binary_integer>
      set diffserv-reverse enable
      set diffservcode-rev <binary_integer>
   end
```

For more information on the different DCSP commands, see the examples below and the CLI Reference. If you only set `diffserv-forward` and `diffserv-reverse` without setting the corresponding `diffvercode` values, the FortiGate unit will reset the bits to zero.

For a list of DSCP values and their ToS equivalents see Differentiated Services on page 3053. DSCP values can also be defined within a shared shaper as a single value, and per-IP shaper for forward and reverse directions.

DSCP examples

For all the following DSCP examples, the FortiGate and client PC configuration is the following diagram and used firewall-based DSCP configurations.



Example

In this example, an ICMP ping is executed between User 1 and FortiGate B, through a FortiGate unit. DSCP is disabled on FortiGate B, and FortiGate A contains the following configuration:

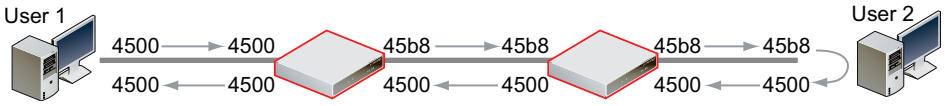
```
config firewall policy
   edit 2
      set srcintf port6
      set dstintf port3
      set src addr all
      set dstaddr all
      set action accept
      set schedule always
      set service ANY
      set diffserv-forward enable
      set diffservcode-forward 101110
end
```

As a result, FortiGate A changes the DSCP field for outgoing traffic, but not to its reply traffic. The binary DSCP values used map to the following hexadecimal

ToS field values, which are observable by a sniffer (also known as a packet tracer):

- DSCP 000000 is TOS field 0x00
- DSCP 101110 is TOS field 0xb8, the recommended DSCP value for expedited forwarding (EF)

If you performed an ICMP ping between User 1 and User 2, the following output illustrates the IP headers for the request and the reply by sniffers on each of FortiGate unit's network interfaces. The right-most two digits of each IP header are the ToS field, which contains the DSCP value.



Example

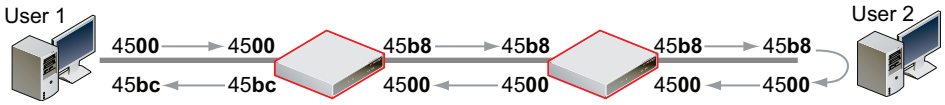
In this example, an ICMP ping is executed between User 1 and FortiGate B, through FortiGate A. DSCP is disabled on FortiGate B, and FortiGate A contains the following configuration:

```
config firewall policy
   edit 2
      set srcintf port6
      set dstintf port3
      set src addr all
      set dstaddr all
      set action accept
      set schedule always
      set service ANY"
      set diffserv-forward enable
      set diffserv-rev enable
      set diffservcode-forward 101110
      set diffservcode-rev 101111
   end
```

As a result, FortiGate A changes the DSCP field for both outgoing traffic and its reply traffic. The binary DSCP values in map to the following hexadecimal ToS field values, which are observable by a sniffer (also known as a packet tracer):

- DSCP 000000 is TOS field 0x**00**
- DSCP 101110 is TOS field 0x**b8**, the recommended DSCP value for expedited forwarding (EF)
- DSCP 101111 is TOS field 0x**bc**

If you performed an ICMP ping between User 1 and User 2, the output below illustrates the IP headers observed for the request and the reply by sniffers on each of FortiGate A's and FortiGate B's network interfaces. The right-most two digits of each IP header are the ToS field, which contains the DSCP value.



Example

In this example, an ICMP ping is executed between User 1 and FortiGate B, through FortiGate A. DSCP is enabled for both traffic directions on FortiGate A, and enabled only for reply traffic on FortiGate B. FortiGate A contains the following configuration:

```
config firewall policy
   edit 2
      set srcintf port6
      set dstintf port3
      set src addr all
      set dstaddr all
      set action accept
      set schedule always
      set service ANY
      set diffserv-forward enable
      set diffserv-rev enable
      set diffservcode-forward 101110
      set diffservcode-rev 101111
   end
```

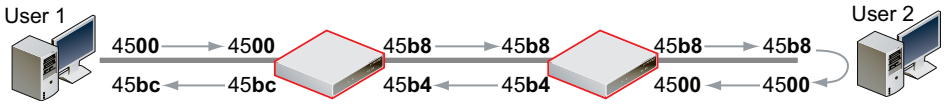
FortiGate B contains the following configuration:

```
config firewall policy
   edit 2
      set srcintf wan2
      set dstintf internal
      set src addr all
      set dstaddr all
      set action accept
      set schedule always
      set service ANY
      set diffserv-rev enable
      set diffservcode-rev 101101
   end
```

As a result, FortiGate A changes the DSCP field for both outgoing traffic and its reply traffic, and FortiGate B changes the DSCP field only for reply traffic. The binary DSCP values in this configuration map to the following hexadecimal ToS field values:

- DSCP 000000 is TOS field 0**x00**
- DSCP 101101 is TOS field 0**xb4**
- DSCP 101110 is TOS field 0**xb8**, the recommended DSCP value for expedited forwarding (EF)
- DSCP 101111 is TOS field 0**xbc**

If you performed an ICMP ping between User 1 and User 2, the output below illustrates the IP headers observed for the request and the reply by sniffers on each of FortiGate A's and FortiGate B's network interfaces. The right-most two digits of each IP header are the ToS field, which contains the DSCP value.



Example

In this example, HTTPS and DNS traffic is sent from User 1 to FortiGate B, through FortiGate A. DSCP is enabled for both traffic directions on FortiGate A, and enabled only for reply traffic on FortiGate B. FortiGate A contains the following configuration:

```
config firewall policy
   edit 2
      set srcintf port6
      set dstintf port3
      set src addr all
      set dstaddr all
      set action accept
      set schedule always
      set service ANY
      set diffserv-forward enable
      set diffserv-rev enable
      set diffservcode-forward 101110
      set diffservcode-rev 101111
   end
```

FortiGate B contains the following configuration:

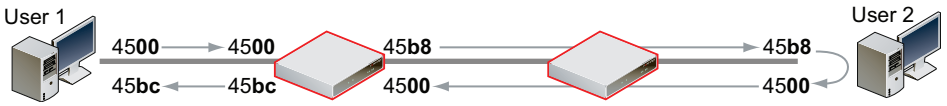
```
config firewall policy
   edit 2
```

```
        set srcintf wan2
        set dstintf internal
        set src addr all
        set dstaddr all
        set action accept
        set schedule always
        set service ANY
        set diffserv-rev enable
        set diffservcode-rev 101101
    end
```

As a result, FortiGate A changes the DSCP field for both outgoing traffic and its reply traffic, but FortiGate B changes the DSCP field only for reply traffic which passes through its internal interface. Since the example traffic does not pass through the internal interface, FortiGate B does not mark the packets. The binary DSCP values in this configuration map to the following hexadecimal ToS field values:

- DSCP 000000 is TOS field 0**x00**
- DSCP 101101 is TOS field 0**xb4**, which is configured on FortiGate B but not observed by the sniffer because the example traffic originates from the FortiGate unit itself, and therefore does not match that security policy.
- DSCP 101110 is TOS field 0**xb8**, the recommended DSCP value for expedited forwarding (EF)
- DSCP 101111 is TOS field 0**xbc**

If you sent HTTPS or DNS traffic from User 1 to FortiGate B, the following would illustrate the IP headers observed for the request and the reply by sniffers on each of FortiGate A's and FortiGate B's network interfaces. The right-most two digits of each IP header are the ToS field, which contains the DSCP value.



ToS and DSCP traffic mapping

There are two types of traffic mapping: Type of Service (ToS) or DSCP (Differentiated Services Code Point). Only one method can be used at a time, with ToS set as the default method. You can set the type used and attributes in the CLI.

To set ToS or DSCP traffic mapping

```
config system global
   set traffic-priority {tos | dscp}
   set traffic-priority-level {low | medium | high }
end
```

Mapping of DSCP and ToS hexadecimal values for QoS

Service Class	DSCP Bits	DSCP Value	ToS Value	ToS Hexidecimal
Network Control	111000	56-63	224	0xE0
Internetwork Control	110000	48-55	192	0xC0

Service Class	DSCP Bits	DSCP Value	ToS Value	ToS Hexidecimal
Critical - Voice Data (RTP)	101110	46	184	0xB8
	101000	40	160	0xA0
Flash Override Video Data	100010	34	136	0x88
	100100	36	144	0x90
	100110	38	152	0x98
	100000	32	128	0x80
Flash Voice Control	011010	26	104	0x68
	011100	28	112	0x70
	011110	30	120	0x78
	011000	24	96	0x60
Immediate Deterministic (SNA)	010010	18	72	0x48
	010100	20	80	0x50
	010110	22	88	0x58
	010000	16	64	0x40
Priority Controlled Load	001010	10	40	0x28
	001100	12	48	0x30
	001110	14	56	0x38
	001000	8	32	0x20
Routine - Best Effort	000000	0	0	0x00
Routine - Penalty Box	000010	2	8	0x08

Traffic Shaper Monitor

You can view statistical information about traffic shapers and their bandwidth from FortiView > Traffic Shaping.

	Refresh the information on the page.
	Table View shows the following columns by default: Shaper, Bytes (Sent/Received), Sessions, Bandwidth, or Dropped Bytes. For more display options, right-click on the column header.
	Bubble Chart shows you which resources consume the most bandwidth. Double-click on a shaper to view more details. Determine whether more granular shaping is required by looking at the bandwidth usage by sources, destinations, applications, policies, and sessions.
	FortiView Settings include the following options: • Include Local traffic (Realtime Only) • Include Unscanned Applications (Applications View Only) • Auto update realtime visualizations • Interval (seconds) • Threat Weight Settings

Examples

While it is possible to configure QoS using a combination of security policies and ToS based priorities, and to distribute traffic over all six of the possible queues for each physical interface, the results of those configurations can be more difficult to analyze due to their complexity. In those cases, prioritization behavior can vary by several factors, including traffic volume, ToS (type of service) or differentiated services markings, and correlation of session to a security policy.

The following simple examples illustrate QoS configurations using either prioritization by security policy, or prioritization by ToS bit, but not both. The examples also assume you are not configuring traffic shaping for interfaces that receive hardware acceleration from network processing units (NPU).

QoS using priority from security policies

Configurations implementing QoS using the priority values defined in the security policies are capable of applying bandwidth limits and guarantees.

In addition to configuring traffic shaping, you may also choose to limit the bandwidth accepted by each interface. This can be useful in scenarios where the bandwidth received on source interfaces frequently exceeds the maximum bandwidth limit defined in the security policy. Rather than waste processing power on packets that will get dropped later in the process, you may choose to preemptively police the traffic.

If you decide to implement QoS using security policies rather than ToS bit, the FortiGate unit applies QoS to all packets controlled by the policy. This type of control is less granular than prioritization by ToS bit, but has the benefits of correlating quality of service to a security policy. This correlation enables you to distribute traffic over up to four of the possible 6 priority queues (queue 0 to queue 3), does not require other devices in your network to set or respect the ToS bit, and enables you to configure bandwidth limits and guarantees.

In the following example, we limit the bandwidth accepted by each source interface, limit the bandwidth used by sessions controlled by the security policy, and then configure prioritized queuing on the destination interface based upon the priority in the security policy, subject to alternative assignment to queue 0 when necessary to achieve the guaranteed packet rate.

To limit bandwidth accepted by an interface

In the CLI, enter the following commands:

```
config system interface
   edit <name_str>
      set inbandwidth <rate_int>
   next
end
```

where `<rate_int>` is the bandwidth limit in Kb/s. Excess packets will be dropped.

To configure bandwidth guarantees, limits, and priorities

1. Go to **Policy & Objects > Traffic Shapers** and select the Create New “Plus” sign.
2. Select **Shared** or **Per-IP**.
3. Enter a name for the shaper.

4. Select the **Traffic Priority**.
   High has a priority value of 1, Medium is 2, and Low is 3. While the current packet rate is below Guaranteed Bandwidth, the FortiGate unit will disregard this setting, and instead use priority queue.
5. Enable **Max Bandwidth** and enter a value.
   Packets greater than this rate will be discarded.
6. Enable **Guaranteed Bandwidth** and enter a value, if any.
   Bandwidth guarantees affect prioritization. While packet rates are less than this rate, they use priority queue 0. If this is not the effect you intend, consider entering a small guaranteed rate, or enter 0 to effectively disable bandwidth guarantees.
7. Enable **DSCP** and set a value.
8. Select **OK**.

Per-IP shapers also include the option to set a maximum number of concurrent connections and to set both **Forward DSCP** and **Reverse DSCP**.

Sample configuration

This sample configuration limits ingressing bandwidth to 500 Kb/s. It also applies separate traffic shapers to FTP and HTTP traffic. In addition to the interface bandwidth limit, HTTP traffic is subject to a security policy bandwidth limit of 200 Kb/s.

All egressing FTP traffic greater than 10 Kb/s is subject to a low priority queue (queue 3), while all egressing HTTP traffic greater than 100 Kb/s is subject to a medium priority queue (queue 2). That is, unless FTP traffic rates are lower than their guaranteed rate, and web traffic rates are greater than their guaranteed rate, FTP traffic is lower priority than web traffic.

Traffic less than these guaranteed bandwidth rates use the highest priority queue (queue 0).

Set the inbandwidth limits. This setting is only available in the CLI:

```
config system interface
   edit wan1
      set inbandwidth 500
   next
end
```

Create traffic shapers for FTP and HTTP.

To configure an FTP shaper - web-based manager:

1. Go to **Policy & Objects > Traffic Shapers**, and select the **Create New** “Plus” icon.
2. Select **Shared**.
3. Enter `FTP` for the name of the shaper.
4. Set **Traffic Priority** to **Low**.
5. Select the **Guaranteed Bandwidth** checkbox and enter `10` Kbps.
6. Select the **Maximum Bandwidth** checkbox and enter `500` Kbps.
7. Select **OK**.
8. Select the FTP shaper, right-click it, and select **Edit in CLI.** Type the following command:
   ```
   set per-policy
   ```

```
end
```

To configure an HTTP shaper - web-based manager:

1. Select the **Create New** "Plus" icon.
2. Set **Type** to **Shared**.
3. Enter `HTTP` for the name of the shaper.
4. Set **Traffic Priority** to **Medium**.
5. Select the **Guaranteed Bandwidth** checkbox and enter `100` Kbps.
6. Select the **Maximum Bandwidth** checkbox and enter `200` Kbps.
7. Select **OK**.
8. Select the HTTP shaper, right-click it, and select **Edit in CLI.** Type the following command:

```
    set per-policy
end
```

To add the FTP shaper to a traffic shaping policy - web-based manager:

1. Go to **Policy & Objects > Traffic Shaping Policy** and click **Create New** to create a traffic shaping policy for FTP.
2. Set the **Matching Criteria** to the following:

Source	**all**
Destination address	**all**
Service	**FTP**

3. Under **Apply shaper**, set the following:

Outgoing interface	any (The outgoing interface should match the outgoing interface of the security policy you wish to apply shaping to.)
Shared Shaper	Enable **Shared Shaper** and select **FTP** from the dropdown menu.
Reverse Shaper	Enable **Shared Shaper** and select **FTP** from the dropdown menu.
Enable this policy	Enable this policy.

4. Select **OK**.

To add the HTTP shaper to a traffic shaping policy - web-based manager:

1. Go to **Policy & Objects > Traffic Shaping Policy**and click **Create New** to create a traffic shaping policy for HTTP.
2. Set the **Matching Criteria** to the following:

Source	**all**

Destination address	**all**
Service	**HTTP**

3. Under **Apply shaper**, set the following:

Outgoing interface	any (The outgoing interface should match the outgoing interface of the security policy you wish to apply shaping to.)
Shared Shaper	Enable **Shared Shaper** and select **HTTP** from the dropdown menu.
Reverse Shaper	Enable **Shared Shaper** and select **HTTP** from the dropdown menu.
Enable this policy	Enable this policy.

4. Select **OK**.
5. On the policy list page, move the FTP traffic shaping policy to the top of the list by clicking on the far left column to drag and drop it. The HTTP traffic shaping policy should be below the FTP policy, and more general internet access policies should be at the bottom of the policy list.

To configure the FTP and HTTP shapers - CLI:

```
config firewall shaper traffic-shaper
   edit FTP
      set maximum-bandwidth 500
      set guaranteed-bandwidth 10
      set per-policy enable
      set priority low
   next
   edit HTTP
      set maximum-bandwidth 200
      set guaranteed-bandwidth 100
      set per-policy enable
      set priority medium
   end
```

To add each shaper to a traffic shaping policy- CLI:

```
config firewall shaping-policy
   edit 1 <shaping policy ID number>
      set srcaddr all
      set dstaddr all
      set service ALL
      set dstintf wan1 <outgoing interface>
      set traffic-shaper FTP
   next
   edit 2 <shaping policy ID number>
      set srcaddr all
      set dstaddr all
      set service ALL
      set dstintf wan1 <outgoing interface>
      set traffic-shaper HTTP
   next
   move 1 before 2
```

```
end
```

QoS using priority from ToS or differentiated services

Configurations implementing QoS using the priority values defined in either global or specific ToS bit values are not capable of applying bandwidth limits and guarantees, but are capable of prioritizing traffic at per-packet levels, rather than uniformly to all services matched by the security policy.

In addition to configuring traffic prioritization, you may also choose to limit bandwidth being received by each interface. This can sometimes be useful in scenarios where you want to limit traffic levels, but do not want to configure traffic shaping within a security policy. This has the benefit of policing traffic at a point before the FortiGate unit performs most processing.

Note that if you implement QoS using ToS octet rather than security policies, the FortiGate unit applies QoS on a packet by packet basis, and priorities may be different for packets and services controlled by the same security policy. This is more granular control than prioritization by security policies, but has the drawbacks that quality of service is may not be uniform for multiple services controlled by the same security policy, packets will only use up to three of the six possible queues (queue 0 to queue 2), and bandwidth cannot be guaranteed. Other devices in your network must also be able to set or preserve ToS bits.

In this example, we limit the bandwidth accepted by each source interface, and then configure prioritized queuing on the destination interface based upon the value of the ToS bit located in the IP header of each accepted packet.

To limit bandwidth accepted by an interface, in the CLI, enter the following commands:

```
config system interface
   edit <name_str>
      set inbandwidth <rate_int>
   next
end
```

where `<rate_int>` is the bandwidth limit in Kb/s. Excess packets will be dropped.

To configure priorities, in the CLI, configure the global priority value using the following commands:

```
config system global
   set tos-based-priority {high | low | medium}
      end
```

where `high` has a priority value of 0 and `low` is 2.

If you want to prioritize some ToS bit values differently than the global ToS-based priority, configure the priority for packets with that ToS bit value using the following commands:

```
config system tos-based-priority
   edit <id_int>
      set tos [0-15]
      set priority {high | low | medium}
   next
end
```

where and `tos` is the value of the ToS bit in the packet's IP header, and `high` has a priority value of 0 and `low` is 2. Priority values configured in this location will override the global ToS-based priority.

Sample configuration

This sample configuration limits ingressing bandwidth to 500 Kb/s. It also queues egressing traffic based upon the ToS bit in the IP header of ingressing packets.

Unless specified for the packet's ToS bit value, packets use the low priority queue (queue 2). For ToS bit values 4 and 15, the priorities are specified as medium (value 1) and high (value 0), respectively.

```
config system interface
   edit wan1
      set inbandwidth 500
   next
end
config system global
   set tos-based-priority low
end
config system tos-based-priority
   edit 4
      set tos 4
      set priority medium
   next
   edit 15
      set tos 15
      set priority high
   next
end
```

Example setup for VoIP

In this example, there are three traffic shaping requirements for a network:

- Voice over IP (VoIP) requires a guaranteed, high-priority for bandwidth for telephone communications.
- FTP bursts must be contained so as not to consume any available bandwidth. As such this traffic needs to be throttled to a smaller amount.
- A consistent bandwidth requirement is needed for all other email and web-based traffic.

To enable this requirement, you need to create three separate shapers and three traffic shaping policies for each traffic type.

In this example, the values used are not recommended values.

Creating the traffic shapers

First create the traffic shapers that define the maximum and guaranteed bandwidth. The shared shapers will be used with some applied per-policy and some applied to all policies, to better control traffic.

VoIP shaper

The VoIP functionary is a key component to the business as a communication tool and as such requires a guaranteed bandwidth. This shaper will be a high priority shaper.

To create a VoIP shaper - web-based manager:

1. Go to **Policy & Objects > Traffic Shapers** and select **Create New**.
2. Set the **Type** to **Shared**.

3. Enter the **Name** `voip`.
4. Set the **Traffic Priority** to **High**.
5. Select **Maximum Bandwidth** and enter `1000` Kb/s.
6. Select **Guaranteed Bandwidth** and enter `800` Kb/s.
7. Select **OK.**
8. Select the HTTP shaper, right-click it, and select **Edit in CLI.** Type the following command:

```
    set per-policy
end
```

To create a VoIP shaper - CLI:

```
config firewall shaper traffic-shaper
   edit voip
      set maximum-bandwidth 1000
      set guaranteed-bandwidth 800
      set per-policy enable
      set priority high
   end
```

Setting the shaper to **per-policy** ensures that regardless of the number of policies that use this shaper, the defined bandwidth will always be the same. At the same time, the bandwidth is continually guaranteed at 800 Kb/s but if available can be as much as 1000 Kb/s. Setting the priority to high ensures that the FortiGate unit always considers VoIP traffic the most important.

FTP shaper

The FTP shaper sets the maximum bandwidth to use to avoid sudden spikes by sudden uploading or downloading of large files, and interfering with other more important traffic.

To create a FTP shaper - web-based manager:

1. Go to **Policy & Objects > Traffic Shapers** and **Create New**.
2. Set the **Type** to **Shared**.
3. Enter the **Name** `ftp`.
4. Set the **Traffic Priority** to **Low**.
5. Select **Maximum Bandwidth** and enter `200` Kb/s
6. Select **Guaranteed Bandwidth** and enter `200` Kb/s.
7. Select **OK**.

To create a FTP shaper - CLI:

```
config firewall shaper traffic-shaper
   edit ftp
      set maximum-bandwidth 200
      set guaranteed-bandwidth 200
      set priority low
   end
```

For this shaper, the maximum and guaranteed bandwidth are set low and to the same value. In this case, the bandwidth is restricted to a specific amount. Setting the traffic priority low ensures that more important traffic will be able to pass before FTP traffic.

Regular traffic shaper

The regular shaper sets the maximum bandwidth and guaranteed bandwidth for everyday business traffic such as web and email traffic.

To create a regular shaper - web-based manager:

1. Go to **Policy & Objects > Traffic Shapers** and **Create New**.
2. Set the **Type** to **Shared**.
3. Enter the **Name** `daily_traffic`..
4. Set the **Traffic Priority** to **Medium**.
5. Select **Maximum Bandwidth** and enter `600` Kb/s
6. Select **Guaranteed Bandwidth** and enter `600` Kb/s.
7. Select **OK**.

To create a regular shaper - CLI:

```
config firewall shaper traffic-shaper
   edit daily_traffic
      set maximum-bandwidth 600
      set guaranteed-bandwidth 600
      set per-policy enable
      set priority medium
   end
```

For this shaper, the maximum and guaranteed bandwidth are set to a moderate value of 600 Kb/s. It is also set for per policy, which ensures each security policy for day-to-day business traffic has the same distribution of bandwidth.

Creating Traffic Shaping Policies

To employ the shapers,create traffic shaping policies that apply to your existing security policy. Create a separate policy for each service and apply the shaper to the outgoing interface you would like to use. For example, a policy for FTP traffic, a policy for SIP and so on.

For the following steps the VoIP traffic shaper is enabled as well as the reverse direction. This ensures that return traffic for a VoIP call has the same guaranteed bandwidth as the outgoing call. The example below shows how to enable each traffic shaper in a traffic shaping policy.

In this example, the traffic shaping policies will apply shaping to the following security policy:

Incoming interface	lan (Internal interface)
Source address	All
Outgoing interface	WAN1

Destination address	All
Schedule	always
Service	all
Action	ACCEPT

To create a VOIP traffic shaping policy- web-based manager:

1. Go to **Policy & Objects > Traffic Shaping Policy** and select **Create New**.
2. Now create a traffic shaping policy that matches the settings you entered for your security policy:

Source	All
Destination	All
Service	All
Application Category	VoIP
Application	SIP
URL Category	Internet Telephony
Outgoing Interface	wan1

3. Enable **Shared Shaper**, select the voip shaper created in the previous steps.
4. Enable **Reverse Shaper**, select the voip shaper created in the previous steps.
5. Select **Enable this policy**.
6. Select **OK**.

To create a VOIP traffic shaping policy- CLI:

```
config firewall shaping-policy
   edit 1 <shaping policy ID number>
      set srcaddr all
      set dstaddr all
      set service ALL
      set application 34640 <SIP>
      set app-category 3 <VoIP>
      set url-category 76 <Internet Telephony>
      set dstintf wan1 <outgoing interface>
      set traffic-shaper voip <high priority custom shaper>
      set reverse-traffic-shaper voip <high priority custom shaper>
   end
```

To create an FTP traffic shaping policy- web-based manager:

1. Go to **Policy & Objects > Traffic Shaping Policy** and select **Create New**.
2. Now create a traffic shaping policy that matches the settings you entered for your security policy:

Source	All
Destination	All
Service	FTP
Outgoing Interface	wan1

3. Enable **Shared Shaper**, select the FTP shaper created in the previous steps.
4. Enable **Reverse Shaper**, select the FTP shaper created in the previous steps.
5. Select **Enable this policy**.
6. Select **OK**.

To create an FTP traffic shaping policy- CLI:

```
config firewall shaping-policy
   edit 2 <shaping policy ID number>
      set srcaddr all
      set dstaddr all
      set service FTP
      set dstintf wan1 <outgoing interface>
      set traffic-shaper FTP <low priority custom shaper>
      set reverse-traffic-shaper FTP <low priority custom shaper>
   end
```

To create a Regular traffic shaping policy- web-based manager:

1. Go to **Policy & Objects > Traffic Shaping Policy** and select **Create New**.
2. Now create a traffic shaping policy that matches the settings you entered for your security policy:

Source	All
Destination	All
Service	ALL
Outgoing Interface	wan1

3. Enable **Shared Shaper**, select the medium-priority shaper.
4. Enable **Reverse Shaper**, select the medium-priority shaper.
5. Select **Enable this policy**.
6. Select **OK**.

To create a Regular traffic shaping policy- CLI:

```
config firewall shaping-policy
   edit 3 <shaping policy ID number>
      set srcaddr all
      set dstaddr all
      set service ALL
      set dstintf wan1 <outgoing interface>
      set traffic-shaper medium-priority <default shaper>
      set reverse-traffic-shaper medium-priority <default shaper>
```

```
end
```

To order your traffic shaping policies- CLI:

```
config firewall shaping-policy
   move 1 before 2
   move 3 below 2
   end
```

Ensure that your high priority SIP/VoIP policy is at the top of the policy list, the low priority FTP shaper comes second, and the medium priority regular-traffic shaper comes last. Restrictive policies should always go above more general access policies.

Alternate Method of enabling traffic shaping in the security policy

It is also possible to create three separate security policies for each type of traffic (VoIP, FTP, and regular). You can enable traffic shaping individually within each security policy in the CLI only, like the example shown below:

To enable traffic shaping in the security policy - CLI:

```
config firewall policy
   edit 6
      set srcintf <internal_interface>
      set scraddr all
      set dstintf wan1
      set dstaddr all
      set action accept
      set schedule always
      set service sip
      set traffic-shaper voip
      set reverse-traffic-shaper voip
   end
```

Troubleshooting traffic shaping

This chapter outlines some troubleshooting tips and steps to diagnose the shapers and whether they are working correctly. These diagnose commands include:

- `diagnose system tos-based-priority`
- `diagnose firewall shaper traffic-shaper`
- `diagnose firewall per-ip-shaper`
- `diagnose debug flow`

Interface diagnosis

To optimize traffic shaping performance, first ensure that the network interface's Ethernet statistics are clean of errors, collisions, or buffer overruns. To check the interface, enter the following diagnose command to see the traffic statistics:

```
diagnose hardware deviceinfo nic <port_name>
```

Shaper diagnose commands

There are specific diagnose commands you can use to verify the configuration and flow of traffic, including packet loss due to the employed shaper.

All of these diagnose troubleshooting commands are supported in both IPv4 and IPv6.

ToS command

Use the following command to list command to view information of the ToS lists and traffic.

```
diagnose system tos-based-priority
```

This example displays the priority value currently correlated with each possible ToS bit value. Priority values are displayed in order of their corresponding ToS bit values, which can range between 0 and 15, from lowest ToS bit value to highest.

For example, if you have not configured ToS-based priorities, the following appears…

```
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
```

…reflecting that all packets are currently using the same default priority, high (value 0).

If you have configured a ToS-based priority of `low` (value 2) for packets with a ToS bit value of 3, the following appears…

```
0 0 0 2 0 0 0 0 0 0 0 0 0 0 0 0
```

…reflecting that most packets are using the default priority value, except those with a ToS bit value of 3.

Shared shaper

To view information for the shared traffic shaper for security policies enter the command

```
diagnose firewall shaper traffic-shaper list
```

The resultant output displays the information on all available shapers. The more shapers available the longer the list. For example:

```
name Throughput
maximum-bandwidth 1200000 Kb/sec
guaranteed-bandwidth 50000 Kb/sec
current-bandwidth 0 B/sec
priority 1
packets dropped 0
```

Additional commands include:

`diagnose firewall shaper traffic-shaper state` - provides the total number of traffic shapers on the FortiGate unit.

`diagnose firewall shaper traffic-shaper stats` - provides summary statistics on the shapers. Sample output looks like the following:

```
shapers 9 ipv4 0 ipv6 0 drops 0
```

Per-IP shaper

To view information for the per-IP shaper for security policies enter the command

```
diagnose firewall shaper per-ip-shaper list
```

The resultant output displays the information on all available per-IP shapers. The more shapers available the longer the list. For example:

```
name accounting_group
maximum-bandwidth 200000 Kb/sec
maximum-concurrent-session 55
packet dropped 0
```

Additional commands include:

`diagnose firewall shaper per-ip-shaper state` - provides the total number of per-ip shapers on the FortiGate unit.

`diagnose firewall shaper per-ip-shaper stats` - provides summary statistics on the shapers. Sample output looks like the following:

```
memory allocated 3 packet dropped: 0
```

You can also clear the per-ip statistical data to begin a fresh diagnoses using:

```
diagnose firewall shaper per-ip-shaper clear
```

Packet loss with statistics on shapers

For each shaper there are counters that allow to verify if packets have been discarded. To view this information, in the CLI, enter the command diagnose firewall shaper. The results will look similar to the following output:

```
diagnose firewall shaper traffic-shaper list
name limit_GB_25_MB_50_LQ
maximum-bandwidth 50 Kb/sec
guaranteed-bandwidth 25 Kb/sec
current-bandwidth 51 Kb/sec
priority 3
dropped 1291985
```

The diagnose command output is different if the shapers are configured either per-policy or shared between policies.

For per-IP the output would be:

```
diagnose firewall shaper per-ip-shaper list

name accounting_group
maximum-bandwidth 200000 Kb/sec
maximum-concurrent-session 55
packet dropped 3264220
```

Packet lost with the debug flow

When using the debug flow diagnostic command, there is a specific message information that a packet has exceed the shaper limits and therefor discarded:

```
diagnose debug flow show console enable
diagnose debug flow filter addr 10.143.0.5
diagnose debug flow trace start 1000

id=20085 trace_id=11 msg="vd-root received a packet(proto=17, 10.141.0.11:3735-
    >10.143.0.5:5001) from port5."
id=20085 trace_id=11 msg="Find an existing session, id-0000eabc, original direction"
id=20085 trace_id=11 msg="exceeded shaper limit, drop"
```

Session list details with dual traffic shaper

When a Security Policy has a different traffic shaper for each direction, it is reflected in the session list output from the CLI:

```
diagnose system session list

session info: proto=6 proto_state=02 expire=115 timeout=3600 flags=00000000 sock
flag=00000000 sockport=0 av_idx=0 use=4
origin-shaper=Limit_25Mbps prio=1 guarantee 25600/sec max 204800/sec traffic 48/sec
reply-shaper=Limit_100Mbps prio=1 guarantee 102400/sec max 204800/sec traffic 0/sec
ha_id=0 hakey=44020
policy_dir=0 tunnel=/
state=may_dirty rem os rs
statistic(bits/packets/allow_err): org=96/2/1 reply=0/0/0 tuples=2

hook=post dir=reply act=snat 10.160.0.1:80->192.168.171.243:2538(192.168.182.110:80)
pos/(before,after) 0/(0,0), 0/(0,0)
misc=0 policy_id=2 auth_info=0 chk_client_info=0 vd=0 serial=00011e81 tos=ff/ff app=0
    dd_type=0 dd_rule_id=0
```

Additional Information

- Packets discarded by the shaper impact flow-control mechanisms like TCP. For more accurate testing results prefer UDP protocol.
- Traffic shaping accuracy is optimum for security policies without a protection profile where no FortiGate content inspection is processed.

- Do not oversubscribe an outbandwith throughput. For example, sum[guaranteed BW] < outbandwith. For accuracy in bandwidth calculation, it is required to set the “outbandwidth” parameter on the interfaces. For more information see Bandwidth guarantee, limit, and priority interactions on page 3032.
- The FortiGate unit is not prioritizing traffic based on the DSCP marking configured in the security policy. However, ToS based prioritizing can be made at ingress. For more information see Traffic shaping methods on page 3039.

Chapter 31 - Transparent Mode

- Introduction to Transparent Mode: an overview of Transparent mode, including available features.
- Transparent Mode Installation: instructions for installing a FortiGate in Trnasparent mode.
- Networking in Transparent Mode: how networking is configured in Transparent mode.
- Firewalls and Security in Transparent Mode: information about using firewalls and security scanning in Transparent mode.
- IPsec VPN in Transparent Mode: configuring IPsec VPNs using FortiGates in Transparent mode.
- Using FortiManager and FortiAnalyzer: using external management and logging.
- High Availability in Transparent Mode: configuring Transparent FortiGates in HA mode.
- Best Practices: the best practices for using Transparent mode.

Introduction to Transparent Mode

This section contains a basic overview of Transparent mode, as well as a chart showing features available in Transparent mode.

What is Transparent Mode?

A FortiGate unit can operate in one of two modes: Transparent or NAT/Route mode.

In Transparent mode, the FortiGate is installed between the internal network and the router. In this mode, the FortiGate does not make any changes to IP addresses and only applies security scanning to traffic. When a FortiGate is added to a network in Transparent mode, no network changes are required, except to provide the FortiGate with a management IP address. Transparent mode is used primarily when there is a need to increase network protection but changing the configuration of the network itself is impractical.

In NAT/Route mode, a FortiGate unit is installed as a gateway or router between two networks. This allows the FortiGate to hide the IP addresses of the private network using network address translation (NAT).

Transparent Mode Features

Different FortiOS features are available depending on whether your FortiGate is in Transparent or NAT/Route mode. The following table shows which features are available for each mode.

For a FortiGate in Transparent mode, the maximum number of Interfaces per VDOM is 254. This value includes both physical and virtual interfaces.

For any other maximum values, please consult the Maximum Values Table, available at docs.fortinet.com.

Feature/capability	NAT	Transparent	Comment
Unicast Routing / Policy Based routing	YES	NO	
VIP / IP pools / NAT	YES	YES	Configurable from CLI only in transparent mode
Multicast routing	YES	NO - Options available to forward multicast packets	
L2 forwarding	NO	YES	In Transparent mode, other frames than IP can be forwarded but with no UTM processing.
Firewall (packet filtering / NAT / Authentication)	YES	YES	
IPv6 capable	YES	YES	
Traffic shaping - TOS classification	YES	YES	
Hardware acceleration	YES	YES	
All Security profile features (ex IPS, Application Control, Web Filter, etc ...)	YES	YES

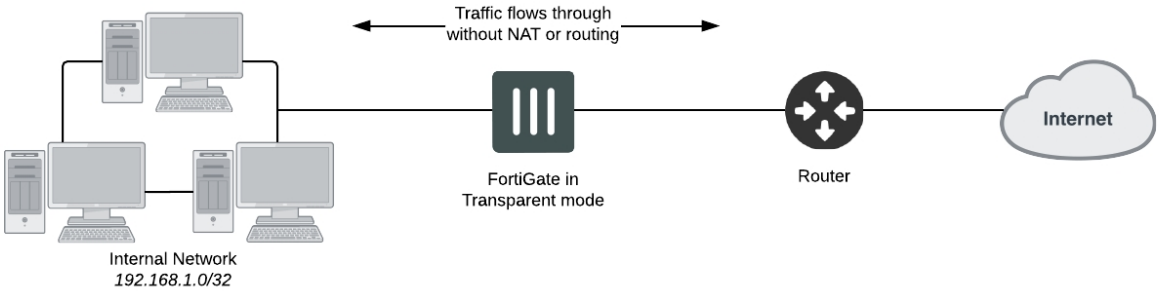
Transparent Mode Installation

This section contains information about installing a FortiGate in Transparent mode and using a virtual wire pair, to simplify Transparent mode. It also contains information about configuring the FortiGate's management IP.

Installing a FortiGate in Transparent mode



Changing to Transparent mode removes most configuration changes made in NAT/Route mode. To keep your current NAT/Route mode configuration, backup the configuration using the **System Information** widget, found in the **Dashboard**.

1. Before connecting the FortiGate unit to your network, go to the **Dashboard** and locate enter the following command into the **CLI Console**:

```
config system settings
 set opmode transparent
 set manageip <address and netmask>
 set gateway <address>
end
```

2. Access the web-based manager by browsing to the new management IP.

3. (Optional) The FortiGate unit's DNS Settings are set to use FortiGuard DNS servers by default, which is sufficient for most networks. However, if you need to change the DNS servers, go to **Network > DNS** and add **Primary** and **Secondary** DNS servers. Select **Apply**.
4. If your network uses IPv4 addresses, go to **Policy & Objects > IPv4 Policy** and select **Create New** to add a security policy that allows users on the private network to access the Internet.

   If your network uses IPv6 addresses, go to **Policy & Objects > IPv6 Policy** and select **Create New** to add a security policy that allows users on the private network to access the Internet. If the IPv6 menu option is not available, go to **System > Feature Select**, turn on **IPv6**, and select **Apply**. For more information on IPv6 networks, see the IPv6 Handbook.

   Set the **Incoming Interface** to the internal interface and the **Outgoing Interface** to the Internet-facing interface (typically WAN1). You will also need to set **Source Address**, **Destination Address**, **Schedule**, and **Service** according to your network requirements. You can set these fields to the default all/ANY settings for now but should create the appropriate objects later after the policies have been verified.
5. Make sure the **Action** is set to **ACCEPT**. Select **OK**.

It is recommended to avoid using any security profiles, such as AntiVirus or web filtering, until after you have successfully installed the FortiGate unit. After the installation is verified, you can apply any required security profiles.

For more information about using security profiles, see the Security Profiles handbook.

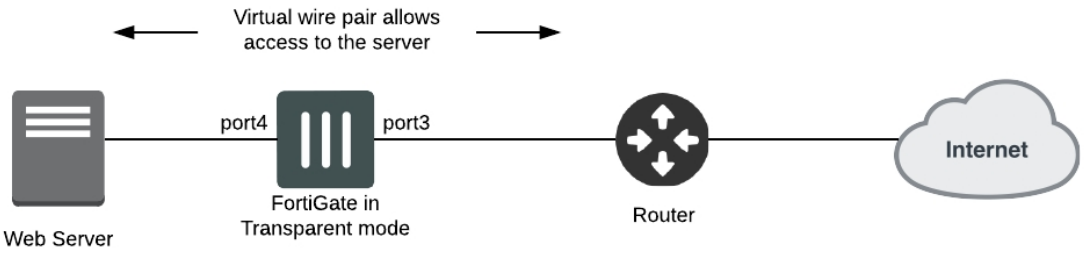
6. Go to the **Dashboard** and locate the **System Resources** widget. Select **Shutdown** to power off the FortiGate unit.
   Alternatively, you can also use the CLI command `execute shutdown`.
7. Connect the FortiGate unit between the internal network and the router.
8. Connect the Internet-facing interface to the router's internal interface and connect the internal network to the FortiGate using an internal port (typically port 1).
9. Power on the FortiGate unit. You will experience downtime before the FortiGate unit starts up completely.

Results

Users on the internal network are now able to browse to the Internet. They should also be able to connect to the Internet using any other protocol or connection method that you defined in the security policy.

If a FortiGate unit operating in Transparent mode is installed between your internet network and a server that is providing a network service to the internal network, such as DNS or DHCP, you must add a wan1-to-internal policy to allow the server's response to flow through the FortiGate unit and reach the internal network.

Using a Virtual Wire Pair to Simplify Transparent Mode



In FortiOS 5.4, virtual wire pair replaces the feature port pairing from earlier firmware versions. Unlike port pairing, virtual wire pair can be used for a FortiGate in either Transparent or NAT/Route mode.

A virtual wire pair consists of two interfaces that have no IP addresses and all traffic received by one interface in the pair can only be forwarded out the other; as controlled by firewall policies. Since the interfaces do not have IP addresses, you can insert a virtual wire pair into a network without having to make any changes to the network.

Interfaces used in a virtual wire pair cannot be used for admin access to the ISFW FortiGate. Before creating a virtual wire pair, make sure you have a different port configured to allow admin access using your preferred protocol.

1. Go to **Network > Interfaces** and select **Create New > Virtual Wire Pair**. Add two ports to the virtual wire pair. These ports cannot be part of a switch, such as the default **internal/lan** interface.
2. Go to **Policy & Objects > IPv4 Virtual Wire Pair Policy** and create a policy will allow traffic to flow between the two ports. Give the policy an appropriate **Name**. Select the direction that traffic is allowed to flow. Configure the other firewall options as needed.
3. If necessary, create a second virtual wire pair policy allowing traffic to flow between the ports in the opposite direction.

Traffic can now flow between the two ports. Go to **FortiView > Policies** to see traffic flowing through both policies.

Management IP configuration

A FortiGate in Transparent mode can be assigned with a single IP address for remote access management and multiple static routes can be configured. This can be used if in-band management wants to be applied.

When out-of-band management is desired (dedicated interface for remote management access), it is recommended to use a separate VDOM in NAT/Route mode.

In-band management details and example

The management IP address is bound to all ports or VLANs belonging to the same VDOM. Remote access services are subject to the same rules as in NAT/Route mode, and must be enabled/disabled on each port.

Example of management IP configuration in Transparent mode:

```
config system settings
   set manageip 10.1.1.100/255.255.255.0
end
config router static
   edit 1
      set gateway 10.1.1.254
   next
end
config system interface
   edit port1
      set allowaccess ping ssh https snmp
end
```

It is also possible to add a second IP address for management and additional default routes:

```
config system settings
   set opmode transparent
   set manageip 192.168.182.136/255.255.254.0 10.1.1.1/255.255.255.0
end

config router static
   edit 1
      set gateway 192.168.183.254
   next
   edit 2
      set gateway 10.1.1.254
   next
end
```

`ping-server` (dead gateway detection) is not supported in Transparent mode.

Out-of-band management details and example

When VDOM is enabled and the VDOMs are operating in Transparent mode, it is recommended, to avoid L2 loops and allow more routing flexibility, to keep one VDOM (generally the root VDOM) in NAT/Route mode, with one or more VLAN or physical interface as out-of-band management.

The management VDOM must have IP connectivity to the Internet to allow communication with the FDS and retrieve services information (AV,IPS, Fortiguard filtering, Support…). All syslog and FortiManager communication also go through the management VDOM.

Networking in Transparent Mode

This section contains information about networking concepts in Transparent mode. It contains the following topics:

- Packet Forwarding
- Network Address Translation (NAT)
- VLANs and Forwarding Domains
- Inter-VDOM links between NAT/Route and Transparent VDOMs
- Packet Forwarding using Cisco Protocols
- Configuration Example

Packet Forwarding

The following sections include information aboutconfiguring packet forwarding in Transparent mode:

- MAC learning and L2 Forwarding Table
- Broadcast, Multicast, and Unicast Forwarding
- Multicast Processing
- Source MAC Addresses
- ARP Table
- Verifying the Forwarding Database
- Spanning Tree BPDUs Forwarding
- Non-IPv4 Ethernet frames forwarding

MAC learning and L2 Forwarding Table

When operating in Transparent mode, a FortiGate behaves like an L2 switch in accordance with 802.1d principles:

- The forwarding database (FDB) is populated with the network devices MAC addresses during a MAC learning process, based on the source addresses seen in the Ethernet frames ingressing a FortiGate port. Static MAC entries can also be configured using the following CLI command:

```
config system mac-address-table
   edit 00:01:02:03:04:05
      set interface "port3"
   next
end
```

  The FDB table can be verified with the following command: `diagnose netlink brctl name host TP.b`

- Ethernet IP frames forwarding is based on known MAC address on each port.
- As Spanning Tree in not running on the FortiGate, a port that comes up goes immediately into forwarding or flooding state. This last state will not occur once unicast MAC addresses are present in the FDB.

If the FortiGate in Transparent mode bridges traffic to a router or host using a virtual MAC for one direction and a different physical MAC for the other direction (for example when VRRP or HSRP protocols are used), it is highly recommended to create a static MAC entry for the virtual MAC. This is to make sure that the virtual MAC address is present in the FDB.

Broadcast, Multicast, and Unicast Forwarding

In Transparent mode, IPv4 packets are typically only forwarded by the FortiGate from a port to another port when a firewall policy is matched with action ACCEPT.

Below are exceptions.

- **L2 (IP) Broadcast frames forwarding:**

L2 (IP) means a L2 frame type 0x0800 (IP) or 0x0806 (ARP)

  - **ARP:** by default, ARP broadcasts and ARP reply packets are flooded/forwarded on all ports or VLANs belonging to the same forwarding domain, without the need of firewall policies between the ports. This default behavior is necessary to allow the population of the FDB and allow further firewall policy lookup (see section Transparent mode Firewall processing for more details). This option is configurable at the interface settings level with the parameter arpforward (enabled by default).
  - **Non-ARP:** To forward non-ARP broadcasts, the following CLI command is used:

```
config system interface
   edit "port2"
      set broadcast-forward enable
   next
end
```

- **L2 (IP) Multicast frames forwarding:** the FortiGate does not forward frames with multicast destination MAC addresses by default. Multicast traffic such as one used by routing protocols or streaming media may need to traverse the FortiGate which should not interfere this communication.

  Fortinet recommends that the FortiGate is set up using Multicast policies. This allows for greater control and predictability on traffic behavior. However Multicast traffic may be forwarded through a Transparent mode device using the multicast-skip-policy setting. This is detailed in the section "Multicast Processing" on page 3083
- **L2 (IP) Unicast frames forwarding:** a frame with a unicast destination MAC address is subject to firewall processing before being forwarded (see "Firewall Policy Look Up" on page 3095 for more details). This does not apply to ARP replies.

Multicast Processing

In Transparent mode, a FortiGate does not forward frames with multicast destination MAC addresses by default. If multicast traffic is required, multicast policies are recommended to allow finer control of this traffic.

Forwarding all multicast traffic with policy

Multicast traffic may have to be forwarded through a Transparent mode device using the `multicast-skip-policy`sytem setting. This is the configuration for this solution:

```
config system settings
   set multicast-skip-policy enable
end
```

In that case, no check is performed on sources/destinations/interfaces. A multicast packet received on an interface is flooded unconditionally to all interfaces (except the incoming interface) belonging to the same forwarding domain.

Configuring firewall multicast-policy

The use of `firewall multicast-policy` allows a finer control over the multicast packets. Hereafter are some commented examples. Note that the parameter multicast-skip-policy mentioned above must be left to disabled.

Those policies can only be configured from the CLI.

1- Simple policy

```
config firewall multicast-policy
   edit 1
      set action accept
   next
end
```

In that case, no check is performed on sources/destinations/interfaces. A multicast packet received on an interface is flooded unconditionally to all interfaces (except the incoming interface) belonging to the same forwarding domain.

2- To restrict incoming and outgoing interfaces:

```
config firewall multicast-policy
   edit 1
      set srcintf "port1"
      set dstintf "port2"
      set action accept
   next
end
```

3- To be more restrictive (example to allow RIP2 packets from port1 to port2 and sourced by 10.10.0.10):

```
config firewall multicast-policy
   edit 1
      set srcintf "port1"
      set srcaddr 10.10.0.10 255.255.255.255
      set dstintf "port2"
      set dstaddr 224.0.0.9 255.255.255.255
      set action accept
   next
end
```

4- This policy will allow all 224.0.0.0/255 range (OSPF, RIPv2, DVMPR…) from port1 to port2

```
config firewall multicast-policy
   edit 1
      set srcintf "port1"
      set dstintf "port2"
      set dstaddr 224.0.0.0 255.255.255
      set action accept
   next
end
```

Source MAC Addresses

When a FortiGate is in Transparent Mode, it does not typically alter the original source and destination address of packets that flow through the unit. Because of this, end devices do not “see” the MAC address of the FortiGate. However, if network address translation (NAT) is enabled by a firewall policy, the source MAC address will be the MAC address of the FortiGate's management interface.

IP packets that are initiated by the FortiGate (remote management, access to FortiGuard server…) are sent in L2 Ethernet frames that have a source MAC address of the interface in the virtual domain (VDOM) with the lowest MAC address. Below is an example with port2 and port3 in the same VDOM, remote access done via port3, but the sniffer trace showing MAC address of port2. The address of port2 is shown in bold.

```
diagnose hardware deviceinfo nic port2
[…]
Current_HWaddr          00:09:0F:85:3F:C4
Permanent_HWaddr        00:09:0F:85:3F:C4

fgt300 (global) # diagnose hardware deviceinfo nic port3
[…]
Current_HWaddr          00:09:0F:85:3F:C5
Permanent_HWaddr        00:09:0F:85:3F:C5

diagnose sniffer packet port3 "port 80" 6
3.774236 port3 -- 192.168.171.165.2619 -> 192.168.182.136.80: syn 3961770249

```

ARP Table

In Transparent mode, the Address Resolution Protocol (ARP) table is used in the following situations:

- For IP traffic received or originated by the FortiGate itself, and in destination of the management device or next-hop.
- When IPsec is used, the FortiGate uses its ARP table to forward the traffic from the IPsec tunnel to the local destination host(s).

All other forwarding decision is based on the Forwarding Database (FDB) table or optional settings.

Verifying the Forwarding Database

To view all instances of the forwarding database (FDB), use the following CLI command:

```
diagnose netlink brctl list
```

Example

```
FGT # diagnose netlink brctl list

list bridge information
1. root.b      fdb: size=256    used=6     num=7     depth=2     simple=no
2. mgmt.b      fdb: size=256    used=5     num=4     depth=2     simple=no
Total 2 bridges
```

Here above we can see two bridge instances for 2 VDOMs in Transparent mode: `root` and `mgmt`.

- This command will dump the L2 forwarding table for each VDOM bridge instance:

```
diagnose netlink brctl name host <VDOM_name>.b
```

Example for the root VDOM:

```
FGT# diag netlink brctl name host root.b

show bridge control interface root.b host.
fdb: size=256, used=6, num=7, depth=2, simple=no
Bridge root.b host table
port no device  devname  mac addr                  ttl      atributes
   2     7      wan2     02:09:0f:78:69:00          0        Local Static
   5     6      trunk_1  02:09:0f:78:69:01          0        Local Static
   3     8      dmz      02:09:0f:78:69:01          0        Local Static
   4     9      internal 02:09:0f:78:69:02          0        Local Static
   3     8      dmz      00:80:c8:39:87:5a          194
   4     9      internal 02:09:0f:78:67:68          8
   1     3      wan1     00:09:0f:78:69:fe          0        Local Static
```

Spanning Tree BPDUs Forwarding

Spanning tree Bridge Protocol Data Units (BPDUs) are not forwarded by default in Transparent Mode. To forward spanning tree BPDUs, the following setting can be applied on each interface where this is required:

```
config system interface
   edit port1
      set stpforward enable
   next
end
```

Non-IPv4 Ethernet frames forwarding

In the situation where non IP frames (or non Ethernet II) frames need to be accepted on a port, the parameter `l2forward` can be enabled (disabled by default). This can be used to forward frames such as PPPoE PADI, Appletalk, on other ports belonging to the same forwarding domain.

The procedure is the following:

```
config system interface
   edit port1
      set l2forward enable
   next
   edit port2
      set l2forward enable
   next
end
```

Network Address Translation (NAT)

While NAT is generally not used by a FortiGate in Transparent mode, both source network address translation (SNAT) and destination network address translation (DNAT) can be configured.

Configuring SNAT

Source Network Address Translation (SNAT) is an option available in Transparent mode and configurable in CLI only, using the following commands:

```
config firewall ippool
   edit "nat-out"
      set endip 192.168.183.48
      set startip 192.168.183.48
      set interface vlan18_p3
   next
end

config firewall policy
   edit 3
      set srcintf "vlan160_p2"
      set dstintf "vlan18_p3"
      set srcaddr "all"
      set dstaddr "all"
      set action accept
      set ippool enable
      set poolname "nat-out"
      set schedule "always"
      set service "ANY"
      set nat enable
   next
end
```

The sniffer trace below shows the source IP 192.168.182.93 being source translated to 192.168.183.48:

```
fgt300 (TP) # diagnose sniffer packet any "host 10.2.2.1" 4

interfaces=[any]
filters=[host 10.2.2.1]
4.891970 vlan160_p2 in 192.168.182.93 -> 10.2.2.1: icmp: echo request
```

```
4.892003 vlan18_p3 out 192.168.183.48 -> 10.2.2.1: icmp: echo request
4.892007 port3 out 192.168.183.48 -> 10.2.2.1: icmp: echo request
4.933216 vlan18_p3 in 10.2.2.1 -> 192.168.183.48: icmp: echo reply
4.933249 vlan160_p2 out 10.2.2.1 -> 192.168.182.93: icmp: echo reply
4.933253 port2 out 10.2.2.1 -> 192.168.182.93: icmp: echo reply
```

Configuring DNAT

The following example shows how to configure Destination Network Address Translation (DNAT) using a virtual IP on a FortiGatein Transparent Mode:

```
config firewall vip
   edit "vip1"
      set extip 192.168.183.48
      set extintf "vlan160_p2"
      set mappedip 192.168.182.78
   next
end

config firewall policy
   edit 4
      set srcintf "vlan160_p2"
      set dstintf "vlan18_p3"
      set srcaddr "all"
      set dstaddr "vip1"
      set action accept
      set schedule "always"
      set service "ANY"
   next
end
```

If the `mappedip` is on a different subnet than the management IP, the FortiGate must have a valid routeto this destination

The sniffer trace below shows the destination IP 192.168.183.48 being translated to 192.168.182.78:

```
fgt300 (TP) # diagnose sniffer packet any "icmp" 4

interfaces=[any]
filters=[icmp]
4.126138 vlan160_p2 in 192.168.182.93 -> 192.168.183.48: icmp: echo request
4.126190 vlan18_p3 out 192.168.182.93 -> 192.168.182.78: icmp: echo request
4.126196 port3 out 192.168.182.93 -> 192.168.182.78: icmp: echo request
4.126628 vlan18_p3 in 192.168.182.78 -> 192.168.182.93: icmp: echo reply
4.126661 vlan160_p2 out 192.168.183.48 -> 192.168.182.93: icmp: echo reply
4.126667 port2 out 192.168.183.48 -> 192.168.182.93: icmp: echo reply
```

VLANs and Forwarding Domains

The following sections include information about configuring virtual local area networks (VLANs) and forwarding domains in Transparent mode:

- VLANs in Transparent Mode
- Forwarding Domains in Transparent Mode
- VLANs vs Forwarding Domains
- VLAN Forwarding
- Unknown VLAN Processing
- VLAN Trunking and MAC Address Learning
- VLAN Translation

VLANs in Transparent Mode

A VLAN configured on a physical port is used to classify a packet in a broadcast domain in ingress and to tag packet in egress. A VLAN on the FortiGate conforms to the standard 802.1q. The following rules apply to VLAN configuration:

- a VLAN ID can be used only once on the same physical port
- the same VLAN ID can be used on a different port
- the VLAN ID range is from 1 to 4094

Forwarding Domains in Transparent Mode

A forwarding domain is used to create separate broadcast domains and confine traffic across two or more ports. It also allows learning the same MAC in different VLANs (IVL).

A forwarding domain and its associated ID number are unique across one VDOM, or a FortiGate with VDOMs disabled. Each new VDOM will create a new bridge instance in the FortiGate.

Even though the forwarding domain ID is not in relation with the actual VLAN numbers, it recommended, for maintenance and troubleshooting purposes, to configure one forwarding domain per VLAN and use the same forwarding domain ID as the VLANs ID.

Once forwarding domains are configured, it is possible to configure firewall policies only between ports or VLAN belonging to the same forwarding domain.

Figure 4 shows an example with three forwarding domains and VLANs configured. In this example, there are two VDOMs in Transparent Mode: root and MGMT. Forwarding domain 0 is the default on the FortiGate or VDOM in Transparent Mode.

- Root VDOM has:
  - 3 forwarding domains, 0, 340, and 341.
  - VLAN 340 configured on port1; packets will be tagged with ID 340
  - VLAN 341 configured on port1; packets will be tagged with ID 341
  - All other ports are untagged
- MGMT VDOM has got only the default forwarding domain 0

The expected behavior is the following:

- Packets untagged ingressing port1, port3 and port4 belong to the same broadcast domain in the root VDOM
- Packets tagged with VLAN 340 ingressing port1 and Packets untagged ingressing port2 belong to the same broadcast domain in the root VDOM
- Packets tagged with VLAN 341 ingressing port1 and Packets untagged ingressing port5 belong to the same broadcast domain in the root VDOM
- Packets untagged ingressing port6 belong to a different broadcast domain in the MGMT VDOM

Configuration example for forwarding domain 340:

```
config system interface
   edit "VLAN340"
      set forward-domain 340
      set interface "port1"
      set vlanid 340
   next
      edit "port3"
         set forward-domain 340
   next
end
```

VLANs vs Forwarding Domains

There are several differences between VLAN and a forwarding domain configured on a FortiGate in Transparent Mode:

- A forwarding domain is used to create separated broadcast domains between VLANs and allow independent VLAN learning - IVL (MAC addresses in the FDB). This would be equivalent to creating VLANs on a regular L2 switch.

When VLANs are used in the network, configuring different forwarding domains is essential to avoid broadcast duplications. See also section Default VLAN forwarding behavior for additional information.

- VLANs configured on interfaces are only used for tagging packets egressing the port and classifying packets at ingress.
- The packets processed by the direct interface (or port) itself are always sent untagged and must be received untagged.

VLAN Forwarding

VLAN forwarding allows you to forward all VLANs traffic of a trunk that was connecting two network devices and where the FortiGate has been introduced, without having to perform any further configuration.

It is recommended to configure forwarding domains for each VLAN and disable this parameter in order to avoid packet from looping into the trunk from one VLAN to another. By default, the parameter `vlanforward` is disabled on each physical interface of a FortiGate or VDOM in Transparent mode.

Unknown VLAN Processing

When a FortiGate receives a tagged frame with an unknown VLAN ID, the processing is the following:

- By default, the ports are set with the parameter `vlanforward enable`; in this scenario, all tagged frames are forwarded to the ports belonging to the same forwarding domain. This allows you to insert the FortiGate between two devices using trunk ports without any further configuration.

- When using forwarding domains in association with VLANs, `vlanforward` should be disabled whenever applicable. In this scenario, any new tagged frames with unknown VLAN IDs are dropped by the FortiGate. This is the solution recommended by Fortinet.

For an example VLAN configuration, see"Configuration Example" on page 3094.

VLAN Trunking and MAC Address Learning

A FortiGate port becomes a trunk when 2 or more VLANs are configured on this port, in the same or different forwarding domains.

When trunks are configured on a FortiGate, it is essential to create forwarddomains, in order to avoid packets looping back on the VLANs of the trunk. This will confine all broadcasts and multicast traffic between the interfaces belonging to a same forward domain.

In the case where a trunk port is configured with a VLAN in a different forwarding domains, the MAC address of the network device connected to this port learns the FDB of each forwarding domain. This is Independent VLAN Learning (IVL).

VLAN Translation

The same forwarding domain can include several different VLANs. Therefore, a frame ingressing an interface with a certain VLAN ID can be forwarded to another port with another VLAN ID. This is sometimes referred as VLAN translation.

Inter-VDOM links between NAT/Route and Transparent VDOMs

Inter-VDOM links between NAT/Route and Transparent mode VDOMS can be useful for configurations where the NAT/Route VDOMs that share a common Internet service route, which can be routed through a Transparent VDOM that provides additional functionality, like common Security inspection, WAN optimization, explicit proxying and so on.

Other examples include:

- Performing SSL offloading in the Transparent mode VDOM and providing Internet access through a NAT/Route mode VDOM.
- Applying WAN optimization in a Transparent mode VDOM and other security features in the NAT/Route mode VDOM.
- Using a dedicated Transparent mode VDOM for the explicit web proxy in front of a NAT/Route mode VDOM that applies other security features.
- An ISP configuration with multiple per-tenant NAT/Route mode VDOMs all sharing a single Internet connection but where the ISP only presents a single routed subnet. Each tenant can then be assigned an IP from the subnet for their respective VDOM link interface while using a single physical port to connect to the ISP router.

For more information about inter-VDOM links, please refer to the Virtual Domains handbook.

Replay Traffic Scenario

Situations can arise where an identical TCP packet enters twice the FortiGate via 2 different ports. This can be due to a firewall or other network device redirecting packets out on the same port it has received it.

The FortiGate will in this condition detect a replay packet and drop it.

If the network topology or culprit devices cannot be changed to avoid this, the workaround on the FortiGate can be to disable TCP replay verification packets.

```
config system global
   set anti-replay | loose | strict | disable |
end
```

The debug flow diagnosis output hereafter shows the message indicating this condition:

```
id=20085 trace_id=179 msg="vd-VDOM_VLAN1 received a packet(proto=6, 10.10.253.9:10709
>10.10.248.5:25) from TO_EXTERNAL ."
id=20085 trace_id=179 msg="Find an existing session, id-00041475, original direction"
id=20085 trace_id=179 msg="replay packet, drop"
```

For additional diagnosis and troubleshooting procedures,go to http://kb.fortinet.com.

Packet Forwarding using Cisco Protocols

In order to pass Cisco Discover Protocol (CDP) or Cisco VLAN Trunk Protocol (VTP) packets through a FortiGate in Transparent mode, the parameter `stpforward` must be applied on the port configuration. VTP and CDP packets are sent to the destination MAC address 01-00-0C-CC-CC-CC.

A Cisco NATIVE VLAN carries CDP/VTP frames. The frames of this VLAN must be received on the FortiGate physical interfaces (not VLAN sub-interface). Physical interfaces are the only ones that can send/accept non-tagged packets.

The example below will allow CDP and VTP packets to be sent from port3 up to the Remote unit, through two VDOMs, via one physical port and three port aggregations.

Port and Port aggregation configuration:

```
config system interface
   edit "port1"
      set vdom "VD1"
   next
   edit "port2"
      set vdom "VD1"
   next
   edit "port3"
      set vdom "VD1"
      set stpforward enable
   next
   edit "port5"
      set vdom "VD3"
   next
   edit "port6"
      set vdom "VD3"
   next
   edit "port17"
      set vdom "VD2"
   next
   edit "port18"
      set vdom "VD2"
   next
   edit "port19"
```

```
      set vdom "VD2"
   next
   edit "port20"
      set vdom "VD2"
   next
   edit "LACP_VD2_IN"
      set vdom "VD2"
      set stpforward enable
      set type aggregate
         set member "port17" "port18"
   next
   edit "LACP_VD2_OUT"
      set vdom "VD2"
      set stpforward enable
      set type aggregate
         set member "port19" "port20"
   next
   edit "LACP_VD1"
      set vdom "VD1"
      set stpforward enable
      set type aggregate
         set member "port1" "port2"
   next
end
```

When using aggregation, the `stpforward` setting needs to be applied only on the port aggregation level, not on the physical port

This will also forward regular Spanning Tree BPDUs

Verification with a sniffer trace:

```
FGT# diagnose sniffer packet any "" 4

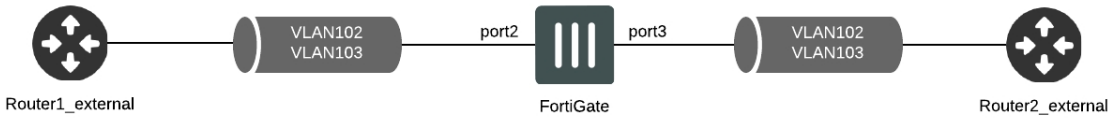
41.365434 port3 in llc unnumbered, ui, flags [command], length 72
41.365437 LACP_VD1 out llc unnumbered, ui, flags [command], length 72
41.365439 port2 out llc unnumbered, ui, flags [command], length 72
41.365479 LACP_VD2_IN in llc unnumbered, ui, flags [command], length 72
41.365482 LACP_VD2_OUT out llc unnumbered, ui, flags [command], length 72
41.365484 port19 out llc unnumbered, ui, flags [command], length 72
```

See above the CDP packet flow from port3, LACP_VD1 (port2), LACP_VD2_IN, LACP_VD2_OUT (port19).

The following sniffer trace command will filter only CDP or VTP packets :

```
FGT# diagnose sniffer packet port_name "ether host 01-00-
0C-CC-CC-CC"
```

Configuration Example



Step 1: Create VLANs and forwarding domains

```
config system interface
   edit "vlan102_intern"
   set forward-domain 102
   set interface "port2"
   set vlanid 102
next
   edit "vlan102_extern"
   set forward-domain 102
   set interface "port3"
   set vlanid 102
next
   edit "vlan103_intern"
   set forward-domain 103
   set interface "port2"
   set vlanid 103
next
   edit "vlan103_extern"
   set forward-domain 103
   set interface "port3"
   set vlanid 103
next
end
```

Step 2: Create the appropriate Firewall Policies

```
config firewall policy
   edit 1
      set srcintf "vlan102_extern"
      set dstintf "vlan102_intern"
         set srcaddr "all"
         set dstaddr "all"
      set action accept
      set schedule "always"
      set service "ANY" next
   edit 2
      set srcintf "vlan102_intern"
      set dstintf "vlan102_extern"
         set srcaddr "all"
         set dstaddr "all"
      set action accept
      set schedule "always"
      set service "ANY" next
   edit 3
      set srcintf "vlan103_intern"
```

```
        set dstintf "vlan103_extern"
           set srcaddr "all"
           set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ANY" next
     edit 4
        set srcintf "vlan103_extern"
        set dstintf "vlan103_intern"
           set srcaddr "all"
           set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ANY" next
end
```

Firewalls and Security in Transparent Mode

This section contains information about using firewalls and security scanning in Transparent mode. It contains the following topics:

- Firewall Policy Look Up
- Firewall Session List
- Security Scanning
- Integrated Switch Fabric Access Control List Policies

Firewall Policy Look Up

In Transparent mode, like in NAT/Route mode, a firewall policy look up is based on the source and destination interfaces. The matching firewall policy will tell which actions to apply to the traffic, including logging and security scanning.

The FortiGate proceeds as follows to look for a matching firewall policy in Transparent mode:

- **Step 1:** an Ethernet IP frame ingresses a port (or a VLAN on a port), corresponding to a specific bridge instance (from the port VDOM and Forwarding domain). This frame contains a destination MAC address that we will call MAC_D.
- **Step 2:** The FortiGate is making a MAC_D address lookup in the bridge instance to determine the port where MAC_D has been learned. This will be the destination interface.
- **Step 3:** The FortiGate is then looking for a firewall policy corresponding to the couple < source interface + destination interface >. If multiple policies with the same couple < source interface + destination interface > exist, the FortiGate screens all of them from TOP to BOTTOM (as displayed in the configuration), until a match is found. It is important to make sure that the most specific firewall policies are located at the top of the policy list, to make sure that traffic is matched to the appropriate policy.

Firewall Session List

The flag **br** in the state line will indicate that this is a “bridged” session. See example below :

```
FGT# diagnose sys session list

session info: proto=17 proto_state=00 duration=59 expire=128 timeout=0 flags=000
```

```
00000 sockflag=00000000 sockport=0 av_idx=0 use=4
origin-shaper=
reply-shaper=
per_ip_shaper=
ha_id=0 hakey=0
policy_dir=0 tunnel=/
state=may_dirty br rem
statistic(bytes/packets/allow_err): org=385/5/1 reply=0/0/0 tuples=2
orgin->sink: org pre->post, reply pre->post dev=3->4/4->3 gwy=0.0.0.0/0.0.0.0
hook=pre dir=org act=noop 192.168.182.93:1025->4.2.2.1:53(0.0.0.0:0)
hook=post dir=reply act=noop 4.2.2.1:53->192.168.182.93:1025(0.0.0.0:0)
misc=0 policy_id=1 auth_info=0 chk_client_info=0 vd=1 serial=000006d3 tos=ff/ff
imp2p=0 app=0
dd_type=0 dd_rule_id=0
```

Security Scanning

Security scanning occurs in the same manner in NAT/Route mode and Transparent mode. When a protection profile is enabled on a firewall policy for content inspection, the FortiGate acts like a transparent proxy for the protocols that need to be inspected.

The FortiGate will therefore intercept the TCP sessions and create its own session from client to server and server to client. The source and destination MAC addresses of the original L2 frames are however not altered in this communication, as described in the section Network operation : source MAC addresses in frames sent by or through the FortiGate.

Devices in the network communicating through the FortiGate do not know the presence of the FortiGate.

For more information about security scanning, see the Security Profiles handbook.

Integrated Switch Fabric Access Control List Policies

Traffic accepted and forwarded by an ISF policy is not subject to security inspection. Normally, you should only create ISF policies for traffic that you consider very low risk.

On FortiGate models that include NP4 and XLR ports and an integrated switch fabric , you can create an integrated switch fabric (ISF) access control list (ACL) firewall policy that allows some traffic (for example, multicast traffic) to bypass security inspection, resulting in reduced CPN and NP4 processor load.

This feature is only available in Transparent mode and only between port pairs.

Use the following command to add an ISF ACL shortcut policy:

```
config firewall isf-acl
   config port-pair-1
      edit 1
         set type binary
         set ingressport {port1 | port2}
         set offset
```

```
        set length
        set matchpattern <pattern in hex>
        set action {bypass | block}
    next
    edit 2
        set type 5-tuple
        set srcaddr: a.b.c.d/32
        set dstaddr 239.A.A.a/32
        set proto UDP
        set port XXX
        set action {bypass | block}
    end
end
```

IPsec VPN in Transparent Mode

This section contains information about configuring IPsec virtual private networks (VPNs) in Transparent mode. It contains the following topics:

- Using IPsec VPNs in Transparent Mode
- Example 1: Remote Sites with Different Subnets
- Example 2: Remote Sites on the Same Subnet

Using IPsec VPNs in Transparent Mode

In Transparent mode, IPsec VPN is supported in Policy-based configuration mode only.

IPsec VPN in Transparent mode can be used in those scenarios:

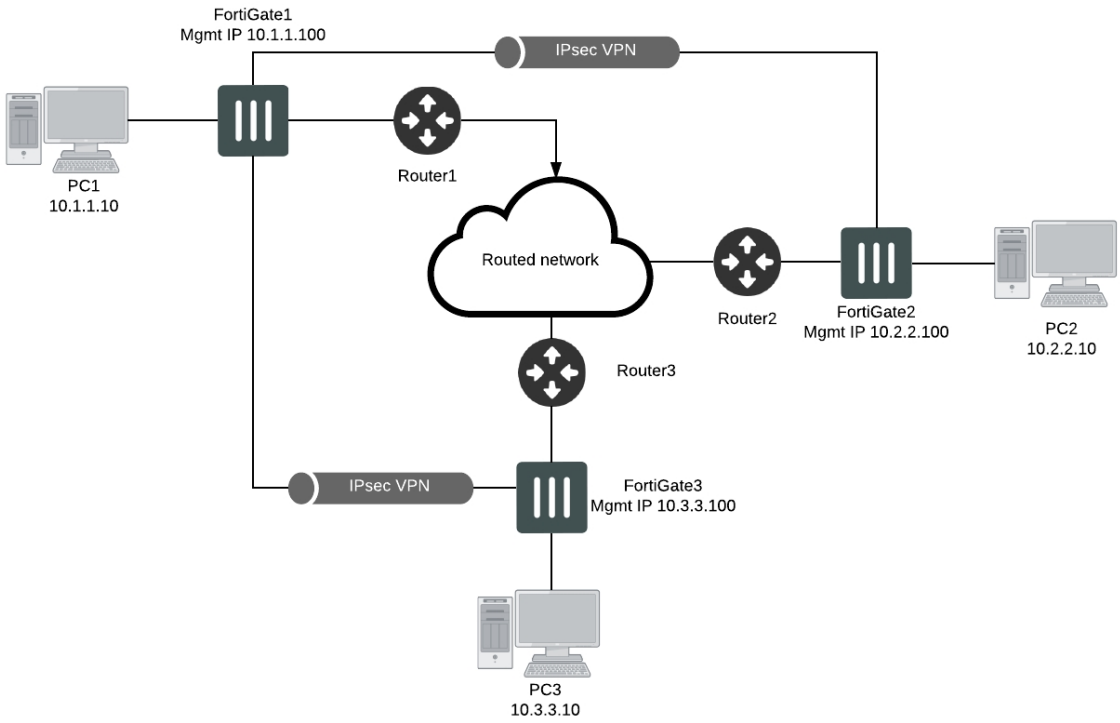
- Encrypt data over routed networks without changing anything on the routers. See example 1.
- Encrypt data over a non-routed transport network (extension of a LAN for example). See example 2.

The following rules apply to IPsec in Transparent mode:

- If both remote FortiGate IPsec gateways are not in the same broadcast domain (separated by routers):
  - The hosts on each side must be on different subnets.
  - The FortiGate management IP addresses must be in the same subnet as the local hosts. This is the preferred option.
- If both remote FortiGate IPsec gateways are in the same broadcast domain (separated by optical switches for examples), the hosts on each side can be :
  - On the same subnet
  - On different subnet if the appropriate static route is configured on the remote Fortigate
  - The FortiGate management IP addresses can be in any different subnet than the local hosts
- A firewall Policy with the action IPsec is used to send traffic to the remote device into the tunnel.
  Therefore, it is important to place all remote devices on the appropriate ports of the Fortigate to allow a proper match < source interface + destination interface > . See section Transparent mode Firewall processing for more details.

This scenario requires that the remote hosts located on the remote FortiGate's protected subnets have their MAC addresses hardcoded in FortiGate's static MAC entry list. If this is not configured then it is expected to see outage in network communications.

Example 1: Remote Sites with Different Subnets



This example provides a configuration example for IPsec VPN tunnels between three FortiGate in Transparent Mode in different subnets, as well as some troubleshooting steps.

The expectation for this example is that PC1 will be able to communicate via the IPsec tunnels with PC2 and PC3, which are in different subnets.

The requirements for this example are:

- Because both FortiGate are not in the same broadcast domain (separated by routers), the hosts on each side must be on different subnets.
- FortiGate management IP addresses must be in the same subnet as the local hosts
- The default gateways (router1 ,router2, router3) for PC1 , PC2 and PC3 must be behind port2 in order for the FortiGate to match the appropriate Encrypt firewall policy (port1 --> port2)

Configuration of FortiGate 1 (FGT1):

Only relevant parts of configuration are provided.

```
config system settings
   set opmode transparent
```

```
   set manageip 10.1.1.100/255.255.255.0
end

config router static
   edit 1
      set gateway 10.1.1.254
   next
end

config firewall address
   edit "10.1.1.0/24"
      set subnet 10.1.1.0 255.255.255.0
   next
   edit "10.2.2.0/24"
      set subnet 10.2.2.0 255.255.255.0
   next
   edit "10.3.3.0/24"
      set subnet 10.3.3.0 255.255.255.0
   next
end

config vpn ipsec phase1
   edit "to_FGT2"
      set proposal 3des-sha1 aes128-sha1 des-md5
      set remote-gw 10.2.2.100
      set psksecret fortinet
   next
   edit "to_FGT3"
      set proposal 3des-sha1 aes128-sha1 des-md5
      set remote-gw 10.3.3.100
      set psksecret fortinet
   next
end

config vpn ipsec phase2
   edit "to_FGT2"
      set keepalive enable
      set phase1name "to_FGT2"
      set proposal 3des-sha1 aes128-sha1
      set dst-subnet 10.2.2.0 255.255.255.0
      set src-subnet 10.1.1.0 255.255.255.0
   next
   edit "to_FGT3"
      set keepalive enable
      set phase1name "to_FGT3"
      set proposal 3des-sha1 aes128-sha1
      set dst-subnet 10.3.3.0 255.255.255.0
      set src-subnet 10.1.1.0 255.255.255.0
   next
end

config firewall policy
   edit 1
      set srcintf "port1"
      set dstintf "port2"
      set srcaddr "10.1.1.0/24"
      set dstaddr "10.2.2.0/24"
```

```
      set action ipsec
      set schedule "always"
      set service "ANY"
      set inbound enable
      set outbound enable
      set vpntunnel "to_FGT2"
   next
   edit 3
      set srcintf "port1"
      set dstintf "port2"
      set srcaddr "10.1.1.0/24"
      set dstaddr "10.3.3.0/24"
      set action ipsec
      set schedule "always"
      set service "ANY"
      set inbound enable
      set outbound enable
      set vpntunnel "to_FGT3"
   next
end
```

Configuration of FortiGate 2 (FGT2):

Only relevant parts of configuration are provided.

```
config system settings
   set opmode transparent
   set manageip 10.2.2.100/255.255.255.0
end

config router static
   edit 1
      set gateway 10.2.2.254
   next
end

config firewall address
   edit "10.1.1.0/24"
      set subnet 10.1.1.0 255.255.255.0
   next
   edit "10.2.2.0/24"
      set subnet 10.2.2.0 255.255.255.0
   next
end

config vpn ipsec phase1
   edit "to_FGT1"
      set nattraversal disable
      set proposal 3des-sha1 aes128-sha1 des-md5
      set remote-gw 10.1.1.100
      set psksecret fortinet
   next
end

config vpn ipsec phase2
   edit "to_FGT1"
      set keepalive enable
      set phase1name "to_FGT1"
```

```
      set proposal 3des-sha1 aes128-sha1
      set dst-subnet 10.1.1.0 255.255.255.0
      set src-subnet 10.2.2.0 255.255.255.0
   next
end

config firewall policy
   edit 1
      set srcintf "port1"
      set dstintf "port2"
      set srcaddr "10.2.2.0/24"
      set dstaddr "10.1.1.0/24"
      set action ipsec
      set schedule "always"
      set service "ANY"
      set inbound enable
      set outbound enable
      set vpntunnel "to_FGT1"
   next
end
```

Troubleshooting procedure

All steps given when PC1 pings PC2.

Verify if IPsec tunnels are up

```
FGT1 # diagnose vpn tunnel list

list all ipsec tunnel in vd 0
------------------------------------------------------
name=to_FGT2 ver=0 serial=1 10.1.1.100:0->10.2.2.100:0 lgwy=dyn tun=tunnel mode= auto
bound_if=0
proxyid_num=1  child_num=0  refcnt=7  ilast=0  olast=0
stat: rxp=0 txp=0 rxb=0 txb=0
dpd: mode=active on=1 idle=5000ms retry=3 count=0 seqno=1455
natt: mode=none draft=0 interval=0 remote_port=0
proxyid=to_FGT2 proto=0 sa=0 ref=1 auto_negotiate=0 serial=5
   src: 10.1.1.0/255.255.255.0:0
   dst: 10.2.2.0/255.255.255.0:0
```

The above tunnel is down (output given as example)!

```
FGT2 # diagnose vpn tunnel list

list all ipsec tunnel in vd 0
------------------------------------------------------
name=to_FGT1 10.2.2.100:0->10.1.1.100:0 lgwy=dyn tun=tunnel mode=auto bound_if=0
proxyid_num=1 child_num=0 refcnt=7 ilast=1 olast=1
stat: rxp=0 txp=0 rxb=0 txb=0
dpd: mode=active on=1 idle=5000ms retry=3 count=0 seqno=21 natt:
mode=none draft=0 interval=0 remote_port=0
proxyid=to_FGT1 proto=0 sa=1 ref=2 auto_negotiate=0 serial=1
   src: 10.2.2.0/255.255.255.0:0
   dst: 10.1.1.0/255.255.255.0:0
   SA: ref=3 options=00000009 type=00 soft=0 mtu=1436 expire=1771 replaywin=0 seq no=1
```

```
life: type=01 bytes=0/0 timeout=1773/1800
dec: spi=c1a8e951 esp=3des key=24 9213fdf22b150e01abb3535d1a647044eebf772b92f2f7ee
ah=sha1 key=20 66a38bf99f0b2d234f64b5a05187995c4f56f6bb
enc: spi=322067b4 esp=3des key=24 720e5680329937fb3630b7ed70bd41bb3114d3c269ae8b61
ah=sha1 key=20 e316113eb6ea03b014b3a5f9c1a3bd386637801a
```

The above tunnel is up!

Verify that destination local hosts are seen in the ARP table (necessary for IPsec despite being in TP mode)

```
FGT2 # get system arp

Address     Age(min)  Hardware Addr       Interface
10.2.2.10   2         00:50:56:00:76:04   root.b
10.2.2.254  0         00:09:0f:30:29:e4   root.b
```

Using the debug flow command on the initiator side (example on FortiGate1)

```
FGT1 # diagnose debug flow filter addr 10.1.1.10
FGT1 # diagnose debug flow show console enable
FGT1 # diagnose debug enable
FGT1 # diagnose debug flow trace start 50

FGT1 # id=36870 trace_id=615 msg="vd-root received a packet(proto=1, 10.1.1.10:512-

id=36870 trace_id=619 msg="enter IPsec tunnel-to_FGT2"
id=36870 trace_id=619 msg="encrypted, and send to 10.2.2.100 with source 10.1.1.100"
id=36870 trace_id=619 msg="send out via dev-port2, dst-mac-00:09:0f:30:29:e0"
id=36870 trace_id=620 msg="vd-root received a packet(proto=1, 10.2.2.10:512->10.1.1.10:0)
    from port2."
id=36870 trace_id=620 msg="Find an existing session, id-00000636, reply direction"
id=36870 trace_id=620 msg="send out via dev-port1, dst-mac-00:50:56:00:76:03"
```

The message "`id=36870 trace_id=615 msg="SA is not ready yet, drop`" simply means that the tunnel was not up yet.

Using the debug flow command on the receiver side (example on FortiGate2)

```
FGT2 # diagnose debug flow filter addr 10.1.1.10
FGT2 # diagnose debug flow show console enable
FGT2 # diagnose debug enable
FGT2 # diagnose debug flow trace start 50

FGT2 # id=36870 trace_id=51 msg="vd-root received a packet(proto=1, 10.1.1.10:512-
    >10.2.2.10:8) from port2."
id=36870 trace_id=51 msg="allocate a new session-00000435"
id=36870 trace_id=51 msg="Allowed by Policy-1:"
id=36870 trace_id=51 msg="send out via dev-port1, dst-mac-00:50:56:00:76:04"
id=36870 trace_id=52 msg="vd-root received a packet(proto=1, 10.2.2.10:512->10.1.1.10:0)
    from port1."
id=36870 trace_id=52 msg="Find an existing session, id-00000435, reply direction"
id=36870 trace_id=52 msg="enter IPsec tunnel-to_FGT1"
id=36870 trace_id=52 msg="encrypted, and send to 10.1.1.100 with source 10.2.2.100"
id=36870 trace_id=52 msg="send out via dev-port2, dst-mac-00:09:0f:30:29:e4"
```

Using the sniffer trace (example on FortiGate2)

```
FGT2 # diagnose sniffer packet any "host 10.2.2.10" 4

9.460021 root.b out arp who-has 10.2.2.10 tell 10.2.2.100

9.460034 port1 out arp who-has 10.2.2.10 tell 10.2.2.100
9.460462 port1 in arp reply 10.2.2.10 is-at 0:50:56:0:76:4
9.460462 root.b in arp reply 10.2.2.10 is-at 0:50:56:0:76:4
[...]
49.477368 port2 in 10.1.1.10 -> 10.2.2.10: icmp: echo request
49.477444 port1 out 10.1.1.10 -> 10.2.2.10: icmp: echo request
49.477898 port1 in 10.2.2.10 -> 10.1.1.10: icmp: echo reply
50.510023 port2 in 10.1.1.10 -> 10.2.2.10: icmp: echo request
50.510079 port1 out 10.1.1.10 -> 10.2.2.10: icmp: echo request
50.510524 port1 in 10.2.2.10 -> 10.1.1.10: icmp: echo reply
```

The above ARP process in Transparent mode with IPsec is allowing the Fortigate to:

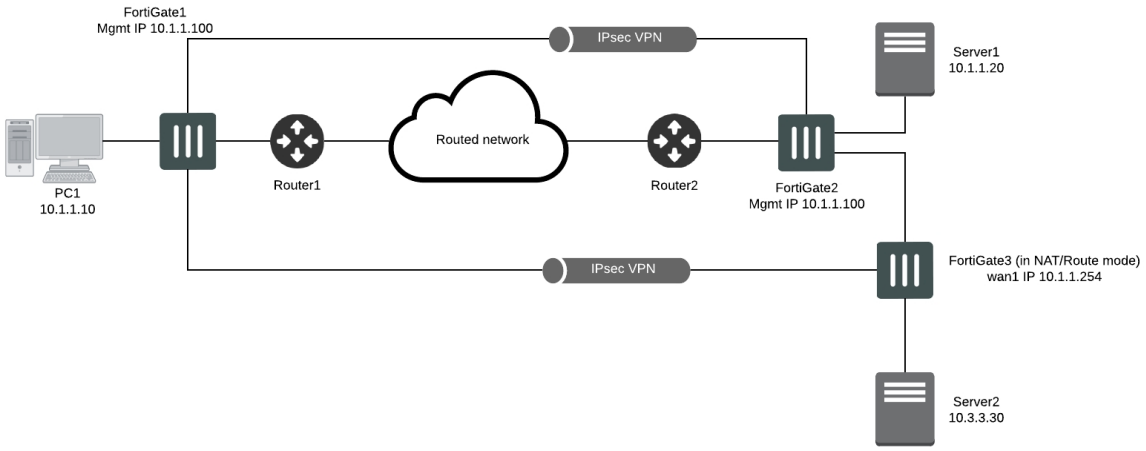
- Identify the MAC address of the destination device 10.2.2.10
- Populate the MAC table (see below), which in turn will give a destination interface and allow a Firewall policy look-up

Check the FDB entries for the destination

```
FGT2 # diagnose netlink brctl name host root.b

port no   device  devname  mac addr            ttl
[..]
1         2       port1    00:50:56:00:76:04    0
```

Example 2: Remote Sites on the Same Subnet



This example provides a configuration example for IPsec VPN tunnels between two FortiGate in Transparent Mode in the same subnet separated by a L2 transparent network and one remote subnet on the second site.

This scenario requires that PC1's MAC address is added to the FortiGate's static MAC table. The preferred scenario would be to have a router installed between the 2 FortiGate's.

The expectation for this example is that PC1 will be able to communicate via the IPsec tunnel with Server1 in the same subnet, and Server2 in a different subnet.

The requirements for this example are:

- The default gateway (FGT3) for PC1 and all remote device must be behind port2 of FGT1, in order for this FortiGate to match the appropriate Encrypt firewall policy (port1 --> port2)
- Despite being in Transparent mode, **FGT2 must have a valid route to Server2**
- FGT3 is used as a router between subnet 10.1.1.0/24 and 10.3.3.0/24.

PC1 MAC address added to FGT2 static MAC entries.

Server1 MAC address added to FGT1 static MAC entries.

Configuration of FortiGate 1 (FGT1):

Only relevant parts of configuration are provided.

```
config system settings
   set opmode transparent
   set manageip 10.1.1.100/255.255.255.0
end

config router static
   edit 1
      set gateway 10.1.1.252
   next
end
```

```
config system mac-address-table
   edit 00:50:56:00:76:04 ==>Server1
      set interface port2
   next
end

config firewall address
   edit "all"
   next
   edit "Server1"
      set subnet 10.1.1.20 255.255.255.255
   next
   edit "Server2"
      set subnet 10.3.3.30 255.255.255.255
   next
   edit "10.1.1.0/24"
      set subnet 10.1.1.0 255.255.255.0
   next
   edit "gateway"
      set subnet 10.1.1.254 255.255.255.255
   next
end

config vpn ipsec phase1
   edit "to_FGT2"
      set proposal 3des-sha1 aes128-sha1 des-md5
      set remote-gw 10.1.1.200
      set psksecret fortinet
   next
end

config vpn ipsec phase2
   edit "to_FGT2"
      set keepalive enable
      set phase1name "to_FGT2"
      set proposal 3des-sha1 aes128-sha1
      set src-subnet 10.1.1.0 255.255.255.0
   next
end

config firewall policy
   edit 1
      set srcintf "port1"
      set dstintf "port2"
      set srcaddr "10.1.1.0/24"
      set dstaddr "Server1"
      set action ipsec
      set schedule "always"
      set service "ANY"
      set inbound enable
      set outbound enable
      set vpntunnel "to_FGT2"
   next
   edit 2
      set srcintf "port1"
      set dstintf "port2"
      set srcaddr "10.1.1.0/24"
```

```
      set dstaddr "Server2"
      set action ipsec
      set schedule "always"
      set service "ANY"
      set inbound enable
      set outbound enable
      set vpntunnel "to_FGT2"
   next
   edit 3
      set srcintf "port1"
      set dstintf "port2"
      set srcaddr "10.1.1.0/24"
      set dstaddr "gateway"
      set action ipsec
      set schedule "always"
      set service "ANY"
      set inbound enable
      set outbound enable
      set vpntunnel "to_FGT2"
   next
end
```

Firewall Policy 3 is not mandatory and is only used to allow PC1 to test a ping reachability to its default gateway 10.1.1.254.

Configuration of FortiGate 2 (FGT2):

Only relevant parts of configuration are provided.

```
config system settings
   set opmode transparent
   set manageip 10.1.1.200/255.255.255.0
end

config router static
   edit 1
      set gateway 10.1.1.252
   next
   edit 2
      set dst 10.3.3.0 255.255.255.0
      set gateway 10.1.1.254
   next
end

config system mac-address-table
   edit 00:50:56:00:76:03
      set interface wan1
   next
end

config firewall address
   edit "all"
   next
   edit "PC1"
```

```
      set subnet 10.1.1.10 255.255.255.255
   next
   edit "10.1.1.0/24"
      set subnet 10.1.1.0 255.255.255.0
   next
   edit "10.3.3.0/24"
      set subnet 10.3.3.0 255.255.255.0
   next
end

config vpn ipsec phase1
   edit "to_FGT1"
      set proposal 3des-sha1 aes128-sha1 des-md5
      set remote-gw 10.1.1.100
      set psksecret fortinet
   next
end

config vpn ipsec phase2
   edit "to_FGT1"
      set keepalive enable
      set phase1name "to_FGT1"
      set proposal 3des-sha1 aes128-sha1
      set dst-subnet 10.1.1.0 255.255.255.0
   next
end

config firewall policy
   edit 1
      set srcintf "internal"
      set dstintf "wan1"
      set srcaddr "10.1.1.0/24" set dstaddr "PC1"
      set action ipsec
      set schedule "always"
      set service "ANY" set inbound enable
      set outbound enable
      set vpntunnel "to_FGT1"
   next
   edit 2
      set srcintf "internal"
      set dstintf "wan1"
      set srcaddr "10.3.3.0/24" set dstaddr "PC1"
      set action ipsec
      set schedule "always"
      set service "ANY" set inbound enable
      set outbound enable
      set vpntunnel "to_FGT1"
   next
end
```

Troubleshooting procedure

Check the ARP entries of PC1

```
C:\ arp -a

Interface: 10.1.1.10 --- 0x20003
```

```
Internet Address        Physical Address       Type
10.1.1.20               00-50-56-00-76-04      dynamic
10.1.1.254              00-09-0f-85-3f-c8      dynamic
```

MAC address **00-09-0f-85-3f-c8** is the FGT3 interface in subnet 10.1.1.0/24.

FDB entries of FGT1

```
FGT1 (global) # diagnose netlink brctl name host Vdom1.b

show bridge control interface Vdom1.b host. fdb:
size=256, used=6, num=6, depth=1
Bridge Vdom1.b host table
port no  device devname  mac addr           ttl   attributes
1        10     port1    00:50:56:00:76:03  0
2        9      port2    00:50:56:00:76:04  44    static
2        9      port2    00:09:0f:85:3f:c8  13
1        10     port1    00:09:0f:88:2f:69  0     Local Static
2        9      port2    00:09:0f:88:2f:68  0     Local Static
2        9      port2    00:09:0f:23:01:d6  0
```

MAC address **00:09:0f:23:01:d6** is “internal” port MAC address of FGT2 00:09:0F:23:01:D6. This is the MAC address used for management in the Transparent mode VDOM of FGT2, chosen between the lowest MAC address between wan1 (00:09:0F:78:00:74) and internal (00:09:0F:23:01:D6).

ARP entries of FGT2

```
FGT2 (TP) # get system arp

Address     Age(min)  Hardware Addr        Interface
10.1.1.20   82        00:50:56:00:76:04    TP.b
10.1.1.100  13        00:09:0f:88:2f:68    TP.b
10.1.1.254  76        00:09:0f:85:3f:c8    TP.b
```

it is important to have the entry for 10.1.1.254 which is the route to 10.3.3.0/24 .

IPsec Tunnel verification on FGT1

```
FGT1 (Vdom1) # diagnose vpn tunnel list

list all ipsec tunnel in vd 3

```

From the above trace, the MAC address **0009 0f88 2f68** is the MAC address of FGT1 port2 . This is the MAC address used for management in the Transparent mode VDOM of FGT1, chosen between the lowest MAC address between port1 (00:09:0F:88:2F:69) and port2 ((00:09:0F:88:2F:68).

Debug flow on FGT1 filtered on Server3

```
FGT1 (Vdom1) # diagnose debug flow filter addr 10.3.3.30
FGT1 (Vdom1) # diagnose debug flow show console enable
```

```
FGT1 (Vdom1) # diagnose debug enable
FGT1 (Vdom1) # diagnose debug flow trace start 10

id=20085 trace_id=11 msg="vd-Vdom1 received a packet(proto=1, 10.1.1.10:512->10.3.3.30:8)
    from port1."
id=20085 trace_id=11 msg="Find an existing session, id-00004e85, original direction"
id=20085 trace_id=11 msg="enter IPsec tunnel-to_FGT2"
id=20085 trace_id=11 msg="encrypted, and send to 10.1.1.200 with source 10.1.1.100"
id=20085 trace_id=11 msg="send out via dev-port2, dst-mac-00:09:0f:23:01:d6"
id=20085 trace_id=12 msg="vd-Vdom1 received a packet(proto=1, 10.3.3.30:512->10.1.1.10:0)
    from port2."
id=20085 trace_id=12 msg="Find an existing session, id-00004e85, reply direction"
id=20085 trace_id=12 msg="send out via dev-port1, dst-mac-00:50:56:00:76:03"
```

From the trace above, **dst-mac-00:09:0f:23:01:d6** is “internal” port MAC address of FGT2 00:09:0F:23:01:D6. This is the MAC address used for management in the Transparent mode VDOM of FGT2, chosen between the lowest MAC address between wan1 (00:09:0F:78:00:74) and internal (00:09:0F:23:01:D6).

Using FortiManager and FortiAnalyzer

FortiManager and FortiAnalyzer are supported similarly to NAT/Route mode. For more information about this please consult the Fortinet documentation at http://docs.fortinet.com or the Knowledge base at http://kb.fortinet.com.

Establishing a communication to a FortiAnalyzer is done as per the example hereafter (from global level if VDOM is enabled). This setting is independent from being in Transparent mode. However, as stated earlier in this section, the management VDOM must have IP connectivity to the FortiAnalyzer.

```
FGT (global) # show system fortianalyzer

config system fortianalyzer
   set status enable
   set server 10.2.2.2
end
```

High Availability in Transparent Mode

This section contains information about configuring high availability in Transparent mode. It contains the following topics:

- Virtual Clustering
- MAC Address Assignment

For complete information about HA, please refer to the Fortigate Administration Guide or the HA Technical guides available at http://docs.fortinet.com or the Knowledge Base at http://kb.fortinet.com.

Any other statement and feature description in this document apply to a FortiGate Cluster running in Active-Passive mode.

Virtual Clustering

If VDOM (virtual domain) is enabled on a cluster operating Transparent Mode, HA Virtual Clustering can be configured in active-passive mode.

This will provide:

- Failover protection between two instances of a VDOM operating on two different FortiGate in the cluster.
- Load balancing between the FortiGate units on a per-VDOM basis.

The roles have been defined such as, in normal operation:

- FortiGate1 is Master for Vdom1 and Slave for Vdom2
- FortiGate2 is Master for Vdom2 and Slave for Vdom1

In case of a failure or reboot of a FortiGate, the remaining unit will become Master for Vdom1 and Vdom2.

The VDOMs given in this example are showing physical ports but a VDOM can also include VLAN interfaces.

The L2 connectivity between the FortiGate is showing 4 separate L2 switches, but it could also be one single switch one each side configured with appropriate VLANs.

Configuration example

- FortiGate1:

```
FGT1 (global) # show system ha

config system ha
   set mode a-p
   set hbdev "port5" 0 "port6" 0
   set vcluster2 enable
   set override disable
   set priority 200
      config secondary-vcluster
         set override enable
         set priority 100
         set vdom "Vdom2"
      end
end
```

- FortiGate2:

```
FGT2 (global) # show system ha

config system ha
   set mode a-p
   set hbdev "port5" 0 "port6" 0
   set vcluster2 enable
```

```
      set override disable
      set priority 200
         config secondary-vcluster
            set override enable
            set priority 100
            set vdom "Vdom2"
         end
   end
```

MAC Address Assignment

If a cluster is operating in Transparent mode, the FortiGate Clustering Protocol (FGCP) assigns a virtual MAC address for the Master unit management IP address. Since you can connect to the management IP address from any interface, all of the FortiGate interfaces appear to have the same virtual MAC address.

Best Practices

1. Create forwarding domains when VLANs are used and set `vlanforward` to `disable` on all relevant physical interface.
2. The forward-domain ID can be different to the VLAN ID, but it is recommended for troubleshooting and readability to keep them the same.
3. Only interfaces from the same forwarding domains can have firewall policies between each others.
4. In order to allow IVL (independent VLAN learning), the VLANs must be placed in separate forwarding domains.
5. If an out-of-band management is desired, use if possible a VDOM in NAT/Route mode as management VDOM and create (an) other Transparent mode VDOM(s) for the user traffic.
6. As Spanning Tree BPDUs are not forwarded by default, insert the FortiGate with caution to avoid L2 loops.
7. Multicast packets are not forwarded by default; this might cause routing protocols (RIP2,OSPF) disruption.
8. When using HSRP or VRRP configure static MAC entries for the Virtual MAC addresses.

Chapter 32 - Troubleshooting

This handbook chapter describes concepts of troubleshooting and solving issues that may occur with FortiGate units.

This FortiOS Handbook chapter contains the following chapters:

Verifying FortiGate admin access security explains how to verify and configure administrative access.

Troubleshooting resources walks you through Fortinet's resources for troubleshooting.

Troubleshooting tools describes some of the basic commands and parts of FortiOS that can help you with troubleshooting.

Troubleshooting methodologies walks you through best practice concepts of FortiOS troubleshooting.

Technical Support Organization Overview describes how Fortinet Support operates, what they will need from you if you contact them, and what you can expect in general.

Common questions answers most of the common questions.

Troubleshooting methodologies

Before you begin troubleshooting anything but the most minor issues, you need to prepare. Doing so will shorten the time to solve your issue. This section helps to explain how you prepare before troubleshooting, as well as creating a troubleshooting plan and contacting support.

This section contains the following topics:

- Establish a baseline
- Define the problem
- Gathering Facts
- Create a troubleshooting plan
- Obtain any required additional equipment
- Ensure you have administrator level access to required equipment
- Contact Fortinet customer support for assistance

Establish a baseline

FortiGate units operate at all layers of the OSI model. For this reason troubleshooting problems can become complex. If you establish a normal operation parameters, or baseline, for your system before the problem occurs it will help reduce the complexity when you are troubleshooting.

Many of the guiding questions in the following sections are some form of comparing the current problem situation to normal operation on your FortiGate unit. For this reason it is a best practice that you know what your normal operating status is, and have a record of it you can refer to. This can easily be accomplished by monitoring the system performance with logs, SNMP tools, or regularly running information gathering commands and saving the output. This regular operation data will show trends, and enable you to see when changes happen and there may be a problem.

Back up your FortiOS configuration on a regular basis. This is a good practice for everyday as well as when troubleshooting. You can restore the backed up configuration when needed and save the time and effort of re-creating it from the factory default settings.

Some fundamental CLI commands you can use to obtain normal operating data for your system:

`get system status`	Displays versions of firmware and FortiGuard engines, and other system information.
`get system performance status`	Displays CPU and memory states, average network usage, average sessions and session setup rate, virus caught, IPS attacks blocked, and uptime.
`get hardware memory`	Displays informations about memory
`get system session status`	Displays total number of sessions

`get router info routing-table all`	Displays all the routes in the routing table including their type, source, and other useful data.
`get ips session`	Displays memory used and max available to IPS as well and counts.
`get webfilter ftgd-statistics`	Displays list of FortiGuard related counts of status, errors, and other data.
`diagnose firewall statistic show`	Displays the amount of network traffic broken down into categories such as email, VoIP, TCP, UDP, IM, Gaming, P2P, and Streaming.
`diag system session list`	Displays current detailed sessions list
`show system dns`	Displays configured DNS servers
`diag sys ntp status`	Displays informations about ntp servers

These commands are just a sample. Feel free to include any extra information gathering commands that apply to your system. For example if you have active VPN connections, record information about them using the `get vpn *` series of commands.

For an extensive snapshot of your system, run the CLI command used by TAC to gather extensive information about a system — `exec tac report`. It runs many diagnostic commands that are for specific configurations. This means no matter what features you are using, this command will record their current state. Then if you need to perform troubleshooting at a later date, you can run the same command again and compare the differences to quickly locate suspicious output you can investigate.

Define the problem

The following questions can help determine the scope of the problem and isolate it:

- **What is the problem?**
  Do not assume that the problem is being experienced is the actual problem. First determine that the problem does not lie elsewhere before starting to troubleshoot the FortiGate device.

- **Has it ever worked before?**
  If the device never worked from the first day, you may not want to spend time troubleshooting something that could well be defective. See “Troubleshooting bootup”.

- **Can the problem be reproduced at will or is it intermittent?**
  If the problem is intermittent, it may be dependent on system load. Also an intermittent problem can be very difficult to troubleshoot due to the difficulty reproducing the issue.

- **What has changed**?
  Do not assume that nothing has changed in the network. Use the FortiGate event log to see if any configuration changes were made. The change could be in the operating environment, for example, a gradual increase in load as more sites are forwarded through the firewall.

If something has changed, see what the affect is if the change is rolled back.

- **Determine the scope of the problem - after you have isolated the problem what applications, users, devices, and operating systems does it effect?**

Before you can solve a problem, you need to understand it. Often this step can be the longest in this process.

Ask questions such as:

- What is not working? Be specific.
- Is there more than one thing not working?
- Is it partly working? If so, what parts are working?
- Is it a connectivity issue for the whole device, or is there an application that isn't reaching the Internet?

Be as specific as possible with your answers, even if it takes awhile to find the answers.

These questions will help you define the problem. Once the problem is defined, you can search for a solution and then create a plan on how to solve it.

Gathering Facts

Fact gathering is an important part of defining the problem. Record the following information as it applies to the problem:

- Where did the problem occur?
- When did the problem occur and to whom?
- What components are involved?
- What is the affected application?
- Can the problem be traced using a packet sniffer?
- Can the problem be traced in the session table or using system debugging?
- Can log files be obtained that indicate a failure has occurred?

Answers to these questions will help you narrow down the problem, and what you have to check during your troubleshooting. The more things you can eliminate, the fewer things you need to check during troubleshooting. For this reason, be as specific and accurate as you can while gathering facts.

Create a troubleshooting plan

Once you have defined the problem, and searched for a solution you can create a plan to solve that problem. Even if your search didn't find a solution to your problem you may have found some additional things to check to further define your problem.

The plan should list all the possible causes of the problem that you can think of, and how to test for each possible cause.

Your troubleshooting plan will act as a checklist so that you know what you have tried and what is left to check. This is important to have if more than one person will be doing the troubleshooting. Without a written plan, people will become easily confused and steps will be skipped. Also if you have to hand over the problem to someone else, providing them with a detailed list of what data has been gathered and what solutions have been already tried demonstrates a good level of professionalism.

Be ready to add to your plan as needed. After you are part way through, you may discover that you forgot some tests or a test you performed discovered new information. This is normal.

Also if you contact support, they will require information about your problem as well as what you have already tried to fix the problem. This should all be part of your plan.

Providing Supporting Elements

If the Fortinet Technology Assistance Center (TAC) needs to be contacted to help you with your issue, be prepared to provide the following information:

- The firmware build version (use the `get system status` command)
- A network topology diagram
- A recent configuration file
- Optionally, a recent debug log
- Tell the support team what troubleshooting steps have already been performed and the results.

Do not provide the output from exec tac report unless Support requests it. The output from that command is very large and is not required in many cases.

For additional information about contacting Fortinet Customer Support, see Technical Support Organization Overview.

All of this is your troubleshooting plan.

Obtain any required additional equipment

You may require additional networking equipment, computers, or other equipment to test your solution.

Normally network administrators have additional networking equipment available either to loan you, or a lab where you can bring the FortiGate unit to test.

If you do not have access to equipment, check for shareware applications that can perform the same task. Often there are software solutions when hardware is too expensive.

Ensure you have administrator level access to required equipment

Before troubleshooting your FortiGate unit, you will need administrator access to the equipment. If you are a client on a FortiGate unit with virtual domains enabled, often you can troubleshoot within your own VDOM. However, you should inform your FortiGate unit's super admin that you will be doing troubleshooting.

Also, you may need access to other networking equipment such as switches, routers, and servers to help you test. If you do not normally have access to this equipment, contact your network administrator for assistance.

Contact Fortinet customer support for assistance

You have defined your problem, researched a solution, put together a plan to find the solution, and executed that plan. At this point if the problem has not been solved, its time to contact Fortinet Customer Support for assistance.

For more information, see Technical Support Organization Overview.

Troubleshooting tools

FortiOS provides a number of tools that help with troubleshooting both hardware and software issues. These tools include diagnostics and ports; ports are used when you need to understand the traffic coming in or going out on a specific port, for example, UDP 53, which is used by the FortiGate unit for DNS lookup and RBL lookup.

This section also contains information about troubleshooting FortiGuard issues.

This section contains the following topics:

- FortiOS diagnostics
- FortiOS ports
- FortiAnalyzer/FortiManager ports
- FortiGuard troubleshooting

FortiOS diagnostics

A collection of diagnostic commands are available in FortiOS for troubleshooting and performance monitoring. Within the CLI commands, the two main groups of diagnostic commands are `get` and `diagnose` commands. Both commands display information about system resources, connections, and settings that enable you to locate and fix problems, or to monitor system performance.

This topic includes diagnostics commands to help with:

- Check date and time
- Resource usage
- Proxy operation
- Hardware NIC
- Traffic trace
- Session table
- Firewall session setup rate
- Finding object dependencies
- Flow trace
- Packet sniffing and packet capture
- NPU based interfaces
- Debug command
- The execute tac report command
- Other commands

Check date and time

The system date and time are important for FortiGuard services, when logging events, and when sending alerts. The wrong time will make the log entries confusing and difficult to use.

Use Network Time Protocol (NTP) to set the date and time if possible. This is an automatic method that does not require manual intervention. However, you must ensure the port is allowed through the firewalls on your network. FortiToken synchronization requires NTP in many situations.

How to check the date and time - web-based manager

1. Go to **System Information > System Time** on the dashboard.
   Alternately, you can check the date and time using the CLI commands `execute date` and `execute time`.
2. If required, select **Change** to adjust the date and time settings.
   You can set the time zone, date and time, and select NTP usage. In the CLI, use the following commands to change the date and time:

```
config system global
   set timezone (use ? to get a list of IDs and descriptions of their timezone)
   end
config system ntp
   set type custom
      config ntpserver
         edit 1
            set server "ntp1.fortinet.net"
         next
         edit 2
            set server "ntp2.fortinet.net"
         next
   end
set ntpsync enable
set syncinterval 60
end
```

Resource usage

Each program running on a computer has one or more processes associated with it. For example if you open a Telnet program, it will have an associated telnet process. The same is true in FortiOS. All the processes have to share the system resources in FortiOS including memory and CPU.

Use `get system performance status` command to show the FortiOS performance status.

Sample output:

```
FGT#get system performance status
CPU states: 0% user 0% system 0% nice 100% idle
CPU0 states: 0% user 0% system 0% nice 100% idle
CPU1 states: 0% user 0% system 0% nice 100% idle
CPU2 states: 0% user 0% system 0% nice 100% idle
CPU3 states: 0% user 0% system 0% nice 100% idle
Memory states: 25% used
Average network usage: 0 kbps in 1 minute, 0 kbps in 10 minutes, 0 kbps in 30 minutes
Average sessions: 5 sessions in 1 minute, 5 sessions in 10 minutes, 4 sessions in 30
    minutes
Average session setup rate: 0 sessions per second in last 1 minute, 0 sessions per second
    in last 10 minutes, 0 sessions per second in last 30 minutes
Virus caught: 0 total in 1 minute
IPS attacks blocked: 0 total in 1 minute
Uptime: 0 days, 12 hours, 7 minutes
```

Monitor the CPU/memory usage of internal processes using the following command:

```
get system performance top <delay> <max_lines>
```

The data listed by the command includes the name of the daemon, the process ID, whether the process is sleeping or running, the CPU percentage being used, and the memory percentage being used.

Sample output:

```
FGT#get system performance top 10 100
Run Time: 0 days, 11 hours and 30 minutes
0U, 0S, 100I; 1977T, 1470F, 121KF

    pyfcgid       120       S              0.0            1.3
    pyfcgid       121       S              0.0            1.3
    pyfcgid       122       S              0.0            1.3
    pyfcgid        53       S              0.0            1.3
  ipsengine        75       S <            0.0            1.3
  ipsengine        66       S <            0.0            1.3
  ipsengine        73       S <            0.0            1.3
  ipsengine        74       S <            0.0            1.3
  ipsengine        79       S <            0.0            1.3
  ipsengine        80       S <            0.0            1.3
    cmdbsvr        43       S              0.0            1.0
proxyworker       110       S              0.0            1.0
proxyworker       111       S              0.0            1.0
     httpsd       125       S              0.0            0.8
     httpsd        52       S              0.0            0.8
     httpsd       124       S              0.0            0.8
     newcli       141       R              0.0            0.7
     newcli       128       S              0.0            0.7
      fgfmd       102       S              0.0            0.7
       iked        86       S              0.0            0.7
```

Proxy operation

Monitor proxy operations using the following command:

```
diag test application <application> <option>
```

The `<application>` value can include the following:

`http`	HTTP proxy.
`smtp`	SMTP proxy.
`ftpd`	FTP proxy.
`pop3`	POP3 proxy.
`imap`	IMAP proxy.
`nntp`	NNTP proxy.
`proxyacceptor`	Proxy acceptor.

proxyworker	Proxy worker.
scanunit	Scanning unit.
sslacceptor	SSL proxy.
sslworker	SSL proxy.
ssh	SSH proxy.
harelay	HA relay daemon.
hasync	HA sync daemon.
forticldd	FortiCloud daemon.
miglogd	Miglog logging daemon.
urlfilter	URL filter daemon.
ovrd	Override daemon.
ipsmonitor	ips monitor
ipsengine	ips sensor
ipldbd	IP load balancing daemon.
ddnscd	DDNS client daemon.
snmpd	SNMP daemon.
acd	Aggregate Controller.
dnsproxy	DNS proxy.
sflowd	sFlow daemon.
init	init process.
l2tpcd	L2TP client daemon.
dhcprelay	DHCP relay daemon.
pptpcd	PPTP client.
wccpd	WCCP daemon.
wad	WAD related processes.

radiusd	RADIUS daemon.
sqldb	SQL database daemon.
reportd	Report daemon.
dlpfingerprint	DLP fingerprint daemon.
dlpfpcache	DLP fingerprint cache daemon.
wpad	WPA daemon.
fsd	FortiExplorer daemon.
ipsufd	IPS urlfilter daemon.
stp	Spanning Tree Protocol daemon.
lted	USB LTE daemon.
swctrl_authd	Switch controller authentication daemon.
forticron	Forticron daemon.
uploadd	Upload daemon.
quarantined	Quarantine daemon.
dhcp6c	DHCP6 client daemon.
info-sslvpnd	SSL-VPN info daemon.
thmd	Traffic history monitor daemon.
dsd	DLP Statistics daemon.
lnkmtd	Link monitor daemon.
dhcp6r	DHCP6 relay daemon.
fnbamd	Fortigate non-blocking auth daemon.

The <option> value depends from the application value used in the command. Here are some examples:

- If the application is http, the CLI command will be:

```
diag test application http <option>
```

The <option> value can be one from the following:

2	Drop all connections.

22	Drop max idle connections.
222	Drop all idle connections.
4	Display connection stat.
44	Display info per connection.
444	Display connections per state.
4444	Display per-VDOM statistics.
44444	Display information about idle connections.
55	Display tcp info per connection.
6	Display ICAP information.
70	Disable ICAP 'Allow: 204' (default).
71	Enable ICAP 'Allow: 204' .
72	Drop all ICAP server connections.
11	Display the SSL session ID cache statistics.
12	Clear the SSL session ID cache statistics.
13	Display the SSL session ID cache.
14	Clear the SSL session ID cache.
80	Show Fortinet bar SSL-VPN bookmark info.
81	Show Fortinet bar SSL-VPN bookmark cache.
82	Show Fortinet bar SSL-VPN bookmark LRU list.

- If the application is `ipsmonitor`, the CLI command will be

```
diag test application ipsmonitor <option>
```

The `<option>` value can be one from the following:

1	Display IPS engine information
2	Toggle IPS engine enable/disable status
3	Display restart log

4	Clear restart log
5	Toggle bypass status
6	Submit attack characteristics now
10	IPS queue length
11	Clear IPS queue length
12	IPS L7 socket statistics
13	IPS session list
14	IPS NTurbo statistics
15	IPSA statistics
97	Start all IPS engines
98	Stop all IPS engines
99	Restart all IPS engines and monitor

Hardware NIC

Monitor hardware network operations using the following command:

```
diag hardware deviceinfo nic <interface>
```

The information displayed by this command is important as errors at the interface are indicative of data link or physical layer issues which may impact the performance of the FortiGate unit.

The following is sample output when `<interface>` = `internal`:

```
System_Device_Name port5
Current_HWaddr 00:09:0f:68:35:60
Permanent_HWaddr 00:09:0f:68:35:60
Link up
Speed 100
Duplex full
[……]
Rx_Packets=5685708
Tx_Packets=4107073
Rx_Bytes=617908014
Tx_Bytes=1269751248
Rx_Errors=0
Tx_Errors=0
Rx_Dropped=0
Tx_Dropped=0
[…..]
```

The `diag hardware deviceinfo nic` command displays a list of hardware related error names and values. The following table explains the items in the list and their meanings.

Possible hardware errors and meanings

Field	Definition
Rx_Errors = rx error count	Bad frame was marked as error by PHY.
Rx_CRC_Errors + Rx_Length_Errors - Rx_Align_Errors	This error is only valid in 10/100M mode.
Rx_Dropped or Rx_No_Buffer_Count	Running out of buffer space.
Rx_Missed_Errors	Equals Rx_FIFO_Errors + CEXTERR (Carrier Extension Error Count). Only valid in 1000M mode, whichis marked by PHY.
Tx_Errors = Tx_Aborted_ Errors	ECOL (Excessive Collisions Count). Only valid in half-duplex mode.
Tx_Window_Errors	LATECOL (Late Collisions Count). Late collisions are collisions that occur after 64-byte time into the transmission of the packet while working in 10 to100Mb/s data rate and 512-byte timeinto the transmission of the packet while working in the 1000Mb/s data rate. This register only increments if transmits are enabled and the device is in half-duplex mode.
Rx_Dropped	See Rx_Errors.
Tx_Dropped	Not defined.
Collisions	Total number of collisions experienced by the transmitter. Valid in half-duplex mode.
Rx_Length_Errors	Transmission length error.
Rx_Over_Errors	Not defined.
Rx_CRC_Errors	Frame CRC error.
Rx_Frame_Errors	Same as Rx_Align_Errors. This error is only valid in 10/100M mode.
Rx_FIFO_Errors	Same as Rx_Missed_Errors - a missed packet count.
Tx_Aborted_Errors	See Tx_Errors.

Field	Definition
Tx_Carrier_Errors	The PHY should assert the internal carrier sense signal during every transmission. Failure to do so may indicate that the link has failed or the PHY has an incorrect link configuration. This register only increments if transmits are enabled. This register is not valid in internal SerDes 1 mode (TBI mode for the 82544GC/EI) and is only valid when the Ethernet controller is operating at full duplex.
Tx_FIFO_Errors	Not defined.
Tx_Heartbeat_Errors	Not defined.
Tx_Window_Errors	See LATECOL.
Tx_Single_Collision_Frames	Counts the number of times that a successfully transmitted packed encountered a single collision. The value only increments if transmits are enabled and the Ethernet controller is in half-duplex mode.
Tx_Multiple_Collision_Frames	A Multiple Collision Count which counts the number of times that a transmit encountered more than one collision but less than 16. The value only increments if transmits are enabled and the Ethernet controller is in half-duplex mode.
Tx_Deferred	Counts defer events. A defer event occurs when the transmitter cannot immediately send a packet due to the medium being busy because another device is transmitting, the IPG timer has not expired, half-duplex deferral events are occurring, XOFF frames are being received, or the link is not up. This register only increments if transmits are enabled. This counter does not increment for streaming transmits that are deferred due to TX IPG.
Rx_Frame_Too_Longs	The Rx frame is over size.
Rx_Frame_Too_Shorts	The Rx frame is too short.
Rx_Align_Errors	This error is only valid in 10/100M mode.
Symbol Error Count	Counts the number of symbol errors between reads - SYMERRS. The count increases for every bad symbol received, whether or not a packet is currently being received and whether or not the link is up. This register only increments in internal SerDes mode.

Traffic trace

Traffic tracing allows a specific packet stream to be followed. This is useful to confirm packets are taking the route you expected on your network.

View the characteristics of a traffic session though specific security policies using:

```
diag sys session
```

Trace per-packet operations for flow tracing using:

```
diag debug flow
```

Trace per-Ethernet frame using:

```
diag sniffer packet
```

Session table

A session is a communication channel between two devices or applications across the network. Sessions enable FortiOS to inspect and act on a sequential group of packets in a session all together instead of inspecting each packet individually. Each of these sessions has an entry in the session table that includes important information about the session.

Use as a tool

Session tables are useful troubleshooting tools because they allow you to verify connections that you expect to see open. For example, if you have a web browser open to browse the Fortinet website, you would expect a session entry from your computer, on port 80, to the IP for the Fortinet website. Another troubleshooting method is if there are too many sessions for FortiOS to process, you can examine the session table for evidence why this is happening.

The FortiGate session table can be viewed from either the CLI or the web-based manager. The most useful troubleshooting data comes from the CLI. The session table in web-based manager also provides some useful summary information, particularly the current policy number that the session is using.

Web-based manager session information

In the web-based manager you can view session information in the FortiView page. Sessions are categorized by **Sources, Applications, Destinations,** and **All Sessions**.

How to find which security policy a specific connection is using

Every program and device on your network must have a communication channel, or session, open to pass information. The FortiGate unit manages these sessions with its many features from traffic shaping, to antivirus scanning, and even blocking known bad web sites. Each session has an entry in the session table.

You may want to find information for a specific session, say a secure web browser session, for troubleshooting. For example if that web browser session is not working properly, you can check the session table to ensure the session is still active, and that it is going to the proper address. It can also tell you the security policy number it matches, so you can check what is happening in that policy.

1. **Know your connection information.**
   You need to be able to identify the session you want. For this you need the source IP address (usually your computer), the destination IP address if you have it, and the port number which is determined by the program being used. Some commons ports are:
   - port 80 (HTTP for web browsing),
   - port 22 (SSH used for secure login and file transfers)
   - port 23 (telnet for a text connection)
   - port 443 (HTTPS for secure web browsing

2. **Find your session and policy ID.**
   Follow **System > FortiView> All Sessions**. Find your session by finding your source IP address,

destination IP address if you have it, and port number. The policy ID is listed after the destination information. If the list of sessions is very long, you can filter the list to make it easier to find your session.

3. **When there are many sessions, use a filter to help you find your session.**
   If there are multiple pages of sessions it is difficult to find a single session. To help you in your search you can use a filter to block out sessions that you don't want. Click the search icon on the column heading to select the filter. Select **Source IP** and enter your source IP address. Now only sessions that originate from your IP address will be displayed in the session table. If the list is still too long, you can do the same for the **Source port**. That will make it easy to find your session and the security policy ID. When you are finished remember to clear the filters.

CLI session information

The session table output from the CLI (`diag sys session list`) is very verbose. Even on a system with a small amount of traffic, displaying the session table will generate a large amount of output. For this reason, filters are used to display only the session data of interest.

You can filter a column in the web-based manager by clicking the search icon on the column heading or from the CLI by creating a filter.

An entry is placed in the session table for each traffic session passing through a security policy. The following command will list the information for a session in the table:

```
diag sys session list
```

Sample Output:

```
FGT# diag sys session list
session info: proto=6 proto_state=05 expire=89 timeout=3600 flags=00000000 av_idx=0 use=3
bandwidth=204800/sec guaranteed_bandwidth=102400/sec traffic=332/sec prio=0
    logtype=session ha_id=0 hakey=4450
tunnel=/
state=log shape may_dirty
statistic(bytes/packets/err): org=3408/38/0 reply=3888/31/0 tuples=2

```

Since output can be verbose, the filter option allows specific information to be displayed, for example:

```
diag sys session filter <option>
```

The `<option>` values available include the following:

`clear`	Clear session filter.
`dintf`	Destination interface.
`dport`	Destination port.

`dst`	Destination IP address.
`duration`	duration
`expire`	expire
`negate`	Inverse filter.
`nport`	NAT'd source port
`nsrc`	NAT'd source ip address
`policy`	Policy ID.
`proto`	Protocol number.
`proto-state`	Protocol state.
`sintf`	Source interface.
`sport`	Source port.
`src`	Source IP address.
`vd`	Index of virtual domain. -1 matches all.

Even though UDP is a sessionless protocol, the FortiGate unit still keeps track of the following two different states:

- UDP reply not seen with a value of 0
- UDP reply seen with a value of 1

The following illustrates FW session states from the session table:

State	Meaning
log	Session is being logged.
local	Session is originated from or destined for local stack.
ext	Session is created by a firewall session helper.
may_dirty	Session is created by a policy. For example, the session for `ftp control channel` will have this state but `ftp data channel` will not. This is also seen when NAT is enabled.
ndr	Session will be checked by IPS signature.
nds	Session will be checked by IPS anomaly.
br	Session is being bridged (TP) mode.

Firewall session setup rate

The number of sessions that can be established in a set period of time is useful information. A session is an end-to-end TCP/IP connection for communication with a limited lifespan. If you record the setup rate during normal operation, when you experience problems you have that setup rate with the current number to see if its very different. While this will not solve your problems, it can be a useful step to help you define your problem.

A reduced firewall session setup rate could be the result of a number of things from a lack of system resources on the FortiGate unit, to reaching the limit of your session count for your VDOM.

To view your session setup rate method 1- CLI

```
FGT# get sys performance status
CPU states: 0% user 0% system 0% nice 100% idle
Memory states: 10% used
Average network usage: 0 kbps in 1 minute, 0 kbps in 10 minutes,
13 kbps in 30 minutes
Average sessions: 31 sessions in 1 minute, 30 sessions in 10
minutes, 31 sessions in 30 minutes
Average session setup rate: 0.5 sessions per second in last 1
minute, 0 sessions per second in last 10 minutes, 0 sessions per
second in last 30 minutes
Virus caught: 0 total in 1 minute
IPS attacks blocked: 0 total in 1 minute
Uptime: 44 days, 18 hours, 42 minutes
```

The information you are looking for is the Average sessions section, highlighted in the above output. In this example you can see there were 31 sessions in 1 minute, or an average of 0.5 sessions per second. The values for 10 minutes and 30 minutes allow you to take a longer average for a more reliable value if your FortiGate unit is working at maximum capacity. The smallest FortiGate unit can have 1 000 sessions established per second across the unit.

Remember that session setup rate is a global command. If you have multiple VDOMs configured with many sessions in each one, the session setup rate per VDOM will be slower than if there were no VDOMs configured.

Finding object dependencies

An administrator may not be permitted to delete a configuration object if there are other configuration objects that depend on it. This command identifies other objects which depend on or *make reference to* the configuration object in question. If an error is displayed that an object is in use and cannot be deleted, this command can help identify the source of the problem.

Another use is if you have a virtual interface with objects that depend on it, you need to find and remove those dependencies before you delete that interface.

CLI method

When running multiple VDOMs, this command is run in the Global configuration only and it searches for the named object both in the Global and VDOM configuration most recently used:

```
diag sys checkused <path.object.mkey>
```

For example, to verify which objects are referred to in a security policy with an ID of 1, enter the command as follows:

```
diag sys checkused firewall.policy.policyid 1
```

To check what is referred to by interface `port1`, enter the following command:

```
diag sys checkused system.interface.name port1
```

To show all the dependencies for an interface, enter the command as follows:

```
diag sys checkused system.interface.name <interface name>
```

Sample Output:

```
entry used by table firewall.address:name '10.98.23.23_host'
entry used by table firewall.address:name 'NAS'
entry used by table firewall.address:name 'all'
entry used by table firewall.address:name 'fortinet.com'
entry used by table firewall.vip:name 'TORRENT_10.0.0.70:6883'
entry used by table firewall.policy:policyid '21'
entry used by table firewall.policy:policyid '14'
entry used by table firewall.policy:policyid '19'
```

In this example, the interface has dependent objects, including four address objects, one VIP, and three security policies.

Web-based manager method

In the web-based manager, the object dependencies for an interface can be easily checked and removed.

To remove interface object dependencies - web-based manager

1. Go to **System > Interfaces**.
   The number in the **Ref.** column is the number of objects that refer to this interface.
2. Select the number in the **Ref.** column for the desired interface.
   A Window listing the dependencies will appear.
3. Use these detailed entries to locate and remove object references to this interface.
   The trash can icon will change from gray when all object dependencies have been removed.
4. Remove the interface by selecting the check box for the interface, and select **Delete**.

Flow trace

To trace the flow of packets through the FortiGate unit, use the following command:

```
diag debug flow trace start
```

If your network is using IPv4, follow packet flow by setting a flow filter using this command:

```
diag debug flow filter <option>
```

Filtering options include the following:

`addr` IPv4 address
`clear` clear filter
`daddr` destination IPv4 address
`dport` destination port
`negate` inverse IPv4 filter
`port` port

`proto` protocol number
`saddr` source IPv4 address
`sport` source port
`vd` index of virtual domain, -1 matches all

If your network is using IPv6, follow packet flow by setting a flow filter using this command:

```
diag debug flow filter6 <option>
```

Filtering options include the following:

`addr` IPv6 address
`clear` clear filter
`daddr` destination IPv6 address
`dport` destination port
`negate` inverse IPv6 filter
`port` port
`proto` protocol number
`saddr` source IPv6 address
`sport` source port
`vd` index of virtual domain, -1 matches all

Enable the output to be displayed to the CLI console using the following command:

```
diag debug flow show console enable
```

`diag debug flow` output is recorded as event log messages and are sent to a FortiCloud or a FortiAnalyzer unit if connected. Do not let this command run longer than necessary since it generates significant amounts of data.

Start flow monitoring with a specific number of packets using this command:

```
diag debug flow trace start <N>
```

Stop flow tracing at any time using:

```
diag debug flow trace stop
```

The following is an example of the flow trace for the device at the following IP address: `203.160.224.97`

```
diag debug enable
diag debug flow filter addr 203.160.224.97
diag debug flow show console enable
diag debug flow show function-name enable
diag debug flow trace start 100
```

Flow trace output example - HTTP

Connect to the web site at the following address to observe the debug flow trace. The display may vary slightly:

```
http://www.fortinet.com
```

Comment: SYN packet received:

```
id=20085 trace_id=209 func=resolve_ip_tuple_fast
line=2700 msg="vd-root received a packet(proto=6,
192.168.3.221:1487->203.160.224.97:80) from port5."
```

SYN sent and a new session is allocated:

```
id=20085 trace_id=209 func=resolve_ip_tuple line=2799
msg="allocate a new session-00000e90"
```

Lookup for next-hop gateway address:

```

msg="find a route: gw-192.168.11.254 via port6"
```

Source NAT, lookup next available port:

```
id=20085 trace_id=209 func=get_new_addr line=1219
msg="find SNAT: IP-192.168.11.59, port-31925"
direction"
```

Matched security policy. Check to see which policy this session matches:

```
id=20085 trace_id=209 func=fw_forward_handler line=317
msg="Allowed by Policy-3: SNAT"
```

Apply source NAT:

```
id=20085 trace_id=209 func=__ip_session_run_tuple
line=1502 msg="SNAT 192.168.3.221->192.168.11.59:31925"
```

SYN ACK received:

```
id=20085 trace_id=210 func=resolve_ip_tuple_fast line=2700
msg="vd-root received a packet(proto=6, 203.160.224.97:80-
>192.168.11.59:31925) from port6."
```

Found existing session ID. Identified as the reply direction:

```
id=20085 trace_id=210 func=resolve_ip_tuple_fast line=2727
msg="Find an existing session, id-00000e90, reply direction"
```

Apply destination NAT to inverse source NAT action:

```
id=20085 trace_id=210 func=__ip_session_run_tuple
line=1516 msg="DNAT 192.168.11.59:31925-
>192.168.3.221:1487"
```

Lookup for next-hop gateway address for reply traffic:

```
id=20085 trace_id=210 func=vf_ip4_route_input line=1543
msg="find a route: gw-192.168.3.221 via port5"
```

ACK received:

```
id=20085 trace_id=211 func=resolve_ip_tuple_fast line=2700
msg="vd-root received a packet(proto=6,
192.168.3.221:1487->203.160.224.97:80) from port5."
```

Match existing session in the original direction:

```
id=20085 trace_id=211 func=resolve_ip_tuple_fast line=2727
msg="Find an existing session, id-00000e90, original
direction"
```

Apply source NAT:

```
id=20085 trace_id=211 func=__ip_session_run_tuple
line=1502 msg="SNAT 192.168.3.221->192.168.11.59:31925"
```

Receive data from client:

```
id=20085 trace_id=212 func=resolve_ip_tuple_fast
line=2700 msg="vd-root received a packet(proto=6,
192.168.3.221:1487->203.160.224.97:80) from port5."
```

Match existing session in the original direction:

```
id=20085 trace_id=212 func=resolve_ip_tuple_fast
line=2727 msg="Find an existing session, id-00000e90,
original direction"
```

Apply source NAT:

```
id=20085 trace_id=212 func=__ip_session_run_tuple
line=1502 msg="SNAT 192.168.3.221->192.168.11.59:31925"
```

Receive data from server:

```
id=20085 trace_id=213 func=resolve_ip_tuple_fast
line=2700 msg="vd-root received a packet(proto=6,
203.160.224.97:80->192.168.11.59:31925) from port6."
```

Match existing session in reply direction:

```
id=20085 trace_id=213 func=resolve_ip_tuple_fast
line=2727 msg="Find an existing session, id-00000e90,
reply direction"
```

Apply destination NAT to inverse source NAT action:

```
id=20085 trace_id=213 func=__ip_session_run_tuple
line=1516 msg="DNAT 192.168.11.59:31925-
>192.168.3.221:1487"
```

Flow trace output example - IPsec (policy-based)

```
id=20085 trace_id=1 msg="vd-root received a packet(proto=1, 10.72.55.240:1->10.71.55.10:8)
    from internal."
id=20085 trace_id=1 msg="allocate a new session-00001cd3"
id=20085 trace_id=1 msg="find a route: gw-66.236.56.230 via wan1"

    from internal."
id=20085 trace_id=2 msg="Find an existing session, id-00001cd3, original direction"
id=20085 trace_id=2 msg="enter IPsec ="encrypted, and send to 15.215.225.22 with source
    66.236.56.226" tunnel-RemotePhase1"
id=20085 trace_id=2 msgid=20085 trace_id=2 msg="send to 66.236.56.230 via intf-wan1"
```

Packet sniffing and packet capture

FortiOS devices can sniff packets using commands in the CLI or capture packets using the web-based manager. The differences between the two methods are not large.

Packet sniffing in the CLI is well suited for spot checking traffic from the CLI, but if you have complex filters to enter it can be a lot of work to enter them each time. You can also save the sniffing output; however, you must log to a file and then analyze the file later by hand.

Packet capture in the web-based manager makes it easy to set up multiple filters at once and just run one or two as you need them. You also have controls to start and stop capturing as you wish. Packet capture output is downloaded to your local computer as a *.pcap file which requires a third party application to read the file, such as Wireshark. This method is useful to send Fortinet support information to help resolve an issue.

Features	Packet sniffing	Packet capture
Command location	CLI	web-based manager
Third party software required	puTTY to log plaintext output	Wireshark to read *.pcap files
Read output in plain text file	yes	no
Read output as *.pcap file using Wireshark	no	yes
Easily configure single quick and simple filter	yes	no
Record packet interface	yes	no
Configure complex sniffer filters on multiple interface	no	yes
sniff IPv6	hard	easy
sniff non-IP packets	no	yes
Filter packets by protocol and/or port	easy	easy
Filter packets by source and/or destination address	easy	easy

Packet sniffing

Before you start sniffing packets on the CLI, you should be prepared to capture the output to a file — there can be huge amounts of data that you will not be able to see without saving it to a file. One method is to use a terminal program like puTTY to connect to the FortiGate unit's CLI. Then once the packet sniffing count is reached you can end the session and analyze the output in the file.

Details within packets passing through particular interfaces can be displayed using the packet sniffer with the following command:

```
diag sniffer packet <interface> <filter> <verbose> <count> <tsformat>
```

The <interface> value is required, with the rest being optional. If not included the default values will be "none".

For example the simplest valid sniffer command would be:

```
diag sniffer packet any
```

The <interface> value can be any physical or virtual interface name. Use *any* to sniff packets on all interfaces.

The <filter> value limits the display of packets using filters, including Berkeley Packet Filtering (BPF) syntax. The <filter> value must be enclosed in quotes.

```
'[[src|dst] host <host_name_or_IP1>] [[src|dst] host <host_name_or_IP2>]
    [[arp|ip|ip6|gre|esp|udp|tcp] [port_no]] [[arp|ip|ip6|gre|esp|udp|tcp] [port_no]]'
```

If a second host is specified in the filter, only the traffic between the two hosts will be displayed. Optionally, you can use logical OR to match only one of the hosts, or match one of multiple protocols or ports. When defining a port, there are up to two parts — protocol and port number.

For example, to display UDP 1812 traffic or TCP 8080 traffic, use the following:

```
'udp port 1812 or tcp port 8080'
```

To display all IP traffic that has a source of 192.168.1.2 and a destination of 192.168.2.3:

```
'ip src host 192.168.1.2 and dst host 192.168.2.3'
```

The <verbose> option allows different levels of information to be displayed. The verbose levels include:

1 Print header of packets

2 Print header and data from the IP header of the packets

3 Print header and data from the Ethernet header of the packets

4 Print header of packets with interface name

5 Print header and data from ip of packets with interface name

6 Print header and data from ethernet of packets with interface name

The <count> value indicates the number of packets to sniff before stopping. If this variable is not included, or is set to zero, the sniffer will run until you manually halt it with Ctrl-C.

The <tsformat> value define the format of timestamp. It can be:

a: absolute UTC time, yyyy-mm-dd hh:mm:ss.ms

l: absolute LOCAL time, yyyy-mm-dd hh:mm:ss.ms

otherwise: relative to the start of sniffing, ss.ms

Packet capture

FortiOS 5.2 includes packet capture to the web-based manager. The FortiGate unit must have a disk and then capture-packet feature can be enabled from the CLI within the firewall policy as below:

```
config firewall policy
   edit <id>
```

```
    set capture-packet enable
end
```

To configure packet capture filters, go to **System > Network > Packet Capture**.

When you add a packet capture filter, enter the following information and select **OK**.

Interface	Select the interface to sniff from the dropdown menu. You must select one interface. You cannot change the interface without deleting the filter and creating a new one, unlike the other fields.
Max Packets to Capture	Enter the number of packets to capture before the filter stops. This number cannot be zero. You can halt the capturing before this number is reached.
Enable Filters	Select this option to specify your filter fields
Host(s)	Enter one or more hosts IP address Separate multiple hosts with commas. Enter a range using a dash without spaces, for example 172.16.1.5-172.16.1.15 or enter a subnet.
Port(s)	Enter one or more ports to capture on the selected interface. Separate multiple ports with commas. Enter a range using a dash without spaces, for example 88-90
VLAN(s)	Enter one or more vlans (if there is any). Separate multiple vlans with commas.
Protocol	Enter one or more protocol. Separate multiple protocol with commas. Enter a range using a dash without spaces, for example 1-6, 17, 21-25
Include IPv6 packets	Select this option if you are troubleshooting IPv6 networking, or if your network uses IPv6. Otherwise, leave it disabled.
Capture Non-IP packets	The protocols available in the list are all IP based except for ICMP (ping). To capture non-IP based packets select this feature. Some examples of non-IP packets include IPsec, IGMP, ARP, and as mentioned ICMP.

If you select a filter and go back to edit it, you have the added option of starting and stopping packet capture in the edit window, or downloading the captured packets. You can also see the filter status and the number of packets captured.

You can also select the filter and select **Start** to start capturing packets. While the filter is running, you will see the number of captured packets increasing until it reaches the max packet count or you select **Stop**. While the filter is running you cannot download the output file.

When the packet capture is complete, you can select **Download** to send the packet capture filter captured packets to your local computer as a *.pcap file. To read this file format, you will need to use Wireshark or a

similar third party application. Using this tool you will have extensive analytics available to you and the full contents of the packets that were captured.

NPU based interfaces

Many Fortinet products contain network processors such as NP1, NP2, and NP4 network processors. Therefore offloading requirements, vary by network processor model.

When using the NPU-based interfaces, only the initial session setup will be seen through the `diag debug flow` command. If the session is correctly programmed into the ASIC (fastpath), the debug flow command will no longer see the packets arriving at the CPU. If the NPU functionality is disabled, the CPU will see all the packets, however, this should only be used for troubleshooting purposes.

First, obtain the NP4 id and the port numbers with the following command:

```
diag npu np4 list
```

Sample output:

```
ID Model Slot Interface
0 On-board port1 fabric1 fabric3 fabric5
1 On-board fabric2 port2 base2 fabric4
```

Run the following commands:

```
diag npu np4 fastpaf th disable <dev_id>
```

(where `dev_id` is the NP4 number)

Then, run this command:

```
diag npu np4 fastpath-sniffer enable port1
```

Sample output:

```
NP4 Fast Path Sniffer on port1 enabled
```

This will cause all traffic on **port1** of NP4 to be sent to the CPU meaning a standard sniffer trace can be taken and other diag commands should work if it was a standard CPU driven port.

These commands are only for the newer NP4 interfaces.

Debug command

Debug output provides continuous, real-time event information. Debugging output continues until it is explicitly stopped or until the unit is rebooted. Debugging output can affect system performance and will be continually generated even though output might not be displayed in the CLI console.

Debug information displayed in the console will scroll in the console display and may prevent CLI commands from being entered, for example, the command to disable the debug display. To turn off debugging output as the display is scrolling by, press the ↑ key to recall the recent diag debug command, press backspace, and type “0”, followed by **Enter**.

Debug output display is enabled using the following command:

```
diag debug enable
```

When finished examining the debug output, disable it using:

```
diag debug disable
```

Once enabled, indicate the debug information that is required using this command:

```
diag debug <option> <level>
```

Debug command options include the following:

enable	Enable debug output.
disable	Disable debug output.
info	Show active debug level settings.
reset	Reset all debug level to default.
report	Report for tech support.
crashlog	Crash log info.
config-error-log	Configure error log info.
sql-log-error	SQL log database error info.
application	application.
kernel	kernel.
remote-extender	remote-extender.
console	console.
cli	Debug CLI.
cmdb-trace	Trace CLI.
rating	Display rating info.
authd	Authentication daemon.
fsso-polling	FSSO active directory poll module.
flow	Trace packet flow in kernel.
urlfilter	urlfilter.
admin	Admin user.

The debug level can be set at the end of the command. Typical values are 2 and 3, for example:

```
diag debug application DHCPS 2
diag debug application spamfilter 2
```

Fortinet support will advise which debugging level to use.

Timestamps can be enabled to the debug output using the following command:

```
diag debug console timestamp enable
```

Debug output example

This example shows the IKE negotiation for a secure logging connection from a FortiGate unit to a FortiAnalyzer system.

```
diag debug reset
diag vpn ike log-filter src-addr4 192.168.11.2
diag debug enable
```

Sample Output:

```
FGh_FtiLog1: IPsec SA connect 0 192.168.11.2->192.168.10.201:500, natt_mode=0 rekey=0
    phase2=FGh_FtiLog1
FGh_FtiLog1: using existing connection, dpd_fail=0
FGh_FtiLog1: found phase2 FGh_FtiLog1
FGh_FtiLog1: IPsec SA connect 0 192.168.11.2 -> 192.168.10.201:500 negotiating
FGh_FtiLog1: overriding selector 225.30.5.8 with 192.168.11.2
FGh_FtiLog1: initiator quick-mode set pfs=1536...
FGh_FtiLog1: try to negotiate with 1800 life seconds.
FGh_FtiLog1: initiate an SA with selectors: 192.168.11.2/0.0.0.0->192.168.10.201,
    ports=0/0, protocol=0/0
Send IKE Packet(quick_outI1):192.168.11.2:500(if0) -> 192.168.10.201:500, len=348
Initiator: sent 192.168.10.201 quick mode message #1 (OK)
FGh_FtiLog1: set retransmit: st=168, timeout=6.
```

In this example:

`192.168.11.2->192.168.10.201:500`	Source and Destination gateway IP address
`dpd_fail=0`	Found existing Phase 1
`pfs=1536...`	Create new Phase 2 tunnel

The execute tac report command

`exec tac report` is an execute command that runs an exhaustive series of diagnostic commands. It runs commands that are only needed if you are using certain features like HA, VPN tunnels, or a modem. The report takes a few minutes to complete due to the amount of output generated. If you have your CLI output logged to a file, you can run this command to familiarize yourself with the CLI commands involved.

When you call Fortinet Customer Support, you will be asked to provide information about your unit and its current state using the output from this CLI command.

Other commands

ARP table

To view the ARP cache, use the following command:

```
get sys arp
```

To view the ARP cache in the system, use this command:

```
diag ip arp list
```

Sample output:

```
index=14 ifname=internal 224.0.0.5 01:00:5e:00:00:05 state=00000040 use=72203
    confirm=78203 update=72203 ref=1
index=13 ifname=dmz 192.168.3.100 state=00000020 use=1843 confirm=650179 update=644179
    ref=2 ? VIP
index=13 ifname=dmz 192.168.3.109 02:09:0f:78:69:ff state=00000004 use=71743 confirm=75743
    update=75743 ref=1
index=14 ifname=internal 192.168.11.56 00:1c:23:10:f8:20 state=00000004 use=10532
    confirm=10532 update=12658 ref=4
```

To remove the ARP cache, use this command:

```
execute clear system arp table
```

To remove a single ARP entry, use:

```
diag ip arp delete <interface name> <IP address>
```

To add static ARP entries, use the following command:

```
config system arp-table
```

Time and date settings

Check time and date settings for log message timestamp synchronization (the Fortinet support group may request this) and for certificates that have a time requirement to check for validity. Use the following commands:

```
execute time
current time is: 12:40:48
last ntp sync:Thu Mar 16 12:00:21 2006
execute date
current date is: 2006-03-16
```

To force synchronization with an NTP server, toggle the following command:

```
Config system ntp
   set ntpsync enable/disable
end
```

If all devices have the same time, it helps to correlate log entries from different devices.

IP address

There may be times when you want to verify the IP addresses assigned to the FortiGate unit interfaces are what you expect them to be. This is easily accomplished from the CLI using the following command.

```
diag ip address list
```

The output from this command lists the IP address and mask if available, the index of the interface (a sort of ID number) and the devname is the name of the interface. While physical interface names are set, virtual interface names can vary. Listing all the virtual interface names is a good use of this command. For vsys_ha and vsys_ fgfm, the IP addresses are the local host — these are internally used virtual interfaces.

```
# diag ip address list
IP=10.31.101.100->10.31.101.100/255.255.255.0 index=3 devname=internal
IP=172.20.120.122->172.20.120.122/255.255.255.0 index=5 devname=wan1
IP=127.0.0.1->127.0.0.1/255.0.0.0 index=8 devname=root
IP=127.0.0.1->127.0.0.1/255.0.0.0 index=11 devname=vsys_ha
IP=127.0.0.1->127.0.0.1/255.0.0.0 index=13 devname=vsys_fgfm
```

FortiOS ports

In the TCP and UDP stacks, there are 65 535 ports available for applications to use when communicating with each other. Many of these ports are commonly known to be associated with specific applications or protocols. These known ports can be useful when troubleshooting your network.

Use the following ports while troubleshooting the FortiGate device:

Port(s)	Functionality
UDP 53	DNS lookup, RBL lookup
UDP 53 or UDP 8888	FortiGuard Antispam or Web Filtering rating lookup
UDP 53 (default) or UDP 8888 and UDP 1027 or UDP 1031	FDN Server List - source and destination port numbers vary by originating or reply traffic. See the article “How do I troubleshoot performance issues when FortiGuard Web Filtering is enabled?” in the Knowledge Base.
UDP 123	NTP Synchronization
UDP 162	SNMP Traps
UDP 514	SYSLOG - All FortiOS versions can use syslog to send log messages to remote syslog servers. FortiOS v2.80 and v3.0 can also view logs stored remotely on a FortiAnalyzer unit.
TCP 22	Configuration backup to FortiManager unit or FortiGuard Analysis and Management Service.
TCP 25	SMTP alert email, encrypted virus sample auto-submit
TCP 389 or TCP 636	LDAP or PKI authentication
TCP 443	FortiGuard Antivirus or IPS update - When requesting updates from a FortiManager unit instead of directly from the FDN, this port must be reconfigured as TCP 8890.
TCP 443	FortiGuard Analysis and Management Service
TCP 514	FortiGuard Analysis and Management Service log transmission (OFTP)
TCP 541	SSL Management Tunnel to FortiGuard Analysis and Management Service (FortiOS v3.0 MR6 or later)

Port(s)	Functionality
TCP 514	Quarantine, remote access to logs and reports on a FortiAnalyzer unit, device registration with FortiAnalyzer units (OFTP)
TCP 1812	RADIUS authentication
TCP 8000 and TCP 8002	FSSO
TCP 10151	FortiGuard Analysis and Management Service contract validation

FortiAnalyzer/FortiManager ports

If you have a FortiAnalyzer unit or FortiManager unit on your network you may need to use the following ports for troubleshooting network traffic.

Functionality	Port(s)
DNS lookup	UDP 53
NTP synchronization	UDP 123
Windows share	UDP 137-138
SNMP traps	UDP 162
Syslog, log forwarding	UDP 514
Log and report upload	TCP 21 or TCP 22
SMTP alert email	TCP 25
User name LDAP queries for reports	TCP 389 or TCP 636
RVS update	TCP 443
RADIUS authentication	TCP 1812
Log aggregation client	TCP 3000

FortiGuard troubleshooting

The FortiGuard service provides updates to Antivirus, Antispam, IPS, Webfiltering, and more. The FortiGuard Distribution System (FDS) involves a number of servers across the world that provide updates to your FortiGate unit. Problems can occur both with connection to FDS, and its configuration on your local FortiGate unit. Some of the more common troubleshooting methods are listed here including

- Troubleshooting process for FortiGuard updates
- FortiGuard server settings

Troubleshooting process for FortiGuard updates

The following process are the logical steps to take when troubleshooting FortiGuard update problems. This includes antivirus (AV), intrusion protection services (IPS), antispam (AS), and web filtering (WB).

1. **Does the device have a valid licence that includes these services?**
   Each device requires a valid FortiGuard license to access updates for some or all of these services. You can verify the support contract status for your devices at the Fortinet Support website — https://support.fortinet.com/.
2. **If the device is part of an HA cluster, do all members of the cluster have the same level of support?**
   As with the previous step, you can verify the support contract status for all the devices in your HA cluster at the Fortinet Support website.
3. **Have services been enabled on the device?**
   To see the FortiGuard information and status for a device, in the web-based manager go to **System > Config > FortiGuard**. On that page you can verify the status of each component, and if required enable each service. If there are problems, see the FortiGuard section of the FortiOS Handbook.
4. **Is the device able to communicate with FortiGuard servers?**
   At **System > Config > FortiGuard** you can also attempt to update AV and IPS, or test the availability of WF and AS default and alternate ports. If there are problems, see the FortiGuard section of the FortiOS Handbook.
5. **Is there proper routing to reach the FortiGuard servers?**
   Ensure there is a static or dynamic route that enables your ForitGate unit to reach the FortiGuard servers. Usually a generic default route to the internet is enough, but you may need to verify this if your network is complex.
6. **Are there issues with DNS?**
   An easy way to test this is to attempt a traceroute from behind the FortiGate unit to an external network using the FQDN for a location. If the traceroute FQDN name does not resolve, you have general DNS problems.
7. **Is there anything upstream that might be blocking FortiGuard traffic, either on the network or ISP side?**
   Many firewalls block all ports by default, and often ISPs block ports that are low. There may be a firewall between the FortiGate unit and the FortiGuard servers that is blocking the traffic. FortiGuard uses port 53 by default, so if it is being blocked you need to either open a hole for it, or change the port it is using.
8. **Is there an issue with source ports?**
   It is possible that ports used to contact FortiGuard are being changed before reaching FortiGuard or on the return trip before reaching your FortiGate unit. A possible solution for this is to use a fixed-port at NATd firewalls to ensure the port remains the same. Packet sniffing can be used to find more information on what is happening with ports.
9. **Are there security policies that include antivirus?**
   If no security policies include antivirus, the antivirus databse will not be updated. If antivirus is included, only the database type used will be updated.

FortiGuard server settings

Your local FortiGate unit connects to remote FortiGuard servers get updates to FortiGuard information such as new viruses that may have been found or other new threats. This section demonstrates ways to display information about FortiGuard server information on your FortiGate unit, and how to use that information and update it to fix potential problems.

Displaying the server list

The `get webfilter status` or `diag debug rating` command shows the list of FDS servers the FortiGate unit is using to send web filtering requests. Rating requests are only sent to the server on the top of the list in normal operation. Each server is probed for Round Trip Time (RTT) every two minutes.

You can optionally add a refresh rate to the end of this command and that will determine how often the server list will be refreshed.

Rating may not be enabled on your FortiGate unit.

```
get webfilter status
```

Sample Output:

```
Locale : english
License : Contract
Expiration : Thu Oct 9 02:00:00 2011
-=- Server List (Mon Feb 18 12:55:48 2008) -=-
```

IP	Weight	RTT	Flags	TZ	Packets	CurrLost	TotalLost
a.b.c.d	0	1	DI	2	1926879	0	11176
10.1.101.1	10	329		1	10263	0	633
10.2.102.2	20	169		0	16105	0	80
10.3.103.3	20	182		0	6741	0	776
10.4.104.4	20	184		0	5249	0	987
10.5.105.5	25	181		0	12072	0	178

Output Details

The Server List includes the IP addresses of alternate servers if the first entry cannot be reached. In this example the IP addresses are not public addresses

The following flags in `get webfilter status` indicate the server status:

- `D` - the server was found through the DNS lookup of the hostname. If the hostname returns more than one IP address, all of them will be flagged with D and will be used first for INIT requests before falling back to the other servers.
- `I` - the server to which the last INIT request was sent.
- `F` - the server has not responded to requests and is considered to have failed.
- `T` - the server is currently being timed.
- `S` - means that rating requests can be sent to the server. The flag is set for a server only in two cases:
  1. The server exists in the servers list received from the Fortimanager or any other INIT server.
  2. The servers list received from the FortiManager is empty so the Fortimanager itself would be the only server known by Fortigate thus it should be used as the rating server.

The servers that are not currently serving will be pushed down to the bottom list (under the available serving servers, and on top of the failed servers) in order for the `load-balance-servers` feature in the `config system fortiguard` to work properly.

Sorting the server list

The server list is sorted first by weight. The server with the smallest RTT is put at the top of the list, regardless of weight. When a packet is lost (there has been no response in 2 seconds), it will be resent to the next server in the list. Therefore, the top position in the list is selected based on RTT while the other list positions are based on weight.

Calculating weight

The weight for each server increases with failed packets and decreases with successful packets. To lower the possibility of using a remote server, the weight is not allowed to dip below a base weight, calculated as the difference in hours between the FortiGate unit and the server times 10. The further away the server is, the higher its base weight and the lower in the list it will appear.

Common questions

The general troubleshooting tips include, and can help answer, the following questions:

How to check hardware connections

- Are all the cables and interfaces connected properly?
- Is the LED for the interface green?

How to check FortiOS network settings

- If you are having problems connecting to the management interface, is your protocol enabled on the interface for administrative access?
- Is there an IP address on the interface?

How to check CPU and memory resources

- Is your CPU running at almost 100 percent usage?
- Are you running low on memory?

How to check modem status

- Is the modem connected?
- Are there PPP issues?

How to run ping and traceroute

- Are you experiencing complete packet loss?

How to check the logs

- Do you need to identify a problem?

How to verify the contents of the routing table (in NAT mode)

- Are there routes in the routing table for default and static routes?
- Do all connected subnets have a route in the routing table?
- Does a route wrongly have a higher priority than it should?

How to verify the correct route is being used

- Has the traffic been routed correctly?

How to verify the correct firewall policy is being used

- Is the correct firewall policy applied to the expected traffic?

How to check the bridging information in Transparent mode

- Are you having problems in Transparent mode?

How to check number of sessions used by UTM proxy

- Have you reached the maximum number of sessions for a protocol?
- Are new sessions failing to start for a certain protocol?

How to examine the firewall session list

- Are there active firewall sessions?

How to check wireless information

- Is the wireless network functioning properly?

How to verify FortiGuard connectivity

- Is the FortiGate unit communicating properly with FortiGuard?

How to perform a sniffer trace (CLI and Packet Capture)

- Is traffic entering the FortiGate unit and does it arrive on the expected interface?
- Is the ARP resolution correct for the next-hop destination?
- Is the traffic exiting the FortiGate unit to the destination as expected?
- Is the traffic being sent back to the originator?

How to debug the packet flow

- Is the traffic entering or leaving the FortiGate unit as expected?

How to check hardware connections

If there is no traffic flowing from the FortiGate unit, it may be a hardware problem.

To check hardware connections:

- Ensure the network cables are properly plugged into the interfaces.
- Ensure there are connection lights for the network cables on the unit.
- Change the cable if the cable or its connector are damaged or you are unsure about the cable's type or quality—such as straight through or crossover, or possibly exposed wires at the connector.
- Connect the FortiGate unit to different hardware.
- Ensure the link status is set to **Up** for the interface, (see **Network > Interface > Status)**. The link status is based on the physical connection and cannot be set in FortiOS.

If any of these solve the problem, it was a hardware connection problem. You should still perform some basic software connectivity tests to ensure complete connectivity. It might also be that the interface is disabled, or has its **Administrative Status** set to **Down**.

To enable an interface - web-based manager

1. Using the web-based management interface, go to **System > Network > Interface**.
2. Select and edit the interface to enable, such as **port1**.
3. Find **Administrative Status** at the bottom of the screen, and select **Up**.
4. Select **Apply**.

To enable an interface - CLI

```
config system interface
   edit port1
      set status up
   next
end
```

How to check FortiOS network settings

FortiOS network settings are present in both the web-based manager interface and the CLI. The following information includes troubleshooting and best practice information. The network settings include:

Interface settings

DNS settings

DHCP Server settings

Interface settings

If you can access the FortiGate unit with the management cable only, the first step is to display the interface settings. To display the settings for the internal interface, use the following CLI command:

```
FGT# show system interface <Interface_mane>
```

For a complete listing of all the possible interface settings, use the following CLI command:

```
config system interface
   edit <Interface_name>
   get
end
```

Check the interface settings to ensure they are not preventing traffic. Specific things to check include (only the web-based manager names are shown, CLI names may vary slightly):

- **Link Status —** *Down* until a valid cable is plugged into this interface, after which it will be **Up**. The Link Status is shown physically by the connection LED for the interface. If it lights up green, it is a good connection. If Link Status is *Down*, the interface does not work. Link Status is also displayed on the **System > Network > Interface** screen by default.
- **Addressing mode —** Do not use **DHCP** if you don't have a DHCP server —you will not be able to logon to an interface in DHCP mode as it will not have an IP address.
- **IP/Netmask —** An interface needs an IP address to be able to connect to other devices. Ensure there is a valid IP address in this field. The one exception is if **DHCP** is enabled for this interface to get its IP address from an external DHCP server.
- **IPv6 address —** The same protocol must be used by both ends to complete the connection. Ensure both this interface and the remote connection are both using IPv4 or both using IPv6 addressing.
- **Administrative access —** If no protocols are selected, you will have to use the local management cable to connect to the unit. If you are using IPv6, configure the IPv6 administrative access protocols.
- **Administrative status —** Set to **Up** or the interface will not work.

DNS settings

While this section is not complicated, many networking problems can be traced back to DNS problems. Things to check in this area include:

- Are there values for both primary and secondary entries?
- Is the local domain name correct?
- Are you using IPv6 addressing? If so, are the IPv6 DNS settings correct?
- Are you using Dynamic DNS (DDNS)? If so, is it using the correct server, credentials, and interface?
- Can you contact both DNS servers to verify the servers are operational?

- If an interface addressing mode is set to DHCP and is set to override the internal DNS, is that interface receiving a valid DNS entry from the DHCP server? Is it a reasonable address and can it be contacted to verify it's operational?
- Are there any DENY security policies that need to allow DNS?
- Can any internal device perform a successful traceroute to a location using the FQDN?

DHCP Server settings

DHCP Servers are common on internal and wireless networks. If the DHCP server is not configured properly it can cause problems. Things to check in this area include:

- Is the DHCP server entry set to **Relay**? If so, verify there is another DHCP server to which requests can be relayed. Otherwise, it should be set to **Server**.
- Is the DHCP server enabled?
- Does this DHCP server use a valid range of IP addresses? Are those addresses in use by other devices? If one or more devices are using IP addresses in this range, you can use the IP reservation feature to ensure the DHCP server does not use these addresses.
- Is there a gateway entry? Include a gateway entry to ensure clients of this server have a default route.
- Is the system DNS setting being used? The best practice is to avoid confusion by using the system DNS whenever possible. However, the option to specify up to three custom DNS servers is available, and all three entries should be used for redundancy.

There are some situations, such as a new wireless interface, or during the initial FortiGate unit configuration, where interfaces override the system DNS entries. When this happens, it often shows up as intermittent Internet connectivity. To fix the problem, go to **System > Network > DNS** and ensure to enable **Use FortiGuard Servers**.

How to check CPU and memory resources

System resources are shared and a number of processes run simultaneously on the FortiGate unit. If one of these processes consumes nearly all the resources.

A quick way to monitor CPU and memory usage is on the System Dashboard using the **System Resources** widgets. They have both a visual gauge displayed to show you the usage.

To check the system resources on your FortiGate unit, run the following CLI command:

```
FGT# get system performance status
```

This command provides a quick and easy snapshot of the FortiGate.

The first line of output shows the CPU usage by category. A FortiGate that is doing nothing will look like:

```
CPU states: 0% user 0% system 0% nice 100% idle
```

However, if your network is running slow you might see something like:

```
CPU states: 1% user 98% system 0% nice 1% idle
```

This line shows that all the CPU is used up by system processes. Normally this should not happen as it shows the FortiGate is overloaded for some reason. If you see this overloading, you should investigate farther as it's possible a process, such as scanunitid, is using all the resources to scan traffic, in which case you need to reduce

the amount of traffic being scanned by blocking unwanted protocols, configuring more security policies to limit scanning to certain protocols, or similar actions. It is also possible that a hacker has gained access to your network and is overloading it with malicious activity such as running a spam server or using zombie PCs to attack other networks on the Internet. You can get additional CPU related information with the CLI command `get system performance top`. This command shows you all the top processes running on the FortiGate unit (names on the left) and their CPU usage. If a process is using most of the CPU cycles, investigate it to determine if it's normal activity.

The second line of output from `get system performance status` shows the memory usage. Memory usage should not exceed 90 percent. If memory is too full, some processes will not be able to function properly. For example, if the system is running low on memory, antivirus scanning will go into failopen mode where it will start dropping connections or bypass the antivirus system.

The other lines of output, such as average network usage, average session setup rate, viruses caught, and IPS attacks blocked can also help you determine why system resource usage it high. For example, if network usage is high it will result in high traffic processing on the FortiGate, or if the session setup rate is very low or zero the proxy may be overloaded and not able to do its job.

How to troubleshoot high memory usage

As with any system, FortiOS has a finite set of hardware resources such as memory and all the running processes share that memory. Depending on their workload, each process will use more or less as needed, usually more in high traffic situations. If some processes use all the available memory, other processes will have no memory available and not be able to function.

When high memory usage happens, you may experience services that appear to freeze up and connections are lost or new connections are refused.

If you are seeing high memory usage in the **System Resources** widget, it could mean that the unit is dealing with high traffic volume, which may be causing the problem, or it could be when the unit is dealing with connection pool limits affecting a single proxy. If the unit is receiving large volumes of traffic on a specific proxy, it is possible that the unit will exceed the connection pool limit. If the number of free connections within a proxy connection pool reaches zero, problems may occur.

Use the following CLI command, which uses the antivirus failopen feature. Setting it to idledrop will drop connections based on the clients that have the most connections open. This helps to determine the behavior of the FortiGate antivirus system if it becomes overloaded in high traffic.

```
config system global
   set av-failopen idledrop
end
```

Use the following CLI command, which gives you information about current memory usage:

```
   diagnose hardware sysinfo memory
```

Sample output:

```
total: used: free: shared: buffers: cached: shm:
Mem: 2074185728 756936704 1317249024 0 20701184 194555904 161046528
Swap:       0       0       0
MemTotal:   2025572 kB
MemFree:    1286376 kB
MemShared:        0 kB
Buffers:      20216 kB
Cached:      189996 kB
SwapCached:       0 kB
Active:       56644 kB
Inactive:    153648 kB
HighTotal:        0 kB
HighFree:         0 kB
LowTotal:   2025572 kB
LowFree:    1286376 kB
SwapTotal:        0 kB
SwapFree:         0 kB
```

How to troubleshoot high CPU usage

FortiOS has many features. If many of them are used at the same time, it can quickly use up all the CPU resources. When this happens, you will experience connection related problems stemming from the FortiOS unit trying to manage its workload by refusing new connections, or even more aggressive methods.

Some examples of features that are CPU intensive are VPN high level encryption, having all traffic undergo all possible scanning, logging all traffic, and packets, and dashboard widgets that frequently update their data.

1. **Determine how high the CPU usage is currently.** There are two main ways to do this. The easiest is to go to **System > Dashboard > Status** and look at the **system resources** widget. This is a dial gauge that displays a percentage use for the CPU. If its at the red-line, you should take action. The other method is to use the Dashboard CLI widget to enter `diag sys top`.

   Sample output:

   ```
   Run Time: 11 days, 23 hours and 36 minutes
   0U, 0S, 98I; 1977T, 758F, 180KF
           newcli 286 R 0.1 0.8
           ipsengine 78 S < 0.0 3.1
           ipsengine 64 S < 0.0 3.0
           ipsengine 77 S < 0.0 3.0
           ipsengine 68 S < 0.0 2.9
           ipsengine 66 S < 0.0 2.9
           ipsengine 79 S < 0.0 2.9
           scanunitd 133 S < 0.0 1.8
           pyfcgid 267 S 0.0 1.8
           pyfcgid 269 S 0.0 1.7
           pyfcgid 268 S 0.0 1.6
           httpsd 139 S 0.0 1.6
           pyfcgid 266 S 0.0 1.5
           scanunitd 131 S < 0.0 1.4
           scanunitd 132 S < 0.0 1.4
           proxyworker 90 S 0.0 1.3
           cmdbsvr 43 S 0.0 1.1
           proxyworker 91 S 0.0 1.1
           miglogd 55 S 0.0 1.1
   ```

```
httpsd 135 S 0.0 1.0
```

Where the codes displayed on the second output line mean the following:

- `U` is % of user space applications using CPU. In the example, `0U` means 0% of the user space applications are using CPU.
- `S` is % of system processes (or kernel processes) using CPU. In the example, `0S` means 0% of the system processes are using the CPU.
- `I` is % of idle CPU. In the example, `98I` means the CPU is 98% idle.
- `T` is the total FortiOS system memory in Mb. In the example, `1977T` means there are 1977 Mb of system memory.
- `F` is free memory in Mb. In the example, `758F` means there is 758 Mb of free memory.
- `KF` is the total shared memory pages used. In the example, `180KF` means the system is using 180 shared memory pages.

Each additional line of the command output displays information for each of the processes running on the FortiGate unit. For example, the third line of the output is:

```
newcli 286 R 0.1 0.8
```

Where:

- `newcli` is the process name. Other process names can include `ipsengine`, `sshd`, `cmdbsrv`, `httpsd`, `scanunitd`, and `miglogd`.
- `286` is the process ID. The process ID can be any number.
- `R` is the current state of the process. The process state can be:

- `R` running
- `S` sleep
- `Z` zombie
- `D` disk sleep.
  - `0.1` is the amount of CPU that the process is using. CPU usage can range from 0.0 for a process that is sleeping to higher values for a process that is taking a lot of CPU time.
  - `0.8` is the amount of memory that the process is using. Memory usage can range from 0.1 to 5.5 and higher.

Enter the following single-key commands when `diagnose sys top` is running:

- Press `q` to quit and return to the normal CLI prompt.
- Press `p` to sort the processes by the amount of CPU that the processes are using.
- Press `m` to sort the processes by the amount of memory that the processes are using.

2. **Determine what features are using most of the CPU resources.**
   There is a command in the CLI to let you see the top few processes currently running that use the most CPU resources. The CLI command `get system performance top` outputs a table of information. You are interested in the second most right column, CPU usage by percentage. If the top few entries are using most of the CPU, note which processes they are and investigate those features to try and reduce their CPU load. Some examples of processes you will see include:
   - `ipsengine` — the IPS engine that scans traffic for intrusions
   - `scanunitd` — antivirus scanner
   - `httpsd` — secure HTTP
   - `iked` — internet key exchange (IKE) in use with IPsec VPN tunnels

- `newcli` — active whenever you are accessing the CLI
- `sshd` — there are active secure socket connections
- `cmdbsrv` — the command database server application

Go to the features that are at the top of the list and look for evidence of them overusing the CPU. Generally the monitor for a feature is a good place to start.

3. Check for unnecessary CPU “wasters”.
These are some best practises that will reduce your CPU usage, even if you are not experiencing high CPU usage. Note that if you require a feature this section tells you to turn off, ignore it.
   - Use hardware acceleration wherever possible to offload tasks from the CPU. Offloading tasks such as encryption frees up the CPU for other tasks.
   - Avoid the use of GUI widgets that require computing cycles, such as the Top Sessions widget. These widgets are constantly polling the system for their information, which uses CPU and other resources.
   - Schedule antivirus, IPS, and firmware updates during off peak hours. Usually these don’t consume CPU resources but they can disrupt normal operation.
   - Check the log levels and which events are being logged. This is the severity of the messages that are recorded. Consider going up one level to reduce the amount of logging. Also if there are events you do not need to monitor, remove them from the list.
   - Log to FortiCloud instead of memory or Disk. Logging to memory quickly uses up resources. Logging to local disk will impact overall performance and reduce the lifetime of the unit. Fortinet recommends logging to FortiCloud which doesn’t use much CPU.
   - If the disk is almost full, transfer the logs or data off the disk to free up space. When a disk is almost full it consumes a lot of resources to find the free space and organize the files.
   - If you have packet logging enabled, consider disabling it. When it’s enabled it records every packet that comes through that policy.
   - Halt all sniffers and traces.
   - Ensure you are not scanning traffic twice. If traffic enters the FortiGate unit on one interface, goes out another, and then comes back in again that traffic does not need to be rescanned. Doing so is a waste of resources. However, ensure that traffic truly is being scanned once.
   - Reduce the session timers to close unused sessions faster. To do this in the CLI enter the following commands and values. These values reduce the values from defaults. Note that `tcp-timewait` has 10 seconds added by the system by default.

     ```
     config system global
        set tcp-halfclose-timer 30
        set tcp-halfopen-timer 30
        set tcp-timewait-timer 0
        set udp-idle-timer 60
     end
     ```
   - Enable only features that you need under **System > Config > Features**.

4. **When CPU usage is under control, use SNMP to monitor CPU usage. Alternately, use logging to record CPU and memory usage every 5 minutes.**
Once things are back to normal, you should set up a warning system to alert you of future CPU overusage. A common method to do this is with SNMP. SNMP monitors many values on the FortiOS and allows you to set high water marks that will generate events. You run an application on your computer to watch for and record these events. Go to **System > Config > SNMP** to enable and configure an SNMP community. If this method is too complicated, you can use the **System Resources** widget to record CPU usage. However, this method will not alert you to problems - it will just record them as they happen.

How to check modem status

Sometimes the modem may not work properly, or the unit may not be detecting the modem. Use the following diagnostic commands to help you troubleshoot issues with the modem.

```
diagnose sys modem {cmd | com | detect | history | external-modem| query| reset}
```

You should always run the following diagnose command after inserting the USB modem into the unit:

```
diagnose sys modem detect
```

You can view the modem configuration by using the `get system modem` command. You can also view the modem's vendor identification as well as the custom product identification number from the information output from the `get system modem` command.

When there are connectivity issues, use the following to help you resolve them:

- `diag debug enable` – activates the debug on the console
- `diag debug application modemd` – dumps communication between the modem and the unit.
- `diag debug application ppp` – dumps the PPP negotiating messages.
- `execute modem dial` – displays modem debug output.

The modem diagnose output should not contain any error on the way to initializing. You should also verify the number that is used to dial with your ISP.

How to run ping and traceroute

Ping and traceroute are useful tools in network troubleshooting. Alone, either one can determine network connectivity between two points. However, ping can be used to generate simple network traffic to view with diagnose commands on the FortiGate unit. This combination can be very powerful when locating network problems.

In addition to their normal uses, ping and traceroute can tell you if your computer or network device has access to a domain name server (DNS). While both tools can use IP addresses alone, they can also use domain names for devices. This is an added troubleshooting feature that can be useful in determining why particular services, such as email or web browsing, may not be working properly.

If ping does not work, you likely have it disabled on at least one of the interface settings, and security policies for that interface.

Both ping and traceroute require particular ports to be open on firewalls, or else they cannot function. Since you typically use these tools to troubleshoot, you can allow them in the security policies and on interfaces only when you need them, and otherwise keep the ports disabled for added security.

Ping

The ping command sends a very small packet to the destination, and waits for a response. The response has a timer that may expire, indicating the destination is unreachable. The behavior of ping is very much like a sonar ping from a submarine, where the command gets its name.

Ping is part of Layer-3 on the OSI Networking Model. Ping sends Internet Control Message Protocol (ICMP) “echo request” packets to the destination, and listens for “echo response” packets in reply. However, many public networks block ICMP packets because ping can be used in a denial of service (DoS) attack (such as Ping of Death or a smurf attack), or by an attacker to find active locations on the network. By default, FortiGate units have ping enabled while broadcast-forward is disabled on the external interface.

What ping can tell you

Beyond the basic connectivity information, ping can tell you the amount of packet loss (if any), how long it takes the packet to make the round trip, and the variation in that time from packet to packet.

If there is some packet loss detected, you should investigate the following:

- Possible ECMP, split horizon, or network loops.
- Cabling to ensure no loose connections.
- Verify which security policy was used (use the packet count column on the **Policy & Objects > Policy** page).

If there is total packet loss, you should investigate the following:

- **Hardware —** ensure cabling is correct, and all equipment between the two locations is accounted for.
- **Addresses and routes —** ensure all IP addresses and routing information along the route is configured as expected.
- **Firewalls —** ensure all firewalls, including FortiGate unit security policies allow PING to pass through.

How to use ping

Ping syntax is the same for nearly every type of system on a network.

To ping from a FortiGate unit

1. Connect to the CLI either through telnet or through the CLI widget on the web-based manager dashboard.
2. Enter `exec ping 10.11.101.101` to send 5 ping packets to the destination IP address. There are no options for this command.

   Sample output:

```
Head_Office_620b # exec ping 10.11.101.101
PING 10.11.101.101 (10.11.101.101): 56 data bytes
64 bytes from 10.11.101.101: icmp_seq=0 ttl=255 time=0.3 ms
64 bytes from 10.11.101.101: icmp_seq=1 ttl=255 time=0.2 ms
64 bytes from 10.11.101.101: icmp_seq=2 ttl=255 time=0.2 ms
64 bytes from 10.11.101.101: icmp_seq=3 ttl=255 time=0.2 ms
64 bytes from 10.11.101.101: icmp_seq=4 ttl=255 time=0.2 ms

--- 10.11.101.101 ping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
round-trip min/avg/max = 0.2/0.2/0.3 ms
```

To ping from an MS Windows PC

1. Open a command window.
   - In Windows XP, select **Start > Run**, enter cmd, and select **OK**.
   - In Windows 7, select the Start icon, enter cmd in the search box, and select cmd.exe from the list.
2. Enter `ping 10.11.101.100` to ping the default internal interface of the FortiGate unit with four packets.

Other options include:

- `-t` to send packets until you press “Control-C”
- `-a` to resolve addresses to domain names where possible
- `-n X` to send X ping packets and stop

Sample output:

```
C:\>ping 10.11.101.101

Pinging 10.11.101.101 with 32 bytes of data:
Reply from 10.11.101.101: bytes=32 time=10ms TTL=255
Reply from 10.11.101.101: bytes=32 time<1ms TTL=255
Reply from 10.11.101.101: bytes=32 time=1ms TTL=255
Reply from 10.11.101.101: bytes=32 time=1ms TTL=255

Ping statistics for 10.11.101.101:
   Packets: Sent = 4, Received = 4, Lost = 0 (0% loss),
Approximate round trip times in milli-seconds:
   Minimum = 0ms, Maximum = 10ms, Average = 3ms
```

To ping from a Linux PC

1. Go to a shell prompt.
2. Enter `“ping 10.11.101.101”.`

Traceroute

Where ping will only tell you if it reached its destination and came back successfully, traceroute will show each step of its journey to its destination and how long each step takes. If ping finds an outage between two points, traceroute can be used to locate exactly where the problem is.

What is traceroute

Traceroute works by sending ICMP packets to test each hop along the route. It will send out three packets, and then increase the time to live (TTL) setting by one each time. This effectively allows the packets to go one hop farther along the route. This is the reason why most traceroute commands display their maximum hop count before they start tracing the route — that is the maximum number of steps it will take before declaring the destination unreachable. Also, the TTL setting may result in steps along the route timing out due to slow responses. There are many possible reasons for this to occur.

By default, traceroute uses UDP datagrams with destination ports numbered from 33434 to 33534. The traceroute utility usually has an option to specify use of ICMP echo request (type 8) instead, as used by the Windows tracert utility. If you have a firewall and if you want traceroute to work from both machines (Unix-like systems and Windows) you will need to allow both protocols inbound through your FortiGate security policies (UDP with ports from 33434 to 33534 and ICMP type 8).

You can also use the packet count column of the **Policy & Objects > Policy** page to track traceroute packets. This allows you to verify the connection, but also confirm which security policy the traceroute packets are using.

What traceroute can tell you

Ping and traceroute have similar functions—to verify connectivity between two points. The big difference is that traceroute shows you each step of the way, where ping does not. Also, ping and traceroute use different protocols

and ports, so one may succeed where the other fails.

You can verify your DNS connection using traceroute. If you enter an FQDN instead of an IP address for the traceroute, DNS will try to resolve that domain name. If the name does not get resolved, you know you have DNS issues.

How to use traceroute

The traceroute command varies slightly between operating systems. Note that in MS Windows the command name is shortened to "`tracert`". Also, your output will list different domain names and IP addresses along your route.

To use traceroute on an MS Windows PC

1. Open a command window.
   - In Windows XP, select **Start > Run**, enter cmd, and select **OK**.
   - In Windows 7, select the Start icon, enter cmd in the search box, and select cmd.exe from the list.
2. Enter "`tracert fortinet.com`" to trace the route from the PC to the Fortinet web site.
   Sample output:

```
C:\>tracert fortinet.com

Tracing route to fortinet.com [208.70.202.225]
over a maximum of 30 hops:
1 <1 ms <1 ms <1 ms 172.20.120.2
2 66 ms 24 ms 31 ms 209-87-254-xxx.storm.ca [209.87.254.221]
3 52 ms 22 ms 18 ms core-2-g0-0-1104.storm.ca [209.87.239.129]
4 43 ms 36 ms 27 ms core-3-g0-0-1185.storm.ca [209.87.239.222]
5 46 ms 21 ms 16 ms te3-x.1156.mpd01.cogentco.com [38.104.158.69]
6 25 ms 45 ms 53 ms te8-7.mpd01.cogentco.com [154.54.27.249]
7 89 ms 70 ms 36 ms te3-x.mpd01.cogentco.com [154.54.6.206]
8 55 ms 77 ms 58 ms sl-st30-chi-.sprintlink.net [144.232.9.69]
9 53 ms 58 ms 46 ms sl-0-3-3-x.sprintlink.net [144.232.19.181]
10 82 ms 90 ms 75 ms sl-x-12-0-1.sprintlink.net [144.232.20.61]
11 122 ms 123 ms 132 ms sl-0-x-0-3.sprintlink.net [144.232.18.150]
12 129 ms 119 ms 139 ms 144.232.20.7
13 172 ms 164 ms 243 ms sl-321313-0.sprintlink.net [144.223.243.58]
14 99 ms 94 ms 93 ms 203.78.181.18
15 108 ms 102 ms 89 ms 203.78.176.2
16 98 ms 95 ms 97 ms 208.70.202.225

Trace complete.
```

The first, or the left column, is the hop count, which cannot go over 30 hops. When that number is reached, the traceroute ends.

The second, third, and fourth columns display how much time each of the three packets takes to reach this stage of the route. These values are in milliseconds and normally vary quite a bit. Typically a value of `<1ms` indicates a local connection.

The fifth, or the column farthest to the right, is the domain name of that device and its IP address or possibly just the IP address.

To perform a traceroute on a Linux PC

1. Go to a command line prompt.
2. Enter "`traceroute fortinet.com`".

The Linux traceroute output is very similar to the MS Windows tracert output.

To perform a traceroute from the FortiGate

1. Connect to the CLI either through telnet or through the CLI widget on the web-based manager dashboard.
2. Enter `exec traceroute www.fortinet.com` to trace the route to the destination IP address. There are no options for this command.

   Output appears as follows:

```
# execute traceroute www.fortinet.com
traceroute to www.fortinet.com (66.171.121.34), 32 hops max, 84 byte packets
1 172.20.120.2 0.637 ms 0.653 ms 0.279 ms
2 209.87.254.221 <static-209-87-254-221.storm.ca> 2.448 ms 2.519 ms 2.458 ms
3 209.87.239.129 <core-2-g0-2.storm.ca> 2.917 ms 2.828 ms 9.324 ms
4 209.87.239.199 <core-3-bdi1739.storm.ca> 13.248 ms 12.401 ms 13.009 ms
5 216.66.41.113 <v502.core1.tor1.he.net> 17.181 ms 12.422 ms 12.268 ms
6 184.105.80.9 <100ge1-2.core1.nyc4.he.net> 21.355 ms 21.518 ms 21.597 ms
7 198.32.118.41 <ny-paix-gni.twgate.net> 83.297 ms 84.416 ms 83.782 ms
8 203.160.228.217 <217-228-160-203.TWGATE-IP.twgate.net> 82.579 ms 82.187 ms 82.066 ms
9 203.160.228.229 <229-228-160-203.TWGATE-IP.twgate.net> 82.055 ms 82.455 ms 81.808 ms
10 203.78.181.2 82.262 ms 81.572 ms 82.015 ms
11 203.78.186.70 83.283 ms 83.243 ms 83.293 ms
12 66.171.127.177 84.030 ms 84.229 ms 83.550 ms
13 66.171.121.34 <www.fortinet.com> 84.023 ms 83.903 ms 84.032 ms
14 66.171.121.34 <www.fortinet.com> 83.874 ms 84.084 ms 83.810 ms
```

How to check the logs

This step in troubleshooting can be forgotten, but its an important one. Logging records the traffic passing through the FortiGate unit to your network and what action the FortiGate unit took during its scanning process of the traffic. This recorded information is called a log message.

When you configure FortiOS initially, log as much information as you can. If needed, logging of unused features can be turned off or scaled back if the logs generated are too large.

As with most troubleshooting steps, before you can determine if the logs indicate a problem, you need to know what logs result from normal operation. Without a baseline it is difficult to properly troubleshoot.

When troubleshooting with log files:

- Compare current logs to a recorded baseline of normal operation.
- If needed increase the level of logging (such as from Warning to Information) to obtain more information.

When increasing logging levels, ensure that alert email is configured and both disk usage and log quota are selected. This ensures you will be notified if the increased logging causes problems. You can also use Logging Monitor (located in **Log&Report > Monitor > Logging volume Monitor**) to determine the activities that generate the most log entries.

- check all logs to ensure important information is not overlooked
- filter or order log entries based on different fields (such as level, service, or IP address) to look for patterns that may indicate a specific problem (such as frequent blocked connections on a specific port for all IP addresses)

Logs will help identify and locate any problems, but they will not solve the problems. The job of logs is to speed up your problem solving and save you time and effort.

For more information on Logging and Log Reports, see the Logging and Reporting handbook chapter.

How to verify the contents of the routing table (in NAT mode)

When you have some connectivity, or possibly none at all a good place to look for information is the routing table.

The routing table is where all the currently used routes are stored for both static and dynamic protocols. If a route is in the routing table, it saves the time and resources of a lookup. If a route is not used for a while and a new route needs to be added, the oldest least used route is bumped if the routing table is full. This ensures the most recently used routes stay in the table. If your FortiGate unit is in Transparent mode, you are unable to perform this step.

If the FortiGate is running in NAT mode, verify that all desired routes are in the routing table: local subnets, default routes, specific static routes, and dynamic routing protocols.

To check the routing table in the web-based manager, use the Routing Monitor by going to **Router > Monitor > Routing Monitor**.

In the CLI, use the command `get router info routing-table all`. Sample output:

```
FGT# get router info routing-table all

Codes:
        K - kernel, C - connected, S - static, R - RIP, B - BGP
        O - OSPF, IA - OSPF inter area
        N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
        E1 - OSPF external type 1, E2 - OSPF external type 2
        i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
        * - candidate default

S* 0.0.0.0/0 [10/0] via 172.20.120.2, wan1
C 10.31.101.0/24 is directly connected, internal
C 172.20.120.0/24 is directly connected, wan1
```

How to verify the correct route is being used

If you have more than one default route and wants to make sure that traffic is flowing as expected via the right route, you can run a trace route from a machine in the local area network, this will indicate you the first hop that the traffic goes through.

Sample output:

```
C:\>tracert www.fortinet.com

Tracing route to www.fortinet.com [66.171.121.34]
over a maximum of 30 hops:

1 <1 ms <1 ms <1 ms 10.10.1.99
2 1 ms <1 ms <1 ms 172.20.120.2
3 3 ms 3 ms 3 ms static-209-87-254-221.storm.ca [209.87.254.221]
4 3 ms 3 ms 3 ms core-2-g0-2.storm.ca [209.87.239.129]
5 13 ms 13 ms 13 ms core-3-bdi1739.storm.ca [209.87.239.199]
6 12 ms 19 ms 11 ms v502.core1.tor1.he.net [216.66.41.113]
7 22 ms 22 ms 21 ms 100ge1-2.core1.nyc4.he.net [184.105.80.9]
8 84 ms 84 ms 84 ms ny-paix-gni.twgate.net [198.32.118.41]
9 82 ms 84 ms 82 ms 217-228-160-203.TWGATE-IP.twgate.net [203.160.22
8.217]
10 82 ms 81 ms 82 ms 229-228-160-203.TWGATE-IP.twgate.net [203.160.22
8.229]
11 82 ms 82 ms 82 ms 203.78.181.2
12 84 ms 83 ms 83 ms 203.78.186.70
13 84 ms * 85 ms 66.171.127.177
14 84 ms 84 ms 84 ms fortinet.com [66.171.121.34]
15 84 ms 84 ms 83 ms fortinet.com [66.171.121.34]

Trace complete.
```

In this scenario, the first hop contains the IP address `10.10.1.99`, which is the internal interface of the FortiGate. The second hop contains the IP address `172.20.120.2`, to which the wan1 interface of the FortiGate is connected, so we can conclude that the route via wan1 interface is being used for this traffic.

Also debug the packet flow in the CLI shows the route taken for each session.

Sample output:

```
id=20085 trace_id=319 func=vf_ip4_route_input line=1597 msg="find a route: gw-172.20.120.2
    via wan1"
```

For more information on debuging the packet flow, see How to debug the packet flow.

How to verify the correct firewall policy is being used

If you have more than one firewall policy, use the count column to check which policy is being used, the count must show traffic increasing. To do so, go to **Policy & Objects > Policy** page.

Also debuging the packet flow in the CLI shows the policy id allowing the traffic.

Sample output:

```
id=13 trace_id=1 func=fw_forward_handler line=650 msg="Allowed by Policy-14: SNAT"
```

For more information on debuging the packet flow, see How to debug the packet flow.

How to check the bridging information in Transparent mode

When FortiOS is in Transparent mode, the unit acts like a bridge sending all incoming traffic out on the other interfaces. The bridge is between interfaces on the FortiGate unit.

Each bridge listed is a link between interfaces. Where traffic is flowing between interfaces, you expect to find bridges listed. If you are having connectivity issues, and there are no bridges listed, that is a likely cause. Check for the MAC address of the interface or device in question.

How to check the bridging information

To list the existing bridge instances on the FortiGate unit, use the following command:

```
diagnose netlink brctl list
```

Sample output:

```
#diagnose netlink brctl list
list bridge information
1. root.b fdb: size=256 used=6 num=7 depth=2 simple=no
Total 1 bridges
```

How to display forwarding domain information

Forwarding domains, or collision domains, are used in routing to limit where packets are forwarded on the network. Layer-2 broadcasts are limited to the same group. By default, all interfaces are in group 0. For example, if the FortiGate unit has 12 interfaces, only two may be in the same forwarding domain, which will limit packets that are broadcast to only those two interfaces. This reduces traffic on the rest of the network.

Collision domains prevent the forwarding of ARP packets to all VLANs on an interface. Without collision domains, duplicate MAC addresses on VLANs may cause ARP packets to be duplicated. Duplicate ARP packets can cause some switches to reset. It is important to know what interfaces are part of which forwarding domains as this determines which interfaces can communicate with each other.

To manually configure forwarding domains in Transparent mode, use the following FortiOS CLI command:

```
config system interface
   edit <interface_name>
   set forward-domain <integer>
end
```

To display the information for forward domains

Use the following command:

```
diagnose netlink brctl domain <name> <id>
```

where <name> is the name of the forwarding domain to display and <id> is the domain id.

Sample output

```
diagnose netlink brctl domain ione 101
show bridge root.b ione forward domain.
id=101 dev=trunk_1 6
```

To list the existing bridge MAC table, use the following command:

```
diagnose netlink brctl name host <name>
```

Sample output

```
show bridge control interface root.b host.
fdb: size=256, used=6, num=7, depth=2, simple=no
Bridge root.b host table
```

port no	device	devname	mac addr	ttl	attributes
2	7	wan2	02:09:0f:78:69:00	0	Local Static
5	6	vlan_1	02:09:0f:78:69:01	0	Local Static
3	8	dmz	02:09:0f:78:69:01	0	Local Static
4	9	internal	02:09:0f:78:69:02	0	Local Static
3	8	dmz	00:80:c8:39:87:5a	194	
4	9	internal	02:09:0f:78:67:68	8	
1	3	wan1	00:09:0f:78:69:fe	0	Local Static

To list the existing bridge port list, use this command:

```
diagnose netlink brctl name port <name>
```

Sample Output:

```
show bridge root.b data port.
```

```
trunk_1 peer_dev=0
internal peer_dev=0
dmz peer_dev=0
wan2 peer_dev=0
wan1 peer_dev=0
```

How to check number of sessions used by UTM proxy

Each FortiGate model has a set limit of the maximum number of sessions the UTM proxy supports. The UTM proxy handles all the traffic for the following protocols: HTTP, SMTP, POP3, IMAP, FTP, and NNTP. If the proxy for a protocol fills up its session table, the FortiGate unit will enter conserve mode, where it behaves differently, until entries and memory free up again.

Conserve or failopen mode

Once you reach the limit, depending on your FortiGate unit's conserve mode configuration, no new sessions are created until an old ones end. You can configure your FortiGate unit's behavior when memory is running low or the proxy connection limit has been reached. There are two related commands for this in the CLI:

```
config system global
   set av-failopen-session {enable | disable}
   set av-failopen { idledrop | off | one-shot | pass}
end
```

`av-failopen-session` must be enabled to set the behavior for these conditions. When it is enabled, and a proxy for a protocol runs out of room in its session table that protocol goes into failopen mode and behaves as defined in the `av-failopen` command.

`av-failopen` determines the behavior of the proxy until entries are free in the session table again for that proxy.

- **idledrop —** This option removes idle sessions from the session table, starting with the clients that have the most sessions currently open. This method assumes that idle sessions are not being used and it will not cause problems to close these sessions. This is usually true, but some applications may have problems with this and start complaining about either not having or being able to open a session. If this occurs, try another method to check if this is really the problem. This is a secure option as no unscanned traffic is allowed to pass.
- **off —** This option turns off accepting any new AV sessions, but will continue to process any existing AV sessions that are currently active. All the protocols listed (HTTP, SMTP, POP3, IMAP, FTP, and NNTP) are scanned by FortiGate Antivirus. If AV scanning is enabled, av-failopen off is selected, and the proxy session table fills up, then no new sessions of that type will be accepted. For example, if POP3 session table is filled and email AV scanning is enabled, no more POP3 connections will be allowed until the session table gets some free space. This is a secure option because no unscanned traffic is allowed to pass.
- **one-shot —** When memory is low, bypass the antivirus system. The name one-shot comes from the fact that once you are in one-shot av-failopen mode, you must set av-failopen to either *pass* or *off* to restart AV scanning. This is a very unsecure option because it allows all traffic without AV scanning, and it never reverts to normal without manual assistance.
- **pass —** When memory is low, bypass the antivirus system much as one-shot. The difference is that when memory is freed up, the system will start AV scanning automatically again. This is an unsecure option because it allows traffic to pass without AV scanning. However, it is better than one-shot because it automatically restarts AV scanning when possible.

If the proxy session table is full for one or more protocols and your FortiGate unit enters into conserve or failopen mode, it will appear as if you have lost connections, network services are intermittent or non-existent, and yet

other services work normally for a while until their sessions end and they join the queue of session-starved applications.

Checking sessions in use

To make troubleshooting this type of problem easier, sessions are broken down by which protocol they use. This provides you with statistics and errors specific to one of the protocols.

Due to the amount of output from this command, you should connect to the CLI with a terminal program, such as puTTY, that logs output. Otherwise, you will likely not be able to access all the output information from the command.

In the following output, only the HTTP entries are displayed. The other protocols have been removed in an attempt to shorten the output. There will be separate entries for each supported protocol (HTTP, SMTP, POP3, IMAP, FTP, and NNTP) in each section of the output.

To check sessions in use and related errors - CLI

```
FGT# # get test proxyworker 4

```

The output from this command falls into the following sections:

- **HTTP Common current connections —** There is an entry for each protocol that displays the connections currently used, and the maximum connections allowed. This maximum is for the UTM proxy, which means all the protocols connections combined cannot be larger than this number. To support this, note that the maximum session count for each protocol is the same. You may also see a line titled `Max Concurrent Connections` for each protocol. This number is the maximum connections of this type allowed at one time. If VDOMs are enabled, this value is defined either on the global or per-VDOM level at **VDOM > Global Resources**.
- **Worker Stat —** This is statistics about the UTM proxy including how long it has been running, and how many errors it has found.
- **HTTP Stat —** This section includes statistics about the HTTP protocol proxy. This is a very extensive list covering errors, web responses, and any UTM positive matches. There are similar sections for each protocol, but the specific entries in each vary based on what UTM scanning is looking for in each — spam control for email, file transfer blocking for FTP, and so on.
- **Worker Accounting —** Lists accounting information about the UTM proxy such as polling statistics, how many sessions were scanned, and how many were just accepted. This information can tell you if expect AV scanning is taking place or not. Under normal operation there should be no errors or fails.
- **HTTP Accounting —** The accounting sections for each protocol provide information about successful session creation, failures, how many sessions are being scanned or filtered, and how many are client or server originated. If setup_fail is larger than zero, run the command again to see if it is increasing quickly. If it is, your FortiGate unit may be in conserve mode.

Related commands

To dump memory usage:

```
# get test proxyworker 1
```

To display statistics per VDOM:

```
# get test proxyworker 4444
```

To restart the proxy:

```
# get test proxyworker 99
```

How to examine the firewall session list

One further step is to examine the firewall session. The firewall session list displays all the sessions the FortiGate unit has open. You will be able to see if there are strange patterns such as no sessions apart from the internal network, or all sessions are only to one IP address.

When examining the firewall session list in the CLI, filters may be used to reduce the output. In the web-based manager, the filters are part of the interface.

To examine the firewall session list - web-based manager

- Go to **System > FortiView> All Sessions**.

To examine the firewall session list - CLI

When examining the firewall session list, there may be too many sessions to display. In this case it will be necessary to limit or filter the sessions displayed by source or destination address, or NATed address or port. If you want to filter by more than one of these, you need to enter a separate line for each value.

The following example shows filtering the session list based on a source address of 10.11.101.112.

```
FGT# diag sys session filter src 10.11.101.112
FGT# diag sys session list
```

The following example shows filtering the session list based on a destination address of 172.20.120.222.

```
FGT# diag sys session filter dst 172.20.120.222
FGT# diag sys session list
```

To clear all sessions corresponding to a filter - CLI

```
FGT# diag sys session filter dst 172.20.120.222
FGT# diag sys session clear
```

Check source NAT information

Remember NAT when troubleshooting connections. NAT is especially important if you are troubleshooting from the remote end of the connection outside the FortiGate unit firewall. On the dashboard session list, pay attention to **Src address after NAT**, and **Src port after NAT**. These columns display the IP and port values after NAT has been applied.

The NAT values can be helpful to ensure they are the values you expect, and to ensure the remote end of the sessions can see the expected IP address and port number.

When displaying the session list in the CLI, you can match the NATed source address (`nsrc`) and port (`nport`). This can be useful if multiple internal IP addresses are NATed to a common external facing source IP address.

```
FGT# diag sys session filter nsrc 172.20.120.122
FGT# diag sys session filter nport 8888
FGT# diag sys session list
```

How to check wireless information

Wireless connections, stations, and interfaces have different issues than other physical interfaces.

Troubleshooting station connection issue

To check whether station entry is created on Access Control:

```
FG600B3909600253 # diagnose wireless-controller wlac -d sta
* vf=0 wtp=70 rId=2 wlan=open ip=0.0.0.0 mac=00:09:0f:db:c4:03 rssi=0 idle=148 bw=0 use=2
vf=0 wtp=70 rId=2 wlan=open ip=172.30.32.122 mac=00:25:9c:e0:47:88 rssi=-40 idle=0 bw=9
    use=2
```

Enable diagnostic for particular station

This example uses the station MAC address to find where it is failing:

```
FG600B3909600253 # diagnose wireless-controller wlac sta_filter 00:25:9c:e0:47:88 1
Set filter sta 00:25:9c:e0:47:88 level 1
```

```
FG600B3909600253 # 71419.245 <ih> IEEE 802.11 mgmt::disassoc <== 00:25:9c:e0:47:88 vap
    open rId 1 wId 0 00:09:0f:db:c4:03

    00:09:0f:db:c4:03 sec open reason I2C_STA_DEL
71419.247 <cc> STA_CFG_RESP(34) 00:25:9c:e0:47:88 <== ws (0-192.168.35.1:5246) rc 0
    (Success).
```

How to verify FortiGuard connectivity

You can verify the FortiGuard connectivity in the **License Information** widget under **System > Dashboard > Status.** When FortiGate is connected to FortiGuard, a green check mark appears for available FortiGuard services.

From CLI, execute ping “service.fortiguard.net” and “update.fortiguard.net”.

Sample output:

```
FG100D# execute ping service.fortiguard.net
PING guard.fortinet.net (208.91.112.196): 56 data bytes
64 bytes from 208.91.112.196: icmp_seq=0 ttl=51 time=61.0 ms
64 bytes from 208.91.112.196: icmp_seq=1 ttl=51 time=60.0 ms
64 bytes from 208.91.112.196: icmp_seq=2 ttl=51 time=59.6 ms
64 bytes from 208.91.112.196: icmp_seq=3 ttl=51 time=58.9 ms
64 bytes from 208.91.112.196: icmp_seq=4 ttl=51 time=59.2 ms

--- guard.fortinet.net ping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
round-trip min/avg/max = 58.9/59.7/61.0 ms

FG100D# execute ping update.fortiguard.net
PING fds1.fortinet.com (208.91.112.68): 56 data bytes
64 bytes from 208.91.112.68: icmp_seq=0 ttl=53 time=62.0 ms
64 bytes from 208.91.112.68: icmp_seq=1 ttl=53 time=61.8 ms
64 bytes from 208.91.112.68: icmp_seq=2 ttl=53 time=61.3 ms
64 bytes from 208.91.112.68: icmp_seq=3 ttl=53 time=61.9 ms
64 bytes from 208.91.112.68: icmp_seq=4 ttl=53 time=61.8 ms
```

How to perform a sniffer trace (CLI and Packet Capture)

When troubleshooting networks and routing in particular, it helps to look inside the headers of packets to determine if they are traveling along the expected route. Packet sniffing can also be called a network tap, packet capture, or logic analyzing.

If your FortiGate unit has NP2/NP4 interfaces that are offloading traffic, this will change the sniffer trace. Before performing a trace on any NP2/NP4 interfaces, you should disable offloading on those interfaces.

What can sniffing packets tell you

If you are running a constant traffic application such as ping, packet sniffing can tell you if the traffic is reaching the destination, what the port of entry is on the FortiGate unit, if the ARP resolution is correct, and if the traffic is

being sent back to the source as expected.

Sniffing packets can also tell you if the FortiGate unit is silently dropping packets for reasons such as Reverse Path Forwarding (RPF), also called Anti Spoofing, which prevents an IP packet from being forwarded if its Source IP does not either belong to a locally attached subnet (local interface), or be part of the routing between the FortiGate unit and another source (static route, RIP, OSPF, BGP). Note that RPF can be disabled by turning on asymmetric routing in the CLI (`config system setting, set asymetric enable`), however this will disable stateful inspection on the FortiGate unit and cause many features to be turned off.

If you configure virtual IP addresses on your FortiGate unit, it will use those addresses in preference to the physical IP addresses. You will notice this when you are sniffing packets because all the traffic will be using the virtual IP addresses. This is due to the ARP update that is sent out when the VIP address is configured.

How do you sniff packets

The general form of the internal FortiOS packet sniffer command is:

```
diag sniffer packet <interface_name> <'filter'> <verbose> <count>
```

To stop the sniffer, type `CTRL+C`.

<interface_name>	The name of the interface to sniff, such as "port1" or "internal". This can also be "any" to sniff all interfaces.
<'filter'>	What to look for in the information the sniffer reads. "none" indicates no filtering, and all packets will be displayed as the other arguments indicate. The filter must be inside single quotes (‘).
<verbose>	The level of verbosity as one of: **1 -** print header of packets **2 -** print header and data from IP of packets **3 -** print header and data from Ethernet of packets **4 -** print header of packets with interface name
<count>	The number of packets the sniffer reads before stopping. If you do not put a number here, the sniffer will run forever unit you stop it with <CTRL C>.

For a simple sniffing example, enter the CLI command `diag sniffer packet port1 none 1 3`. This will display the next three packets on the port1 interface using no filtering, and using verbose level 1. At this verbosity level you can see the source IP and port, the destination IP and port, action (such as ack), and sequence numbers.

In the output below, port 443 indicates these are HTTPS packets, and 172.20.120.17 is both sending and receiving traffic.

```
Head_Office_620b # diag sniffer packet port1 none 1 3
interfaces=[port1]
filters=[none]

0.545306 172.20.120.17.52989 -> 172.20.120.141.443: psh 3177924955 ack 1854307757
```

```
0.545963 172.20.120.141.443 -> 172.20.120.17.52989: psh 1854307757 ack 3177925808

0.562409 172.20.120.17.52988 -> 172.20.120.141.443: psh 4225311614 ack 3314279933
```

For a more advanced example of packet sniffing, the following commands will report packets on any interface travelling between a computer with the host name of “PC1” and the computer with the host name of “PC2”. With verbosity 4 and above, the sniffer trace will display the interface names where traffic enters or leaves the FortiGate unit. Remember to stop the sniffer, type `CTRL+C`.

```
FGT# diagnose sniffer packet any "host <PC1> or host <PC2>" 4
```

or

```
FGT# diagnose sniffer packet any "(host <PC1> or host <PC2>) and icmp" 4
```

The following sniffer CLI command includes the ARP protocol in the filter which may be useful to troubleshoot a failure in the ARP resolution (for instance PC2 may be down and not responding to the FortiGate ARP requests).

```
FGT# diagnose sniffer packet any "host <PC1> or host <PC2> or arp" 4
```

Packet Capture

When troubleshooting networks, it helps to look inside the header of the packets. This helps to determine if the packets, route, and destination are all what you expect. Packet capture can also be called a network tap, packet sniffing, or logic analyzing.

To use the packet capture:

1. Go to **System > Network > Packet Capture**.
2. Select the interface to monitor and select the number of packets to keep.
3. Select **Enable Filters**.
4. Enter the information you want to gather from the packet capture.
5. Select **OK**.

To run the capture, select the **play** button in the progress column in the packet capture list. If not active, **Not Running** will also appear in the column cell. The progress bar will indicate the status of the capture. You can stop and restart it at any time.

When the capture is complete, click the **Download** icon to save the packet capture file to your hard disk for further analysis.

Packet capture tells you what is happening on the network at a low level. This can be very useful for troubleshooting problems, such as:

- Finding missing traffic.
- Seeing if sessions are setting up properly.
- Locating ARP problems such as broadcast storm sources and causes.
- Confirming which address a computer is using on the network if they have multiple addresses or are on multiple networks.
- Confirming routing is working as you expect.
- Wireless client connection problems.
- Intermittent missing PING packets.
- A particular type of packet is having problems, such as UDP, which is commonly used for streaming video.

If you are running a constant traffic application such as ping, packet capture can tell you if the traffic is reaching the destination, how the port enters and exits the FortiGate unit, if the ARP resolution is correct, and if the traffic is returning to the source as expected. You can also use packet switching to verify that NAT or other configuration is translating addresses or routing traffic the way that you want it to.

Before you start capturing packets, you need to have a good idea of what you are looking for. Capture is used to confirm or deny your ideas about what is happening on the network. If you try capture without a plan to narrow your search, you could end up with too much data to effectively analyze. On the other hand, you need to capture enough packets to really understand all of the patterns and behavior that you are looking for.

How to debug the packet flow

Traffic should come in and leave the FortiGate unit. If you have determined that network traffic is not entering and leaving the FortiGate unit as expected, debug the packet flow.

Debugging can only be performed using CLI commands. Debugging the packet flow requires a number of debug commands to be entered as each one configures part of the debug action, with the final command starting the debug.

If your FortiGate unit has FortiASIC NP4 interface pairs that are offloading traffic, this will change the packet flow. Before performing the debug on any NP4 interfaces, you should disable offloading on those interfaces.

The following configuration assumes that PC1 is connected to the internal interface of the FortiGate unit and has an IP address of 10.11.101.200. PC1 is the host name of the computer.

To debug the packet flow in the CLI, enter the following commands:

```
FGT# diag debug disable
FGT# diag debug flow filter add <PC1>
FGT# diag debug flow show console enable
FGT# diag debug flow show function-name enable
FGT# diag debug flow trace start 100
FGT# diag debug enable
```

The `start 100` argument in the above list of commands will limit the output to 100 packets from the flow. This is useful for looking at the flow without flooding your log or displaying too much information.

To stop all other debug activities, enter the command:

```
FGT# diag debug flow trace stop
```

The following is an example of debug flow output for traffic that has no matching security policy, and is in turn blocked by the FortiGate unit. The denied message indicates that the traffic was blocked.

```
id=20085 trace_id=319 func=resolve_ip_tuple_fast line=2825 msg="vd-root received a packet
    (proto=6, 192.168.129.136:2854->192.168.96.153:1863) from port3."

```

Troubleshooting resources

Before you begin troubleshooting, you need to know Fortinet's troubleshooting resources. Doing so will shorten the time to solve your issue. Indeed, an administrator can save time and effort during the troubleshooting process by first checking if the issue has been experienced before. Several self-help resources are available to provide valuable information about FortiOS technical issues, including:

Technical Documentation

Installation Guides, Administration Guides, Quick Start Guides, and other technical documents are available online at the following URL:

http://docs.fortinet.com

Fortinet Video Library

The Fortinet Video Library hosts a collection of video which provide valuable information about Fortinet products.

http://video.fortinet.com

Release Notes

Issues that are uncovered after the technical documentation has been published will often be listed in the Release Notes that accompany the device.

Knowledge Base

The Fortinet Knowledge Base provides access to a variety of articles, white papers, and other documentation providing technical insight into a range of Fortinet products. The Knowledge Base is available online at the following URL:

http://kb.fortinet.com

Fortinet Technical Discussion Forums

An online technical forums allow administrators to contribute to discussions about issues related to their Fortinet products. Searching the forum can help the administrator identify if an issue has been experienced by another user. The support forums can be accessed at the following URL:

http://forum.fortinet.com

Fortinet Training Services Online Campus

The Fortinet Training Services Online Campus hosts a collection of tutorials and training materials which can be used to increase knowledge of the Fortinet products.

http://www.fortinet.com/training/

Fortinet Customer Support

You have defined your problem, researched a solution, put together a plan to find the solution, and executed that plan. At this point if the problem has not been solved, its time to contact Fortinet Customer Support for assistance.

http://support.fortinet.com

Technical Support Organization Overview

This section explains how Fortinet's technical support works, as well as how you can easily create an account to get technical support for when issues arise that you cannot solve yourself.

This section contains the following topics:

- Fortinet Global Customer Services Organization
- Creating an account
- Registering a device
- Reporting problems
- Assisting technical support
- Support priority levels
- Return material authorization process

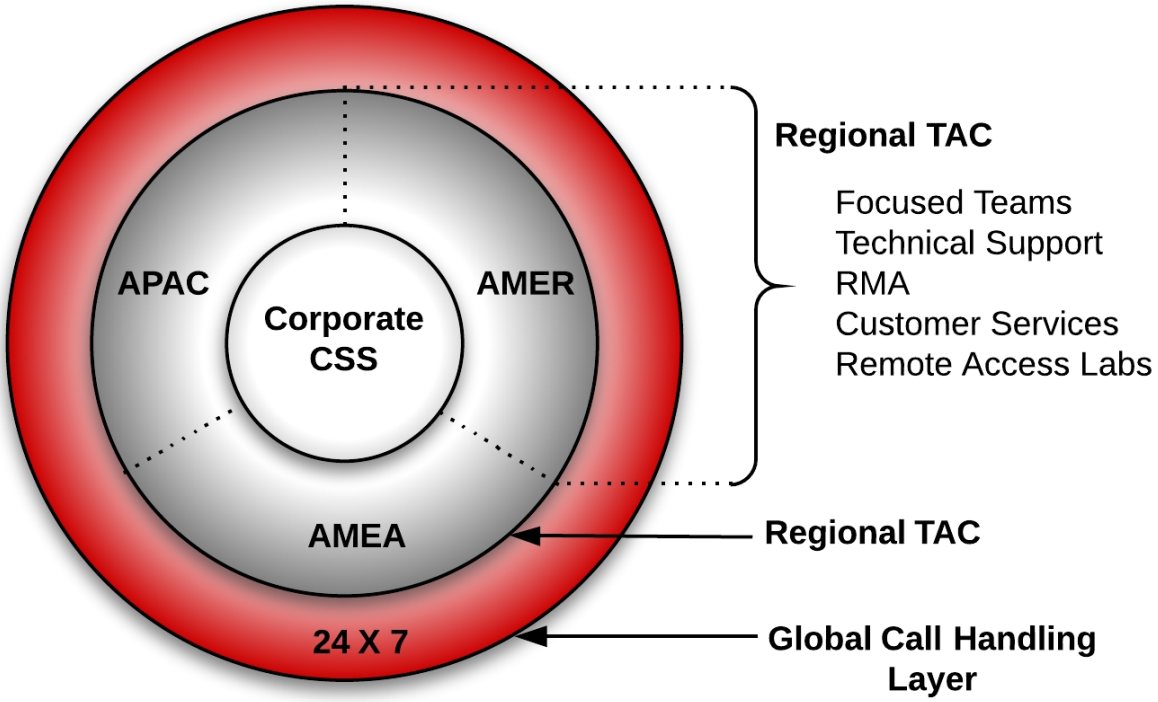
Fortinet Global Customer Services Organization

The Fortinet Global Customer Services Organization is composed of three regional **Technical Assistance Centers** (TAC):

- The Americas (AMER)
- Europe, Middle East, and Africa (EMEA)
- Asia Pacific (APAC)

The regional TACs are contacted through a global call center. Incoming service requests are then routed to the appropriate TAC. Each regional TAC delivers technical support to the customers in its regions during its hours of operation. These TACs also combine to provide seamless, around-the-clock support for all customers.

Fortinet regions and TAC



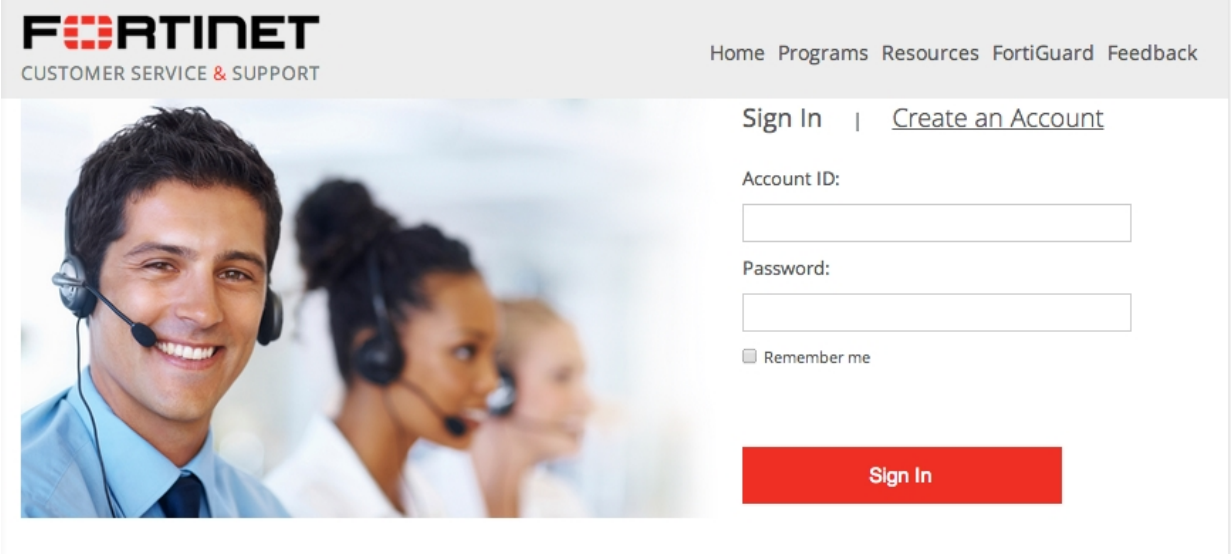
Creating an account

To receive technical support and service updates, Fortinet products in the organization must be registered. The **Product Registration Form** on the support website will allow the registration to be completed online. Creating an account on the support website is the first step in registering products.

Go to the Fortinet support site shown below:

https://support.fortinet.com/

Customer service and support home page



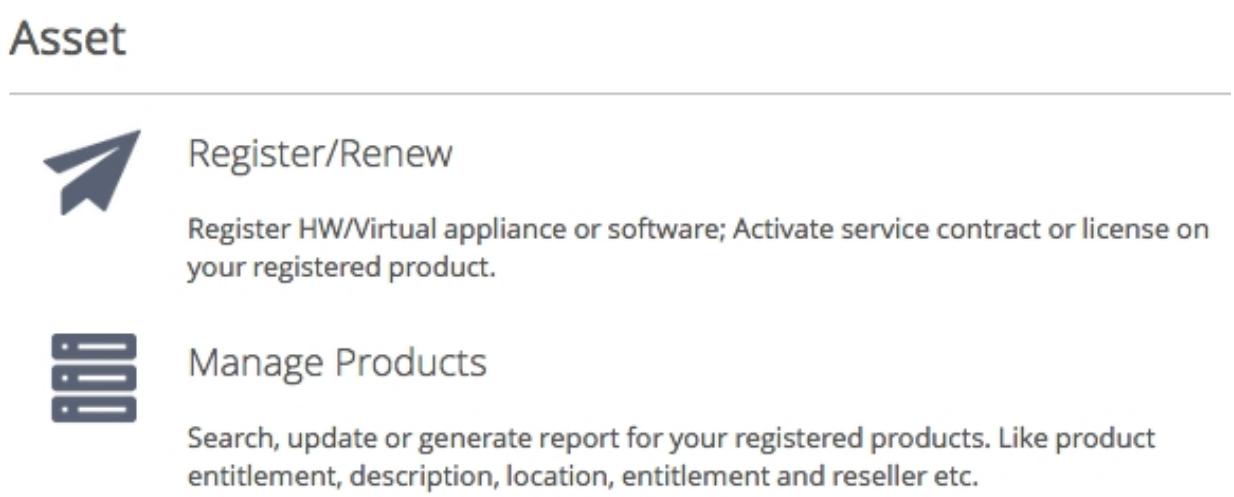
Once the support account has been created, product details can be provided by going to the **Product Register/Renew** and **Manage Product** buttons displayed on the home page. Alternately, the product registration can be completed at a later time.

Registering a device

Complete the following steps when registering a device for support purposes:

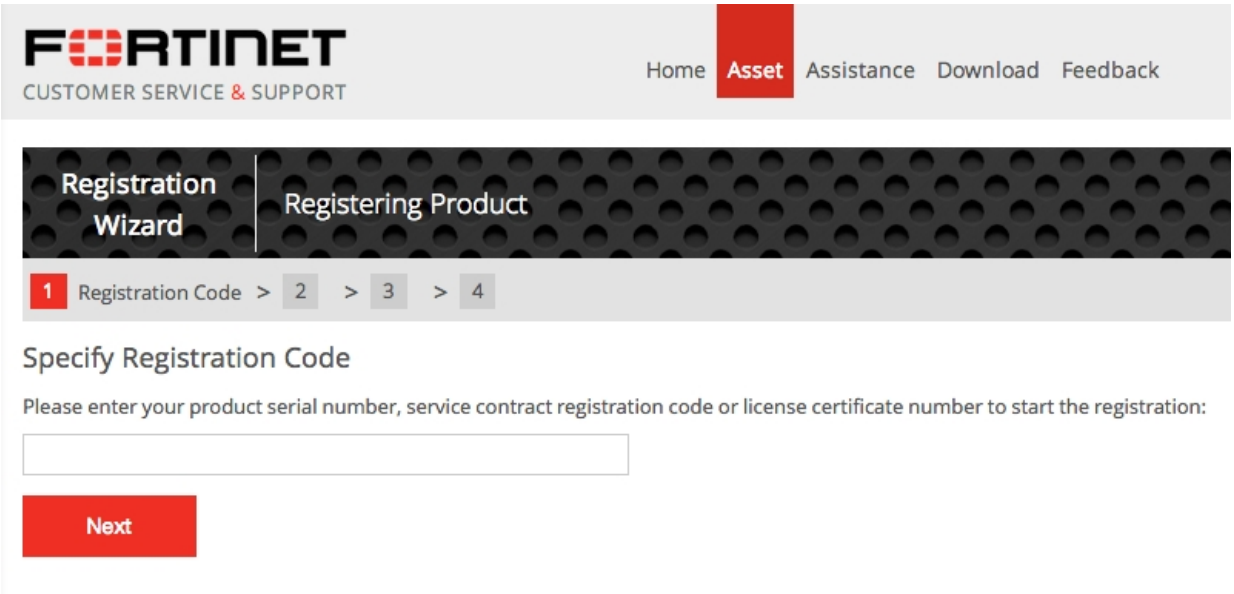
1. Log in using the **Username** and **Password** defined when the account was created
2. Under the Asset section, select **Register/Renew** to go to the Registration Wizard. Alternatively, use the Asset menu at the top of the page.

Register/Renew and Manage Products menu



3. Get a serial number from the back of the FortiGate unit or from the exterior of the FortiGate shipping box.
4. Enter the serial number, service contract registration code or license certificate number to start the product registration.

Adding a product to a support account



5. Enter your registration information.
6. Read and accept the license agreement.
7. Complete the verification process.
8. Select **Finish** to complete the registration process.
9. Registration wizard

Reporting problems

Problems can be reported to a Fortinet Technical Assistance Center in the following ways:

- By logging an online ticket
- By phoning a technical support center

Logging online tickets

Problem reporting methods differ depending on the type of customer.

Fortinet partners

Fortinet Partners are entitled to priority web-based technical support. This service is designed for partners who provide initial support to their customers and who need to open a support ticket with Fortinet on their behalf. We strongly encourage submission and follow up of support tickets using this service.

The support ticket can be submitted after logging into the partner website using one of the following links using FortiPartner account details:

http://partners.fortinet.com

This link will redirect to the general **Fortinet Partner Portal** extranet website. Click **Support** > **Online Support Ticket**.

https://forticare.fortinet.com/customersupport/Login/CommonLogin.aspx

Fortinet customers

There are two methods to report a technical issue on the Fortinet Support website: creating a technical support ticket by product or creating any type of ticket with the Ticket Wizard for more options.

Fortinet customers should complete the following steps to create a support ticket by product:

1. Log in to the support website at the following address with the account credentials used when the account was created: https://support.fortinet.com
2. Navigate to the top menu, click **Asset** and select **Manage/View Products.**
3. In the product list, select the product that is causing the problem.
4. On the left side bar, go to the Assistance category, and select **Technical Request** to create a TA Ticket.
5. Complete the **Create TA Ticket** fields.
6. Click **View Products**.
7. In the **Products List**, select the product that is causing the problem.
8. Complete the **Create Support Ticket** fields.
9. Select **Finish** to complete the support ticket.

Fortinet customers who would like to submit a customer service ticket, DOA ticket, RMA ticket, or FortiGuard service ticket should use the Ticket Wizard and complete the following steps:

1. Log in to the support website at the following address with the account credentials used when the account was created: https://support.fortinet.com
2. Navigate to the top menu, click **Assistance** and select **Create a Ticket** from the drop down menu.
3. Select a ticket type and complete the remaining steps in the Ticket Wizard.
4. Select **Finish** to complete the ticket.

Following up on online tickets

Perform the following steps to follow up on an existing issue.

Partners should log into the following web site:

http://partners.fortinet.com

Customers should log into the following site:

http://support.fortinet.com

1. Log in with the account credentials used when the account was created.
2. Navigate to the top menu, click **Assistance**, and select **Manage Tickets**.
3. Use the search field on the View Tickets page to locate the tickets assigned to the account.
4. Select the appropriate ticket number. Closed tickets cannot be updated. A new ticket must be submitted if it concerns the same problem.

5. Add a **New Comment** or **Attachment**.
6. Click **Submit** when complete.

Every web ticket update triggers a notification to the ticket owner, or ticket queue supervisor.

Telephoning a technical support center

The Fortinet Technical Assistance Centers can also be contacted by phone.

Call Fortinet Support Center at 1-408-486-7899 (international) or go to http://www.fortinet.com/support/contact_support.html and select your country from the drop-down list for local contact number.

Assisting technical support

The more information that can be provided to Fortinet technical support, the better they can assist in resolving the issue. Every new support request should contain the following information:

- A valid contact name, phone number, and email address.
- A clear and accurate problem description.
- A detailed network diagram with complete IP address schema.
- The configuration file, software version, and build number of the Fortinet device.
- Additional log files such as **Antivirus** log, **Attack** log, **Event** log, **Debug** log or similar information to include in the ticket as an attachment. If a third-party product is involved, for example, email server, FTP server, router, or switch, please provide the information on its software revision version, configuration, and brand name.

Support priority levels

Fortinet technical support assigns the following priority levels to support cases:

Priority 1

This **Critical** priority is assigned to support cases in which:

- The network or system is down causing customers to experience a total loss of service.
- There are continuous or frequent instabilities affecting traffic-handling capability on a significant portion of the network.
- There is a loss of connectivity or isolation to a significant portion of the network.
- This issue has created a hazard or an emergency.

Priority 2

This **Major** priority is assigned to support cases in which:

- The network or system event is causing intermittent impact to end customers.
- There is a loss of redundancy.
- There is a loss of routine administrative or diagnostic capability.
- There is an inability to deploy a key feature or function.
- There is a partial loss of service due to a failed hardware component.

Priority 3

This **Medium** priority is assigned to support cases in which:

- The network event is causing only limited impact to end customers.
- Issues seen in a test or pre-production environment exist that would normally cause adverse impact to a production network.
- The customer is making time sensitive information requests.
- There is a successful workaround in place for a higher priority issue.

Priority 4

This **Minor** priority is assigned to support cases in which:

- The customer is making information requests and asking standard questions about the configuration or functionality of equipment.

Customers must report Priority 1 and 2 issues by phone directly to the Fortinet EMEA Support Center.

For lower priority issues, you may submit an assistance request (ticket) via the web system.

The web ticket system also provides a global overview of all ongoing support requests.

Return material authorization process

In some cases hardware issues are experienced and a replacement unit must be sent. This is referred to as a Return Material Authorization (RMA). In these cases or RMAs, the support contract must be moved to the new device. Customers can move the support contract from the failing production unit to the new device through the support web site.

To move the support contract to a new device

1. Log in to the support web site with the credentials indicated when the account was created.
2. From **Manage Products**, locate the serial number of the defective unit from the list of devices displayed for the account. The **Product Info** for the selected device will be displayed.
3. In the left side bar under the **Assistance section**, select **RMA Transfer**.
4. Enter the **Original Serial Number** of the original device, enter the **New Serial Number,** and click **Replace** to complete the transfer.

This will transfer the support contract from the defective unit to the new unit with the serial number provided.

Chapter 33 - Virtual Domains

- Virtual Domains in NAT/Route mode: detailed explanations and examples for configuring VDOM features for a FortiGate in NAT/Route mode.
- Virtual Domains in Transparent modedetailed explanations and examples for configuring VDOM features for a FortiGate in Transparent mode.
- Inter-VDOM routing: concepts and scenarios for inter-VDOM routing.
- Troubleshooting Virtual Domains: diagnostic and troubleshooting information for some potential VDOM issues.

Before you begin using this guide, take a moment to note the following:

- By default, most FortiGate units support 10 VDOMs. Many FortiGate models support purchasing a license key to increase the maximum number
- This guide uses a FortiGate unit with interfaces named port1 through port4 for examples and procedures. The interface names on some models will vary. Where possible aliases for these ports are indicated to show their intended purpose and to help you determine which ports to use if your ports are labelled differently.
- Administrators are assumed to be super_admin administrators unless otherwise specified. Some restrictions will apply to other administrators.

What's new in FortiOS 5.4

The following new features have been added for Virtual Domains (VDOMs) in FortiOS 5.4:

- Stackable VDOM licenses
- Support execution of global CLI commands from within VDOMs
- GUI features can now be enabled and disabled per VDOM
- Improvements and changes to per-VDOM certificates
- Adding option for VDOM logs through management VDOM

Stackable VDOM licenses

VDOM licenses are now stackable, allowing you to buy additional licenses and stack them on top existing licenses to increase the number of VDOMs you can have.

Support execution of global CLI commands from within VDOMs

A new CLI command, `sudo`, allows the running of global commands from within the vdom context of the CLI.This means that the user no longer has to:

1. exit from the VDOM
2. enter global
3. run the command
4. return to the previous VDOM

The syntax for the command is:

```
sudo {global | vdom-name} {diagnose | execute | show | get}
```

These commands will only work if the user already has permissions to run the command. Unlike the the sudo command in some other operating systems like Linux, this command does not allow the user to run programs with the privileges of another user.

GUI features can now be enabled and disabled per VDOM

When VDOMs are enabled, most of the items in the Features section of the menu are moved to a similar menu section within the VDOM menu and are now customizable on a per VDOM basis. Some items such as IPv6 and Certificates are still configured on a global basis.

From the GUI, you can enable or disable GUI features from **System > Feature Select**.

Improvements and changes to per-VDOM certificates

The CA and local certificate configuration is now available per-VDOM. When an admin uploads a certificate to a VDOM, it will only be accessible inside that VDOM. When an admin uploads a certificate to global, it will be accessible to all VDOMs and global.

There are factory default certificates such as Fortinet_CA_SSL, Fortinet_SSL, PositiveSSL_CA, Fortinet_Wifi, and Fortinet_Factory, these certificates are moved to per-VDOM and automatically generated when a new VDOM is created.

The Fortinet_Firmware certificate has been removed and all the attributes that use Fortinet_Firmware now use Fortinet_Factory.

CLI Changes

Two new attributes `range` and `source` have been added:

`range` can be global or per-VDOM, if the certificate file is imported from global, it is a global certificate. If the certificate file is imported from a VDOM, it is VDOM certificate.

`source` can be `factory`, `user` or `fortiguard`:

`factory`: The factory certificate file with FortiOS version, this includes: Fortinet_CA_SSL, Fortinet_SSL, PositiveSSL_CA, Fortinet_Wifi, Fortinet_Factory.

`user`: Certificate file imported by the user.

`fortiguard`: Certificate file imported from FortiGuard.

```
config certificate local
   edit Fortinet_Factory
```

```
        set range global/vdom
        set source factory/user/fortiguard
    end
end
```

GUI Changes

Global and per-VDOM certificate configuration includes **view details**, **download**, **delete**, and **import** certificate.

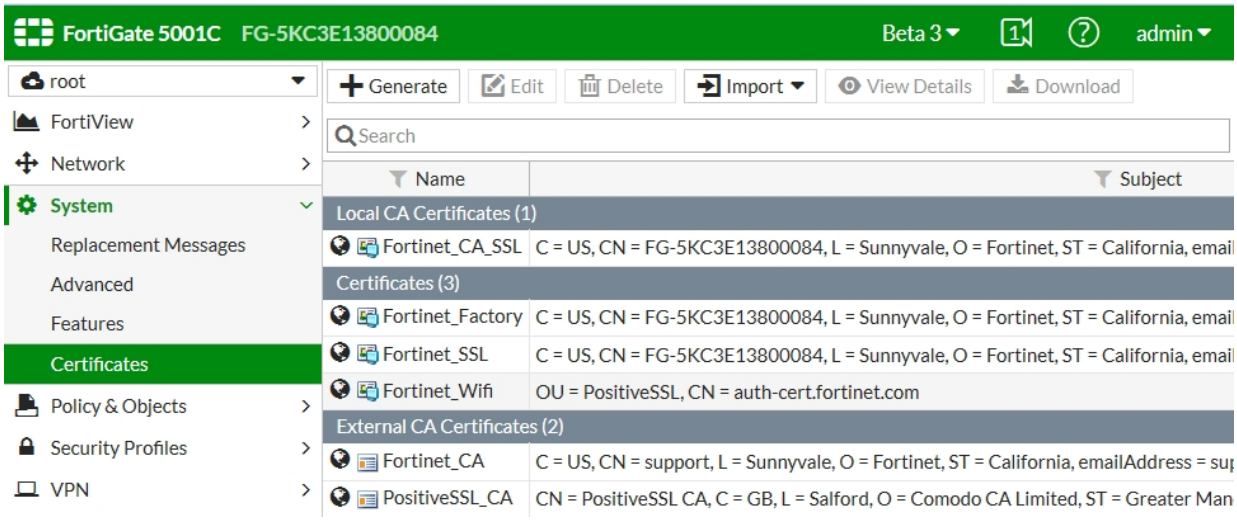
A **Source** and a **Status** columns have been added.

A global icon for **Name** column when VDOMs are enabled is added to show that the certificate is global.

A new VDOM now has the following default certificates: Fortinet_CA_SSL, Fortinet_Factory, Fortinet_SSL, Fortinet_Wifi, Fortinet_CA, and PositiveSSL_CA. These certificates are created automatically when the VDOM is created and every VDOM will have its own individual versions of these certificates.

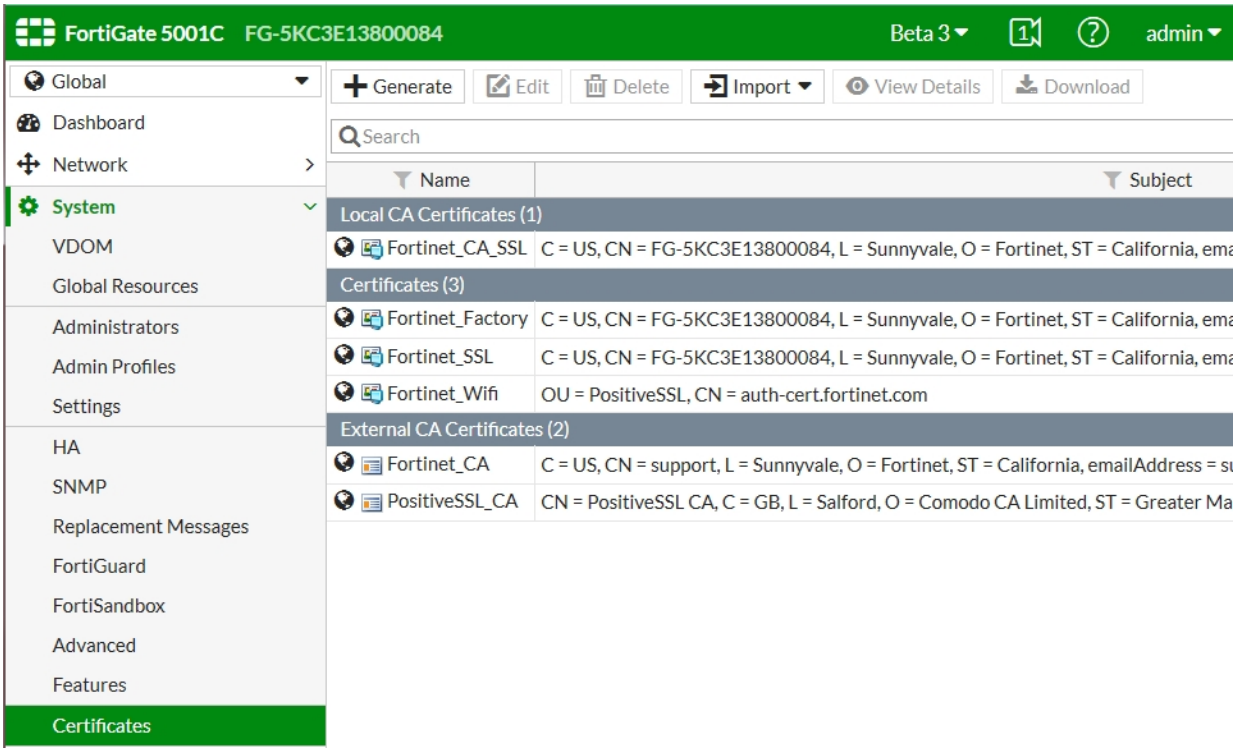
The Fortinet_firmware certificate has been removed. All default configurations that formerly used the Fortinet_ firmware certificate now use the Fortinet_Factory certificate.

Default root VDOM certificates



Certificates with the same names are also available from the global configuration. These are generated with you turn on VDOMs.

Default global certificates



Adding certificates to VDOMs and to the global configuration

If an administrator adds a certificate to a VDOM the certificate will only be available for that VDOM. If an administrator adds a certificate to the global configuration it will available for all VDOMs.

Adding option for VDOM logs through management VDOM

FortiOS supports the definition of per VDOM FortiAnalyzers. However it is required that each VDOM logs independently to its FortiAnalyzer server.

A new option, `use-management-vdom`, has been added to the CLI.

```
config vdom
   edit xxx
      config log fortianalyzer override-setting
         set use-management-vdom enable/disable
      end
   end
end
```

If this option is enabled, source-ip will become hidden and when FortiGate sends logs to FortiAnalyzer, it uses management vdom ip setting as source ip. Also if IPsec is enabled, the tunnel is created in management vdom and source ip belongs to management vdom.

Virtual Domains Overview

Virtual domains (VDOMs) are a method of dividing a FortiGate unit into two or more virtual units that function as multiple independent units. VDOMs can provide separate firewall policies and, in NAT/Route mode, completely separate configurations for routing and VPN services for each connected network or organization.

This chapter will cover the basics of VDOMs, how they change your FortiGate unit, and how to work with VDOMs.

VDOMs let you split your physical FortiGate unit into multiple virtual units. The resulting benefits range from limiting Transparent mode ports to simplified administration, to reduced space and power requirements.

In FortiOS 5.4.1, multiple VDOM support is disabled when Cooperative Security Fabric is enabled.

When VDOMs are disabled on any FortiGate unit, there is still one VDOM active: the root VDOM. It is always there in the background. When VDOMs are disabled, the root VDOM is not visible but it is still there.

The root VDOM must be there because the FortiGate unit needs a management VDOM for management traffic among other things. It is also why when you enable VDOMs, all your configuration is preserved in the root VDOM- because that is where you originally configured it.

This section includes:

- Benefits of Virtual Domains
- Enabling and accessing Virtual Domains
- Configuring Virtual Domains

Benefits of Virtual Domains

VDOMs provide the following benefits:

- Easier administration
- Continued security
- Savings in physical space and power
- Improving Transparent mode configuration
- More flexible MSSP configurations

Easier administration

VDOMs provide separate security domains that allow separate zones, user authentication, firewall policies, routing, and VPN configurations. VDOMs separate security domains and simplify administration of complex configurations—you do not have to manage as many settings at one time.

By default, each FortiGate unit has a VDOM named root. This VDOM includes all of the unit's physical interfaces, modem, VLAN subinterfaces, zones, firewall policies, routing settings, and VPN settings.

Also, you can optionally assign an administrator account restricted to one VDOM. If the VDOM is created to serve an organization, this feature enables the organization to manage its own configuration.

In order to connect to a VDOM, an admin must log in using an interface belonging to that VDOM. This allows for proper authentication and restricts that admin's access to a single VDOM.

Each physical FortiGate unit requires a FortiGuard license to access security updates. VDOMs do not require any additional FortiGuard licenses, or updating — all the security updates for all the VDOMs are performed once per update at the global level. Combined this can be a potentially large money and time saving feature in your network.

Management systems such as SNMP, logging, alert email, FDN-based updates, and NTP-based time setting use addresses and routing in the management VDOM to communicate with the network. They can connect only to network resources that communicate with the management VDOM. Using a separate VDOM for management traffic enables easier management of the FortiGate unit global settings, and VDOM administrators can also manage their VDOMs more easily.

Continued security

When a packet enters a VDOM, it is confined to that VDOM and is subject to any firewall policies for connections between VLAN subinterfaces or zones in that VDOM, just like those interfaces on a FortiGate unit without VDOMs enabled.

To travel between VDOMs, a packet must first pass through a firewall policy on a physical interface. The packet then arrives at another VDOM on that same FortiGate unit, but on a different interface, where it must pass through another firewall before entering. It doesn't matter if the interface is physical or virtual — inter-VDOM packets still require the same security measures as when passing through physical interfaces.

VDOMs provide an additional level of security because regular administrator accounts are specific to one VDOM — an administrator restricted to one VDOM cannot change information on other VDOMs. Any configuration changes and potential errors will apply only to that VDOM and limit any potential down time. Using this concept, you can farther split settings so that the management domain is only accessible by the super_admin and does not share any settings with the other VDOMs.

Savings in physical space and power

To increase the number of physical FortiGate units, you need more rack space, cables, and power to install the new units. You also need to change your network configuration to accommodate the new physical units. In the future, if you need fewer physical units you are left with expensive hardware that is idle.

Increasing VDOMs involves no additional hardware, no additional cabling, and very few changes to existing networking configurations. VDOMs save physical space and power. You are limited only by the size of the VDOM license you buy and the physical resources on the FortiGate unit.

For example, if you are using one FortiGate 620B unit with 10 VDOMs instead of 10 physical units, over a year you will save an estimated 18,000 kWh. You could potentially save ten times that amount with a 100 VDOM license.

By default, most FortiGate units support 10 VDOMs. Many FortiGate models support purchasing a license key to increase the maximum number.

Improving Transparent mode configuration

When VDOMs are not enabled and you put your FortiGate unit into Transparent mode, all the interfaces on your unit become broadcast interfaces. The problem with this is that there are no interfaces free to do anything else.

With multiple VDOMs you can have one of them configured in Transparent mode, and the rest in NAT/Route mode. In this configuration, you have an available transparent mode FortiGate unit you can drop into your network for troubleshooting, and you also have the standard NAT for networking.

More flexible MSSP configurations

If you are a managed security and service provider (MSSP), VDOMs are fundamental to your business. As a service provider you have multiple customers, each with their own needs and service plans. VDOMs allow you to have a separate configuration for each customer, or group of customers; with up to 500 VDOMs configured per FortiGate unit on high end models.

Not only does this provide the exact level of service needed by each customer, but administration of the FortiGate unit is easier as well - you can provide uninterrupted service generally with immediate changes as required. Most importantly, it allows you to only use the resources that each customer needs. Inter-VDOM links allow you to customize the level of interaction you need between each of your customers and your administrators.

Enabling and accessing Virtual Domains

While Virtual Domains are essentially the same as your regular FortiGate unit for menu configuration, CLI command structure, and general task flow, there are some small differences.

After first enabling VDOMs on your FortiGate unit, you should take the time to familiarize yourself with the interface. This section will help walk you through virtual domains.

This section includes:

- Enabling Virtual Domains
- Viewing the VDOM list
- Global and per-VDOM settings
- Resource settings
- Virtual Domain Licensing
- Logging in to VDOMs

Enabling Virtual Domains

Using the default admin administration account, you can enable or disable VDOM operation on the FortiGate unit.

To enable VDOM configuration - web-based manager:

1. Log in with a super_admin account.
2. Go to the **Dashboard**.
3. In the **System Information** widget, locate **Virtual Domain**. Select **Enable** and confirm your selection.

The FortiGate unit logs off all sessions. You can now log in again as admin.

To enable VDOM configuration - CLI:

```
config system global
   set vdom-admin enable
end
```

Changes to the web-based manager and CLI

When Virtual Domains are enabled, your FortiGate unit will change. The changes will be visible in both the web-based manager and CLI, just the web-based manager, or just the CLI.

When enabling VDOMs, the web-based manager and the CLI are changed as follows:

- Global and per-VDOM configurations are separated. This is indicated in the Online Help by Global and VDOM icons.
- Only admin accounts using the super_admin profiles can view or configure global options
- Admin accounts using the super_admin profile can configure all VDOM configurations.
- All other administrator accounts can configure only the VDOM to which they are assigned.

The following changes are specific to the web-based manager:

- In the Global view, the System section of the left-hand menu is renamed to Global, and includes a VDOM sub-menu.
- The Log Config menu is moved from Log & Report into the new Global section.
- For admin accounts using the super_admin profile, a new section called Virtual Domains is added at the bottom of the left-hand menu. It lists all the individual VDOMs as expandable menus, with all VDOM specific options in that menu, which allows you to easily select which VDOM to configure, including the root VDOM.

In the CLI, admin accounts using the super_admin profile must specify either the global or a VDOM-specific shell before entering commands:

- To change FortiGate unit system settings, from the top level you must first enter the following CLI before entering commands:

```
config global
```

- To change VDOM settings, from the top level you must first enter the following CLI before entering commands for that VDOM:

```
config vdom
   edit <vdom_name>
```

Settings configured outside of a VDOM are called global settings. These settings affect the entire FortiGate unit and include areas such as interfaces, HA, maintenance, some antivirus settings, and some logging settings. In general, any unit settings that should only be changed by the top level administrator are global settings.

Settings configured configwithin a VDOM are called VDOM settings. These settings affect only that specific VDOM and include areas such as operating mode, routing, firewall, VPN, some antivirus, some logging, and reporting.

Viewing the VDOM list

The VDOM list shows all virtual domains, their status, and which VDOM is the management VDOM. It is accessible if you are logged in on an administrator account with the super_admin profile such as the “admin” administrator account.

In the VDOM list you can create or delete VDOMs, edit VDOMs, change the management VDOM, and enable or disable VDOMs.

You can access the VDOM list when viewing by going to **Global > System > VDOM**.

The root domain cannot be disabled, even if it is not the management VDOM.

Global and per-VDOM settings

Settings configured outside of a VDOM are called global settings. These settings affect the entire FortiGate unit and include areas such as interfaces, HA, maintenance, some antivirus, and some logging. In general, any unit settings that should only be changed by the top level administrator are global settings.

Settings configured within a VDOM are called VDOM settings. These settings affect only that specific VDOM and include areas such as operating mode, routing, firewall, VPN, some antivirus, some logging settings, and reporting.

When Virtual Domains are not enabled, the entire FortiGate unit is effectively a single VDOM. Per-VDOM limits apply. For some resource types, the global limit cannot be reached with only one VDOM.

Resource settings

Your FortiGate unit has a limited amount of hardware resources such as memory, disk storage, CPU operations. When Virtual Domains are disabled, this limit is not a major concern because all sessions, users, and other processes share all the resources equally.

When using Virtual Domains, hardware resources can be divided differently between Virtual Domains as they are needed. Minimum levels of resources can be specified for each VDOM, so that no Virtual Domain will suffer a complete lack of resources.

For example, if one VDOM has only a web server and logging server connected, and a second VDOM has an internal network of 20 users, these two VDOMs will require different levels of resources. The first VDOM will require many sessions but no user accounts. This compares to the second VDOM where user accounts and management resources are required, but fewer sessions.

Using the global and per-VDOM resource settings, you can customize the resources allocated to each VDOM to ensure the proper level of service is maintained on each VDOM.

Global resource settings

Global Resources apply to the whole FortiGate unit. They represent all of the hardware capabilities of your unit. By default the values are set to their maximum values. These values vary by your model due to each model having differing hardware capabilities.

It can be useful to change the maximum values for some resources to ensure there is enough memory available for other resources that may be more important to your configuration.

To use the earlier example, if your FortiGate unit is protecting a number of web servers and other publicly accessible servers you would want to maximize the available sessions and proxies while minimizing other settings that are unused such as user settings, VPNs, and dial-up tunnels.

Global Resources are only configurable at the global level, and only the admin account has access to these settings. To view the resource list, go to **Global > System > Global Resources**. You can also use the following CLI command:

```
config global
   config system resource-limits
   get
```

Note that global resources, such as the log disk quota resource, will only be visible if your FortiGate unit hardware supports those resources, such as having a hard disk to support the log disk resource.

For explicit proxies, when configuring limits on the number of concurrent users, you need to allow for the number of users based on their authentication method. Otherwise you may run out of user resources prematurely.

Each session-based authenticated user is counted as a single user using their authentication membership (RADIUS, LDAP, FSAE, local database etc.) to match users in other sessions. So one authenticated user in multiple sessions is still one user.

For all other situations, the source IP address is used to determine a user. All sessions from a single source address are assumed to be from the same user.

Per-VDOM resource settings

While Global resources apply to resources shared by the whole FortiGate unit, per-VDOM resources are specific to only one Virtual Domain.

By default all the per-VDOM resource settings are set to no limits. This means that any single VDOM can use up all the resources of the entire FortiGate unit if it needs to do so. This would starve the other VDOMs for resources to the point where they would be unable to function. For this reason, it is recommended that you set some maximums on resources that are most vital to your customers.

Each Virtual Domain has its own resource settings. These settings include both maximum, and minimum levels. The maximum level is the highest amount of that resource that this VDOM can use if it is available on the FortiGate unit. Minimum levels are a guaranteed level that this minimum level of the resource will always be available no matter what the other VDOMs may be using.

For example, consider a FortiGate unit that has ten VDOMs configured. vdom1 has a maximum of 5000 sessions and a minimum of 1000 sessions. If the FortiGate unit has a global maximum of 20,000 sessions, it is possible that vdom1 will not be able to reach its 5000 session upper limit. However, at all times vdom1 is guaranteed to have 1000 sessions available that it can use. On the other hand, if the remaining nine VDOMs use only 1000 sessions each, vdom1 will be able to reach its maximum of 5000.

To view per-VDOM resource settings - web-based manager:

1. Select **Global > System > VDOM**.
2. Select the `root` VDOM, and select **Edit**.
3. Adjust the settings in the **Resource Usage** section of the page.
4. Select **OK**.

To view per-VDOM resource settings - CLI:

```
config global
   config system vdom-property
      edit root
   get
```

Virtual Domain Licensing

For select FortiGate models in the 1U category and higher, you can purchase a license key to increase the maximum number of VDOMs. Most Enterprise and Large Enterprise (2U) models can support up to 500 VDOMs. Chassis-based models can support over 500 VDOMs. For specific information, see the product data sheet.

Configuring 500 or more VDOMs will result in reduced system performance. See Troubleshooting Virtual Domains.

Your FortiGate unit has limited resources that are divided among all configured VDOMs. These resources include system memory and CPU. Running security features on many VDOMs at once can limit resources available for basic processing. If you require many VDOMs, all with active security features, it is recommended to upgrade to a more powerful FortiGate unit.

It is important to backup your configuration before upgrading the VDOM license on your FortiGate unit or units, especially with FortiGate units in HA mode.

To obtain a VDOM license key

1. Log in with a super_admin account.
2. Go to the **Dashboard**.
3. Record your FortiGate unit serial number as shown in **System Information** widget.
4. In the **License Information** widget, locate **Virtual Domain** and select **Purchase More**.

If you do not see the **Purchase More** option on the System Dashboard, your FortiGate model does not support more than 10 VDOMs.

5. You will be taken to the Fortinet customer support website where you can log in and purchase a license key for 25, 50, 100, 250, 500, or more VDOMs.
6. When you receive your license key, go to the Dashboard and select **Upload License** under **License Information**, **Virtual Domains**.
7. In the **Input License Key** field, enter the 32-character license key you received from Fortinet customer support.
8. Select **Apply**.

To verify the new VDOM license, in global configuration go to **System > Dashboard**. Under **License Information**, **Virtual Domains** the maximum number of VDOMs allowed is shown.

VDOMs created on a registered FortiGate unit are recognized as real devices by any connected FortiAnalyzer unit. The FortiAnalyzer unit includes VDOMs in its total number of registered devices. For example, if three FortiGate units are registered on the FortiAnalyzer unit and they contain a total of four VDOMs, the total number of registered FortiGate units on the FortiAnalyzer unit is seven. For more information, see the FortiAnalyzer Administration Guide.

Logging in to VDOMs

Management services communicate using the management VDOM, which is the root VDOM by default.

Management traffic requires an interface that has access to the Internet. If there is no interface assigned to the VDOM containing the management traffic, services including updates will not function.

Accessing a VDOM if you are the FortiGate's Administrator - web-based manager:

1. Log in with a super_admin account.
2. In the **Virtual Domains** menu on the left-hand side, select the VDOM to configure.
   The menu will expand to show the various pages and settings for that VDOM.
3. When you have finished configuring the VDOM, you can
   - open the **Global** menu to return to global configuration
   - log out

Accessing a VDOM if you are the FortiGate's Administrator - CLI:

With the super_admin, logging into the CLI involves also logging into the specific VDOM. If you need a reminder, use `edit ?` to see a list of existing VDOMs before you editing a VDOM.

If you misspell a VDOM you are trying to switch to, you will create a new VDOM by that name. Any changes you make will be part of the new VDOM, and not the intended VDOM. If you are having problems where your changes aren't visible, back up to the top level and use `edit ?` to see a list of VDOMs to ensure this has not happened. If it has happened, see Enabling and accessing Virtual Domains.

```
config vdom
   edit ?
   edit <chosen_vdom>
      ..
      <enter vdom related commands>
      ..
   end
exit
```

Accessing a VDOM if you are the VDOM's Administrator - web-based manager:

1. Connect to the FortiGate unit using an interface that belongs to the VDOM to be configured.
2. Log in using an administrator account that has access to the VDOM.
   The main web-based manager page opens. The interface is largely the same as if the device has VDOMs disabled. From here you can access VDOM-specific settings.

Accessing a VDOM if you are the VDOM's Administrator - CLI:

A non-super_admin account has access to only one VDOM and must log in through an interface that belongs to the same VDOM, but the process is the same as logging into a non-VDOM unit.

```
Login: regular_admin
```

```
Password: <password>
..
<enter vdom related commands>
..
exit
```

Configuring Virtual Domains

Only a super_admin administrator account such as the default “admin” account can create, disable, or delete VDOMs. That account can create additional administrators for each VDOM.

This section includes:

- Creating a Virtual Domain
- Disabling a Virtual Domain
- Deleting a VDOM
- Administrators in Virtual Domains

Creating a Virtual Domain

Once you have enabled Virtual Domains on your FortiGate unit, you can create additional Virtual Domains beyond the default root Virtual Domain.

By default new Virtual Domains are set to NAT/Route operation mode. If you want a Virtual Domain to be in Transparent operation mode, you must manually change it.

You can name new Virtual Domains as you like with the following restrictions:

- only letters, numbers, “-”, and “_” are allowed
- no more than 11 characters are allowed
- no spaces are allowed
- VDOMs cannot have the same names as interfaces, zones, switch interfaces, or other VDOMs.

When creating large numbers of VDOMs you should not enable advanced features such as proxies, web filtering, and antivirus due to limited FortiGate unit resources. Also when creating large numbers of VDOMs, you may experience reduced performance for the same reason.

To create a VDOM - web-based manager:

1. Log in with a super_admin account.
2. Select **Global > System > VDOM**.
3. Select **Create New**.
4. Enter a unique name for your new VDOM.
5. Enter a short and descriptive comment to identify this VDOM.
6. Select **OK**.

Repeat Steps 3 through 6 to add additional VDOMs.

To create a VDOM - CLI:

```
config vdom
   edit <new_vdom_name>
```

```
end
```

If you want to edit an existing Virtual Domain in the CLI, and mistype the name a new Virtual Domain will be created with this new misspelled name. If you notice expected configuration changes are not visible, this may be the reason. You should periodically check your VDOM list to ensure there are none of these misspelled VDOMs present.

Disabling a Virtual Domain

The status of a VDOM can be Enabled or Disabled.

Active status VDOMs can be configured. Active is the default status when a VDOM is created. The management VDOM must be an Active VDOM.

Disabled status VDOMs are considered “offline”. The configuration remains, but you cannot use the VDOM, and only the super_admin administrator can view it. You cannot delete a disabled VDOM without first enabling it, and removing references to it like usual—there is no **Delete** icon for disabled status VDOMs. You can assign interfaces to a disabled VDOM.

The following procedures show how to disable a VDOM called “test-vdom”.

To disable a VDOM - web-based manager:

1. Go to **Global > System > VDOM**.
2. Open the VDOM for editing.
3. Ensure **Enable** is not selected and then select **OK**.
   The VDOM’s Enable icon in the VDOM list is a grey X.

To disable a VDOM - CLI:

```
config vdom
   edit test-vdom
      config system settings
         set status disable
      end
end
```

To enable a VDOM - web-based manager:

1. Go to **Global > System > VDOM**.
2. Open the VDOM for editing.
3. Ensure **Enable** is selected and then select **OK**.
   The VDOM’s Enable icon in the VDOM list is a green checkmark.

To enable a VDOM - CLI:

```
config vdom
   edit test-vdom
      config system settings
         set status enable
      end
end
```

Deleting a VDOM

Deleting a VDOM removes it from the FortiGate unit configuration.

Before you can delete a VDOM, all references to it must be removed, including any per-VDOM objects. If there are any references to the VDOM remaining, you will see an error message and not be able to delete the VDOM.

A disabled VDOM cannot be deleted. You can also not delete the root VDOM or the management VDOM.

Before deleting a VDOM, a good practice is to reset any interface referencing that VDOM to its default configuration, with “root” selected as the Virtual Domain.

The following procedures show how to delete the `test-vdom` VDOM.

To delete a VDOM - web-based manager:

1. Go to **Global > System > VDOM**.
2. Select the check box for the VDOM and then select the **Delete** icon.

   If the **Delete** icon is not active, there are still references to the VDOM that must first be removed. The **Delete** icon is available when all the references to this VDOM are removed.

3. Confirm the deletion.

To delete a VDOM - CLI:

```
config vdom
   delete test-vdom
end
```

Removing references to a VDOM

When you are going to delete a VDOM, all references to that VDOM must first be removed. It can be difficult to find all the references to the VDOM. This section provides a list of common objects that must be removed before a VDOM can be deleted, and a CLI command to help list the dependencies.

Interfaces are an important part of VDOMs. If you can move all the interfaces out of a VDOM, generally you will be able to delete that VDOM.

Common objects that refer to VDOMs

When you are getting ready to delete a VDOM check for, and remove the following objects that refer to that VDOM or its components:

- Routing - both static and dynamic routes
- Firewall addresses, policies, groups, or other settings
- Security Features/Profiles
- VPN configuration
- Users or user groups
- Logging
- DHCP servers

- Network interfaces, zones, custom DNS servers
- VDOM Administrators

Administrators in Virtual Domains

When Virtual Domains are enabled, permissions change for administrators. Administrators are now divided into per-VDOM administrators, and `super_admin` administrators. Only `super_admin` administrator accounts can create other administrator accounts and assign them to a VDOM.

Administrator VDOM permissions

Different types of administrator accounts have different permissions within VDOMs. For example, if you are using a super_admin profile account, you can perform all tasks. However, if you are using a regular admin account, the tasks available to you depend on whether you have read only or read/write permissions. The following table shows what tasks can be performed by which administrators.

Administrator VDOM permissions

Tasks	Regular administrator account		Super_admin profile administrator account
	Read only permission	Read/write permission	
View global settings	yes	yes	yes
Configure global settings	no	no	yes
Create or delete VDOMs	no	no	yes
Configure multiple VDOMs	no	no	yes
Assign interfaces to a VDOM	no	no	yes
Revision Control Backup and Restore	no	no	yes
Create VLANs	no	yes - for 1 VDOM	yes - for all VDOMs
Assign an administrator to a VDOM	no	no	yes
Create additional admin accounts	no	yes - for 1 VDOM	yes - for all VDOMs
Create and edit protection profiles	no	yes - for 1 VDOM	yes - for all VDOMs

The only difference in admin accounts when VDOMs are enabled is selecting which VDOM the admin account belongs to. Otherwise, by default the administration accounts are the same as when VDOMs are disabled and closely resemble the `super_admin` account in their privileges.

Creating administrators for Virtual Domains

Using the admin administrator account, you can create additional administrator accounts and assign them to VDOMs.

The newly-created administrator can access the FortiGate unit only through network interfaces that belong to their assigned VDOM or through the console interface. The network interface must be configured to allow management access, such as HTTPS and SSH. Without these in place, the new administrator will not be able to access the FortiGate unit and will have to contact the super_admin administrator for access.

The following procedure creates a new Local administrator account called `admin_sales` with a password of `fortinet` in the `sales` VDOM using the `admin_prof` default profile.

To create an administrator for a VDOM - web-based manager:

1. Log in with a super_admin account.
2. Go to **System > Administrators**.
3. Select **Create New**.
4. Select **Regular** for Type, as you are creating a Local administrator account.
5. Enter the necessary information about the administrator: email, password, etc.
6. If this admin will be accessing the VDOM from a particular IP address or subnet, enable **Restrict this Admin Login from Trusted Hosts Only** and enter the IP in **Trusted Host #1**.
7. Select `prof_admin` for the **Admin Profile**.
8. Select `sales` from the list of **Virtual Domains**.
9. Select **OK**.

To create administrators for VDOMs - CLI:

```
config global
   config system admin
      edit <new_admin_name>
         set vdom <vdom_for_this_account>
         set password <pwd>
         set accprofile <an_admin_profile>
         ...
      end
```

Virtual Domain administrator dashboard display

When administrators logs into their virtual domain, they see a different dashboard than the global administrator will see. The VDOM dashboard displays information only relevant to that VDOM — no global or other VDOM information is displayed.

VDOM dashboard information

Information	per-VDOM	Global
System Information	read-only	yes
License Information	no	yes
CLI console	yes	yes
Unit Operation	read-only	yes
Alert Message Console	no	yes
Top Sessions	limited to VDOM sessions	yes
Traffic	limited to VDOM interfaces	yes
Statistics	yes	yes

Virtual Domains in NAT/Route mode

By default, a Virtual Domain (VDOM) uses NAT/Route mode. In this mode, the VDOM is installed as a gateway or router between two networks. In most cases, it is used between a private network and the Internet. This allows the VDOM to hide the IP addresses of the private network using network address translation (NAT).

Each VDOM on a FortiGate can be configured for NAT/Route mode or Transparent mode, regardless of the operation mode of other VDOMs on the FortiGate. For more information about Transparent mode, see "Virtual Domains in Transparent mode" on page 3219.

This chapter contains the following sections:

- Using a VDOM in NAT/Route mode
- Example configuration: VDOM in NAT/Route mode

Using a VDOM in NAT/Route mode

Once you have enabled virtual domains and created one or more VDOMs, you need to configure them. Configuring VDOMs on your FortiGate unit includes tasks such as the ones listed here; while you may not require all for your network topology, it is recommended that you perform them in the order given:

- Changing the management virtual domain
- Configuring interfaces
- Configuring VDOM routing
- Configuring security policies
- Changing the inspection mode
- Configuring security profiles
- Configuring VPNs for a VDOM

Changing the management virtual domain

The management virtual domain is the virtual domain where all the management traffic for the FortiGate unit originates. This management traffic needs access to remote servers, such as FortiGuard services and NTP, to perform its duties. It needs access to the Internet to send and receive this traffic.

Management traffic includes, but is not limited to

- DNS lookups
- logging to FortiAnalyzer or syslog
- FortiGuard service
- sending alert emails
- Network time protocol traffic (NTP)
- Sending SNMP traps
- Quarantining suspicious files and email.

By default the management VDOM is the root domain. When other VDOMs are configured on your FortiGate unit, management traffic can be moved to one of these other VDOMs.

Reasons to move the management VDOM include selecting a non-root VDOM to be your administration VDOM, or the root VDOM not having an interface with a connection to the Internet.

You cannot change the management VDOM if any administrators are using RADIUS authentication.

The following procedure will change the management VDOM from the default `root` to a VDOM named `mgmt_vdom`. It is assumed that `mgmt_vdom` has already been created and has an interface that can access the Internet.

To change the management VDOM - web-based manager:

1. Select **Global > System > VDOM.**
2. Select the checkbox next to the required VDOM.
3. Select **Switch Management.**
   The current management VDOM is shown in square brackets, “[root]” for example.

To change the management VDOM - CLI:

```
config global
   config system global
      set management-vdom mgmt_vdom
   end
```

Management traffic will now originate from `mgmt_vdom`.

Configuring interfaces

A VDOM must contain at least two interfaces to be useful. These can be physical interfaces or VLAN interfaces. By default, all physical interfaces are in the root VDOM. When you create a new VLAN, it is in the root VDOM by default.

When there are VDOMs on the FortiGate unit in both NAT and Transparent operation modes, some interface fields will be displayed as “-” on **Network > Interfaces**. Only someone with a super_admin account can view all the VDOMs.

When moving an interface to a different VDOM, firewall IP pools and virtual IPs for this interface are deleted. You should manually delete any routes that refer to this interface. Once the interface has been moved to the new VDOM, you can add these services to the interface again.

When configuring VDOMs on FortiGate units with accelerated interfaces you must assign both interfaces in the pair to the same VDOM for those interfaces to retain their acceleration. Otherwise they will become normal interfaces.

This section includes the following topics:

- Adding a VLAN to a NAT/Route VDOM
- Moving an interface to a VDOM
- Deleting an interface
- Adding a zone to a VDOM

Adding a VLAN to a NAT/Route VDOM

The following example shows one way that multiple companies can maintain their security when they are using one FortiGate unit with VLANs that share interfaces on the unit.

This procedure will add a VLAN interface called `client1-v100` with a VLAN ID of 100 to an existing VDOM called `client1` using the physical interface called `port2`.

The physical interface does not need to belong to the VDOM that the VLAN belongs to.

To add a VLAN subinterface to a VDOM - web-based manager:

1. Go to **Global > Network > Interfaces**.
2. Select **Create New**.
3. Enter the following information and select **OK**:

Name	client1-v100
Interface	port2
VLAN ID	100
Virtual Domain	Client1
Addressing mode	Manual
IP/Netmask	172.20.120.110/255.255.255.0
Administrative Access	HTTPS, SSH

You will see an expand arrow added to the port2 interface. When the arrow is expanded, the interface shows the `client1-v100` VLAN subinterface.

To add a VLAN subinterface to a VDOM - CLI:

```
config global
   config system interface
      edit client1-v100
         set type vlan
         set vlanid 100
         set vdom Client1
         set interface port2
         set ip 172.20.120.110 255.255.255.0
         set allowaccess https ssh
      end
```

Moving an interface to a VDOM

Interfaces belong to the root VDOM by default. Moving an interface is the same procedure no matter if its moving from the root VDOM or a any other VDOM.

If you have an accelerated pair of physical interfaces both interfaces must be in the same VDOM or you will lose their acceleration.

The following procedure will move the port3 interface to the Client2 VDOM. This is a common action when configuring a VDOM. It is assumed that the Client2 VDOM has already been created. It is also assumed that your FortiGate unit has a port3 interface. If you are using a different model, your physical interfaces may not be named `port2`, `external` or `port3`.

To move an existing interface to a different VDOM - web-based manager:

1. Go to **Global > Network > Interfaces**.
2. Select **Edit** for the port3 interface.
3. Select `Client2` as the new **Virtual Domain**.
4. Select **OK**.

To move an existing interface to a different VDOM - CLI:

```
config global
   config system interface
      edit port3
         set vdom Client2
      end
```

Deleting an interface

Before you can delete a virtual interface, or move an interface from one VDOM to another, all references to that interface must be removed. For a list of objects that can refer to an interface see Virtual Domains Overview.

The easiest way to be sure an interface can be deleted is when the Delete icon is no longer greyed out. If it remains greyed out when an interface is selected, that interface still has objects referring to it, or it is a physical interface that cannot be deleted.

To delete a virtual interface - web-based manager:

1. Ensure all objects referring to this interface have been removed.
2. Select **Global > Network > Interfaces**.
3. Select the interface to delete.
4. Select the delete icon.

Adding a zone to a VDOM

Grouping interfaces and VLAN subinterfaces into zones simplifies policy creation. You can configure policies for connections to and from a zone, but not between interfaces in a zone.

Zones are VDOM-specific. A zone cannot be moved to a different VDOM. Any interfaces in a zone cannot be used in another zone. To move a zone to a new VDOM requires deleting the current zone and re-creating a zone in the new VDOM.

The following procedure will create a zone called `accounting` in the `client2` VDOM. It will not allow intra-zone traffic, and both `port3` and `port2` interfaces belong to this zone. This is a method of grouping and isolating traffic over particular interfaces—it is useful for added security and control within a larger network.

To add a zone to a VDOM - web-based manager:

1. In **Virtual Domains**, select the client2 VDOM.
2. Go to **Network > Interfaces**.
3. Select **Create New > Zone**.
4. Enter the following information and select **OK**:

Zone Name	accounting
Block intra-zone traffic	Select
Interface Members	port3, port2

To add a zone to a VDOM - CLI:

```
config vdom
   edit client2
      config system zone
         edit accounting
            set interface port3 port2
            set intrazone deny
         end
   end
```

Configuring VDOM routing

Routing is VDOM-specific. Each VDOM should have a default static route configured as a minimum. Within a VDOM, routing is the same as routing on your FortiGate unit without VDOMs enabled.

When configuring dynamic routing on a VDOM, other VDOMs on the FortiGate unit can be neighbors. The following topics give a brief introduction to the routing protocols, and show specific examples of how to configure dynamic routing for VDOMs. Figures are included to show the FortiGate unit configuration after the successful completion of the routing example.

Default static route for a VDOM

The routing you define applies only to network traffic entering non-ssl interfaces belonging to this VDOM. Set the administrative distance high enough, typically 20, so that automatically configured routes will be preferred to the default.

In the following procedure, it is assumed that a VDOM called “Client2” exists. The procedure will create a default static route for this VDOM. The route has a destination IP of 0.0.0.0, on the port3 interface. It has a gateway of 10.10.10.1, and an administrative distance of 20.

The values used in this procedure are very standard, and this procedure should be part of configuring all VDOMs.

To add a default static route for a VDOM - web-based manager:

1. In **Virtual Domains**, select the client2 VDOM.
2. Go to **Network > Static Routes**.

3. Select **Create New**.
4. Enter the following information and select **OK**:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port2
Gateway	10.10.10.1
Distance	20

To add a default static route for a VDOM - CLI:

```
config vdom
   edit client2
      config router static
         edit 4
            set device port2
            set dst 0.0.0.0 0.0.0.0
            set gateway 10.10.10.1
            set distance 20
         end
   end
```

Dynamic Routing in VDOMs

Dynamic routing is VDOM-specific, like all other routing. Dynamic routing configuration is the same with VDOMs as with your FortiGate unit without VDOMs enabled, once you are at the routing menu. If you have multiple VDOMs configured, the dynamic routing configuration between them can become quite complex.

VDOMs provide some interesting changes to dynamic routing. Each VDOM can be a neighbor to the other VDOMs. This is useful in simulating a dynamic routing area or AS or network using only your FortiGate unit.

You can separate different types of routing to different VDOMs if required. This allows for easier troubleshooting. This is very useful if your FortiGate unit is on the border of a number of different routing domains.

For more information on dynamic routing in FortiOS, see the Advanced Routing handbook.

Inter-VDOM links must have IP addresses assigned to them if they are part of a dynamic routing configuration. Inter-VDOM links may or may not have IP addresses assigned to them. Without IP addresses, you need to be careful how you configure routing. While the default static route can be assigned an address of 0.0.0.0 and rely instead on the interface, dynamic routing almost always requires an IP address.

RIP

The RIP dynamic routing protocol uses hop count to determine the best route, with a hop count of 1 being directly attached to the interface and a hop count of 16 being unreachable. For example if two VDOMs on the same FortiGate unit are RIP neighbors, they have a hop count of 1.

OSPF

OSPF communicates the status of its network links to adjacent neighbor routers instead of the complete routing table. When compared to RIP, OSPF is more suitable for large networks, it is not limited by hop count, and is

more complex to configure. For smaller OSPF configurations its easiest to just use the backbone area, instead of multiple areas.

BGP

BGP is an Internet gateway protocol (IGP) used to connect autonomous systems (ASes) and is used by Internet service providers (ISPs). BGP stores the full path, or path vector, to a destination and its attributes which aid in proper routing.

Configuring security policies

Security policies are VDOM-specific. This means that all firewall settings for a VDOM, such as firewall addresses and security policies, are configured within the VDOM.

In VDOMs, all firewall related objects are configured per-VDOM including addresses, service groups, security profiles, schedules, traffic shaping, and so on. If you want firewall addresses, you will have to create them on each VDOM separately. If you have many addresses, and VDOMs this can be tedious and time consuming. Consider using a FortiManager unit to manage your VDOM configuration — it can get firewall objects from a configured VDOM or FortiGate unit, and push those objects to many other VDOMs or FortiGate units. See the FortiManager Administration Guide.

You can customize the **Policy** display by including some or all columns, and customize the column order onscreen. Due to this feature, security policy screenshots may not appear the same as on your screen.

Configuring a security policy for a VDOM

Your security policies can involve only the interfaces, zones, and firewall addresses that are part of the current VDOM, and they are only visible when you are viewing the current VDOM. The security policies of this VDOM filter the network traffic on the interfaces and VLAN subinterfaces in this VDOM.

A firewall service group can be configured to group multiple services into one service group. When a descriptive name is used, service groups make it easier for an administrator to quickly determine what services are allowed by a security policy.

In the following procedure, it is assumed that a VDOM called `Client2` exists. The procedure will configure an outgoing security policy. The security policy will allow all HTTPS, SSH, and DNS traffic for the `SalesLocal` address group on VLAN_200 going to all addresses on port3. This traffic will be scanned and logged.

To configure a security policy for a VDOM - web-based manager:

1. In **Virtual Domains**, select the client2 VDOM.
2. Go to **Policy & Objects > IPv4 Policy**.
3. Select **Create New**.
4. Enter the following information and select **OK**:

Name	Client2-outgoing
Incoming Interface	VLAN_200

Outgoing Interface	port3
Source Address	SalesLocal
Destination Address	any
Schedule	always
Service	HTTPS, SSH, DNS
Action	ACCEPT
Log Allowed Traffic	enable

To configure a security policy for a VDOM - CLI:

```
config vdom
   edit Client2
      config firewall policy
         edit 12
            set srcintf VLAN_200
            set srcaddr SalesLocal
            set dstintf port3(dmz)
            set dstaddr any
            set schedule always
            set service HTTPS SSH
            set action accept
            set status enable
            set logtraffic enable
         end
   end
```

Changing the inspection mode

If you wish to change the inspection mode for a VDOM, go to **System > VDOM** and edit the VDOM you want to configure. Set **Inspection Mode** to either **Proxy** or **Flow-based**.

VDOMs on the same FortiGate can use different inspection modes.

Configuring security profiles

In NAT/Route VDOMs, security profiles are exactly like regular FortiGate unit operation with one exception. In VDOMs, there are no default security profiles.

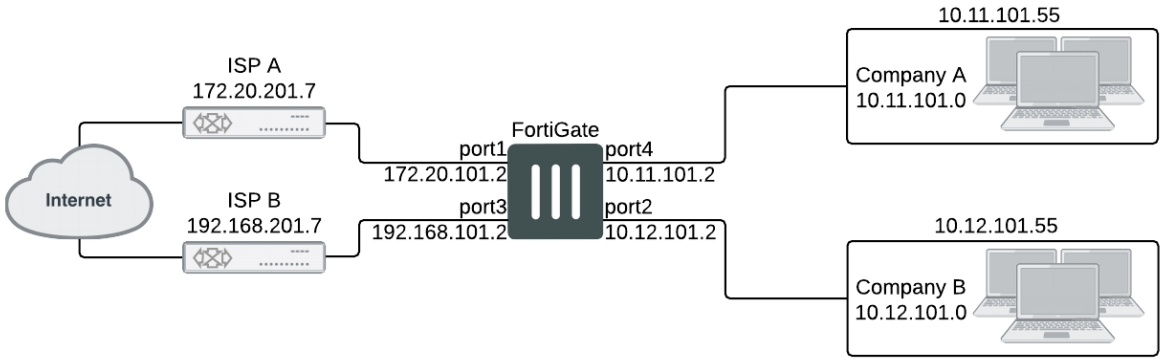
If you want security profiles in VDOMs, you must create them yourself. If you have many security profiles to create in each VDOM, you should consider using a FortiManager unit. It can get existing profiles from a VDOM or FortiGate unit, and push those profiles down to multiple other VDOMs or FortiGate units. See the FortiManager Administration Guide.

When VDOMs are enabled, you only need one FortiGuard license for the physical unit, and download FortiGuard updates once for the physical unit. This can result in a large time and money savings over multiple physical units if you have many VDOMs.

Configuring VPNs for a VDOM

Virtual Private Networking (VPN) settings are VDOM-specific, and must be configured within each VDOM. Configurations for IPsec Tunnel, IPsec Interface, PPTP and SSL are VDOM-specific.

Example configuration: VDOM in NAT/Route mode



Company A and Company B each have their own internal networks and their own ISPs. They share a FortiGate unit that is configured with two separate VDOMs, with each VDOM running in NAT/Route mode enabling separate configuration of network protection profiles. Each ISP is connected to a different interface on the FortiGate unit.

This network example was chosen to illustrate one of the most typical VDOM configurations.

This example has the following sections:

- Network topology and assumptions
- General configuration steps
- Creating the VDOMs
- Configuring the FortiGate interfaces
- Configuring the vdomA VDOM
- Configuring the vdomB VDOM
- Testing the configuration

Network topology and assumptions

Both companies have their own ISPs and their own internal interface, external interface, and VDOM on the FortiGate unit.

For easier configuration, the following IP addressing is used:

- all IP addresses on the FortiGate unit end in ".2" such as 10.11.101.2.
- all IP addresses for ISPs end in ".7", such as 172.20.201.7.
- all internal networks are 10.*.*.* networks, and sample internal addresses end in ".55".

The IP address matrix for this example is as follows.

Address	Company A	Company B
ISP	172.20.201.7	192.168.201.7
Internal network	10.11.101.0	10.012.101.0
FortiGate / VDOM	172.20.201.2 (port1) 10.11.101.2 (port4)	192.168.201.2 (port3) 10.012.101.2 (port2)

The Company A internal network is on the 10.11.101.0/255.255.255.0 subnet. The Company B internal network is on the 10.12.101.0/255.255.255.0 subnet.

There are no switches or routers required for this configuration.

There are no VLANs in this network topology.

The interfaces used in this example are port1 through port4. Different FortiGate models may have different interface labels. port1 and port3 are used as external interfaces. port2 and port4 are internal interfaces.

The administrator is a super_admin account. If you are a using a non-super_admin account, refer to "Global and per-VDOM settings" to see which parts a non-super_admin account can also configure.

When configuring security policies in the CLI always choose a policy number that is higher than any existing policy numbers, select `services` before `profile-status`, and `profile-status` before `profile`. If these commands are not entered in that order, they may not be available to enter.

General configuration steps

For best results in this configuration, follow the procedures in the order given. Also, note that if you perform any additional actions between procedures, your configuration may have different results.

1. Creating the VDOMs
2. Configuring the FortiGate interfaces
3. Configuring the vdomA VDOM, and Configuring the vdomB VDOM
4. Testing the configuration

Creating the VDOMs

In this example, two new VDOMs are created — vdomA for Company A and vdomB for Company B. These VDOMs will keep the traffic for these two companies separate while enabling each company to access its own ISP.

To create two VDOMs - web-based manager:

1. Log in with a super_admin account.
2. Go to **Global > System > VDOM**, and select **Create New**.
3. Enter `vdomA` and select **OK**.
4. Select **OK** again to return to the VDOM list.
5. Select **Create New**.
6. Enter `vdomB` and select **OK**.

To create two VDOMs - CLI:

```
config vdom
   edit vdomA
   next
   edit vdomB
end
```

Configuring the FortiGate interfaces

This section configures the interfaces that connect to the companies' internal networks, and to the companies' ISPs.

All interfaces on the FortiGate unit will be configured with an IP address ending in ".2" such as 10.11.101.2. This will simplify network administration both for the companies, and for the FortiGate unit global administrator. Also the internal addresses for each company differ in the second octet of their IP address - Company A is 10.11.*, and Company B is 10.12.*.

This section includes the following topics:

- Configuring the vdomA interfaces
- Configuring the vdomB interfaces

If you cannot change the VDOM of an network interface it is because something is referring to that interface that needs to be deleted. Once all the references are deleted the interface will be available to switch to a different VDOM. For example a common reference to the external interface is the default static route entry. See Example configuration: VDOM in NAT/Route mode.

Configuring the vdomA interfaces

The `vdomA` VDOM includes two FortiGate unit interfaces: port1 and external.

The port4 interface connects the Company A internal network to the FortiGate unit, and shares the internal network subnet of 10.11.101.0/255.255.255.0.

The external interface connects the FortiGate unit to ISP A and the Internet. It shares the ISP A subnet of 172.20.201.0/255.255.255.0.

To configure the vdomA interfaces - web-based manager:

1. Go to **Global > Network > Interfaces**.
2. Select **Edit** on the port1 interface.
3. Enter the following information and select **OK**:

Virtual Domain	vdomA
Addressing mode	Manual
IP/Netmask	172.20.201.2/255.255.255.0

4. Select **Edit** on the port4 interface.
5. Enter the following information and select **OK**:

Virtual Domain	vdomA
Addressing mode	Manual
IP/Netmask	10.11.101.2/255.255.255.0

To configure the vdomA interfaces - CLI:

```
config global
   config system interface
      edit port1
         set vdom vdomA
         set mode static
         set ip 172.20.201.2 255.255.255.0
      next
      edit port4
         set vdom ABCDomain
         set mode static
         set ip 10.11.101.2 255.255.255.0
      end
```

Configuring the vdomB interfaces

The `vdomB` VDOM uses two FortiGate unit interfaces: port2 and port3.

The port2 interface connects the Company B internal network to the FortiGate unit, and shares the internal network subnet of 10.12.101.0/255.255.255.0.

The port3 interface connects the FortiGate unit to ISP B and the Internet. It shares the ISP B subnet of 192.168.201.0/255.255.255.0.

To configure the vdomB interfaces - web-based manager:

1. Go to **Global > Network > Interfaces**.
2. Select **Edit** on the port3 interface.
3. Enter the following information and select **OK**:

Virtual domain	vdomB
Addressing mode	Manual
IP/Netmask	192.168.201.2/255.255.255.0

4. Select **Edit** on the port2 interface.
5. Enter the following information and select **OK**:

Virtual domain	vdomB
Addressing mode	Manual
IP/Netmask	10.12.101.2/255.255.255.0

To configure the vdomB interfaces - CLI:

```
config global
   config system interface
      edit port3
         set vdom vdomB
         set mode static
         set ip 192.168.201.2 255.255.255.0
      next
      edit port2
         set vdom vdomB
         set mode static
         set ip 10.12.101.2 255.255.255.0
   end
```

Configuring the vdomA VDOM

With the VDOMs created and the ISPs connected, the next step is to configure the vdomA VDOM.

Configuring the vdomA includes the following:

- Adding vdomA firewall addresses
- Adding the vdomA security policy
- Adding the vdomA default route

Adding vdomA firewall addresses

You need to define the addresses used by Company A's internal network for use in security policies. This internal network is the 10.11.101.0/255.255.255.0 subnet.

The FortiGate unit provides one default address, "all", that you can use when a security policy applies to all addresses as the source or destination of a packet.

To add the vdomA firewall addresses - web-based manager:

1. In **Virtual Domains**, select **vdomA**.
2. Go to **Policy & Objects > Addresses**.
3. Select **Create New**.
4. Enter the following information and select **OK**:

Address Name	Ainternal
Type	Subnet / IP Range
Subnet / IP Range	10.11.101.0/255.255.255.0
Interface	port4

To add the ABCDomain VDOM firewall addresses - CLI:

```
config vdom
   edit vdomA
      config firewall address
         edit Ainternal
            set type ipmask
```

```
            set subnet 10.11.101.0 255.255.255.0
        end
    end
```

Adding the vdomA security policy

You need to add the `vdomA` security policy to allow traffic from the internal network to reach the external network, and from the external network to internal as well. You need two policies for this domain.

To add the vdomA security policy - web-based manager:

1. In **Virtual Domains**, select **vdomA**.
2. Go to **Policy & Objects > IPv4 Policy**.
3. Select **Create New**.
4. Enter the following information and select **OK**:

Name	VDOMA-internal-to-external
Incoming Interface	port4
Outgoing Interface	port1
Source Address	Ainternal
Destination Address	all
Schedule	Always
Service	ANY
Action	ACCEPT

5. Select **Create New**.
6. Enter the following information and select **OK**:

Name	VDOMA-external-to-internal
Incoming Interface	port1
Outgoing Interface	port4
Source Address	all
Destination Address	Ainternal
Schedule	Always
Service	ANY
Action	ACCEPT

To add the vdomA security policy - CLI:

```
config vdom
   edit vdomA
```

```
config firewall policy
   edit 1
      set srcintf port4
      set srcaddr Ainternal
      set dstintf port1
      set dstaddr all
      set schedule always
      set service ANY
      set action accept
      set status enable
   next
   edit 2
      set srcintf port1
      set srcaddr all
      set dstintf port4
      set dstaddr Ainternal
      set schedule always
      set service ANY
      set action accept
      set status enable
   end
```

Adding the vdomA default route

You also need to define a default route to direct packets from the Company A internal network to ISP A. Every VDOM needs a default static route, as a minimum, to handle traffic addressed to external networks such as the Internet.

The administrative distance should be set slightly higher than other routes. Lower admin distances will get checked first, and this default route will only be used as a last resort.

To add a default route to the vdomA - web-based manager:

1. For **Virtual Domains**, select **vdomA**
2. Go to **Network > Static Routes**.
3. Select **Create New**.
4. Enter the following information and select **OK**:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port1
Gateway	172.20.201.7
Distance	20

To add a default route to the vdomA - CLI:

```
config vdom
   edit vdomA
      config router static
         edit 1
            set device port1
            set gateway 172.20.201.7
         end
```

Configuring the vdomB VDOM

In this example, the vdomB VDOM is used for Company B. Firewall and routing settings are specific to a single VDOM.

vdomB includes the FortiGate port2 interface to connect to the Company B internal network, and the FortiGate port3 interface to connect to ISP B. Security policies are needed to allow traffic from port2 to external and from external to port2 interfaces.

This section includes the following topics:

- Adding the vdomB firewall address
- Adding the vdomB security policy
- Adding a default route to the vdomB VDOM

Adding the vdomB firewall address

You need to define addresses for use in security policies. In this example, the vdomB VDOM needs an address for the port2 interface and the “all” address.

To add the vdomB firewall address - web-based manager:

1. In **Virtual Domains**, select **vdomB**.
2. Go to **Policy & Objects > Addresses**.
3. Select **Create New**.
4. Enter the following information and select **OK**:

Address Name	Binternal
Type	Subnet / IP Range
Subnet / IP Range	10.12.101.0/255.255.255.0
Interface	port2

To add the vdomB firewall address - CLI:

```
config vdom
   edit vdomB
      config firewall address
         edit Binternal
            set type ipmask
            set subnet 10.12.101.0 255.255.255.0
         end
   end
```

Adding the vdomB security policy

You also need a security policy for the Company B domain. In this example, the security policy allows all traffic.

To add the vdomB security policy - web-based manager:

1. Log in with a super_admin account.
2. In **Virtual Domains**, select vdomB.

3. Go to **Policy & Objects > IPv4 Policy**
4. Select **Create New**.
5. Enter the following information and select **OK**:

Name	VDOMB-internal-to-external
Incoming Interface	port2
Outgoing Interface	port3
Source Address	Binternal
Destination Address	all
Schedule	Always
Service	ANY
Action	ACCEPT

6. Select **Create New**.
7. Enter the following information and select **OK**:

Name	VDOMB-external-to-internal
Incoming Interface	port3
Outgoing Interface	port2
Source Address	all
Destination Address	Binternal
Schedule	Always
Service	ANY
Action	ACCEPT

To add the vdomB security policy - CLI:

```
config vdom
   edit vdomB
      config firewall policy
         edit 1
            set srcintf port2
            set dstintf port3
            set srcaddr Binternal
            set dstaddr all
            set schedule always
            set service ANY
            set action accept
            set status enable
         edit 1
            set srcintf port3
```

```
            set dstintf port2
            set srcaddr all
            set dstaddr Binternal
            set schedule always
            set service ANY
            set action accept
            set status enable
        end
    end
```

Adding a default route to the vdomB VDOM

You need to define a default route to direct packets to ISP B.

To add a default route to the vdomB VDOM - web-based manager:

1. Log in as the super_admin administrator.
2. In **Virtual Domains**, select vdomB.
3. Go to **Network > Static Routes**.
4. Select **Create New**.
5. Enter the following information and select **OK**:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port3
Gateway	192.168.201.7
Distance	20

To add a default route to the vdomB VDOM - CLI:

```
config vdom
   edit vdomB
      config router static
         edit 1
            set dst 0.0.0.0/0
            set device external
            set gateway 192.168.201.7
         end
   end
```

Testing the configuration

Once you have completed configuration for both company VDOMs, you can use diagnostic commands, such as `tracert` in Windows, to test traffic routed through the FortiGate unit. Alternately, you can use the `traceroute` command on a Linux system with similar output.

Possible errors during the traceroute test are:

- "`* * * Request timed out`" - the trace was not able to make the next connection towards the destination fast enough
- "`Destination host unreachable`" - after a number of timed-out responses the trace will give up

Possible reasons for these errors are bad connections or configuration errors.

For additional troubleshooting, see Troubleshooting Virtual Domains.

Testing traffic from the internal network to the ISP

In this example, a route is traced from the Company A internal network to ISP A. The test was run on a Windows PC with an IP address of 10.11.101.55.

The output here indicates three hops between the source and destination, the IP address of each hop, and that the trace was successful.

From the Company A internal network, access a command prompt and enter this command:

```
C:\>tracert 172.20.201.7
Tracing route to 172.20.201.7 over a maximum of 30 hops:
  1   <10 ms   <10 ms   <10 ms  10.11.101.2
  2   <10 ms   <10 ms   <10 ms  172.20.201.2
  3   <10 ms   <10 ms   <10 ms  172.20.201.7
Trace complete.
```

Virtual Domains in Transparent mode

A VDOM in Transparent mode is installed between the internal network and the router. In this mode, the VDOM does not make any changes to IP addresses and only applies security scanning to traffic. When a VDOM is added to a network in Transparent mode, no network changes are required, except to provide the VDOM with a management IP address.

Each VDOM on a FortiGate can be configured for NAT/Route mode or Transparent mode, regardless of the operation mode of other VDOMs on the FortiGate. For more information about NAT/Route mode, see "Virtual Domains in NAT/Route mode" on page 3200.

This chapter includes the following sections:

- Transparent Mode Overview
- Using a VDOM in Transparent mode
- Virtual Domains in Transparent mode

Transparent Mode Overview

In transparent mode, a VDOM becomes a layer-2 IP forwarding bridge. This means that Ethernet frames are forwarded based on destination MAC address, and no other routing is performed. All incoming traffic that is accepted by the firewall, is broadcast out on all interfaces.

In transparent mode the VDOM is a forwarding bridge, not a switch. A switch can develop a port table and associated MAC addresses, so that it can bridge two ports to deliver the traffic instead of broadcasting to all ports. In transparent mode, the VDOM does not following this switch behavior, but instead is the forwarding bridge that broadcasts all packets out over all interfaces, subject to security policies.

Differences between NAT/Route and Transparent mode

The differences between NAT/Route mode and Transparent mode include:

Differences between NAT/Route and Transparent modes

Features	NAT/Route mode	Transparent mode
Specific Management IP address required	No	Yes
Perform Network Address Translation (NAT)	Yes	Yes
Stateful packet inspection	Yes	Yes
Layer-2 forwarding	Yes	Yes
Layer-3 routing	Yes	No

Features	NAT/Route mode	Transparent mode
Unicast Routing / Policy Based routing	Yes	No
DHCP server	Yes	No
IPsec VPN	Yes	Yes
PPTP/L2TP VPN	Yes	No
SSL VPN	Yes	No
Security features	Yes	Yes
VLAN support	Yes	Yes - limited to VLAN trunks.
Ping servers (dead gateway detection)	Yes	No

To provide administrative access to a FortiGate unit or VDOM in Transparent mode, you must define a management IP address and a gateway. This step is not required in NAT/Route mode where you can access the FortiGate unit through the assigned IP address of any interface where administrative access is permitted.

If you incorrectly set the Transparent mode management IP address for your FortiGate unit, you will be unable to access your unit through the web-based manager. In this situation, you will need to connect to the FortiGate unit using the console cable and change the settings so you can access the unit. Alternately, if your unit has an LCD panel, you can change the operation mode and interface information through the LCD panel.

Operation mode differences in VDOMs

A VDOM, such as root, can have a maximum of 255 interfaces in Network Address Translation (NAT) mode or Transparent mode. This includes VLANs, other virtual interfaces, and physical interfaces. To have more than a total of 255 interfaces configured, you need multiple VDOMs with multiple interfaces on each.

In Transparent mode without VDOMs enabled, all interfaces on the FortiGate unit act as a bridge — all traffic coming in on one interface is sent back out on all the other interfaces. This effectively turns the FortiGate unit into a two interface unit no matter how many physical interfaces it has. When VDOMs are enabled, this allows you to determine how many interfaces to assign to a VDOM running in Transparent mode. If there are reasons for assigning more than two interfaces based on your network topology, you are able to. However, the benefit of VDOMs in this case is that you have the functionality of Transparent mode, but you can use interfaces for NAT/Route traffic as well.

You can add more VDOMs to separate groups of VLAN subinterfaces. When using a FortiGate unit to serve multiple organizations, this configuration simplifies administration because you see only the security policies and settings for the VDOM you are configuring.

One essential application of VDOMs is to prevent problems caused when a FortiGate unit is connected to a layer-2 switch that has a global MAC table. FortiGate units normally forward ARP requests to all interfaces, including VLAN subinterfaces. It is then possible for the switch to receive duplicate ARP packets on different VLANs. Some layer-2 switches reset when this happens. As ARP requests are only forwarded to interfaces in the same VDOM, you can solve this problem by creating a VDOM for each VLAN.

For more information about Transparent mode, see the Transparent Mode & Internal Segmentation Firewall (ISFW) handbook.

Using a VDOM in Transparent mode

The essential steps to configure a VDOM in Transparent mode are:

- Switching to Transparent mode
- Adding VLAN subinterfaces
- Creating security policies

You can also configure the security profiles that manage antivirus scanning, web filtering and spam filtering.

In Transparent mode, you can access the web-based manager by connecting to an interface configured for administrative access and using HTTPS to access the management IP address. In the following examples, administrative access is enabled by default on the internal interface and the default management IP address is `10.11.0.1`.

Switching to Transparent mode

A VDOM is in NAT/Route mode by default when it is created. You must switch it to Transparent mode, and add a management IP address so you can access the VDOM from your management computer.

Before applying the change to Transparent mode, ensure the VDOM has administrative access on the selected interface, and that the selected management IP address is reachable on your network.

Switching the VDOM to Transparent mode cannot be done through the GUI. It must be done through the CLI only.

To switch the VDOM to Transparent mode - CLI:

```
config vdom
   edit <name>
      config system settings
         set opmode transparent
         set mangeip 10.11.0.99 255.255.255.0
      end
   end
```

Adding VLAN subinterfaces

There are a few differences when adding VLANs in Transparent mode compared to NAT/Route mode.

In Transparent mode, VLAN traffic is trunked across the VDOM. That means VLAN traffic cannot be routed, changed, or inspected. For this reason when you assign a VLAN to a Transparent mode VDOM, you will see the **Addressing Mode** section of the interface configuration disappear in from the web-based manager. It is because with no routing, inspection, or any activities able to be performed on VLAN traffic the VDOM simply re-broadcasts the VLAN traffic. This requires no addressing.

Also any routing related features such as dynamic routing or Virtual Router Redundancy Protocol (VRRP) are not available in Transparent mode for any interfaces.

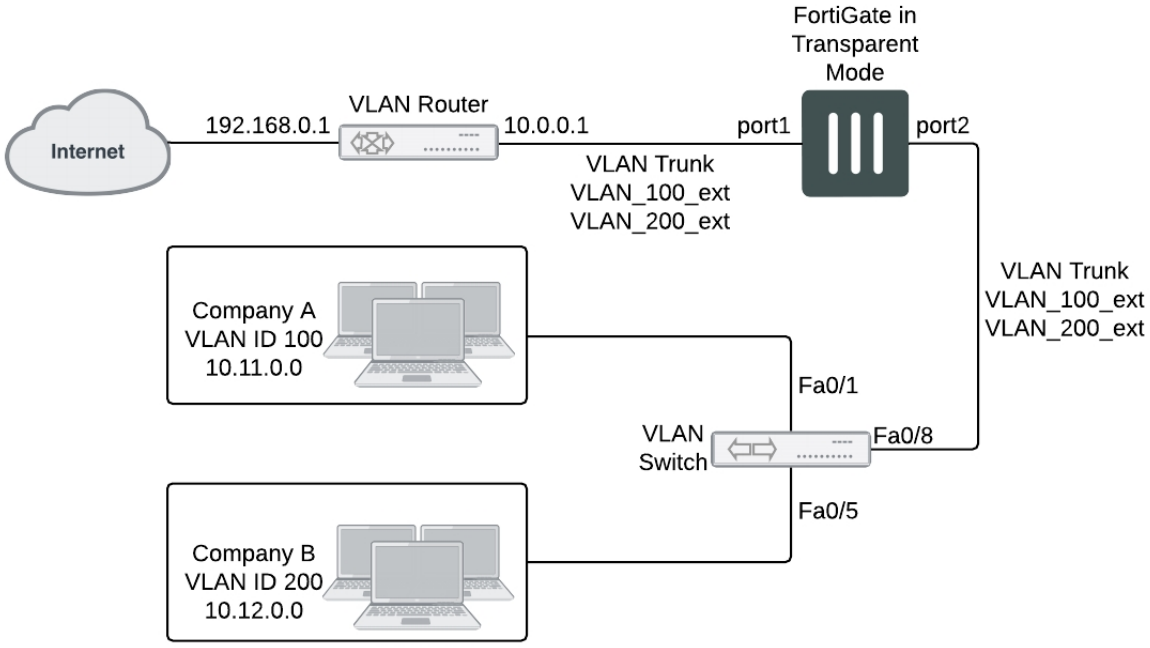
Creating security policies

Security policies permit communication between the FortiGate unit's network interfaces based on source and destination IP addresses. Typically you will also limit communication to desired times and services for additional security.

In Transparent mode, the FortiGate unit performs antivirus and antispam scanning on each packet as it passes through the unit. You need security policies to permit packets to pass from the VLAN interface where they enter the unit to the VLAN interface where they exit the unit. If there are no security policies configured, no packets will be allowed to pass from one interface to another.

For more information, see the Firewall handbook.

Example configuration: VDOM in Transparent mode



In this example, the FortiGate unit provides network protection to two organizations — Company A and Company B. Each company has different policies for incoming and outgoing traffic, requiring three different security policies and protection profiles.

VDOMs are not required for this configuration, but by using VDOMs the profiles and policies can be more easily managed on a per-VDOM basis either by one central administrator or separate administrators for each company. Also future expansion is simply a matter of adding additional VDOMs, whilst not disrupt the existing VDOMs.

For this example, firewalls are only included to deal with web traffic. This is to provide an example without making configuration unnecessarily complicated.

This example includes the following sections:

- Network topology and assumptions
- General configuration steps
- Configuring common items
- Creating virtual domains
- Configuring the Company_A VDOM
- Configuring the Company_B VDOM
- Configuring the VLAN switch and router
- Testing the configuration

Network topology and assumptions

Each organization's internal network consists of a different range of IP addresses:

- 10.11.0.0/255.255.0.0 for Company A.
- 10.12.0.0/255.255.0.0 for Company B.

For the procedures in this section, it is assumed that you have enabled VDOM configuration on your FortiGate unit. For more information, see Virtual Domains Overview.

The VDOM names are similar to the company names for easy recognition. The root VDOM cannot be renamed and is not used in this example.

Interfaces used in this example are port1 and port2. Some FortiGate models may not have interfaces with these names. port1 is an external interface. port2 is an internal interface.

General configuration steps

The following steps summarize the configuration for this example. For best results, follow the procedures in the order given. Also, note that if you perform any additional actions between procedures, your configuration may have different results.

1. Configuring common items
2. Creating virtual domains
3. Configuring the Company_A VDOM
4. Configuring the Company_B VDOM
5. Configuring the VLAN switch and router
6. Testing the configuration

Configuring common items

Both VDOMs require you configure security profiles. These will be configured the same way, but need to be configured in both VDOMs.

The relaxed profile allows users to surf websites they are not allowed to visit during normal business hours. Also a quota is in place to restrict users to one hour of access to these websites to ensure employees do not take long and unproductive lunches.

To create a strict web filtering profile - web-based manager:

1. Go to the proper VDOM, and select **Security Profiles > Web Filter**.
2. Select **Create New**.
3. Enter `strict` for the **Name**.

4. Expand FortiGuard Web Filtering, and select block for all Categories except Business Oriented, and Other.
5. Block all Classifications except Cached Content, and Image Search.
6. Ensure **FortiGuard Quota** for all Categories and Classifications is Disabled.
7. Select **OK**.

To create a strict web filtering profile - CLI:

```
config vdom
   edit <vdom_name>
      config webfilter profile
         edit strict
            config ftgd-wf
               set allow g07 g08 g21 g22 c01 c03
               set deny g01 g02 g03 g04 g05 g06 c02 c04 c05 c06 c07
            end
            set web-ftgd-err-log enable
         end
```

To create a relaxed web filtering profile - web-based manager:

1. Go to the proper VDOM, and select **Security Profiles > Web Filter**.
2. Select **Create New**.
3. Enter `relaxed` for the **Name**.
4. Expand FortiGuard Web Filtering, and select block for Potentially Security Violating Category, and Spam URL Classification.
5. Enable FortiGuard Quotas to allow 1 hour for all allowed Categories and Classifications.

Creating virtual domains

The FortiGate unit supports 10 virtual domains. Root is the default VDOM. It cannot be deleted or renamed. The root VDOM is not used in this example. New VDOMs are created for Company A and Company B

To create the virtual domains - web-based manager:

1. With VDOMs enabled, select **Global > System > VDOM**.
2. Select **Create New**.
3. Enter `Company_A` for Name, and select **OK**.
4. Select **Create New**.
5. Enter `Company_B` for Name, and select **OK**.

To create the virtual domains - CLI:

```
config system vdom
   edit Company_A
   next
   edit Company_B
end
```

Configuring the Company_A VDOM

This section describes how to add VLAN subinterfaces and configure security policies for the Company_A VDOM.

This section includes the following topics:

- Adding VLAN subinterfaces
- Creating the Lunch schedule
- Configuring Company_A firewall addresses
- Creating Company_A security policies

Adding VLAN subinterfaces

You need to create a VLAN subinterface on the port2 interface and another one on the port1 interface, both with the same VLAN ID.

To add VLAN subinterfaces - web-based manager:

1. Go to **Global > Network > Interfaces**.
2. Select **Create New**.
3. Enter the following information and select **OK**:

Name	VLAN_100_int
Interface	port2
VLAN ID	100
Virtual Domain	Company_A

4. Select **Create New**.
5. Enter the following information and select **OK**:

Name	VLAN_100_ext
Interface	port1
VLAN ID	100
Virtual Domain	Company_A

To add the VLAN subinterfaces - CLI:

```
config system interface
   edit VLAN_100_int
      set interface port2
      set vlanid 100
      set vdom Company_A
   next
   edit VLAN_100_ext
      set interface port1
      set vlanid 100
      set vdom Company_A
   end
```

Creating the Lunch schedule

Both organizations have the same lunch schedule, but only Company A has relaxed its security policy to allow employees more freedom in accessing the Internet during lunch. Lunch schedule will be Monday to Friday from 11:45am to 2:00pm (14:00).

To create a recurring schedule for lunchtime - web-based manager:

1. In Company_A VDOM, go to **Policy & Objects > Schedules**.
2. Select **Create New**.
3. Enter `Lunch` as the name for the schedule.
4. Select **Mon**, **Tues**, **Wed**, **Thu**, and **Fri**.
5. Set the **Start** time as `11:45` and set the **Stop** time as `14:00`.
6. Select **OK**.

To create a recurring schedule for lunchtime - CLI:

```
config vdom
   edit Company_A
      config firewall schedule recurring
         edit Lunch
            set day monday tuesday wednesday thursday friday
            set start 11:45
            set end 14:00
         end
```

Configuring Company_A firewall addresses

For Company A, its networks are all on the 10.11.0.0 network, so restricting addresses to that domain provides added security.

To configure Company_A firewall addresses - web-based manager:

1. In the Company_A VDOM, go to **Policy & Objects > Addresses**.
2. Select **Create New**.
3. Enter `CompanyA` in the **Address Name** field.
4. Type 10.11.0.0/255.255.0.0 in the **Subnet / IP Range** field.
5. Select **OK**.

To configure vdomA firewall addresses - CLI:

```
config firewall address
   edit CompanyA
      set type ipmask
      set subnet 10.11.0.0 255.255.0.0
   end
```

Creating Company_A security policies

A security policy can include varying levels of security feature protection. This example only deals with web filtering. The following security policies use the custom security `strict` and `relaxed` profiles configured earlier.

For these security policies, we assume that all protocols will be on their standard ports, such as port 80 for http traffic. If the ports are changed, such as using port 8080 for http traffic, you will have to create custom services for protocols with non-standard ports, and assign them different names.

The firewalls configured in this section are:

- internal to external — always allow all, security features - web filtering: strict
- internal to external — Lunch allow all, security features - web filtering:relaxed

Security policies allow packets to travel between the internal VLAN_100 interface to the external interface subject to the restrictions of the protection profile. Entering the policies in this order means the last one configured is at the top of the policy list, and will be checked first. This is important because the policies are arranged so if one does not apply the next is checked until the end of the list.

To configure Company_A security policies - web-based manager:

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select **Create New**.
3. Enter the following information and select **OK**:

Name	CompanyA-lunch
Incoming Interface	VLAN_100_int
Outgoing Interface	VLAN_100_ext
Source Address	CompanyA
Destination Address	all
Schedule	Lunch
Service	all
Action	ACCEPT
Security Features	enable
Web Filtering	relaxed

This policy provides relaxed protection during lunch hours — going from strict down to scan for protocol options and web filtering. AntiVirus and Email Filtering remain at strict for security — relaxing them would not provide employees additional access to the Internet and it would make the company vulnerable.

1. Select **Create New**.
2. Enter the following information and select **OK**:

Name	CompanyA-strict
Incoming Interface	VLAN_100_int
Outgoing Interface	VLAN_100_ext

Source Address	CompanyA
Destination Address	all
Schedule	always
Service	all
Action	ACCEPT
Security Features	enable
Web Filtering	strict

This policy enforces strict scanning at all times, while allowing all traffic. It ensures company policies are met for network security.

4. Verify that the policy list arranged **By Sequence** to make sure the CompanyA-lunch policy is located above the CompanyA-strict policy. If necessary, rearrange the policies so that the appropriate policy is applied to outgoing traffic.

To configure Company_A security policies - CLI:

```
config vdom
   edit Company_A
      config firewall policy
         edit 1
            set name "CompanyA-lunch"
            set srcintf VLAN_100_int
            set dstintf VLAN_100_ext
            set srcaddr all
            set dstaddr all
            set action accept
            set schedule Lunch
            set webfiltering relaxed
         next
         edit 2
            set name "CompanyA-strict"
            set srcintf VLAN_100_int
            set dstintf VLAN_100_ext
            set srcaddr all
            set dstaddr all
            set action accept
            set schedule always
            set webfiltering strict
         end
```

Configuring the Company_B VDOM

This section describes how to add VLAN subinterfaces and configure security policies for the Company B VDOM.

This section includes the following topics:

- Adding VLAN subinterfaces
- Creating Company_B service groups

- Configuring Company_B firewall addresses
- Configuring Company_B security policies

Adding VLAN subinterfaces

You need to create a VLAN subinterface on the internal interface and another one on the external interface, both with the same VLAN ID.

To add VLAN subinterfaces - web-based manager:

1. Go to **Network > Interfaces**.
2. Select **Create New**.
3. Enter the following information and select **OK**:

Name	VLAN_200_int
Interface	port2
VLAN ID	200
Virtual Domain	Company_B

4. Select **Create New**.
5. Enter the following information and select **OK**:

Name	VLAN_200_ext
Interface	port1
VLAN ID	200
Virtual Domain	Company_B

To add the VLAN subinterfaces - CLI:

```
config system interface
   edit VLAN_200_int
      set interface internal
      set vlanid 200
      set vdom Company_B
   next
   edit VLAN_200_ext
      set interface external
      set vlanid 200
      set vdom Company_B
   end
```

Creating Company_B service groups

Company_B does not want its employees to use any online chat software except NetMeeting, which the company uses for net conferencing. To simplify the creation of a security policy for this purpose, you create a service group that contains all of the services you want to restrict. A security policy can manage only one service or one group.

To create a chat service group - web-based manager:

1. Go to **Policy & Objects > Services** and select **Create New > Service Group**.
2. Enter `Chat` in the **Group Name** field.
3. For each of IRC, AOL, SIP-MSNmessenger and TALK, select the service in the **Available Services** list and select the right arrow to add it to the **Members** list.

If a particular service does not appear in the **Available Services** list, see the list in **Policy & Objects > Services**. Some services do not appear by default unless edited.

4. Select **OK**.

To create a games and chat service group - CLI:

```
config firewall service group
   edit Chat
      set member IRC SIP-MSNmessenger AOL TALK
   end
```

Configuring Company_B firewall addresses

Company B's network is all in the 10.12.0.0 network. Security can be improved by only allowing traffic from IP addresses on that network.

To configure Company_B firewall address - web-based manager:

1. In the Company_B VDOM, go to **Policy & Objects > Addresses.**
2. Select **Create New**.
3. Enter `new` in the **Address Name** field.
4. Type 10.12.0.0/255.255.0.0 in the **Subnet / IP Range** field.
5. Select **OK**.

To configure Company_B firewall addresses - CLI:

```
config vdom
   edit Company_B
      config firewall address
         edit all
            set type ipmask
            set subnet 10.12.0.0 255.255.0.0
         end
```

Configuring Company_B security policies

Security policies allow packets to travel between the internal and external VLAN_200 interfaces subject to the restrictions of the protection profile.

To configure Company_B security policies - web-based manager:

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select **Create New**.
3. Enter the following information and select **OK**:

Name	CompanyB-deny-games-chat
Incoming Interface	VLAN_200_int
Outgoing Interface	VLAN_200_ext
Source Address	all
Destination Address	all
Schedule	BusinessDay
Service	games-chat
Action	DENY

This policy prevents the use of network games or chat programs (except NetMeeting) during business hours.

4. Enter the following information and select **OK**:

Name	CompanyB-lunch
Incoming Interface	VLAN_200_int
Outgoing Interface	VLAN_200_ext
Source Address	all
Destination Address	all
Schedule	Lunch
Service	HTTP, DNS
Action	ACCEPT
Security Features	enable
Web Filter	relaxed

This policy relaxes the web category filtering during lunch hour.

5. Select **Create New**.
6. Enter the following information and select **OK**:

Name	CompanyB-strict
Incoming Interface	VLAN_200_int
Outgoing Interface	VLAN_200_ext
Source Address	all

Destination Address	all
Schedule	BusinessDay
Service	HTTP, DNS
Action	ACCEPT
Security Profiles	enabled
Web Filter	strict

This policy provides rather strict web category filtering during business hours.

7. Select **Create New**.
8. Enter the following information and select **OK**:

Name	CompanyB-after-hours
Incoming Interface	VLAN_200_int
Outgoing Interface	VLAN_200_ext
Source Address	all
Destination Address	all
Schedule	always
Service	ANY
Action	ACCEPT
Security Profiles	enabled
Web Filter	relaxed

Because it is last in the list, this policy applies to the times and services not covered in preceding policies. This means that outside of regular business hours, the Relaxed protection profile applies to email and web browsing, and online chat and games are permitted. Company B needs this policy because its employees sometimes work overtime. The other companies in this example maintain fixed hours and do not want any after-hours Internet access.

To configure Company_B security policies - CLI:

```
config firewall policy
   edit 1
      set name "CompanyB-deny-games-chat"
      set srcintf VLAN_200_int
      set srcaddr all
      set dstintf VLAN_200_ext
      set dstaddr all
      set schedule BusinessDay
      set service Games
      set action deny
```

```
next
edit 2
   set name "CompanyB-lunch"
   set srcintf VLAN_200_int
   set srcaddr all
   set dstintf VLAN_200_ext
   set dstaddr all
   set action accept
   set schedule Lunch
   set service HTTP
   set profile_status enable
   set profile Relaxed
next
edit 3
   set name "CompanyB-strict"
   set srcintf VLAN_200_int
   set srcaddr all
   set dstintf VLAN_200_ext
   set dstaddr all
   set action accept
   set schedule BusinessDay
   set service HTTP
   set profile_status enable
   set profile BusinessOnly
next
edit 4
   set name "CompanyB-after-hours"
   set srcintf VLAN_200_int
   set srcaddr all
   set dstintf VLAN_200_ext
   set dstaddr all
   set action accept
   set schedule always
   set service ANY
   set profile_status enable
   set profile Relaxed
end
```

Configuring the VLAN switch and router

The Cisco switch is the first VLAN device internal passes through, and the Cisco router is the last device before the Internet or ISP.

This section includes the following topics:

- Configuring the Cisco switch
- Configuring the Cisco router

Configuring the Cisco switch

On the Cisco Catalyst 2900 ethernet switch, you need to define the VLANs 100, 200 and 300 in the VLAN database, and then add configuration files to define the VLAN subinterfaces and the 802.1Q trunk interface.

Add this file to Cisco VLAN switch:

```
!
interface FastEthernet0/1
switchport access vlan 100
```

```
!
interface FastEthernet0/5
switchport access vlan 300
!
interface FastEthernet0/6
switchport trunk encapsulation dot1q
switchport mode trunk
!
```

Switch 1 has the following configuration:

Port 0/1	VLAN ID 100
Port 0/3	VLAN ID 200
Port 0/6	802.1Q trunk

Configuring the Cisco router

The configuration for the Cisco router in this example is the same as in the basic example, except we add VLAN_300. Each of the three companies has its own subnet assigned to it.

The IP addressees assigned to each VLAN on the router are the gateway addresses for the VLANs. For example, devices on VLAN_100 would have their gateway set to 10.11.0.1/255.255.0.0.

```
!
interface FastEthernet0/0
 switchport trunk encapsulation dot1q
 switchport mode trunk
!
interface FastEthernet0/0.1
 encapsulation dot1Q 100
 ip address 10.11.0.1 255.255.0.0
!
interface FastEthernet0/0.3
 encapsulation dot1Q 200
 ip address 10.12.0.1 255.255.0.0
!
```

The router has the following configuration:

Port 0/0.1	VLAN ID 100
Port 0/0.3	VLAN ID 200
Port 0/0	802.1Q trunk

Testing the configuration

Use diagnostic commands, such as tracert, to test traffic routed through the network.

You should test traffic between the internal VLANs as well as from the internal VLANs to the Internet to ensure connectivity.

For additional troubleshooting, see Troubleshooting Virtual Domains.

This section includes the following topics:

- Testing traffic from VLAN_100 to the Internet
- Testing traffic from VLAN_100 to VLAN_200

Testing traffic from VLAN_100 to the Internet

In this example, a route is traced from VLANs to a host on the Internet. The route target is www.example.com.

From a host on VLAN_100, access a command prompt and enter this command:

```
C:\>tracert www.example.com
Tracing route to www.example.com [208.77.188.166]
over a maximum of 30 hops:
 1 <10 ms <10 ms <10 ms 10.100.0.1
...
14 172 ms 141 ms 140 ms 208.77.188.166
Trace complete.
```

The number of steps between the first and the last hop, as well as their IP addresses, will vary depending on your location and ISP. However, all successful tracerts to www.example.com will start and end with these lines.

Repeat the tracert for VLAN_200.

The tracert for each VLAN will include the gateway for that VLAN as the first step. Otherwise, the tracert should be the same for each VLAN.

Testing traffic from VLAN_100 to VLAN_200

In this example, a route is traced between two internal networks. The route target is a host on VLAN_200. The Windows traceroute command `tracert` is used.

From VLAN_100, access a Windows command prompt and enter this command:

```
C:\>tracert 10.12.0.2
Tracing route to 10.12.0.2 over a maximum of 30 hops:
1 <10 ms <10 ms <10 ms 10.100.0.1
2 <10 ms <10 ms <10 ms 10.12.0.2
Trace complete.
```

You can repeat this for different routes in the topology. In each case the IP addresses will be the gateway for the starting VLAN, and the end point at the ending VLAN.

Inter-VDOM routing

Inter-VDOM routing changes this allows VDOMs to communicate internally without using additional physical interfaces, using VDOM links. VDOM links are virtual interfaces that connect VDOMs. A VDOM link contains a pair of interfaces with each one connected to a VDOM, and forming either end of the inter-VDOM connection.

This chapter contains the following sections:

- Benefits of inter-VDOM routing
- Configuring VDOM links
- Inter-VDOM configurations
- Dynamic routing over inter-VDOM links
- HA virtual clusters and VDOM links
- Example configuration: Inter-VDOM routing

Benefits of inter-VDOM routing

Inter-VDOM routing has a number of advantages over independent VDOM routing. These benefits include:

- Freed-up physical interfaces
- More speed than physical interfaces
- Continued support for secure firewall policies
- Configuration flexibility

Freed-up physical interfaces

Tying up physical interfaces on the FortiGate unit presents a problem. With a limited number of interfaces available, configuration options for the old style of communication between VDOMs are very limited. VLANs can be an answer to this, but they have some limitations.

For example, the FortiGate-800 has 8 physical ethernet ports. If they are assigned 2 per VDOM (one each for external and internal traffic) there can only be 4 VDOMs at most configured, not the 10 VDOMs the license will allow. Adding even one additional interface per VDOM to be used to communicate between VDOMs leaves only 2 VDOMs for that configuration, since it would required 9 interfaces for 3 VDOMs. Even using one physical interface for both external traffic and inter-VDOM communication would severely lower the available bandwidth for external traffic on that interface.

With the introduction of inter-VDOM routing, traffic can travel between VDOMs internally, freeing up physical interfaces for external traffic. Using the above example we can use the 4 VDOM configuration and all the interfaces will have their full bandwidth.

More speed than physical interfaces

Internal interfaces are faster than physical interfaces. Their speed depends on the FortiGate unit CPU and its load. That means that an inter-VDOM link interface will be faster than a outbound physical interface connected to another inbound physical interface.

However, while one virtual interface with normal traffic would be considerably faster than on a physical interface, the more traffic and more internal interfaces you configure, the slower they will become until they are slower than

the physical interfaces. CPU load can come from other sources such as AV or content scanning. This produces the same effect—internal interfaces such as inter-VDOM links will be slower.

Continued support for secure firewall policies

VDOMs help to separate traffic based on your needs. This is an important step in satisfying regulations that require proof of secure data handling. This is especially important to health, law, accounting, and other businesses that handle sensitive data every day.

By keeping things separate, traffic has to leave the FortiGate unit and re-enter to change VDOMs. This forces traffic to go through the firewall when leaving and enter through another firewall, keeping traffic secure.

With inter-VDOM routing, the need for the physical interfaces is greatly reduced. However, firewall policies still need to be in place for traffic to pass through any interface, physical or virtual, and thus provide the same level of security both internally and externally. Configuration of firewall policies is the same for inter-VDOM links as for any other interface, and your data will continue to have the high level of security.

Configuration flexibility

A typical VDOM uses at least two interfaces, typically physical interfaces, one for internal and one for external traffic. Depending on the configuration, more interfaces may be required. This means that the maximum number of VDOMs configurable on a FortiGate unit using physical interfaces is the number of interfaces available divided by two. VLANs can increase the number by providing multiple virtual interfaces over a single physical interface, but VLANs have some limitations. Using physical interfaces for inter-VDOM communication therefore limits the number of possible configurations on your FortiGate unit.

To overcome this limitation, inter-VDOM links can be created within the FortiGate unit. Using virtual interfaces, inter-VDOM links free up the physical interfaces for external traffic. Using VDOM links on a FortiGate unit with 8 physical interfaces, you can have 4 VDOMs communicating with each other (meshed configuration) and continue to have 2 physical interfaces each for internal and external connections. This configuration would have required 20 physical interfaces without inter-VDOM routing. With inter-VDOM routing it only requires 8 physical interfaces, with the other 12 interfaces being internal VDOM links.

Inter-VDOM routing allows you to make use of standalone VDOMs, Management VDOMs, and Meshed VDOMs without being limited by the number of physical interfaces on your FortiGate unit. For more information about these types of VDOMs, see "Inter-VDOM configurations" on page 3237.

Inter-VDOM configurations

By using fewer physical interfaces to inter-connect VDOMs, inter-VDOM links provide you with more configuration options.

None of these configurations use VLANs to reduce the number of physical interfaces. It is generally assumed that an internal or client network will have its own internal interface and an external interface to connect to its ISP and the Internet.

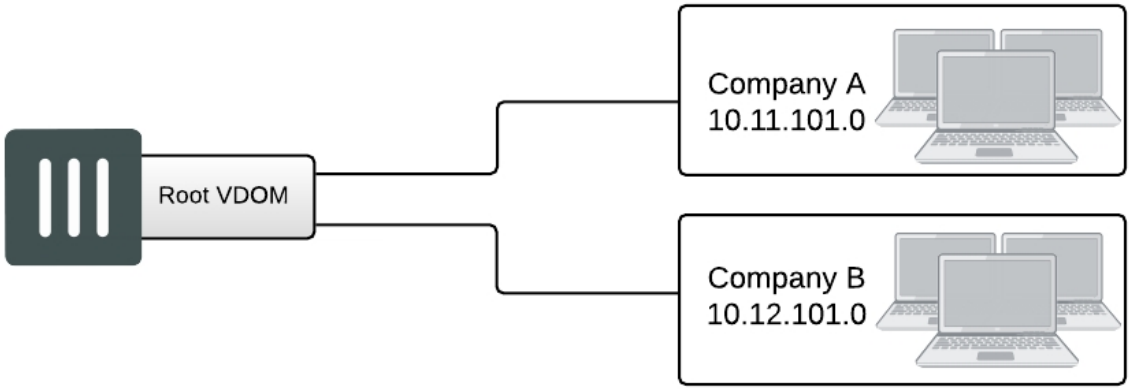
These inter-VDOM configurations can use any FortiGate model with possible limitations based on the number of physical interfaces. VLANs can be used to work around these limitations.

There are four different types of inter-VDOM configurations:

- Standalone VDOM
- Independent VDOMs

- Management VDOM
- Meshed VDOM

Standalone VDOM



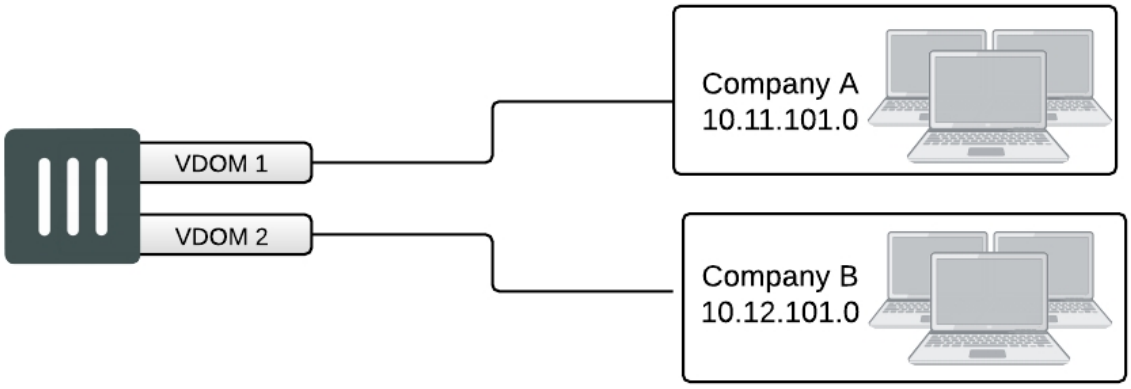
The standalone VDOM configuration uses a single VDOM on your FortiGate unit — the root VDOM that all FortiGate units have by default. This is the VDOM configuration you are likely familiar with. It is the default configuration for FortiGate units before you create additional VDOMs.

The configuration shown above has no VDOM inter-connections and requires no special configurations or settings.

The standalone VDOM configuration can be used for simple network configurations that only have one department or one company administering the connections, firewalls and other VDOM-dependent settings.

However, with this configuration, keeping client networks separate requires many interfaces, considerable firewall design and maintenance, and can quickly become time consuming and complex. Also, configuration errors for one client network can easily affect other client networks, causing unnecessary network downtime.

Independent VDOMs



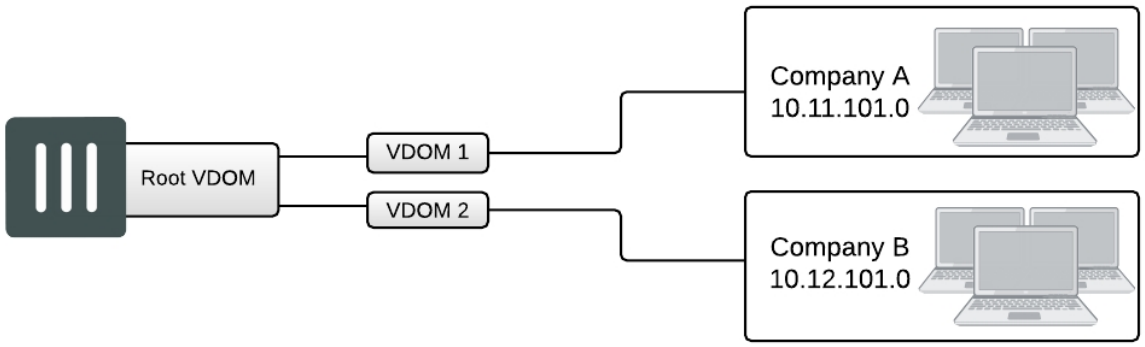
The independent VDOMs configuration uses multiple VDOMs that are completely separate from each other. This is another common VDOM configuration.

This configuration has no communication between VDOMs and apart from initially setting up each VDOM, it requires no special configurations or settings. Any communication between VDOMs is treated as if communication is between separate physical devices.

The independent inter-VDOM configuration can be used where more than one department or one company is sharing the FortiGate unit. Each can administer the connections, firewalls and other VDOM-dependent settings for only its own VDOM. To each company or department, it appears as if it has its own FortiGate unit. This configuration reduces the amount of firewall configuration and maintenance required by dividing up the work.

However, this configuration lacks a management VDOM for VDOMs 1, 2, and 3. This is illustrated in Figure 50. This management VDOM would enable an extra level of control for the FortiGate unit administrator, while still allowing each company or department to administer its own VDOM.

Management VDOM



In the management VDOM configuration, the root VDOM is the management VDOM. The other VDOMs are connected to the management VDOM with inter-VDOM links. There are no other inter-VDOM connections.

The inter-VDOM links connect the management VDOM to the other VDOMs. This does not require any physical interfaces, and the bandwidth of inter-VDOM links can be faster than physical interfaces, depending on the CPU workload.

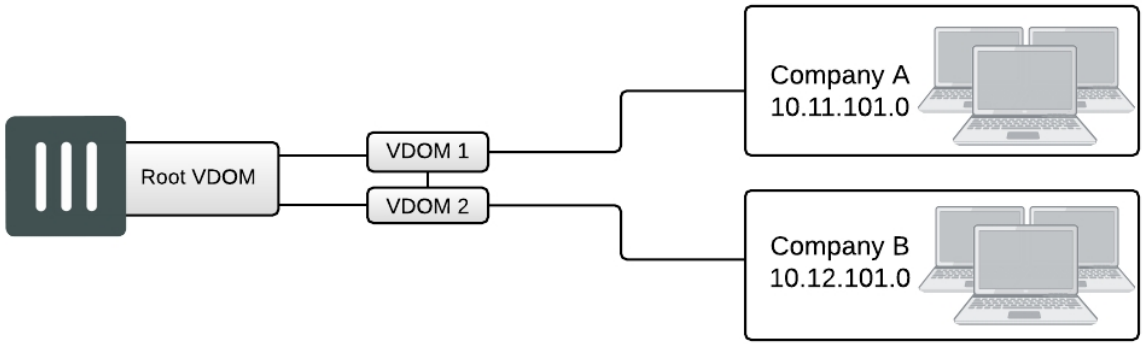
Only the management VDOM is connected to the Internet. The other VDOMs are connected to internal networks. All external traffic is routed through the management VDOM using inter-VDOM links and firewall policies between the management VDOM and each VDOM. This ensures the management VDOM has full control over access to the Internet, including what types of traffic are allowed in both directions. There is no communication directly between the non-root VDOMs. Security is greatly increased with only one point of entry and exit. Only the management VDOM needs to be fully managed to ensure network security in this case. Each client network can manage its own configuration without compromising security or bringing down another client network.

The management VDOM configuration is ideally suited for a service provider business. The service provider administers the management VDOM with the other VDOMs as customers. These customers do not require a dedicated IT person to manage their network. The service provider controls the traffic and can prevent the customers from using banned services and prevent Internet connections from initiating those same banned services. One example of a banned service might be Instant Messaging (IM) at a company concerned about intellectual property. Another example could be to limit bandwidth used by file-sharing applications without

banning that application completely. Firewall policies control the traffic between the customer VDOM and the management VDOM and can be customized for each customer.

The management VDOM configuration is limited in that the customer VDOMs have no inter-connections. In many situations this limitation is ideal because it maintains proper security. However, some configurations may require customers to communicate with each other, which would be easier if the customer VDOMs were inter-connected.

Meshed VDOM



The meshed VDOMs configuration, including partial and full mesh, has VDOMs inter-connected with other VDOMs. There is no special feature to accomplish this—they are just complex VDOM configurations.

Partial mesh means only some VDOMs are inter-connected. In a full mesh configuration, all VDOMs are inter-connected to all other VDOMs. This can be useful when you want to provide full access between VDOMs but handle traffic differently depending on which VDOM it originates from or is going to.

With full access between all VDOMs being possible, it is extra important to ensure proper security. You can achieve this level of security by establishing extensive firewall policies and ensuring secure account access for all administrators and users.

Meshed VDOM configurations can become complex very quickly, with full mesh VDOMs being the most complex. Ensure this is the proper solution for your situation before using this configuration. Generally, these configurations are seen as theoretical and are rarely deployed in the field.

Configuring VDOM links

Once VDOMs are configured on your FortiGate unit, configuring inter-VDOM routing and VDOM-links is very much like creating a VLAN interface. VDOM-links are managed through the web-based manager or CLI. In the web-based manager, VDOM link interfaces are managed in the network interface list.

This section includes the following topics:

- Creating VDOM links
- IP addresses and inter-VDOM links
- Deleting VDOM links
- NAT to Transparent VDOM links

Creating VDOM links

VDOM links connect VDOMs together to allow traffic to pass between VDOMs as per firewall policies. Inter-VDOM links are virtual interfaces that are very similar to VPN tunnel interfaces except inter-VDOM links do not require IP addresses.

To create a VDOM link, you first create the point-to-point interface, and then bind the two interface objects associated with it to the virtual domains.

In creating the point-to-point interface, you also create two additional interface objects by default. They are called `vlink10` and `vlink11` - the interface name you chose with a 1 or a 0 to designate the two ends of the link.

Once the interface objects are bound, they are treated like normal FortiGate interfaces and need to be configured just like regular interfaces.

The assumptions for this example are as follows:

- Your FortiGate unit has VDOMs enabled and you have 2 VDOMs called `customer1` and `customer2` already configured. For more information on configuring VDOMs see Configuring Virtual Domains.
- You are using a super_admin account.

To configure an inter-VDOM link - web-based manager:

1. Go to **Global > Network > Interfaces**.
2. Select **Create New > VDOM link**, enter the following information, and select **OK**.

Name	vlink1 (The name can be up to 11 characters long. Valid characters are letters, numbers, "-", and "_". No spaces are allowed.)
Interface #0	
Virtual Domain	customer1
IP/Netmask	10.11.12.13/255.255.255.0
Administrative Access	HTTPS, SSL
Interface #1	
Virtual Domain	customer2
IP/Netmask	172.120.100.13/255.255.255.0
Administrative Access	HTTPS, SSL

To configure an inter-VDOM link - CLI:

```
config global
   config system vdom-link
      edit vlink1
      end
   config system interface
      edit vlink10
         set vdom customer1
```

```
next
edit vlink11
   set vdom customer2
end
```

Once you have created and bound the interface ends to VDOMs, configure the appropriate firewall policies and other settings that you require. To confirm the inter-VDOM link was created, find the VDOM link pair and use the expand arrow to view the two VDOM link interfaces. You can select edit to change any information.

IP addresses and inter-VDOM links

Besides being virtual interfaces, here is one main difference between inter-VDOM links and regular interfaces—default inter-VDOM links do not require IP addresses. IP addresses are not required by default because an inter-VDOM link is an internal connection that can be referred to by the interface name in firewall policies, and other system references. This introduces three possible situations with inter-VDOM links that are:

- **unnumbered** - an inter-VDOM link with no IP addresses for either end of the tunnel
- **half numbered** - an inter-VDOM link with one IP address for one end and none for the other end
- **full numbered** - an inter-VDOM link with two IP addresses, one for each end.

Not using an IP address in the configuration can speed up and simplify configuration for you. Also you will not use up all the IP addresses in your subnets if you have many inter-VDOM links.

Half or full numbered interfaces are required if you are doing NAT, either SNAT or DNAT as you need an IP number on both ends to translate between.

You can use unnumbered interfaces in static routing, by naming the interface and using `0.0.0.0` for the gateway. Running traceroute will not show the interface in the list of hops. However you can see the interface when you are sniffing packets, which is useful for troubleshooting.

Deleting VDOM links

When you delete the VDOM link, the two link objects associated with it will also be deleted. You cannot delete the objects by themselves. The example uses a VDOM routing connection called “vlink1”. Removing vlink1 will also remove its two link objects vlink10 and vlink11.

Before deleting the VDOM link, ensure all policies, firewalls, and other configurations that include the VDOM link are deleted, removed, or changed to no longer include the VDOM link.

To remove a VDOM link - web-based manager:

1. Go to **Global > Network > Interfaces**.
2. Select **Delete** for the VDOM link **vlink1**.

To remove a VDOM link - CLI:

```
config global
   config system vdom-link
      delete vlink1
   end
```

NAT to Transparent VDOM links

Inter-VDOM links can be created between VDOMs in NAT mode and VDOMs in Transparent mode, but it must be done through the CLI, as the VDOM link type must be changed from the default PPP to Ethernet for the two VDOMs to communicate. The below example assumes one vdom is in NAT mode and one is Transparent.

An IP address must be assigned to the NAT VDOM's interface, but no IP address should be assigned to the Transparent VDOM's interface.

To configure a NAT to Transparent VDOM link - CLI:

```
config global
   config system vdom-link
      edit vlink1
      set type ethernet
      end
   config system interface
      edit vlink10
         set vdom (interface 1 name)
         set ip (interface 1 ip)
      next
      edit vlink11
         set vdom (interface 2 name)
      end
```

Ethernet-type is not recommended for standard NAT to NAT inter-VDOM links, as the default PPP-type link does not require the VDOM links to have addresses, while Ethernet-type does. VDOM link addresses are explained in IP addresses and inter-VDOM links.

Dynamic routing over inter-VDOM links

BGP is supported over inter-VDOM links. Unless otherwise indicated, routing works as expected over inter-VDOM links.

If an inter-VDOM link has no assigned IP addresses to it, it may be difficult to use that interface in dynamic routing configurations. For example BGP requires an IP address to define any BGP router added to the network.

In OSPF, you can configure a router using a router ID and not its IP address. In fact, having no IP address avoids possible confusing between which value is the router ID and which is the IP address. However for that router to become adjacent with another OSPF router it will have to share the same subnet, which is technically impossible without an IP address. For this reason, while you can configure an OSPF router using an IP-less inter-VDOM link, it will likely be of limited value to you.

In RIP the metric used is hop count. If the inter-VDOM link can reach other nodes on the network, such as through a default route, then it may be possible to configure a RIP router on an inter-VDOM link. However, once again it may be of limited value due to limitations.

As stated earlier, BGP requires an IP address to define a router — an IP-less inter-VDOM link will not work with BGP.

In Multicast, you can configure an interface without using an IP address. However that interface will be unable to become an RP candidate. This limits the roles available to such an interface.

HA virtual clusters and VDOM links

FortiGate HA is implemented by configuring two or more FortiGate units to operate as an HA cluster. To the network, the HA cluster appears to function as a single FortiGate unit, processing network traffic and providing normal security services such as firewall, VPN, IPS, virus scanning, web filtering, and spam filtering.

Virtual clustering extends HA features to provide failover protection and load balancing for a FortiGate unit operating with virtual domains. A virtual cluster consists of a cluster of two FortiGate units operating with virtual domains. Traffic on different virtual domains can be load balanced between the cluster units.

With virtual clusters (vclusters) configured, inter-VDOM links must be entirely within one vcluster. You cannot create links between vclusters, and you cannot move a VDOM that is linked into another virtual cluster. If your FortiGate units are operating in HA mode, with multiple vclusters when you create the vdom-link, the CLI command `config system vdom-link` includes an option to set which vcluster the link will be in.

What is virtual clustering?

Virtual clustering is an extension of the FGCP for FortiGate units operating with multiple VDOMS enabled. Virtual clustering operates in active-passive mode to provide failover protection between two instances of a VDOM operating on two different cluster units. You can also operate virtual clustering in active-active mode to use HA load balancing to load balance sessions between cluster units. Alternatively, by distributing VDOM processing between the two cluster units you can also configure virtual clustering to provide load balancing by distributing sessions for different VDOMs to each cluster unit.

Virtual clustering and failover protection

Virtual clustering operates on a cluster of two (and only two) FortiGate units with VDOMs enabled. Each VDOM creates a cluster between instances of the VDOMs on the two FortiGate units in the virtual cluster. All traffic to and from the VDOM stays within the VDOM and is processed by the VDOM. One cluster unit is the primary unit for each VDOM and one cluster unit is the subordinate unit for each VDOM. The primary unit processes all traffic for the VDOM. The subordinate unit does not process traffic for the VDOM. If a cluster unit fails, all traffic fails over to the cluster unit that is still operating.

Virtual clustering and heartbeat interfaces

The HA heartbeat provides the same HA services in a virtual clustering configuration as in a standard HA configuration. One set of HA heartbeat interfaces provides HA heartbeat services for all of the VDOMs in the cluster. You do not have to add a heartbeat interface for each VDOM.

Virtual clustering and HA override

For a virtual cluster configuration, override is enabled by default for both virtual clusters when you:

- Enable VDOM portioning from the web-based manager by moving virtual domains to virtual cluster 2
- Enter set vcluster2 enable from the CLI config system ha command to enable virtual cluster 2.

Usually you would enable virtual cluster 2 and expect one cluster unit to be the primary unit for virtual cluster 1 and the other cluster unit to be the primary unit for virtual cluster 2. For this distribution to occur override must be enabled for both virtual clusters. Otherwise you will need to restart the cluster to force it to renegotiate.

Virtual clustering and load balancing or VDOM partitioning

There are two ways to configure load balancing for virtual clustering. The first is to set the HA mode to active-active. The second is to configure VDOM partitioning. For virtual clustering, setting the HA Mode to active-active has the same result as active-active HA for a cluster without virtual domains. The primary unit receives all sessions and load balances them among the cluster units according to the load balancing schedule. All cluster units process traffic for all virtual domains.

Note: If override is enabled the cluster may renegotiate too often. You can choose to disable override at any time. If you decide to disable override, for best results, you should disable it for both cluster units.

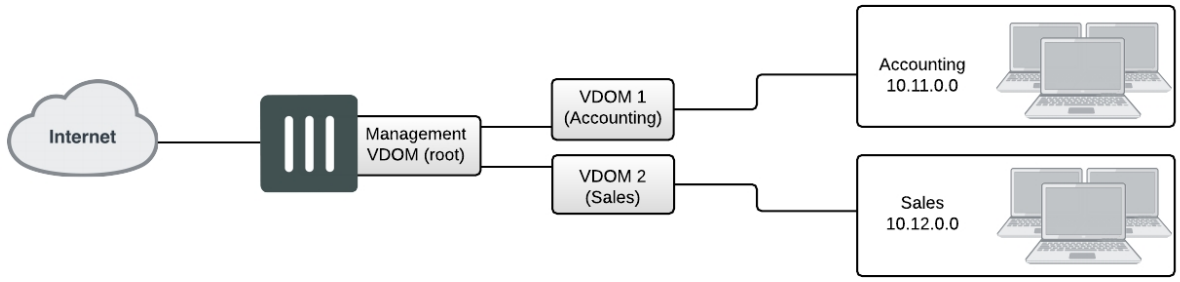
In a VDOM partitioning virtual clustering configuration, the HA mode is set to active-passive. Even though virtual clustering operates in active-passive mode you can configure a form of load balancing by using VDOM partitioning to distribute traffic between both cluster units. To configure VDOM partitioning you set one cluster unit as the primary unit for some virtual domains and you set the other cluster unit as the primary unit for other virtual domains. All traffic for a virtual domain is processed by the primary unit for that virtual domain. You can control the distribution of traffic between the cluster units by adjusting which cluster unit is the primary unit for each virtual domain.

For example, you could have 4 VDOMs, two of which have a high traffic volume and two of which have a low traffic volume. You can configure each cluster unit to be the primary unit for one of the high volume VDOMs and one of the low volume VDOMs. As a result each cluster unit will be processing traffic for a high volume VDOM and a low volume VDOM, resulting in an even distribution of traffic between the cluster units. You can adjust the distribution at any time. For example, if a low volume VDOM becomes a high volume VDOM you can move it from one cluster unit to another until the best balance is achieved. From the web-based manager you configure VDOM partitioning by setting the HA mode to active-passive and distributing virtual domains between Virtual Cluster 1 and Virtual Cluster 2. You can also configure different device priorities, port monitoring, and remote link failover, for Virtual Cluster 1 and Virtual Cluster 2.

From the CLI you configure VDOM partitioning by setting the HA mode to a-p. Then you configure device priority, port monitoring, and remote link failover and specify the VDOMs to include in virtual cluster 1. You do the same for virtual cluster 2 by entering the config secondary-vcluster command.

Failover protection does not change. If one cluster unit fails, all sessions are processed by the remaining cluster unit. No traffic interruption occurs for the virtual domains for which the still functioning cluster unit was the primary unit. Traffic may be interrupted temporarily for virtual domains for which the failed unit was the primary unit while processing fails over to the still functioning cluster unit. If the failed cluster unit restarts and rejoins the virtual cluster, VDOM partitioning load balancing is restored.

Example configuration: Inter-VDOM routing



This example shows how to configure a FortiGate unit to use inter-VDOM routing.

This section contains the follow topics:

- Network topology and assumptions
- Creating the VDOMs
- Configuring the physical interfaces
- Configuring the VDOM links
- Configuring the firewall and Security Profile settings
- Testing the configuration

Network topology and assumptions

Two departments of a company, Accounting and Sales, are connected to one FortiGate 800 unit. To do its work, the Sales department receives a lot of email from advertising companies that would appear to be spam if the Accounting department received it. For this reason, each department has its own VDOM to keep firewall policies and other configurations separate. A management VDOM makes sense to ensure company policies are followed for traffic content.

The traffic between Accounting and Sales will be email and HTTPS only. It could use a VDOM link for a meshed configuration, but we will keep from getting too complex. With the configuration, inter-VDOM traffic will have a slightly longer path to follow than normal—from one department VDOM, through the management VDOM, and back to the other department VDOM. Since inter-VDOM links are faster than physical interfaces, this longer path should not be noticed.

Firewall policies will be in place. For added security, firewall policies will allow only valid office services such as email, web browsing, and FTP between either department and the Internet. Any additional services that are required can be added in the future.

The company uses a single ISP to connect to the Internet. The ISP uses DHCP to provide an IP address to the FortiGate unit. Both departments use the same ISP to reach the Internet.

Other assumptions for this example are as follows:

- Your FortiGate unit has interfaces labelled port1 through port4 and VDOMs are not enabled.
- You are using the super_admin account.
- You have the FortiClient application installed.
- You are familiar with configuring interfaces, firewalls, and other common features on your FortiGate unit.

General configuration steps

This example includes the following general steps. For best results, follow the steps in the order given. Also, note that if you perform any additional actions between procedures, your configuration may have different results.

1. Creating the VDOMs
2. Configuring the physical interfaces
3. Configuring the VDOM links
4. Configuring the firewall and Security Profile settings
5. Testing the configuration

Creating the VDOMs

This procedure enables VDOMs and creates the Sales and Accounting VDOMs.

To create the VDOMs - web-based manager:

1. Log in as the super_admin administrator.
2. Go tothe **Dashboard** and locate the **System Information** widget. Enable **Virtual Domain**.
3. Log in again.
4. Go to **Global > System > VDOM**.
5. Select **Create New**, enter `Accounting` for the VDOM Name, and select **OK**.
6. Select **Create New**, enter `Sales` for the VDOM Name, and select **OK**.

To create the VDOMs - CLI:

```
config system global
   set vdom enable
end
config system vdom
   edit Accounting
   next
   edit Sales
   next
end
```

Configuring the physical interfaces

Next, the physical interfaces must be configured. This example uses three interfaces on the FortiGate unit - port2 (internal), port3(dmz), and port1(external). port2 and port3 interfaces each have a department's network connected. port1 is for all traffic to or from the Internet and will use DHCP to configure its IP address, which is common with many ISPs.

To configure the physical interfaces - web-based manager:

1. Go to **Global > Network > Interfaces**.
2. Select **Edit** for the port2 interface, enter the following information, and select **OK.**

Alias	AccountingLocal
Virtual Domain	Accounting
Addressing mode	Manual
IP/Netmask	172.100.1.1/255.255.0.0
Administrative Access	HTTPS, PING, SSH
Description	This is the accounting department internal interface.

3. Select **Edit** for the port3 interface, enter the following information, and select **OK**.

Alias	SalesLocal
Virtual Domain	Sales
Addressing mode	Manual

IP/Netmask	192.168.1.1/255.255.0.0
Administrative Access	HTTPS, PING, SSH
Description	This is the sales department internal interface.

4. Select **Edit** for the port1 interface, enter the following information, and select **OK**.

Alias	ManagementExternal
Virtual Domain	root
Addressing Mode	DHCP
Distance	5
Retrieve default gateway from server	Enable
Override internal DNS	Enable
Administrative Access	HTTPS, SSH, SNMP
Description	This is the accounting department internal interface.

When the mode is set to DHCP or PPoE on an interface you can set the distance field. This is the administrative distance for any routes learned through the gateway for this interface. The gateway is added to the static route table with these values. A lower distance indicates a preferred route.

To configure the physical interfaces - CLI:

```
config global
   config system interface
      edit port2
         set alias AccountingLocal
         set vdom Accounting
         set mode static
         set ip 172.100.1.1 255.255.0.0
         set allowaccess https ping ssh
         set description "The accounting dept internal interface"
      next
      edit port3
         set alias SalesLocal
         set vdom Sales
         set mode static
         set ip 192.168.1.1 255.255.0.0
         set allowaccess https ping ssh
         set description "The sales dept. internal interface"
      next
      edit port1
         set alias ManagementExternal
         set vdom root
         set mode DHCP
```

```
    set distance 5
    set gwdetect enable
    set dns-server-override enable
    set allowaccess https ssh snmp
    set description "The systemwide management interface."
  end
```

Configuring the VDOM links

To complete the connection between each VDOM and the management VDOM, you need to add the two VDOM links; one pair is the Accounting - management link and the other is for Sales - management link.

When configuring inter-VDOM links, you do not have to assign IP addresses to the links unless you are using advanced features such as dynamic routing that require them. Not assigning IP addresses results in faster configuration, and more available IP addresses on your networks.

If you require them, or if you simply want to assign IP addresses for clarity can do so.

To configure the Accounting and management VDOM link - web-based manager:

1. Go to **Global > Network > Interfaces**.
2. Select the expand arrow to select **Create New > VDOM link**.
3. Enter the following information, and select **OK**.

Name		AccountVlnk
Interface #0		
	Virtual Domain	Accounting
	IP/Netmask	0.0.0.0/0.0.0.0
	Administrative Access	HTTPS, PING, SSH
	Description	The Accounting VDOM side of the link.
Interface #1		
	Virtual Domain	root
	IP/Netmask	0.0.0.0/0.0.0.0
	Administrative Access	HTTPS, PING, SSH
	Description	The Management VDOM side of the link.

To configure the Accounting and management VDOM link - CLI:

```
config global
  config system vdom-link
    edit AccountVlnk
    next
  end
  config system interface
```

```
edit AccountVlnk0
   set vdom Accounting
   set ip 0.0.0.0 0.0.0.0
   set allowaccess https ping ssh
   set description "Accounting side of the VDOM link"
next
edit AccountVlnk1
   set vdom root
   set ip 0.0.0.0 0.0.0.0
   set allowaccess https ping ssh
   set description "Management side of the VDOM link"
end
```

To configure the Sales and management VDOM link - web-based manager:

1. Go to **Global > Network > Interfaces**.
2. Select the expand arrow and select **Create New > VDOM link**.
3. Enter the following information, and select **OK**.

Name		SalesVlnk
Interface #0		
	Virtual Domain	Sales
	IP/Netmask	0.0.0.0/0.0.0.0
	Administrative Access	HTTPS, PING, SSH
	Description	The Sales VDOM side of the link.
Interface #1		
	Virtual Domain	root
	IP/Netmask	0.0.0.0/0.0.0.0
	Administrative Access	HTTPS, PING, SSH
	Description	The Management VDOM side of the link.

To configure the Sales and management VDOM link - CLI:

```
config global
   config system vdom-link
      edit SalesVlnk
   end
   config system interface
      edit SalesVlnk0
         set vdom Accounting
         set ip 0.0.0.0 0.0.0.0
         set allowaccess https ping ssh
         set description "Sales side of the VDOM link"
      next
```

```
    edit SalesVlnk1
      set vdom root
      set ip 0.0.0.0 0.0.0.0
      set allowaccess https ping ssh
      set description "Management side of the VDOM link"
    end
end
```

Configuring the firewall and Security Profile settings

With the VDOMs, physical interfaces, and VDOM links configured the firewall must now be configured to allow the proper traffic. Firewalls are configured per-VDOM, and firewall objects must be created for each VDOM separately.

For this example, the firewall group of services allowed between the internal networks and the Internet are the basic services for web browsing, file transfer, and email. These include: HTTP, HTTPS, SSL, FTP, DNS, NTP, POP3, and SMTP.

The only services allowed between Sales and Accounting are secure web browsing (HTTPS) and email (POP3 and SMTP).

The limited number of services ensures security between departments. The list of services can be expanded in the future if needed.

Security profile settings will block all non-essential business websites while logging all web traffic, scan and file filter all web and email protocols, and block game and peer-to-peer applications using application control.

For added security, FortiClient is required on internal computers with AntiVirus scanning configured. This is enforced by **Endpoint NAC** in firewall policies.

Using firewall addresses makes the firewall policies easier to read. Also if any changes need to be made in the future, you can simply update the addresses without changing the firewall policies. The addresses required are:

- `AccountingLocal` - all traffic from the internal accounting network
- `AccountingVlnk` - all traffic from the VDOM link between accounting and management VDOMs
- `SalesLocal` - all traffic from the internal sales network
- `SalesVlnk` - all traffic from the VDOM link between sales and management VDOM.

The Accounting VDOM requires `AccountingLocal`, `AccountingVlnk`, and `SalesLocal`. The Sales VDOM requires `SalesLocal`, `SalesVlnk`, and `AccountingLocal`.

This section includes the following topics:

- Configuring firewall service groups
- Configuring Security Profile settings for the Accounting VDOM
- Configuring firewall settings for the Accounting VDOM
- Configuring Security Profile settings for the Sales VDOM
- Configuring firewall settings for the Sales VDOM
- Configuring firewall settings between the Accounting and Sales VDOMs

Configuring firewall service groups

Service groups are an easy way to manage multiple services, especially if the same services are used on different networks.

The two service groups used here are intended for normal office traffic to the Internet, and for restricted traffic between departments. In both cases network traffic will be limited to the services listed to prevent any potential security risks or bandwidth-robbing applications.

These service groups can be changed as needed to either include additional valid services that are being used on the network, or to exclude services that are not required. Also, custom services can be created as needed for applications that are not listed.

To configure two firewall service groups - web-based manager:

1. Open the **Accounting** VDOM.
2. Go to **Policy & Objects > Services** and select **Create New > Service Group.**
3. Select **Create New**, enter the following information, and select **OK.**

Group Name	OfficeServices
Members	HTTP, HTTPS, SSL, FTP, DNS, NTP, POP3, PING, SMTP

4. Select **Create New**, enter the following information, and select **OK**.

Group Name	AccountingSalesServices
Members	HTTPS, POP3, PING, SMTP

To configure two firewall service groups - CLI:

```
config vdom
   edit Accounting
      config firewall service group
         edit OfficeServices
            set member HTTP HTTPS SSH FTP DNS NTP POP3 PING SMTP
         next
         edit AccountingSalesServices
            set member HTTPS POP3 PING SMTP
         end
   end
```

Configuring Security Profile settings for the Accounting VDOM

Security Profile settings include web filtering, antivirus, application control, and other features. This example just uses those three features to ensure that

- the business environment is free from viruses
- employees do not surf grossly inappropriate websites, and
- employees do not use games or peer-to-peer applications at work.

To configure web filtering for the Accounting VDOM - web-based manager:

1. Open the **Accounting** VDOM.
2. Go to **Security Profiles > Web Filter**.
3. Select **Create New**.
4. Enter `webStrict` for the **Name**.
5. Select the arrow to expand the **FortiGuard Web Filtering** section.
6. Block all **Categories** except Business Oriented, Other, and Unrated.
7. Block all **Classifications** except Image Search..
8. Log all **Categories** and **Classifications**.
9. Select **OK**.

To configure AntiVirus for the Accounting VDOM - web-based manager:

1. Open the **Accounting** VDOM.
2. Go to **Security Profiles > AntiVirus**.
3. Select **Create New**.
4. Enter `avStrict` for the **Name**.
5. Set **Detect Virues** to **Block** and enable all **Inspected Protocols**.
6. Select **OK**.

To configure application control for the Accounting VDOM - web-based manager:

1. Open the **Accounting** VDOM.
2. Go to **Security Profiles > Application Control.**
3. Select **Create New** (+ button at top right of page).
4. Enter `appStrict` for **Name** and select OK.
5. Select **Create New**.
6. In **Filters**, set **Category** to **game**.
7. In **Applications/Settings**, enter the following, and select **OK**.

Action	Block
Packet Logging	Enable

8. Select **Create New**.
9. In **Filters**, set **Category** to **p2p**.
10. In **Applications/Settings**, enter the following, and select **OK**.

Action	Block
Packet Logging	Enable

11. Select **Apply**.

To configure application control for the Accounting VDOM - CLI:

```
config vdom
```

```
edit Accounting
   config application list
      edit appStrict
         config entries
            edit 1
               set category 2
            next
            edit 2
               set category 8
            end
      end
end
```

Configuring firewall settings for the Accounting VDOM

This configuration includes two firewall addresses and two firewall policies for the Accounting VDOM - one for the internal network, and one for the VDOM link with the management VDOM (root).

For added security, all traffic allowed will be scanned. Only valid office traffic will be allowed using the service group `OfficeServices`.

Note the spelling of `AccountVlnk` which is due to the eleven character limit on VDOM link names.

To configure firewall addresses - web-based manager:

1. Open the **Accounting** VDOM.
2. Select **Policy & Objects > Addresses**.
3. Select **Create New**, enter the following information, and select **OK**.

Address Name	AccountingLocal
Type	Subnet/ IP Range
Subnet / IP Range	172.100.0.0
Interface	port1

4. Select **Create New**, enter the following information, and select **OK**.

Address Name	AccountManagement
Type	Subnet/ IP Range
Subnet / IP Range	10.0.1.0
Interface	AccountVlnk

To configure firewall addresses - CLI:

```
config vdom
   edit Accounting
      config firewall address
         edit AccountingLocal
            set type iprange
            set subnet 172.100.0.0
```

```
      set associated-interface port1
    next
    edit AccountManagement
      set type iprange
      set subnet 10.0.1.0
      set associated-interface AccountVlnk
    end
end
```

To configure the firewall policies from AccountingLocal to the Internet - web-based manager:

1. Open the **Accounting** VDOM.
2. Go to **Policy & Objects > IPv4 Policy**.
3. Select **Create New**, enter the following information, and then select **OK**.

Name	Accounting-Local-to-Management
Incoming Interface	port2
Outgoing Interface	AccountVlnk
Source Address	AccountingLocal
Destination Address	AccountManagement
Schedule	always
Service	OfficeServices
Action	ACCEPT
Enable NAT	enable
Security Features	enabled
Web Filtering	webStrict
AntiVirus Filtering	avStrict
Application Control	appStrict

4. Open the **root** VDOM.
5. Go to **Policy & Objects > IPv4 Policy.**
6. Select **Create New**, enter the following information, and then select **OK**.

Name	Accounting-VDOM-to-Internet
Incoming Interface	AccountVlnk
Outgoing Interface	ManagementExternal
Source Address	AccountManagement

Destination Address	all
Schedule	always
Service	OfficeServices
Action	ACCEPT
Enable NAT	enable
Security Features	enabled
Web Filtering	webStrict
AntiVirus Filtering	avStrict
Application Control	appStrict

To configure the firewall policies from AccountingLocal to Internet - CLI:

```
config vdom
   edit Accounting
      config firewall policy
         edit 1
            set name "Accounting-Local-to-Management"
            set srcintf port2
            set dstintf AccountVlnk
            set srcaddr AccountingLocal
            set dstaddr AccountManagement
            set action accept
            set schedule always
            set service OfficeServices
            set nat enable
            set av-profile avStrict
            set webfilter-profile webStrict
            set application-list appStrict
         end
   end
config vdom
   edit root
      config firewall policy
         edit 2
            set name "Accounting-VDOM-to-Internet"
            set srcintf AccountVlnk
            set dstintf port1
            set srcaddr AccountManagement
            set dstaddr all
            set action accept
            set schedule always
            set service OfficeServices
            set nat enable
            set av-profile scan
            set webfilter-profile scan
            set application-list AppControlList
         end
   end
```

To configure the firewall policies from Internet to AccountingLocal - web-based manager:

1. Open the **root** VDOM.
2. Go to **Policy & Objects > IPv4 Policy**.
3. Select **Create New**, enter the following information, and select **OK**.

Name	Internet-access-to-Accounting-VDOM
Incoming Interface	port1
Outgoing Interface	AccountVlnk
Source Address	all
Destination Address	AccountManagement
Schedule	always
Service	OfficeServices
Action	ACCEPT
Enable NAT	enable
Security Features	enabled
Web Filtering	webStrict
AntiVirus Filtering	avStrict
Application Control	appStrict

4. Open the **Accounting** VDOM.
5. Go to **Policy & Objects > IPv4 Policy.**
6. Select **Create New**, enter the following information, and select **OK**.

Name	Management-access-to-Accounting-local
Incoming Interface	AccountVlnk
Outgoing Interface	port2
Source Address	AccountManagement
Destination Address	AccountingLocal
Schedule	always
Service	OfficeServices
Action	ACCEPT
Enable NAT	enable

Security Features	enabled
Web Filtering	webStrict
AntiVirus Filtering	avStrict
Application Control	appStrict

To configure the firewall policies from Internet to AccountingLocal - CLI:

```
config vdom
   edit root
      config firewall policy
         edit 3
            set name "Internet-access-to-Accounting-VDOM"
            set srcintf port1
            set dstintf AccountVlnk
            set srcaddr all
            set dstaddr AccountManagement
            set action accept
            set schedule always
            set service OfficeServices
            set nat enable
            set av-profile avStrict
            set webfilter-profile webStrict
            set application-list appstrict
         end
   end
config vdom
   edit Accounting
      config firewall policy
         edit 4
            set name "Management-access-to-Accounting-local"
            set srcintf AccountVlnk
            set dstintf port2
            set srcaddr AccountManagement
            set dstaddr AccountingLocal
            set action accept
            set schedule always
            set service OfficeServices
            set nat enable
            set av-profile avStrict
            set webfilter-profile webStrict
            set application-list appstrict
         end
   end
```

Configuring Security Profile settings for the Sales VDOM

Security profile settings include web filtering, antivirus, application control, and other features. This example just uses those three features to ensure that

- the business environment is free from viruses
- employees do not surf grossly inappropriate websites, and
- employees do not use games or peer-to-peer applications at work.

Note that Sales web traffic is different from Accounting, and web filtering is different to account for this.

To configure web filtering for the Sales VDOM - web-based manager:

1. Open the **Sales** VDOM.
2. Go to **Security Profiles > Web Filter**.
3. Select **Create New**.
4. Enter `webStrict` for the **Name**.
5. In **FortiGuard Categories**, select all of the categories except **Bandwidth Consuming**, **General Interest - Business** and **Unrated**.
6. In **Change Action for Selected Categories** select **Block**.
7. Select **Apply**.

To configure web filtering for the Sales VDOM - CLI:

```
config vdom
   edit Sales
      config webfilter profile
         edit webStrict
            config ftgd-wf
               set allow g07 g08 g21 g22 c01 c03
               set deny g01 g02 g03 g04 g05 g06 c02 c04 c05 c06 c07
            end
            set web-ftgd-err-log enable
         end
   end
```

To configure AntiVirus for the Sales VDOM - web-based manager:

1. Open the **Sales** VDOM.
2. Go to **Security Profiles > AntiVirus**.
3. Select **Create New**.
4. Enter `avStrict` for the **Name**.
5. Set **Detect Virues** to **Block** and enable all **Inspected Protocols**.
6. Select **Apply**.

To configure AntiVirus for the Sales VDOM - CLI:

```
config vdom
   edit Sales
      config antivirus profile
         edit "avStrict"
            config http
               set options scan file-filter
            end
            config ftp
               set options scan file-filter
            end
            config imap
               set options scan file-filter
            end
            config pop3
               set options scan file-filter
```

```
            end
            config smtp
               set options scan file-filter
            end
            config nntp
               set options scan file-filter
            end
            config im
               set options scan file-filter
            end
            set filepattable 1
            set av-virus-log enable
            set av-block-log enable
         end
   end
```

To configure application control for the Sales VDOM - web-based manager:

1. Open the **Accounting** VDOM.
2. Go to **Security Profiles > Application Control.**
3. Select **Create New** (+ button at top right of page).
4. Enter `appStrict` for **Name** and select OK.
5. Select **Create New**.
6. In **Filters**, set **Category** to **game**.
7. In **Applications/Settings**, enter the following, and select **OK**.

Action	Block
Packet Logging	Enable

8. Select **Create New**.
9. In **Filters**, set **Category** to **p2p**.
10. In **Applications/Settings**, enter the following, and select **OK**.

Action	Block
Packet Logging	Enable

11. Select **Apply**.

To configure application control for the Sales VDOM - CLI:

```
config vdom
   edit Sales
      config application list
         edit "appStrict"
            config entries
               edit 1
                  set category 2
               next
               edit 2
                  set category 8
```

```
            end
        end
    end
```

Configuring firewall settings for the Sales VDOM

Like the Accounting firewall settings, this configuration includes two firewall addresses and two firewall policies for the sales VDOM: one for the internal network, and one for the VDOM link with the management VDOM.

When entering the CLI commands, the number of the firewall policies must be high enough to be a new policy. Depending on the number of firewall policies on your FortiGate unit, this may require starting at a higher number than the 6 required for the default configuration. This number is added automatically when you configure firewall policies using the web manager interface.

The FortiClient application must be used on Sales network computers to ensure additional protection for the sensitive information and for protection against spam.

To configure firewall addresses - web-based manager:

1. Open the **Sales** VDOM.
2. Go to **Policy & Objects > Addresses**.
3. Select **Create New,** enter the following information, and select **OK**.

Address Name	SalesLocal
Type	Subnet / IP Range
Subnet / IP Range	172.100.0.0
Interface	port3

4. Go to **Policy & Objects > Addresses**.
5. Select **Create New**, enter the following information, and select **OK**.

Address Name	SalesManagement
Type	Subnet / IP Range
Subnet / IP Range	10.0.1.0
Interface	SalesVlnk

To configure the firewall addresses - CLI:

```
config vdom
   edit Sales
      config fireall address
         edit SalesLocal
            set type iprange
            set subnet 172.100.0.0
            set associated-interface port2
         next
         edit SalesManagement
            set type iprange
```

```
            set subnet 10.0.1.0
            set associated-interface SalesVlnk
        end
    end
```

To configure the firewall policies from SalesLocal to the Internet - web-based manager:

1. Open the **Sales** VDOM.
2. Go to **Policy & Objects > IPv4 Policy**.
3. Select **Create New**, enter the following information, and select **OK**.

Name	Sales-local-to-Management
Incoming Interface	port3
Outgoing Interface	SalesVlnk
Source Address	SalesLocal
Destination Address	SalesManagement
Schedule	always
Service	OfficeServices
Action	ACCEPT
Log Allowed Traffic	enabled

4. Open the **root** VDOM.
5. Go to **Policy & Objects > IPv4 Policy.**
6. Select **Create New**, enter the following information, and select **OK**.

Name	Sales-VDOM-to-Internet
Incoming Interface	SalesVlnk
Outgoing Interface	ManagementExternal
Source Address	SalesManagement
Destination Address	all
Schedule	always
Service	OfficeServices
Action	ACCEPT
Log Allowed Traffic	enabled

To configure the firewall policies from SalesLocal to the Internet - CLI:

```
config vdom
   edit root
```

```
        config firewall policy
          edit 6
            set name "Sales-local-to-Management"
            set srcintf port2
            set srcaddr SalesLocal
            set dstintf SalesVlnk
            set dstaddr SalesManagement
            set schedule always
            set service OfficeServices
            set action accept
            set logtraffic enable
          end
      end
    config vdom
      edit Sales
        config firewall policy
          edit 7
            set name "Sales-VDOM-to-Internet"
            set srcintf SalesVlnk
            set srcaddr SalesManagement
            set dstintf external
            set dstaddr all
            set schedule always
            set service OfficeServices
            set action accept
            set logtraffic enable
          end
      end
```

To configure the firewall policies from the Internet to SalesLocal - web-based manager:

1. Open the **root** VDOM.
2. Go to **Policy & Objects > IPv4 Policy.**
3. Select **Create New**, enter the following information, and select **OK**.

Name	Internet-access-to-Sales-VDOM
Incoming Interface	ManagementExternal
Outgoing Interface	SalesVlnk
Source Address	all
Destination Address	SalesManagement
Schedule	always
Service	OfficeServices
Action	ACCEPT
Protection Profile	scan
Log Allowed Traffic	enabled

4. Open the **Sales** VDOM.
5. Go to **Policy & Objects > IPv4 Policy.**
6. Select **Create New**, enter the following information, and select **OK**.

Name	Management-access-to-Sales-local
Incoming Interface	SalesVlnk
Outgoing Interface	port2
Source Address	SalesManagement
Destination Address	SalesLocal
Schedule	always
Service	OfficeServices
Action	ACCEPT
Log Allowed Traffic	enabled

To configure the firewall policies from the Internet to SalesLocal - CLI:

```
config vdom
   edit root
      config firewall policy
         edit 8
            set name "Internet-access-to-Sales-VDOM"
            set srcintf external
            set srcaddr all
            set dstintf SalesVlnk
            set dstaddr SalesManagement
            set schedule always
            set service OfficeServices
            set action accept
            set logtraffic enable
         end
   end
config vdom
   edit Sales
      config firewall policy
         edit 9
            set name "Management-access-to-Sales-local"
            set srcintf SalesVlnk
            set srcaddr SalesManagement
            set dstintf port2
            set dstaddr SalesLocal
            set schedule always
            set service OfficeServices
            set action accept
            set logtraffic enable
         end
   end
```

Configuring firewall settings between the Accounting and Sales VDOMs

Firewall policies are required for any communication between each internal network and the Internet. Policies are also required for the two internal networks to communicate with each other through the management VDOM.

The more limited AccountingSalesServices group of services will be used between Sales and Accounting to ensure the traffic is necessary business traffic only. These policies will result in a partially meshed VDOM configuration. The FortiClient application must be used to ensure additional protection for the sensitive accounting information.

Two firewall policies are required to allow traffic in both directions between Sales and Accounting.

To configure the firewall policy between Sales and Accounting on the management VDOM - web-based manager:

1. Open the **root** VDOM.
2. Go to **Policy & Objects > IPv4 Policy.**
3. Select **Create New**, enter the following information, and select **OK**.

Name	Sales-VDOM-to-Accounting-VDOM
Incoming Interface	SalesVlnk
Outgoing Interface	AccountVlnk
Source Address	SalesManagement
Destination Address	AccountingManagement
Schedule	always
Service	AccountingSalesServices
Action	ACCEPT
Protection Profile	scan
Log Allowed Traffic	enabled

4. Go to **Policy & Objects > IPv4 Policy.**
5. Select **Create New**, enter the following information, and select **OK**.

Name	Accounting-VDOM-to-Sales-VDOM
Incoming Interface	AccountVlnk
Outgoing Interface	SalesVlnk
Source Address	AccountingManagement
Destination Address	SalesManagement
Schedule	always

Service	AccountingSalesServices
Action	ACCEPT
Log Allowed Traffic	enabled

To configure the firewall policy between Sales and Accounting on the management VDOM - CLI:

```
config vdom
   edit root
      config system firewall policy
         edit 9
            set name "Sales-VDOM-to-Accounting-VDOM"
            set srcintf SalesVlnk
            set srcaddr SalesManagement
            set dstintf AccountVlnk
            set dstaddr AccountManagement
            set schedule always
            set service AccountingSalesServices
            set action accept
            set logtraffic enable
         next
         edit 10
            set name "Accounting-VDOM-to-Sales-VDOM"
            set srcintf AccountVlnk
            set srcaddr AccountManagement
            set dstintf SalesVlnk
            set dstaddr SalesManagement
            set schedule always
            set service AccountingSalesServices
            set action accept
            set logtraffic enable
         end
   end
```

Testing the configuration

Once the inter-VDOM routing has been configured, tests must be conducted to confirm proper operation. If there are any problems, use the troubleshooting tips to resolve them.

This section includes the following topics:

- Testing connectivity
- Troubleshooting Tips

Testing connectivity

Testing connectivity ensures that physical networking connections as well as FortiGate unit interface configurations, including firewall policies, are properly configured.

The easiest way to test connectivity is to use the `ping` and `traceroute` commands to confirm the connectivity of different routes on the network. Include testing:

- from AccountingLocal to Internet
- from Internet to AccountingLocal

- from SalesLocal to Internet
- from Internet to SalesLocal
- from AccountingLocal to SalesLocal.

When using the commands on a Windows computer, go to a command line prompt and enter either `ping <IP address>` or `tracert <IP address>`.

When using the commands on a FortiGate unit, go to the CLI and enter either `exec ping <IP address>` or `exec traceroute <IP address>`.

Troubleshooting Tips

When there are problems with connectivity, the following troubleshooting tips will help resolve the issues.

- If a multiple hop test, such as traceroute, is not successful then reduce it to a single hop to simplify the test. Test each link of the path to see which hop is down. If all hops are up, check the FortiGate unit policies to ensure they allow basic traffic to flow as expected.
- If ping does not work, confirm that the FortiGate unit interfaces have Ping enabled and also ensure Ping is enabled in the firewall policies. Otherwise the Ping traffic will be blocked.
- If one protocol does not work but others do work, check the FortiGate unit firewall policies for that one protocol to ensure it is allowed.
- If there are unexplained connectivity problems, check the local computer to ensure it does not have a software firewall running that may be blocking traffic. MS Windows computers have a firewall running by default that can cause problems.

For additional troubleshooting, see Troubleshooting Virtual Domains.

Troubleshooting Virtual Domains

When you are configuring VDOMs you may run into some issues, with your VDOM configuration, your network configuration, or your device setup. This section addresses common problems and specific concerns that an administrator of a VDOM network may have.

This section includes:

- VDOM admin having problems gaining access
- FortiGate unit running very slowly
- General VDOM tips and troubleshooting

VDOM admin having problems gaining access

With VDOMs configured, administrators have an extra layer of permissions and may have problems accessing their information.

Confirm the admin's VDOM

Each administrator account, other than the super_admin account, is tied to one specific VDOM. That administrator is not able to access any other VDOM. It may be possible they are trying to access the wrong VDOM.

Confirm the VDOM's interfaces

An administrator can only access their VDOM through interfaces that are assigned to that VDOM. If interfaces on that VDOM are disabled or unavailable there will be no method of accessing that VDOM by its local administrator. The super_admin will be required to either bring up the interfaces, fix the interfaces, or move another interface to that VDOM to restore access.

Confirm the VDOMs admin access

As with all FortiGate units, administration access on the VDOM's interfaces must be enabled for that VDOM's administrators to gain access. For example if SSH is not enabled, that is not available to administrators.

To enable admin access, the super_admin will go to the **Global > Network > Interfaces** page, and for the interface in question enable the admin access.

FortiGate unit running very slowly

You may experience a number of problems resulting from your FortiGate unit being overloaded. These problems may appear as:

- CPU and memory threshold limits exceeded on a continual basis
- AV failopen happening on a regular basis
- dropped traffic or sessions due to lack of resources

These problems are caused by a lack of system resources. There are a number of possible reasons for this.

Too many VDOMs

If you have configured many VDOMs on your system, past the default ten VDOMs, this could easily be your problem.

Each VDOM you create on your FortiGate unit requires system resources to function - CPU cycles, memory, and disk space. When there are too many VDOMs configured there are not enough resources for operation. This may be a lack of memory in the session table, or no CPU cycles for processing incoming IPS traffic, or even a full disk drive.

Go to **Global > System > VDOM** and see the number of configured VDOMs on your system. If you are running 500 or more VDOMs, you must have a FortiGate 5000 chassis. Otherwise you need to reduce the number of VDOMs on your system to fix the problem. Even if you have the proper hardware, you may encounter noticeably slow throughput if you are using advanced features such as security profiles or deep content inspection with many configured VDOMs.

One or more VDOMs are consuming all the resources

If you have sufficient hardware to support the number of VDOMs you are running, check the global resources on your FortiGate unit. At a glance it will tell you if you are running out of a particular resource such as sessions, or users. If this is the case, you can then check your VDOMs to see if one particular VDOM is using more than its share of resources. If that is the case you can change the resource settings to allow that VDOM (or those VDOMs) fewer resources and in turn allow the other VDOMs access to those resources.

Too many Security Features in use

It is likely that reducing the Security Features in use regardless of number of VDOMs will greatly improve overall system performance and should be considered as an option.

Finally it is possible that your FortiGate unit configuration is incorrect in some other area, which is using up all your resources. For example, forgetting that you are running a network sniffer on an interface will create significant amounts of traffic that may prevent normal operation.

General VDOM tips and troubleshooting

Besides ping and traceroute, there are additional tools for troubleshooting your VDOM configurations. These include packet sniffing and debugging the packet flow.

Perform a sniffer trace

When troubleshooting networks, it helps to look inside the headers of packets to determine if they are traveling along the route you expect that they are. Packet sniffing can also be called a network tap, packet capture, or logic analyzing.

If your FortiGate unit has NP interfaces that are offloading traffic, this will change the sniffer trace. Before performing a trace on any NP interfaces, you should disable offloading on those interfaces.

What sniffing packets can tell you

If you are running a constant traffic application such as ping, packet sniffing can tell you if the traffic is reaching the destination, what the port of entry is on the FortiGate unit, if the ARP resolution is correct, and if the traffic is

being sent back to the source as expected.

Sniffing packets can also tell you if the Fortigate unit is silently dropping packets for reasons such as RPF (Reverse Path Forwarding), also called Anti Spoofing, which prevents an IP packet from being forwarded if its Source IP does not either belong to a locally attached subnet (local interface), or be part of the routing between the FortiGate and another source (static route, RIP, OSPF, BGP). Note that RPF can be disabled by turning on asymmetric routing in the CLI (`config system setting, set asymmetric enable`), however this will disable stateful inspection on the FortiGate unit and cause many features to be turned off.

If you configure virtual IP addresses on your Fortigate unit, it will use those addresses in preference to the physical IP addresses. You will notice this when you are sniffing packets because all the traffic will be using the virtual IP addresses. This is due to the ARP update that is sent out when the VIP address is configured.

How to sniff packets

When you are using VDOMs, you must be in a VDOM to access the `diag sniffer` command. At the global level, the command is not available. This is limit the packets only to the ones on your VDOM, and protects the privacy of other VDOM clients.

The general form of the internal FortiOS packet sniffer command is:

```
diag sniffer packet <interface_name> <'filter'> <verbose> <count>
```

To stop the sniffer, type `CTRL+C`.

<interface_name>	The name of the interface to sniff, such as “port1” or “internal”. This can also be “any” to sniff all interfaces.
<'filter'>	What to look for in the information the sniffer reads. `none` indicates no filtering, and all packets will be displayed as the other arguments indicate. The filter must be inside single quotes (‘).
<verbose>	The level of verbosity as one of: **1 -** print header of packets **2 -** print header and data from IP of packets **3 -** print header and data from Ethernet of packets
<count>	The number of packets the sniffer reads before stopping. If you don’t put a number here, the sniffer will run forever unit you stop it with <CTRL C>.

For a simple sniffing example, enter the CLI command `diag sniffer packet port1 none 1 3`. This will display the next 3 packets on the port1 interface using no filtering, and using verbose level 1. At this verbosity level you can see the source IP and port, the destination IP and port, action (such as ack), and sequence numbers.

In the output below, port 443 indicates these are HTTPS packets, and 172.20.120.17 is both sending and receiving traffic.

```
Head_Office_620b # diag sniffer packet port1 none 1 3
interfaces=[port1]
filters=[none]
0.545306 172.20.120.17.52989 -> 172.20.120.141.443: psh 3177924955 ack 1854307757

0.545963 172.20.120.141.443 -> 172.20.120.17.52989: psh 1854307757 ack 3177925808

0.562409 172.20.120.17.52988 -> 172.20.120.141.443: psh 4225311614 ack 3314279933
```

For a more advanced example of packet sniffing, the following commands will report packets on any interface travelling between a computer with the host name of `PC1` and the computer with the host name of `PC2`. With verbosity 4 and above, the sniffer trace will display the interface names where traffic enters or leaves the FortiGate unit. Remember to stop the sniffer, type `CTRL+C`. Note that `PC1` and `PC2` may be VDOMs.

```
FGT# diagnose sniffer packet any "host <PC1> or host <PC2>" 4
```

or

```
FGT# diagnose sniffer packet any "(host <PC1> or host <PC2>) and icmp" 4
```

The following sniffer CLI command includes the ARP protocol in the filter which may be useful to troubleshoot a failure in the ARP resolution (for instance PC2 may be down and not responding to the FortiGate ARP requests).

```
FGT# diagnose sniffer packet any "host <PC1> or host <PC2> or arp" 4
```

Debugging the packet flow

Traffic should come in and leave the VDOM. If you have determined that network traffic is not entering and leaving the VDOM as expected, debug the packet flow.

Debugging can only be performed using CLI commands. Debugging the packet flow requires a number of debug commands to be entered as each one configures part of the debug action, with the final command starting the debug.

If your FortiGate unit has NP interfaces that are offloading traffic, this will change the packet flow. Before performing the debug on any NP interfaces, you should disable offloading on those interfaces.

The following configuration assumes that `PC1` is connected to the internal interface of the FortiGate unit and has an IP address of `10.11.101.200`. `PC1` is the host name of the computer.

To debug the packet flow in the CLI, enter the following commands:

```
FGT# diag debug enable
FGT# diag debug flow filter add <PC1>
FGT# diag debug flow show console enable
FGT# diag debug flow trace start 100
FGT# diag debug enable
```

The `start 100` argument in the above list of commands will limit the output to 100 packets from the flow. This is useful for looking at the flow without flooding your log or your display with too much information.

To stop all other debug activities, enter the command:

```
FGT# diag debug flow trace stop
```

The following is an example of debug flow output for traffic that has no matching Firewall Policy, and is in turn blocked by the FortiGate unit. The denied message indicates the traffic was blocked. Note that even with VDOMs not enabled, vd-root is still shown.

```
id=20085 trace_id=319 func=resolve_ip_tuple_fast line=2825 msg="vd-root received a
    packet(proto=6, 192.168.129.136:2854->192.168.96.153:1863) from port3."

id=20085 trace_id=319 func=resolve_ip_tuple line=2924 msg="allocate a new session-
    013004ac"

id=20085 trace_id=319 func=vf_ip4_route_input line=1597 msg="find a route: gw-
    192.168.150.129 via port1"

id=20085 trace_id=319 func=fw_forward_handler line=248 msg=" Denied by forward policy
    check"
```

Chapter 34 - VM Installation

This document describes how to deploy a FortiGate virtual appliance in several virtualization server environments. This includes how to configure the virtual hardware settings of the virtual appliance.

This document assumes:

- you have already successfully installed the virtualization server on the physical machine,
- you have installed appropriate VM management software on either the physical server or a computer to be used for VM management.

This document does not cover configuration and operation of the virtual appliance after it has been successfully installed and started. For these issues, see the FortiGate 5.2 Handbook.

This document includes the following sections:

- FortiGate VM Overview
- Deployment example – VMware
- Deployment example – MS Hyper-V
- Deployment example – KVM
- Deployment example – OpenXen
- Deployment example – Citrix XenServer

What's new in VM in 5.4

New Features in 5.4.1

FortiGate VM cloud-init integration (300398)

Cloud-init is a set of pythons scripts and utilities commonly used for multi-distribution of VMs into cloud environments.

With cloud-init integration, when users launch a new instance of Fortigate VM, they can:

- Upload a license to a FGT-VM
- Provide initial management configuration, e.g. IP, default gateway, DNS
- Set port configuration mode (DHCP or static)
- Provision initial firewall policies

Cloud-init documentation can be found at https://cloudinit.readthedocs.io/en/latest/

Allow VM tools (VMWare platform) to set network settings for FortiGate VMS (292248)

Changes have been made to the firmware to mitigate the following issues:

- FGVM does not allow IP configuration during deployment.
- The use of multiple OVF files for different network adapter types is redundant.

- The sequence of interfaces is not kept in consistent with network adapters in VM settings.

These issues are corrected by the following changes:

- During deployment, the user will be prompted for an IP allocation policy (when using the new vApp OVF file). Static/DHCP can be selected for each port. Gateway can be configured for port1. Hostname, as well as primary/secondary DNS address, can be configured.
- During deployment, the user will be able to select either E1000 virtual network adapter or VMXNET3 ones (when using the new vApp OVF file).
- The new process keeps FGTVM's interface in the same sequence as the order shown in VM settings.
- There is an added CLI command "`diag vmware show-ovfenv`" to print out the whole OVF environment.

All additional features during deployment are only available when FGTVM is deployed through vCenter as a vApp.

- FGTVM interface sequence is determined with the following logic (and priority):
  - If OVF environment is available, the sequence present in the OVF environment will be used. (This is the preferred case. As the sequence can kept consistent with VM settings, regardless of whether adapters are removed/added, or mixed types of adapters are used.)
  - If the first network adapter is VMXNET3, FGTVM will use a dynamic mapping of interface, according to the total number of network adapters present. (This assumes all the network adapters are VMXNET3.)
  - If the above conditions do not qualify, FGTVM will use a static mapping of interface, which assumes every network adapter is E1000
- Even when a fixed IP allocation policy is selected during deployment, DHCP might be enabled on port1. This happens when the interface IP is set to 0.0.0.0 on port1. Unfortunately, OVF environment is unable to provide which IP allocation policy has been selected. Rather, it is only able to give a set of IP/netmask on each of the interfaces.
- Configuration is applied AFTER IP allocation policy. This means, IP allocation policy works as default settings of interface, and is ignored when any existing configuration presents on a certain interface.

FortiKVM removed from most FortiGates (366859)

The FortiKVM feature that allowed a virtual instance of FortiGate on a FortiGate device is no longer part of FortiOS for most models. With few exceptions, this feature is being moved to FortiHypervisor, a specialised appliance with resources optimized for the purpose.

FortiKVM support added to select models (282335)

FortiKVM functionality is now available on the following models:

- FGT1500D
- FGT3700D
- FGT3700DX
- FGT3810D

Interface assignment CLI:

```
config system vm
   edit 0
      set name vm1
         config interface
            edit 1
               set name vnic1
               set device [physical | vlan | softswitch]
```

```
            mode [bridge | passthrough]
            end
        end
    end
```

[device]: can assign physical, VLAN, or softwitch type host interface to this attribute.

[mode]: this attribute is available only when device is assigned physical type interface, bridge mode means several vNIC can share this interface, when packet arrives, host will lookup vNIC by dst mac address, in passthrough mode, host will send all packets to the vNIC, only one vNIC can use the physical interface in passthrough mode.

FGT-VM VMX (v2) (306438)

FortiGate-VM VMX version 2 allows for automated deployment of virtual FortiGate instances running FortiOS 5.4.1 in a specific VMWare SDN environment. For more details read the Release Notes and Admin Guides for FortiGate-VM VMX.

FortiOS On-Demand (308130)

New VM platform to support a consumption based FOS VM pricing model.FortiOS On-Demand supports VMWare hypervisor, and Openstack KVM hypervisor platforms.

- These platforms have three interfaces only: mgmt, port1, and port2.
- port1 and port2 are used for metering, and is reported to a FortiManager via the updated process.
- The FortiManager is configured externally via Vapp for VMware or user-data in KVM.
- FortiGuard updates and webfiltering servers will initially point to the FortiManager.
- The FortiManager will authorize the FOSVM instance. If not authorized the vdom is disabled.

New Features in 5.4.0

Changes to FG-VM00 Min/Max Values (246780,372030)

- The maximum memory virtual memory has changed from 1 to 1.5 GB.
- The maximum number of VDOMs has changed from 1 to 2.

Integrate VMtools Into FortiGate-VM for VMware (248842)

The following VMtools sub set of features has been integrated into the FortiGate-VM for VMWare images:

- Start
- Stop
- Reboot
- IP state in vCenter

VM License Check Time Extension (262494)

VM license check time has been extended to 30 days, with daily warning notifications and a counter.

FortiGate VM Single Root I/O Virtualization (SR-IOV) support (275432)

SR-IOV is a specification that allows a PCIe device to be treated as multiple separate PCIe devices.This feature will enable better performance with Intel based servers across multiple VM platforms, including Citrix and AWS.

In fact, AWS has optimized some instance types to take advantage of this feature.

You can reset FortiGate VMs to factory defaults without deleting the VM license (280471)

New command , **`execute factoryreset keepvmlicense`**, resets FortiGate VMs to factory defaults without deleting the VM license.

FortiGate VM Overview

The following topics are included in this section:

FortiGate VM models and licensing

Fortinet offers the FortiGate VM in five virtual appliance models determined by license. When configuring your FortiGate VM, be sure to configure hardware settings within the ranges outlined below. Contact your Fortinet Authorized Reseller for more information.

FortiGate VM model information

Technical Specification	FG-VM00	FG-VM01	FG-VM02	FG-VM04	FG-VM08
Virtual CPUs (min / max)	1 / 1	1 / 1	1 / 2	1 / 4	1 / 8
Virtual Network Interfaces (min / max)			2 / 10		
Virtual Memory (min / max)	1GB / 1.5GB	1GB / 2GB	1GB / 4GB	1GB / 6GB	1GB /12GB
Virtual Storage (min / max)			32GB / 2TB		
Managed Wireless APs (tunnel mode / global)	32 / 32	32 / 64	256 / 512	256 / 512	1024 / 4096
Virtual Domains (default / max)	1 / 2	10 / 10	10 / 25	10 / 50	10 / 250

There may be times the min/max values can change. An example for this is when the maximum memory for FG-VM00 changed between 5.2 and 5.4 from 1 GB to 1.5 GM. If that is the case, the settings for the VM will have to be manually changed to accommodate the new parameters.

After placing an order for FortiGate VM, a license registration code is sent to the email address used on the order form. Use the registration number provided to register the FortiGate VM with Customer Service & Support and then download the license file. Once the license file is uploaded to the FortiGate VM and validated, your FortiGate VM appliance is fully functional.

The number of Virtual Network Interfaces is not solely dependent on the FortiGate VM. Some virtual environments have their own limitations on the number of interfaces allowed. As an example, if you go to https://docs.microsoft.com/en-us/azure/virtual-network/virtual-networks-multiple-nics, you will find that Azure has its own restrictions for VMs, depending on the type of deployment or even the size of the VM.

FortiGate VM evaluation license

FortiGate VM includes a limited embedded 15-day trial license that supports:

- 1 CPU maximum
- 1024 MB memory maximum
- low encryption only (no HTTPS administrative access)
- all features except FortiGuard updates

You cannot upgrade the firmware, doing so will lock the Web-based Manager until a license is uploaded. Technical support is not included. The trial period begins the first time you start FortiGate VM. After the trial license expires, functionality is disabled until you upload a license file.

Registering FortiGate VM with Customer Service & Support

To obtain the FortiGate VM license file you must first register your FortiGate VM with Customer Service & Support.

To register your FortiGate VM:

1. Log in to the Customer Service & Support portal using an existing support account or select **Sign Up** to create a new account.
2. In the main page, under **Asset**, select **Register/Renew**.

   The **Registration** page opens.
3. Enter the registration code that was emailed to you and select **Register**. A registration form will display.
4. After completing the form, a registration acknowledgement page will appear.
5. Select the **License File Download** link.
6. You will be prompted to save the license file (`.lic`) to your local computer. See "Upload the license file" for instructions on uploading the license file to your FortiGate VM via the Web-based Manager.

Downloading the FortiGate VM deployment package

FortiGate VM deployment packages are included with FortiGate firmware images on the Customer Service & Support site. First, see the following table to determine the appropriate VM deployment package for your VM platform.

Selecting the correct FortiGate VM deployment package for your VM platform

VM Platform	FortiGate VM Deployment File
Citrix XenServer v5.6sp2, 6.0 and later	FGT_VM64-v500-buildnnnn-FORTINET.out.CitrixXen.zip
OpenXen v3.4.3, 4.1	FGT_VM64-v500-buildnnnn-FORTINET.out.OpenXen.zip
Microsoft Hyper-V Server 2008R2 and 2012	FGT_VM64-v500-buildnnnn-FORTINET.out.hyperv.zip
KVM (qemu 0.12.1)	FGT_VM64-v500-buildnnnn-FORTINET.out.kvm.zip
VMware ESX 4.0, 4.1 ESXi 4.0/4.1/5.0/5.1/5.5	FGT_VM32-v500-buildnnnn-FORTINET.out.ovf.zip (32-bit) FGT_VM64-v500-buildnnnn-FORTINET.out.ovf.zip

For more information see the FortiGate product datasheet available on the Fortinet web site, http://www.fortinet.com/products/fortigate/virtualappliances.html.

The firmware images FTP directory is organized by firmware version, major release, and patch release. The firmware images in the directories follow a specific naming convention and each firmware image is specific to the device model. For example, the FGT_VM32-v500-build0151-FORTINET.out.ovf.zip image found in the v5.0 Patch Release 2 directory is specific to the FortiGate VM 32-bit environment.

You can also download the FortiOS Release Notes, FORTINET-FORTIGATE MIB file, FSSO images, and SSL VPN client in this directory. The Fortinet Core MIB file is located in the main FortiGate v5.00 directory.

To download the FortiGate VM deployment package:

1. In the main page of the Customer Service & Support site, select **Download** > **Firmware Images**.

   The **Firmware Images** page opens.
2. In the **Firmware Images** page, select **FortiGate**.
3. Browse to the appropriate directory on the FTP site for the version that you would like to download.
4. Download the appropriate `.zip` file for your VM server platform.

   You can also download the FortiGate Release Notes.
5. Extract the contents of the deployment package to a new file folder.

Deployment package contents

Citrix XenServer

The FORTINET.out.CitrixXen.zip file contains:

- fortios.vhd: the FortiGate VM system hard disk in VHD format
- fortios.xva: binary file containing virtual hardware configuration settings
- in the ovf folder:
  - FortiGate-VM64.ovf: Open Virtualization Format (OVF) template file, containing virtual hardware settings for Xen
  - fortios.vmdk: the FortiGate VM system hard disk in VMDK format
  - datadrive.vmdk: the FortiGate VM log disk in VMDK format

The ovf folder and its contents is an alternative method of installation to the .xva and VHD disk image.

OpenXEN

The FORTINET.out.OpenXen.zip file contains only fortios.qcow2, the FortiGate VM system hard disk in qcow2 format. You will need to manually:

- create a 32GB log disk
- specify the virtual hardware settings

Microsoft Hyper-V

The FORTINET.out.hyperv.zip file contains:

- in the Virtual Hard Disks folder:
  - fortios.vhd: the FortiGate VM system hard disk in VHD format
  - DATADRIVE.vhd: the FortiGate VM log disk in VHD format
- In the Virtual Machines folder:
  - fortios.xml: XML file containing virtual hardware configuration settings for Hyper-V. This is compatible with Windows Server 2012.
- Snapshots folder: optionally, Hyper-V stores snapshots of the FortiGate VM state here

KVM

The FORTINET.out.kvm.zip contains only fortios.qcow2, the FortiGate VM system hard disk in qcow2 format. You will need to manually:

- create a 32GB log disk
- specify the virtual hardware settings

VMware ESX/ESXi

You will need to create a 32GB log disk.

The FORTINET.out.ovf.zip file contains:

- fortios.vmdk: the FortiGate VM system hard disk in VMDK format
- datadrive.vmdk: the FortiGate VM log disk in VMDK format
- Open Virtualization Format (OVF) template files:
  - FortiGate-VM64.ovf: OVF template based on Intel e1000 NIC driver
  - FortiGate-VM64.hw04.ovf: OVF template file for older (v3.5) VMware ESX server
  - FortiGate-VMxx.hw07_vmxnet2.ovf: OVF template file for VMware vmxnet2 driver
  - FortiGate-VMxx.hw07_vmxnet3.ovf: OVF template file for VMware vmxnet3 driver

Use the VMXNET3 interface (FortiGate-VMxx.hw07_vmxnet3.ovf template) if the virtual appliance will distribute workload to multiple processor cores.

Deploying the FortiGate VM appliance

Prior to deploying the FortiGate VM appliance, the VM platform must be installed and configured so that it is ready to create virtual machines. The installation instructions for FortiGate VM assume that

- You are familiar with the management software and terminology of your VM platform.
- An Internet connection is available for FortiGate VM to contact FortiGuard to validate its license or, for closed environments, a FortiManager can be contacted to validate the FortiGate VM license. See "Validate the FortiGate VM license with FortiManager".

For assistance in deploying FortiGate VM, refer to the deployment chapter in this guide that corresponds to your VMware environment. You might also need to refer to the documentation provided with your VM server. The deployment chapters are presented as examples because for any particular VM server there are multiple ways to create a virtual machine. There are command line tools, APIs, and even alternative graphical user interface tools.

Before you start your FortiGate VM appliance for the first time, you might need to adjust virtual disk sizes and networking settings. The first time you start FortiGate VM, you will have access only through the console window of your VM server environment. After you configure one FortiGate network interface with an IP address and administrative access, you can access the FortiGate VM web-based manager.

After deployment and license validation, you can upgrade your FortiGate VM appliance's firmware by downloading either FGT_VM32-v500-buildnnnn-FORTINET.out (32-bit) or FGT_VM64-v500-buildnnnn-FORTINET.out (64-bit) firmware. Firmware upgrading on a VM is very similar to upgrading firmware on a hardware FortiGate unit.

Deployment example – VMware

Once you have downloaded the FGT_VMxx-v5-build0xxx-FORTINET.out.ovf.zip file from http://support.fortinet.com and extracted the package contents to a folder on your local computer, you can use the vSphere client to create the virtual machine from the deployment package OVF template.

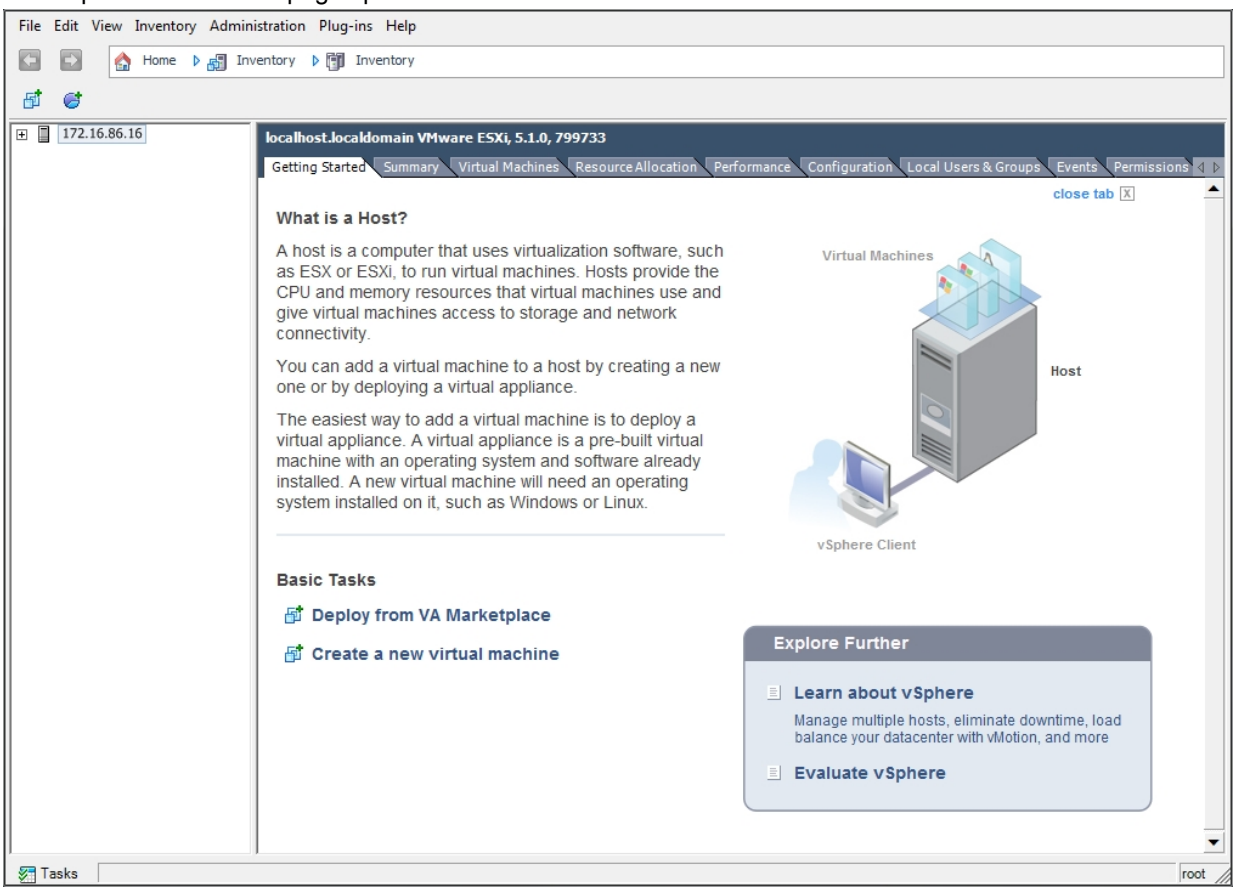
The following topics are included in this section:

Open the FortiGate VM OVF file with the vSphere client

To deploy the FortiGate VM OVF template:

1. Launch the VMware vSphere client, enter the IP address or host name of your server, enter your user name and password and select **Login**.

   The vSphere client home page opens.

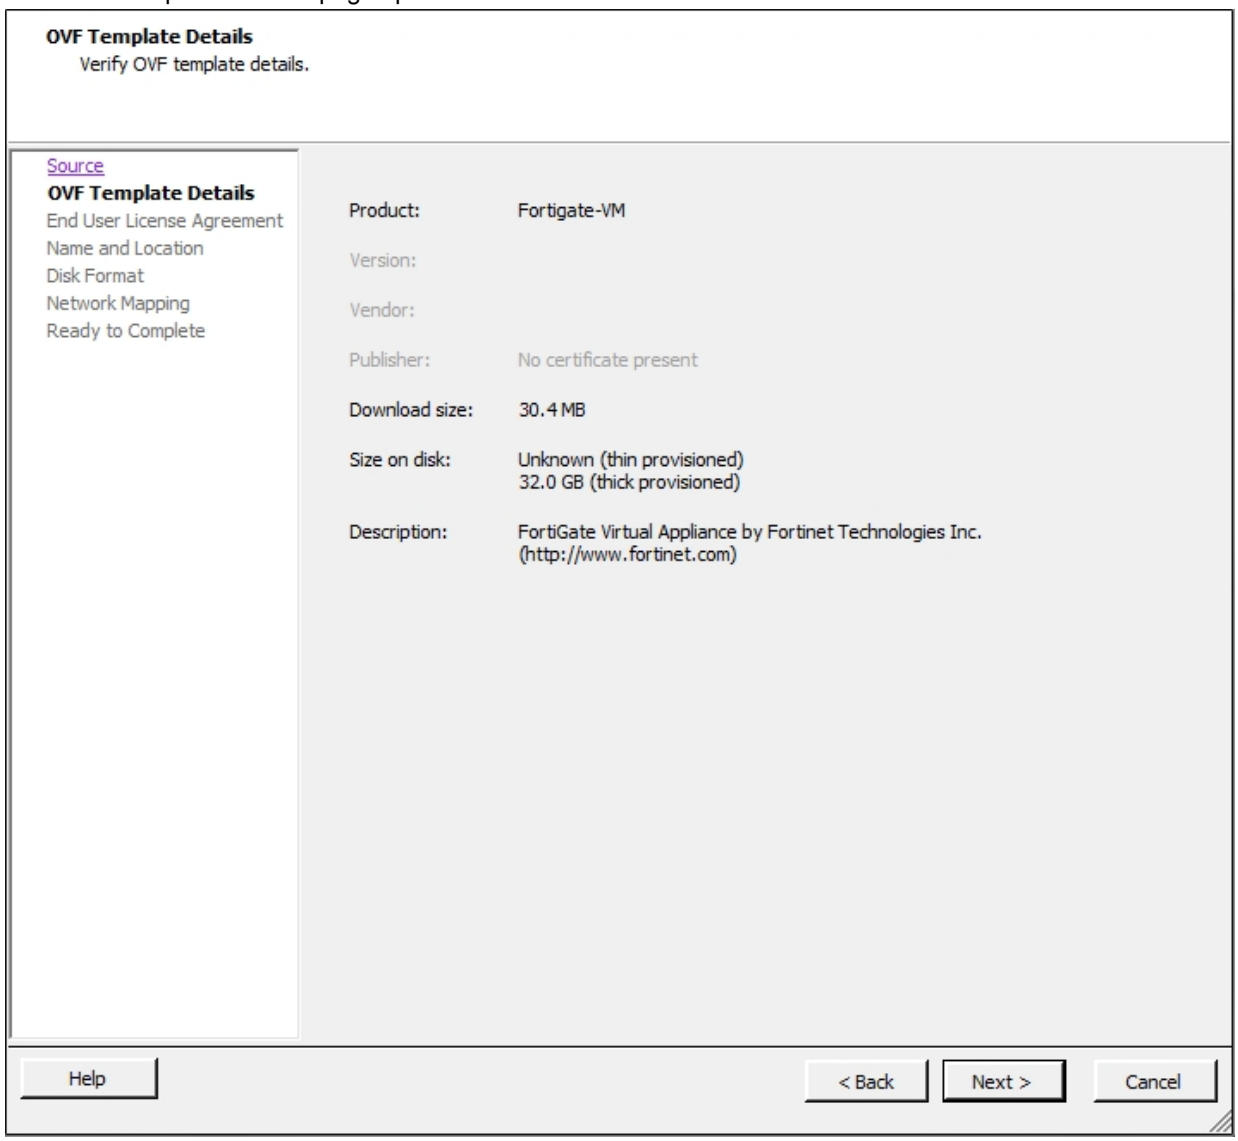


2. Select **File > Deploy OVF Template** to launch the OVF Template wizard.

   The OVF Template **Source** page opens.

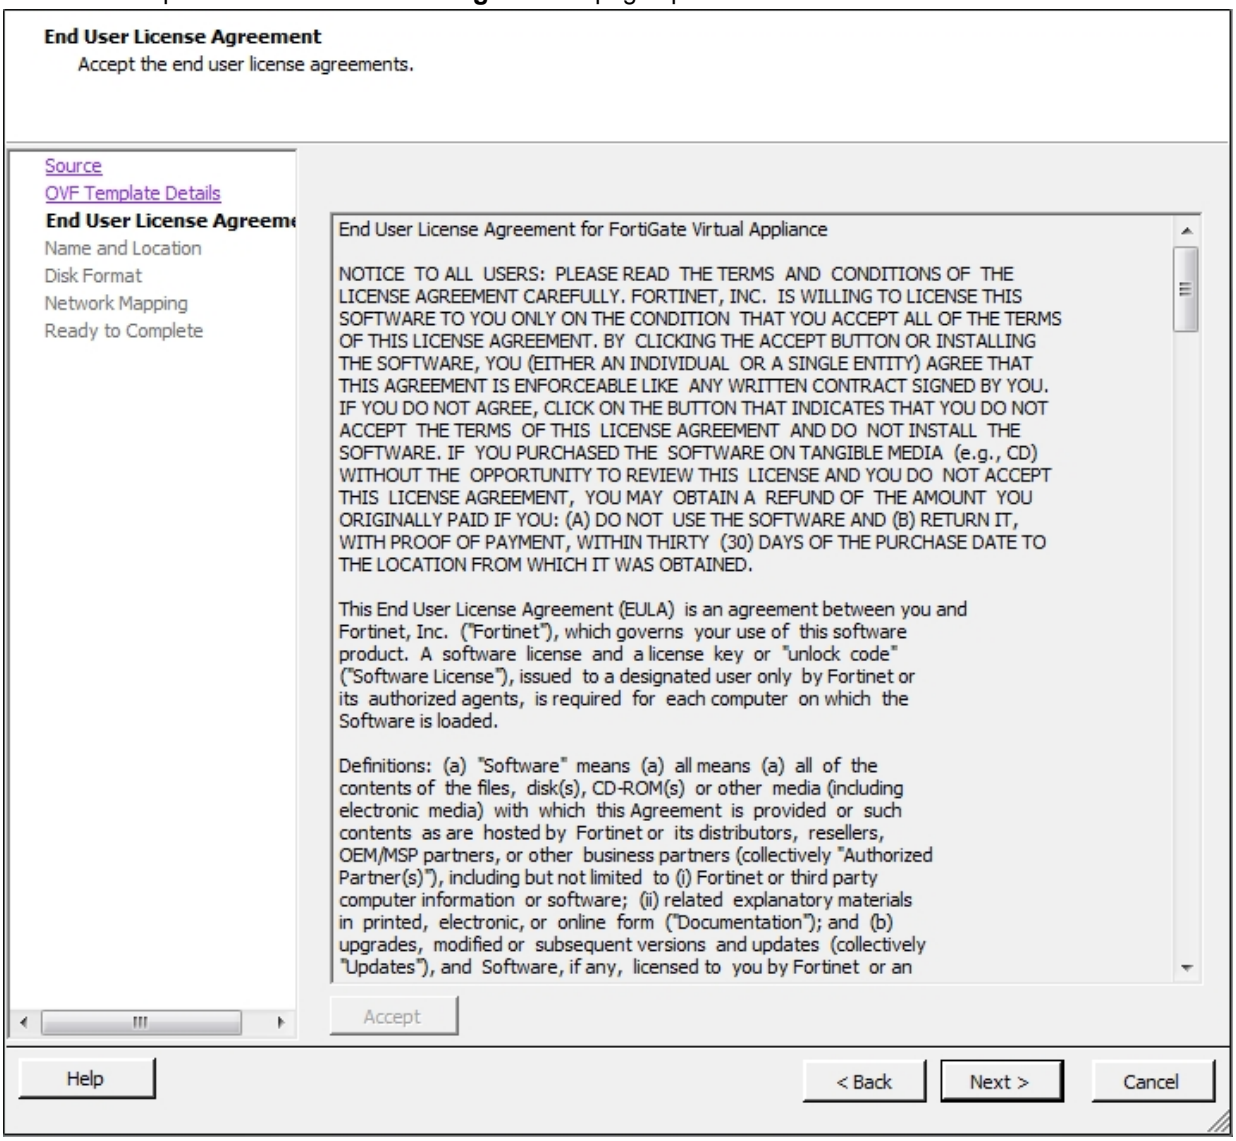
3. Select the source location of the OVF file. Select **Browse** and locate the OVF file on your computer. Select **Next** to continue.

   The OVF Template **Details** page opens.



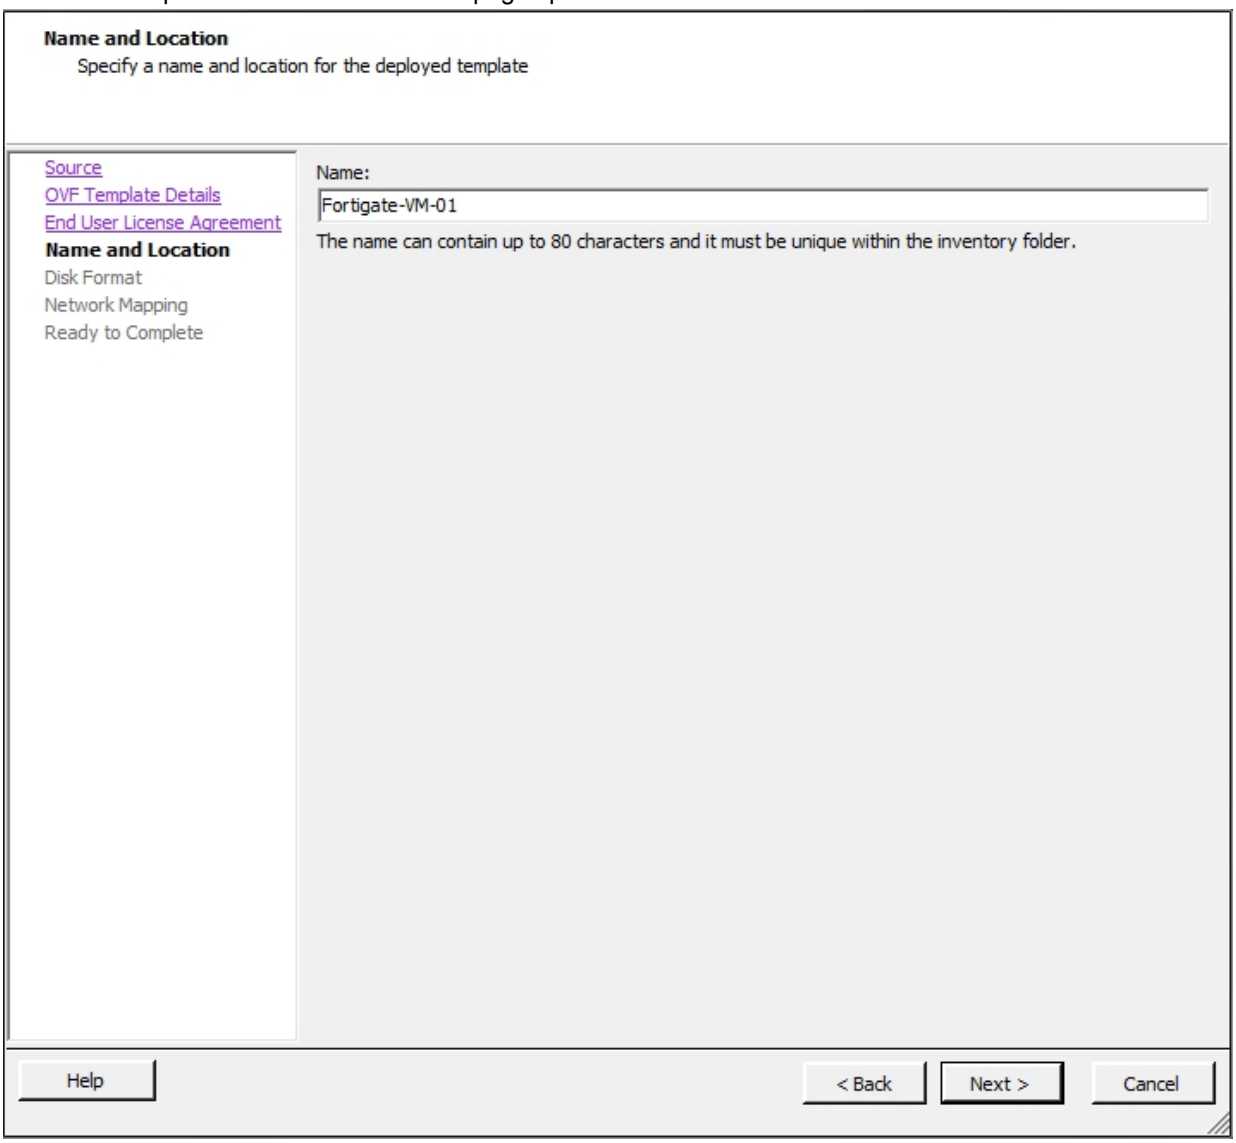
4. Verify the OVF template details. This page details the product name, download size, size on disk, and description. Select **Next** to continue.

The OVF Template **End User License Agreement** page opens.



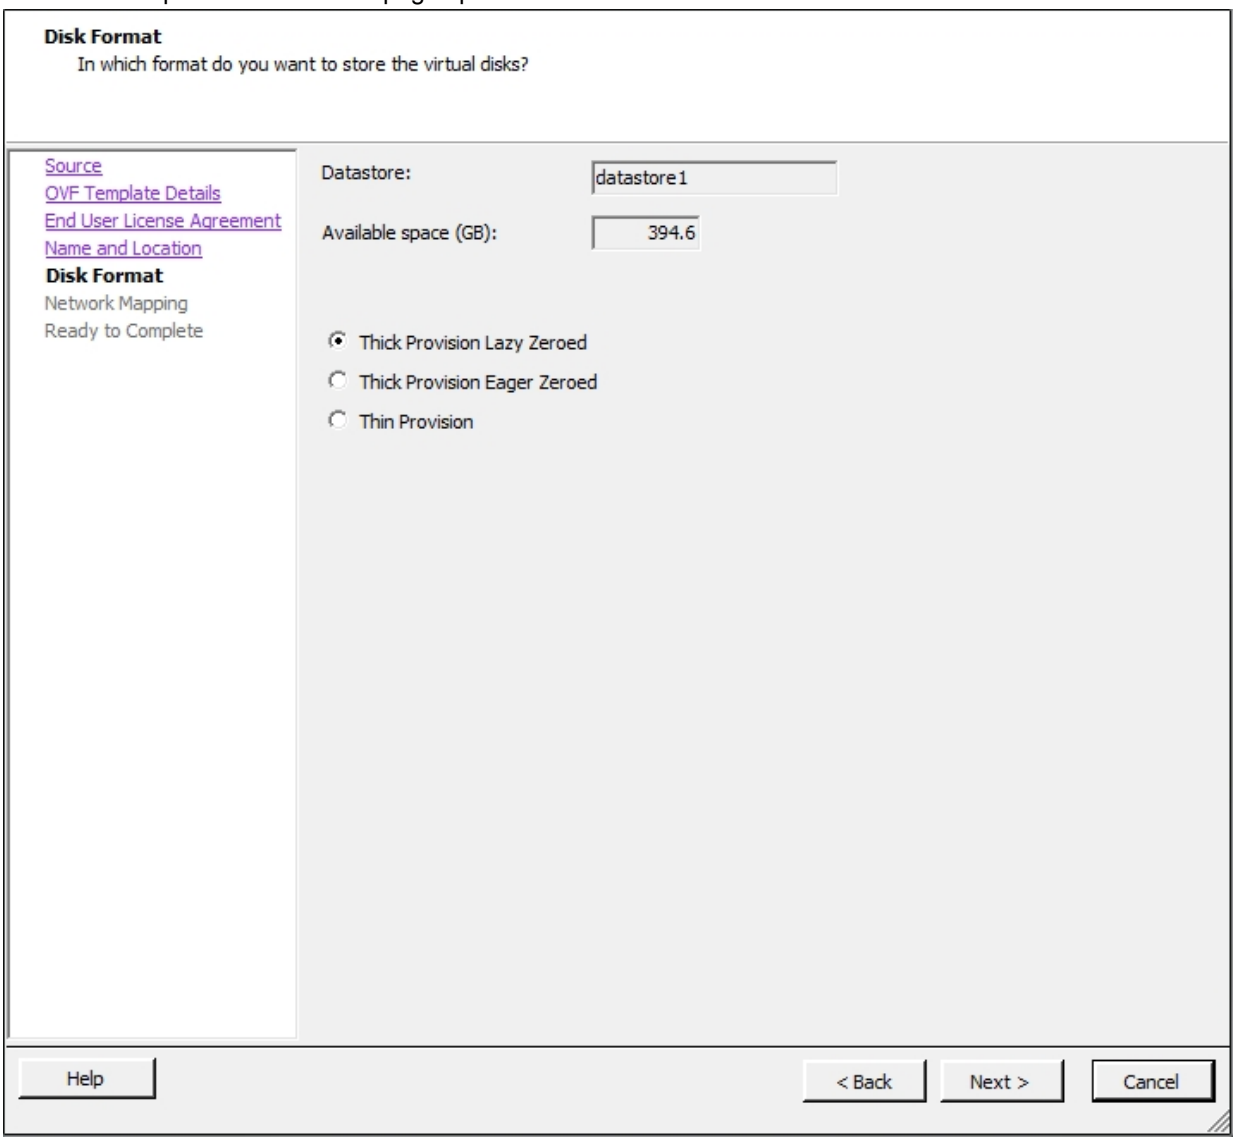
5. Read the end user license agreement for FortiGate VM. Select **Accept** and then select **Next** to continue.

The OVF Template **Name and Location** page opens.



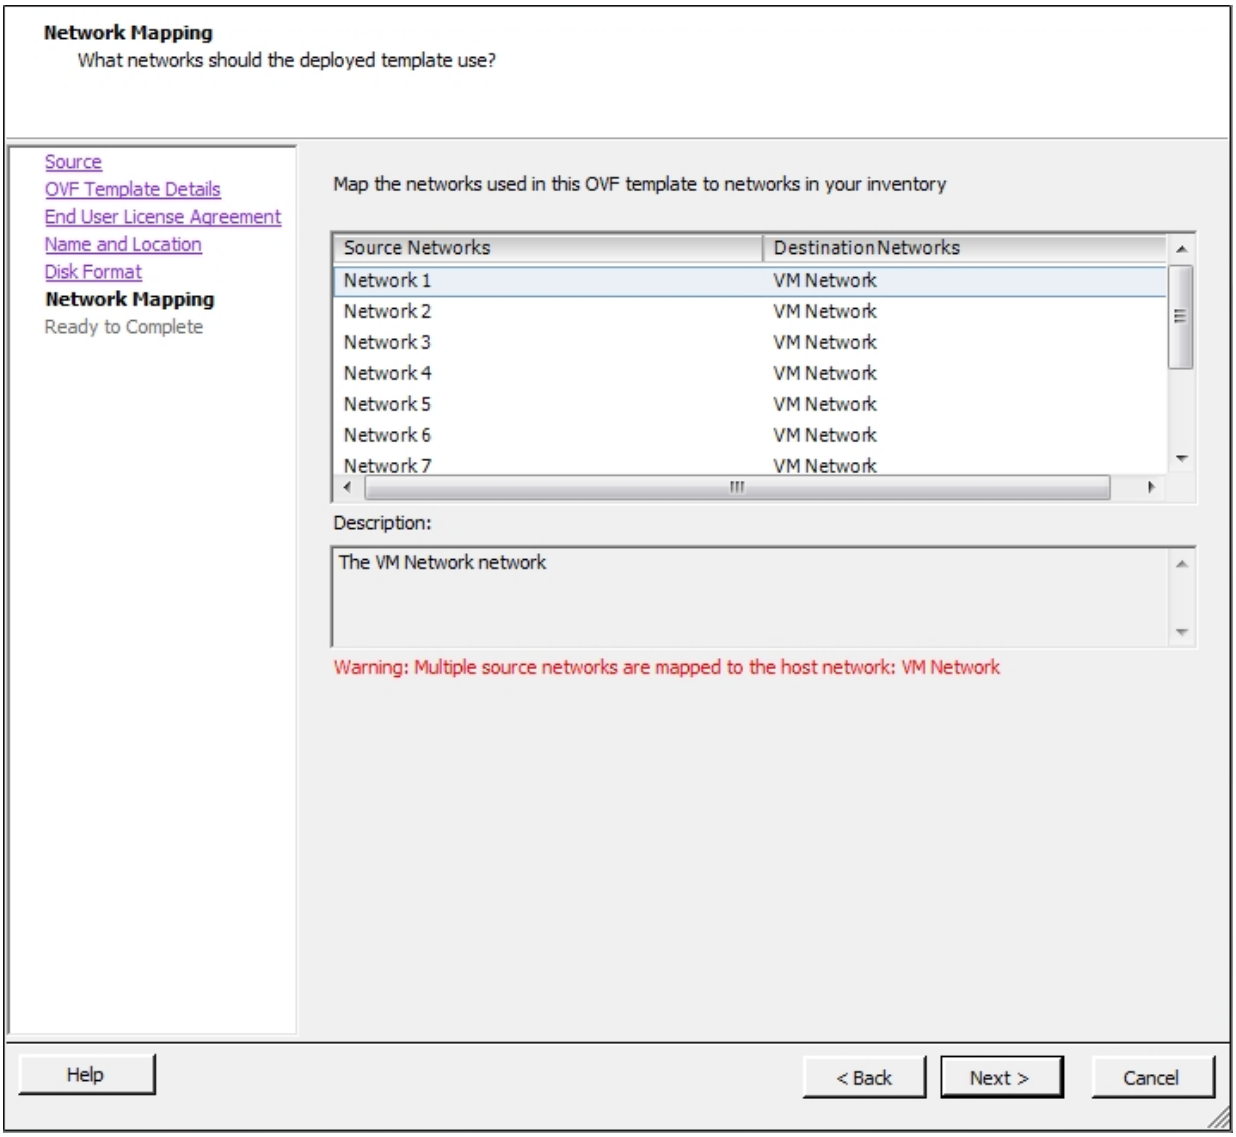
6. Enter a name for this OVF template. The name can contain up to 80 characters and it must be unique within the inventory folder. Select **Next** to continue.

The OVF Template **Disk Format** page opens.



7. Select one of the following:
   - **Thick Provision Lazy Zeroed**: Allocates the disk space statically (no other volumes can take the space), but does not write zeros to the blocks until the first write takes place to that block during runtime (which includes a full disk format).
   - **Thick Provision Eager Zeroed**: Allocates the disk space statically (no other volumes can take the space), and writes zeros to all the blocks.
   - **Thin Provision**: Allocates the disk space only when a write occurs to a block, but the total volume size is reported by VMFS to the OS. Other volumes can take the remaining space. This allows you to float space between your servers, and expand your storage when your size monitoring indicates there is a problem. Note that once a Thin Provisioned block is allocated, it remains on the volume regardless if you have deleted data, etc.
8. Select **Next** to continue.

   The OVF Template **Network Mapping** page opens.

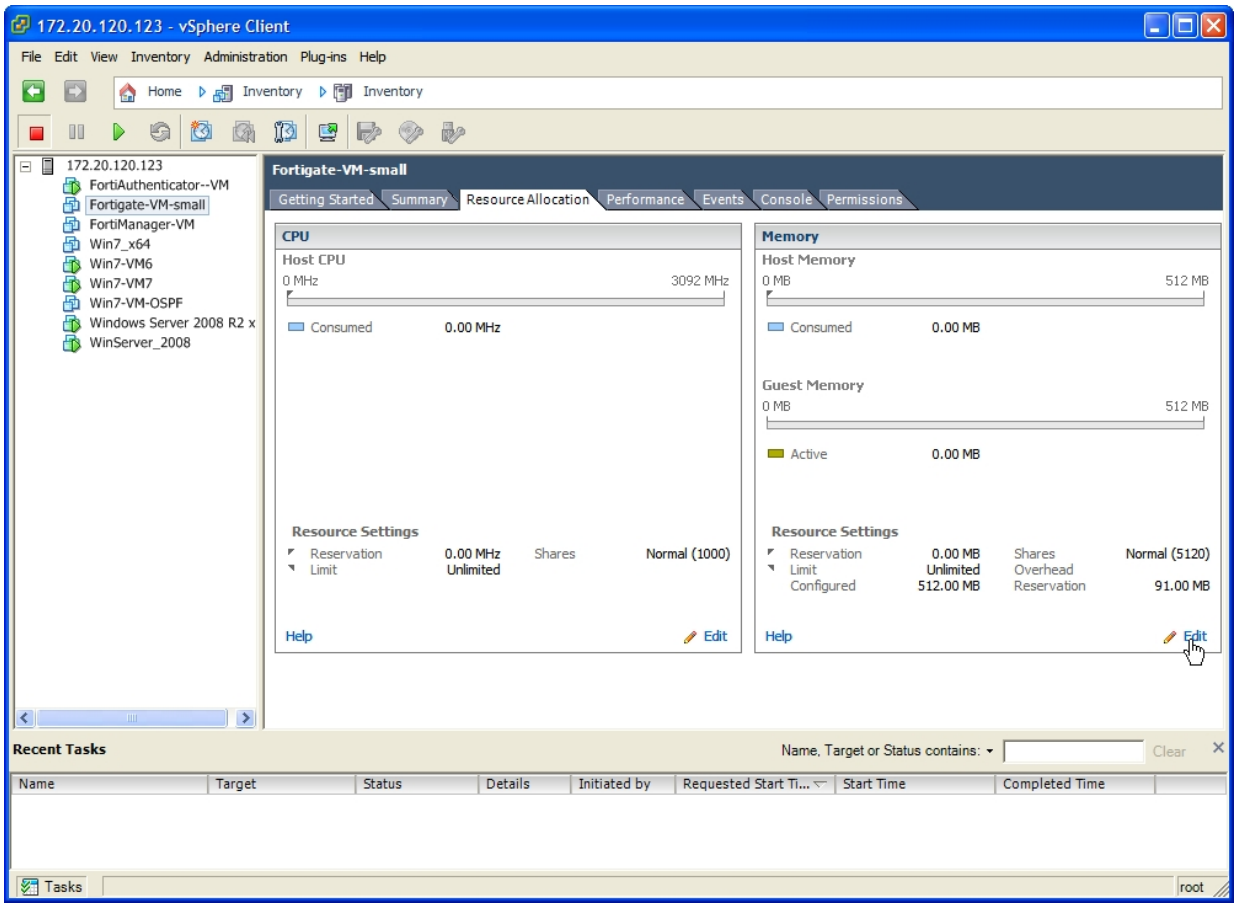


9. Map the networks used in this OVF template to networks in your inventory. Network 1 maps to port1 of the FortiGate VM. You must set the destination network for this entry to access the device console. Select **Next** to continue.

   The OVF Template **Ready to Complete** page opens.
10. Review the template configuration. Make sure that **Power on after deployment** is not enabled. You might need to configure the FortiGate VM hardware settings prior to powering on the FortiGate VM.
11. Select **Finish** to deploy the OVF template. You will receive a **Deployment Completed Successfully** dialog box once the FortiGate VM OVF template wizard has finished.

Configure FortiGate VM hardware settings

Before powering on your FortiGate VM you must configure the virtual memory, virtual CPU, and virtual disk configuration to match your FortiGate VM license.



Transparent mode VMware configuration

If you want to use your FortiGate-VM in transparent mode, your VMware server's virtual switches must operate in promiscuous mode. This permits these interfaces to receive traffic that will pass through the FortiGate unit but was not addressed to the FortiGate unit.

In VMware, promiscuous mode must be explicitly enabled:

1. In the vSphere client, select your VMware server in the left pane and then select the **Configuration** tab in the right pane.
2. In **Hardware**, select **Networking**.
3. Select **Properties** of vSwitch0.
4. In the **Properties** window left pane, select **vSwitch** and then select **Edit**.
5. Select the **Security** tab, set **Promiscuous Mode** to **Accept**, then select **OK**.
6. Select **Close**.
7. Repeat steps 3 through 6 for other vSwitches that your transparent mode FortiGate-VM uses.

High Availability VMware configuration

If you want to combine two or more FortiGate-VM instances into a FortiGate Clustering Protocol (FGCP) High Availability (HA) cluster the VMware server's virtual switches used to connect the heartbeat interfaces must operate in promiscuous mode. This permits HA heartbeat communication between the heartbeat interfaces. HA

heartbeat packets are non-TCP packets that use Ethertype values 0x8890, 0x8891, and 0x8890. The FGCP uses link-local IPv4 addresses in the 169.254.0.x range for HA heartbeat interface IP addresses.

To enable promiscuous mode in VMware:

1. In the vSphere client, select your VMware server in the left pane and then select the **Configuration** tab in the right pane.
2. In **Hardware**, select **Networking**.
3. Select **Properties** of a virtual switch used to connect heartbeat interfaces.
4. In the **Properties** window left pane, select **vSwitch** and then select **Edit**.
5. Select the **Security** tab, set **Promiscuous Mode** to **Accept**, then select **OK**.
6. Select **Close**.

You must also set the virtual switches connected to other FortiGate interfaces to allow MAC address changes and to accept forged transmits. This is required because the FGCP sets virtual MAC addresses for all FortiGate interfaces and the same interfaces on the different VM instances in the cluster will have the same virtual MAC addresses.

To make the required changes in VMware:

1. In the vSphere client, select your VMware server in the left pane and then select the **Configuration** tab in the right pane.
2. In **Hardware**, select **Networking**.
3. Select **Properties** of a virtual switch used to connect FortiGate VM interfaces.
4. Set **MAC Address Changes**to**Accept**.
5. Set **Forged Transmits** to **Accept**.

Power on your FortiGate VM

You can now proceed to power on your FortiGate VM. There are several ways to do this:

- Select the name of the FortiGate VM you deployed in the inventory list and select **Power on the virtual machine** in the **Getting Started** tab.
- In the inventory list, right-click the name of the FortiGate VM you deployed, and select **Power > Power On**.
- Select the name of the FortiGate VM you deployed in the inventory list. Click the **Power On** button on the toolbar.

Select the Console tab to view the console. To enter text, you must click in the console pane. The mouse is then captured and cannot leave the console screen. As the FortiGate console is text-only, no mouse pointer is visible. To release the mouse, press Ctrl-Alt.

Deployment example – MS Hyper-V

Once you have downloaded the FGT_VMxx_HV-v5-build0xxx-FORTINET.out.hyperv.zip file and extracted the package contents to a folder on your Microsoft server, you can deploy the VHD package to your Microsoft Hyper-V environment.

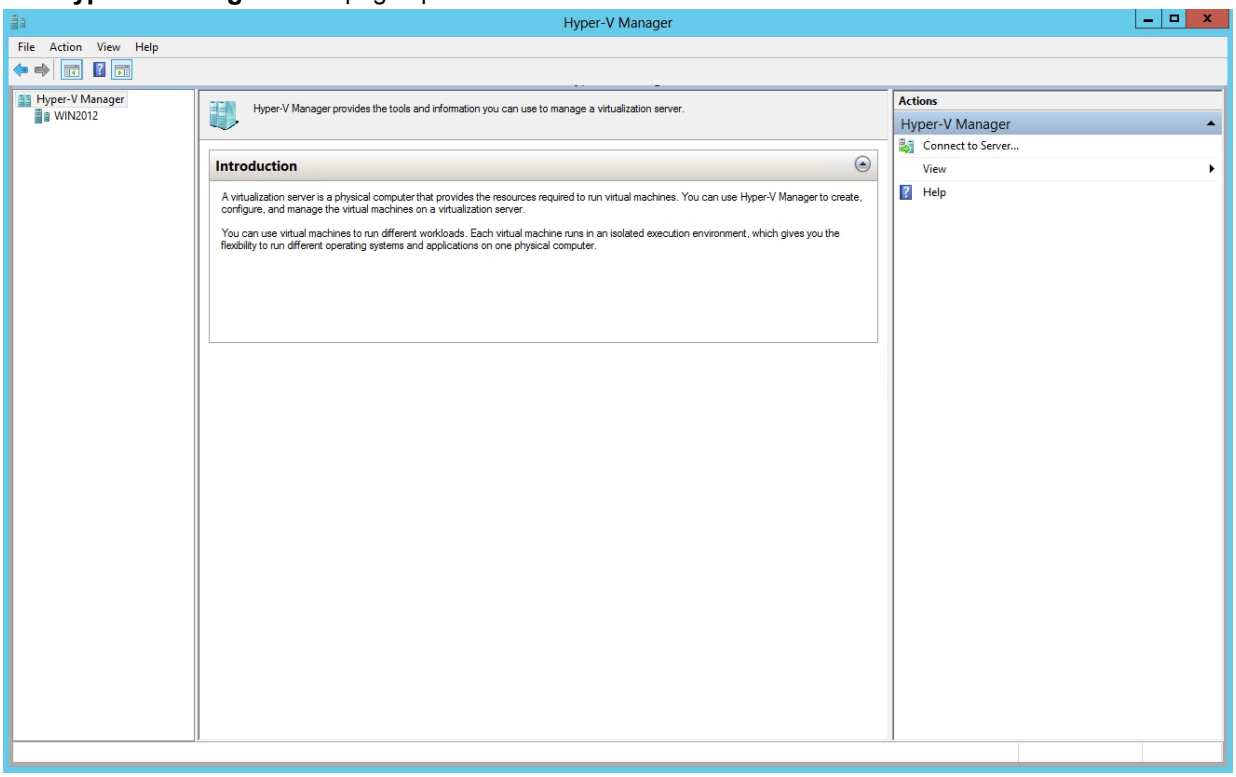
The following topics are included in this section:

Create the FortiGate VM virtual machine

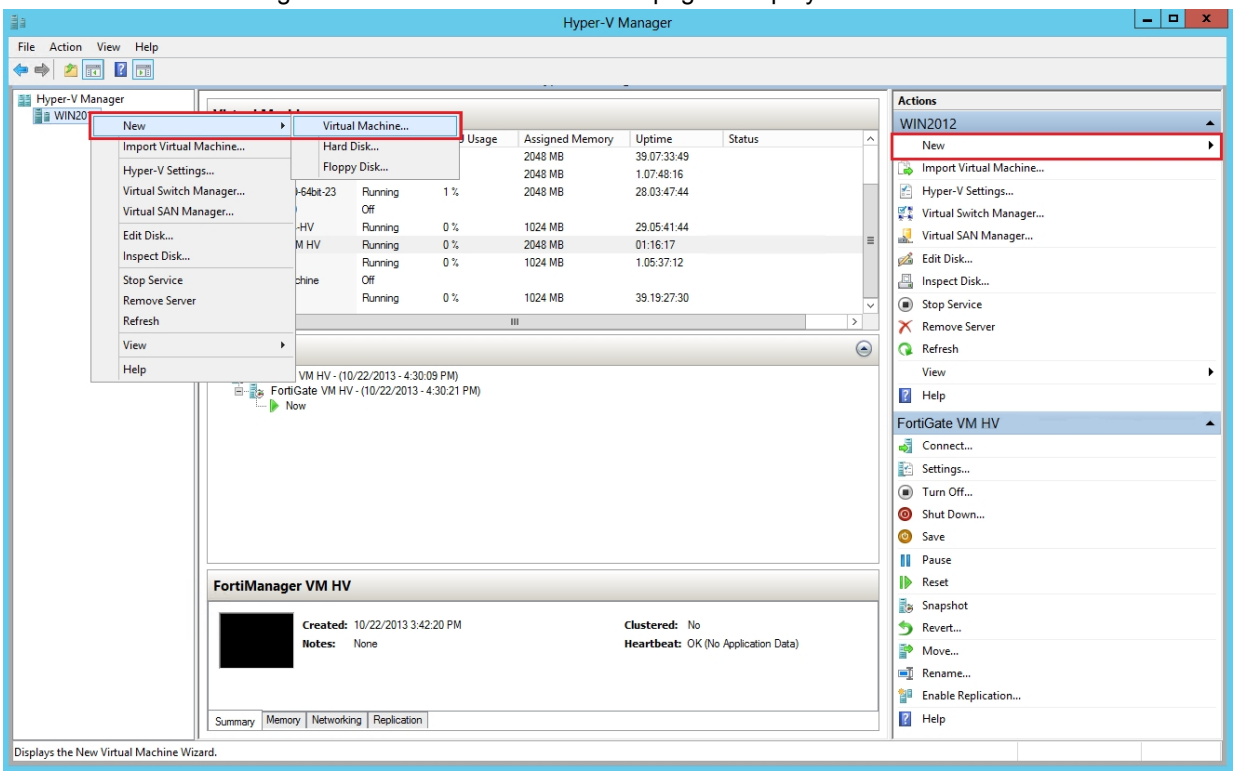
To create the FortiGate VM virtual machine:

1. Launch the Hyper-V Manager in your Microsoft server.

   The **Hyper-V Manager** home page opens.

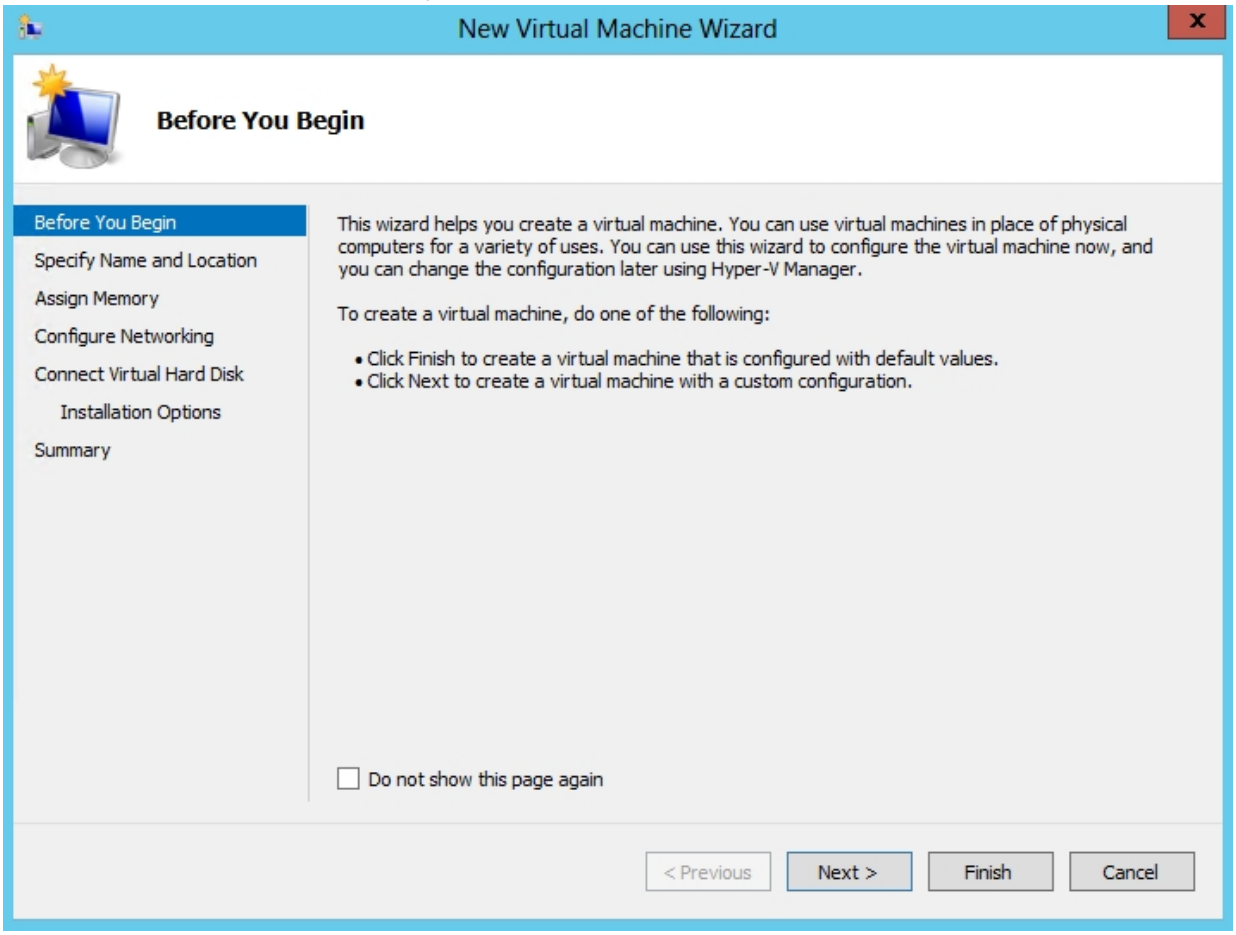


2. Select the server in the right-tree menu. The server details page is displayed.



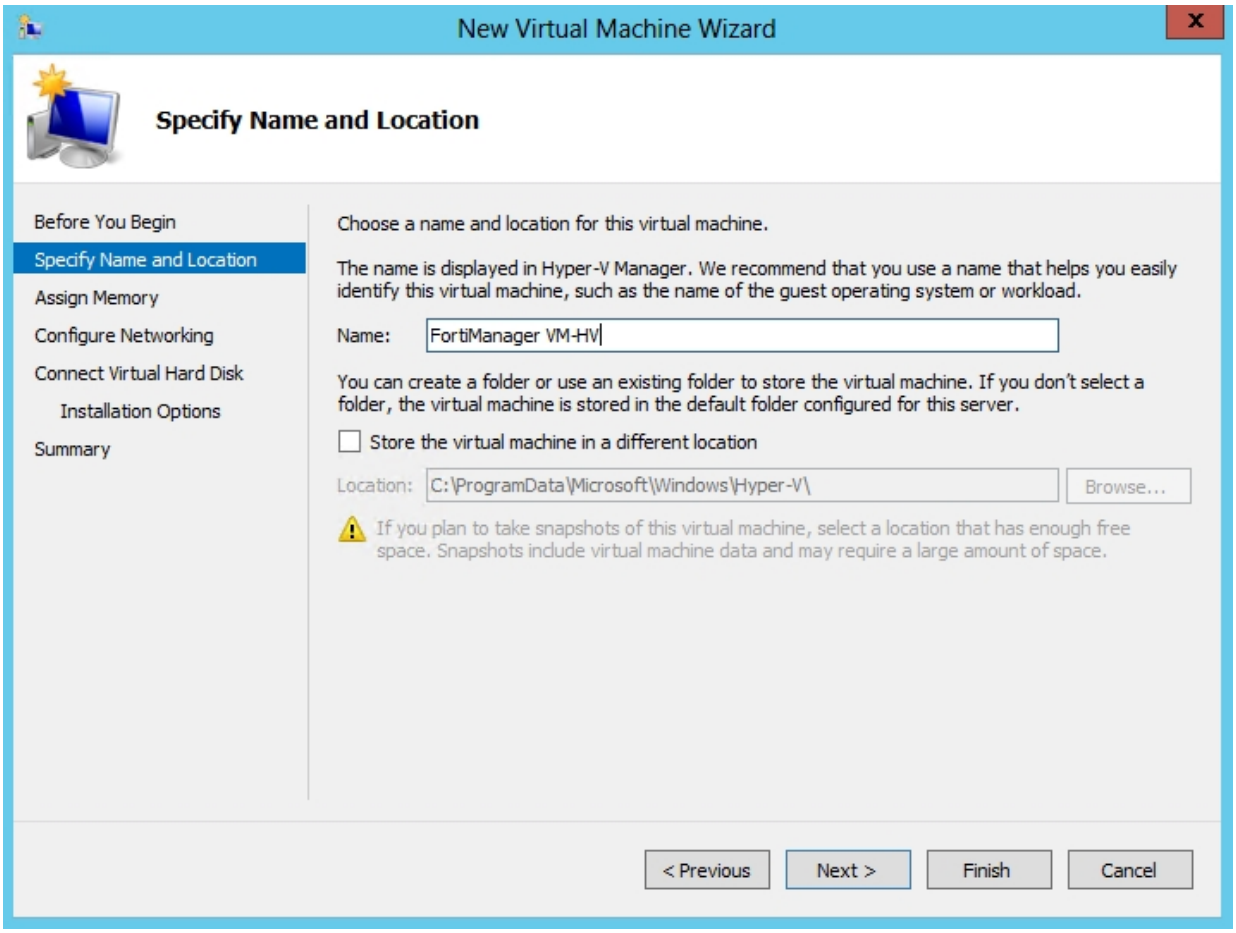
3. Right-click the server and select **New and select Virtual Machine** from the menu. Optionally, in the **Actions** menu, select **New** and select **Virtual Machine** from the menu.

The **New Virtual Machine Wizard** opens.



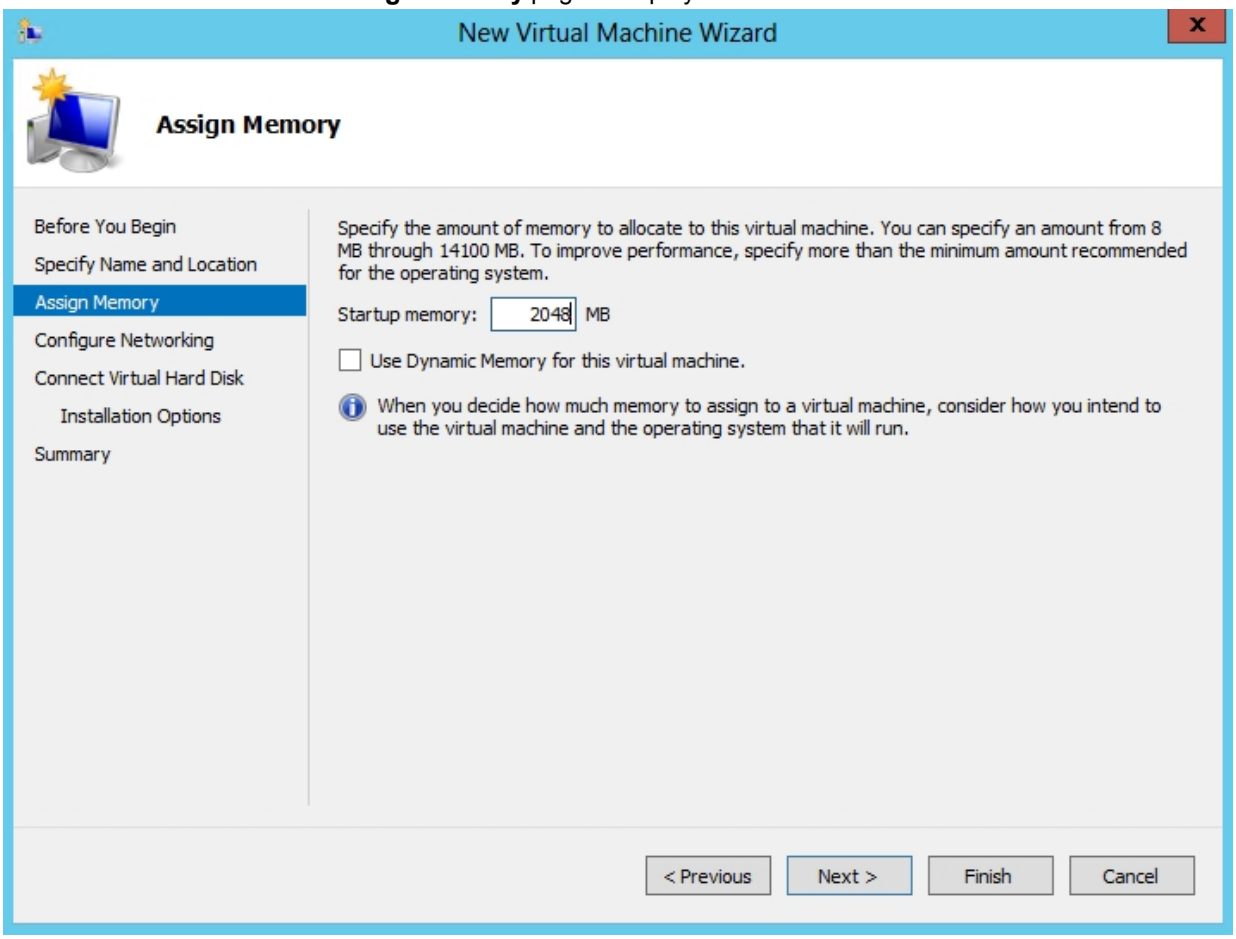
4. Select **Next** to create a virtual machine with a custom configuration.

   The **Specify Name and Location** page is displayed.



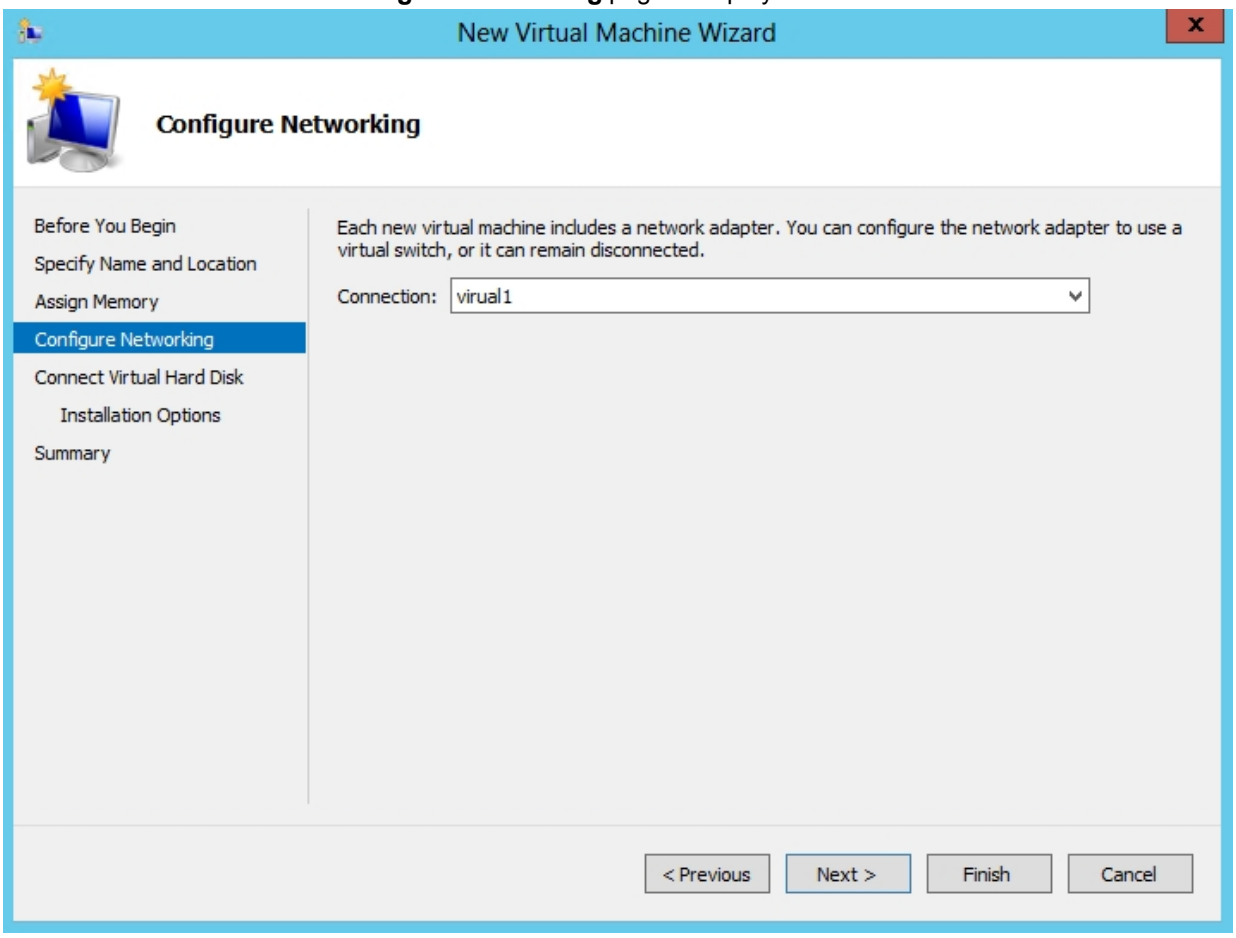
5. Enter a name for this virtual machine. The name is displayed in the Hyper-V Manager.

Select **Next** to continue. The **Assign Memory** page is displayed.



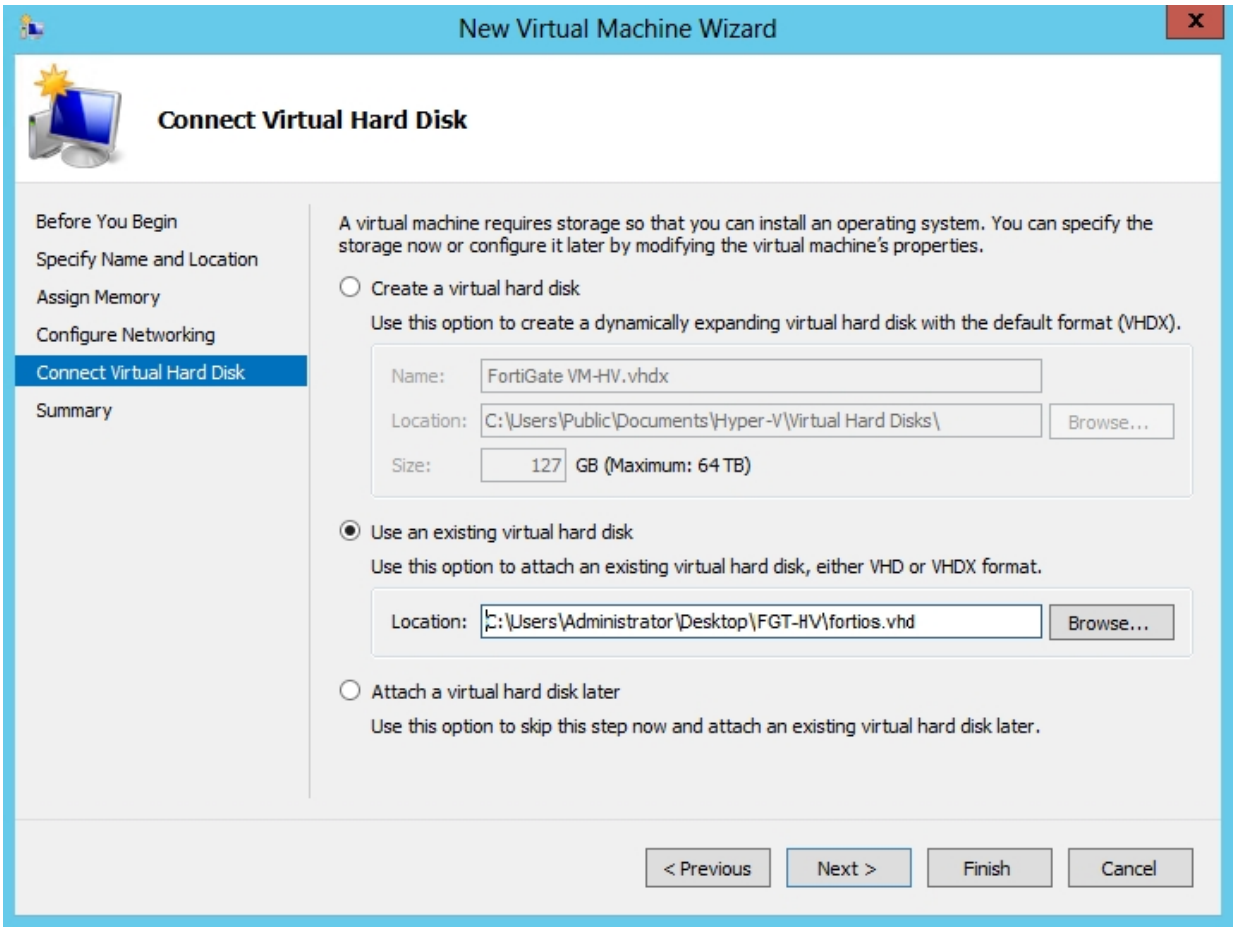
6. Specify the amount of memory to allocate to this virtual machine. The default memory for FortiGate VM is 1GB (1024MB).

Select **Next** to continue. The **Configure Networking** page is displayed.



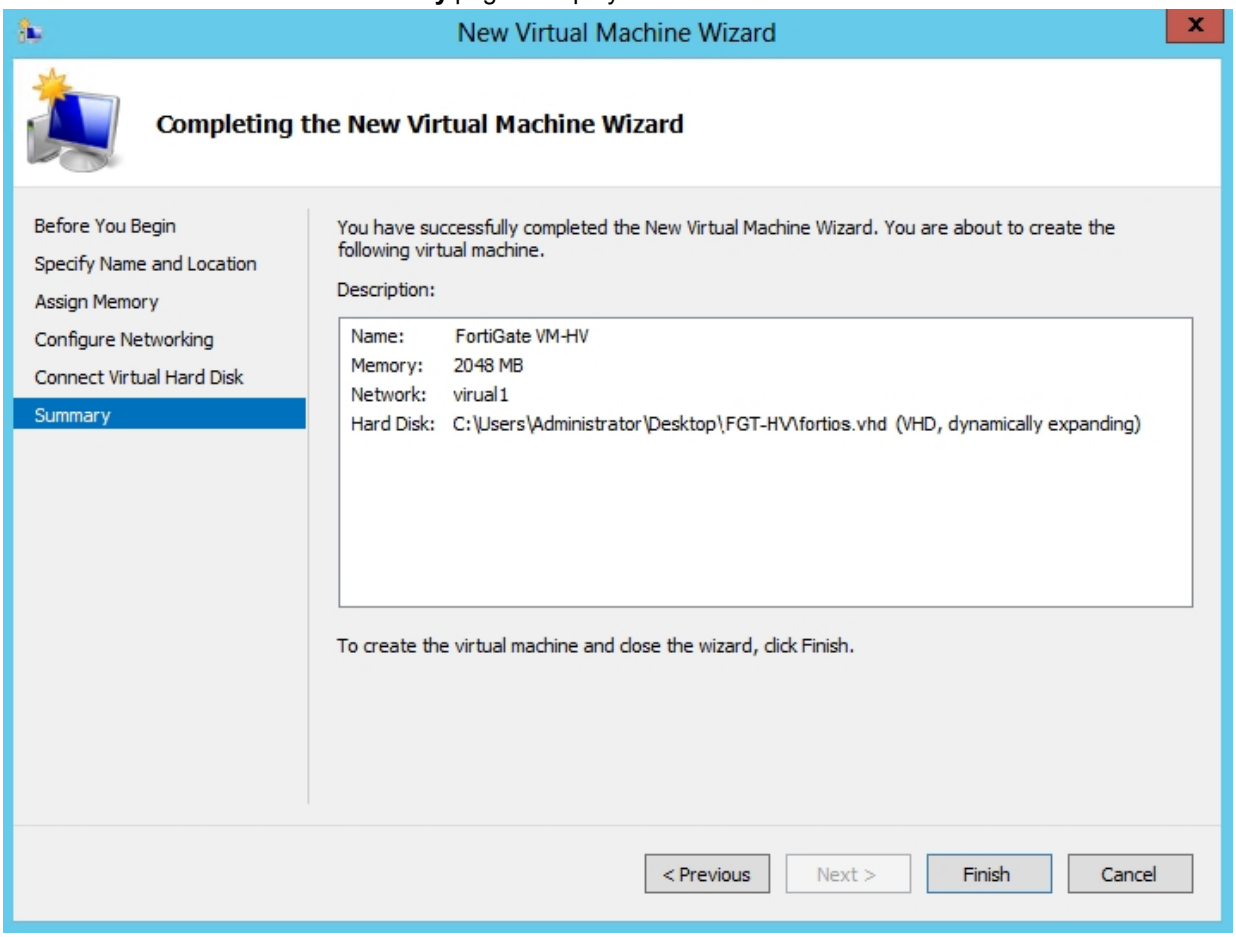
7. Each new virtual machine includes a network adapter. You can configure the network adapter to use a virtual switch, or it can remain disconnected. FortiGate VM requires four network adapters. You must configure network adapters in the **Settings** page.

   Select **Next** to continue. The **Connect Virtual Hard Disk** page is displayed.



8. Select to use an existing virtual hard disk and browse for the `fortios.vhd` file that you downloaded from the Fortinet Customer Service & Support portal.

Select **Next** to continue. The **Summary** page is displayed.



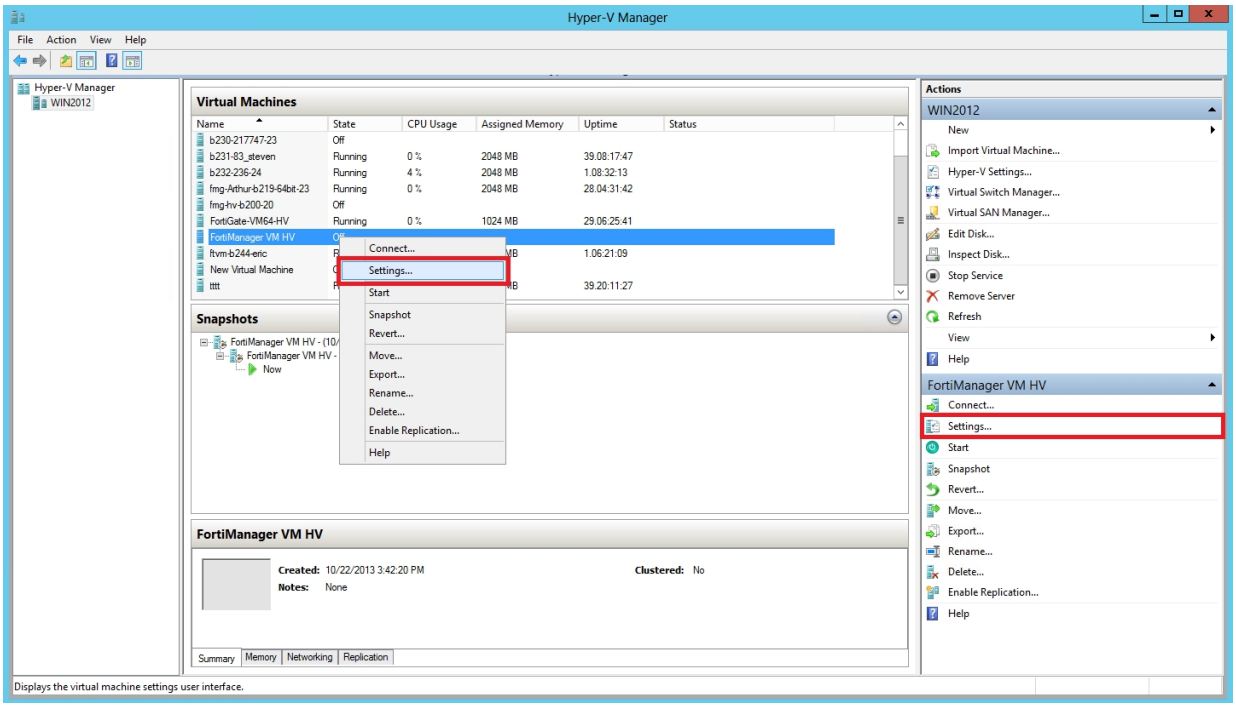
9. To create the virtual machine and close the wizard, select **Finish**.

Configure FortiGate VM hardware settings

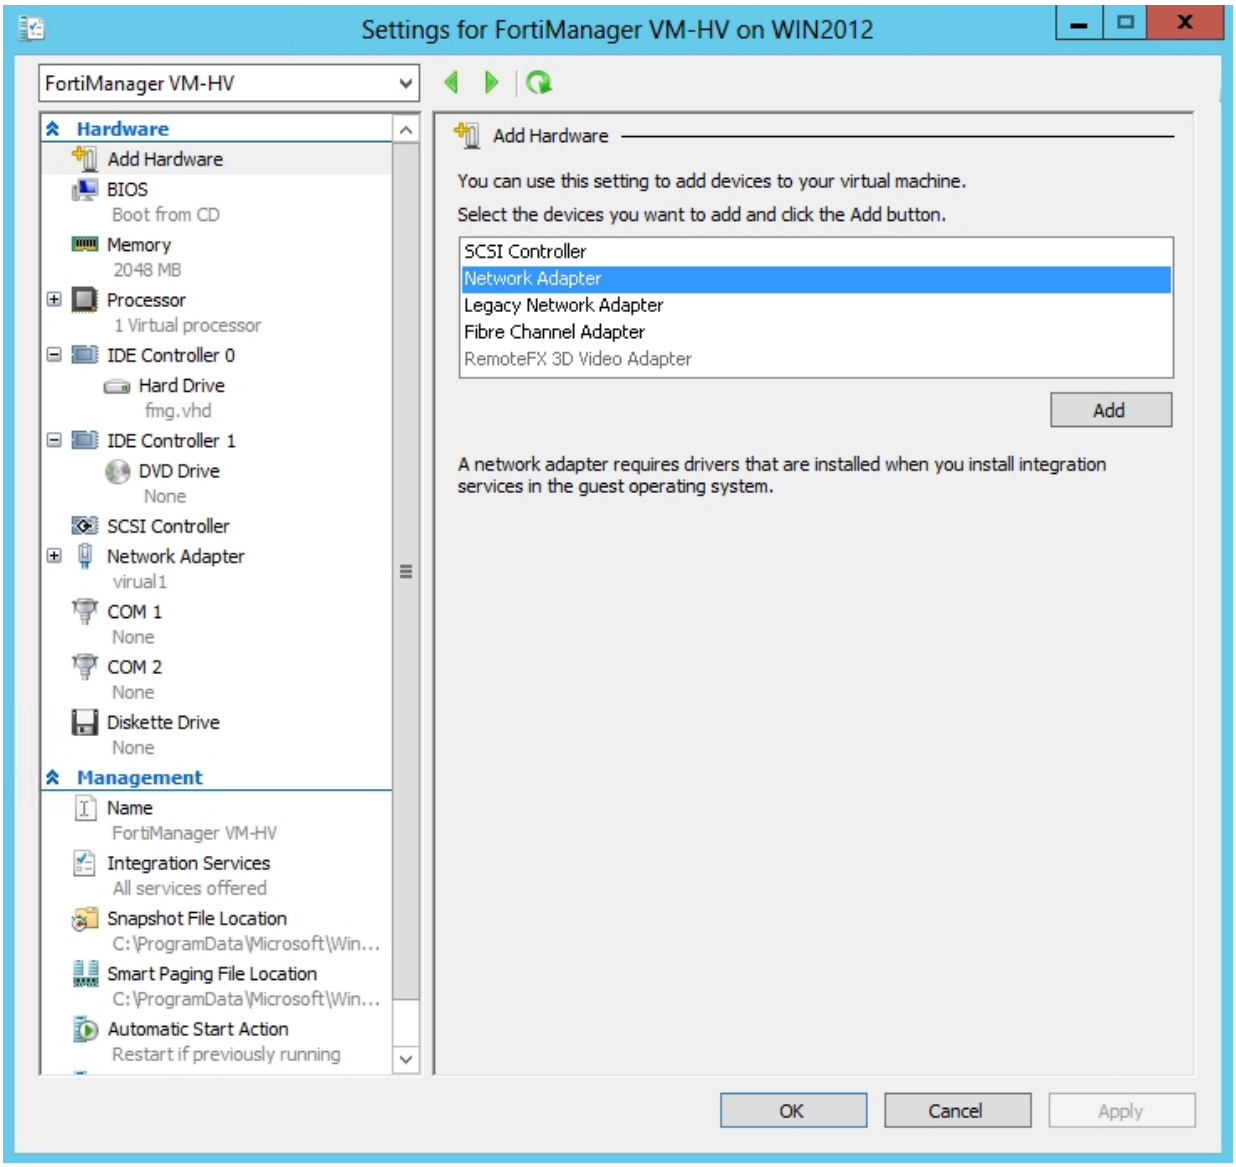
Before powering on your FortiGate VM you must configure the virtual memory, virtual CPU, and virtual disk configuration to match your FortiGate VM license.

To configure settings for FortiGate VM on the server:

1. In the Hyper-V Manager, locate the name of the virtual machine, right-click the entry, and select **Settings** from the menu. Optionally, you can select the virtual machine and select **Settings** in the **Actions** menu.



The **Settings** page is displayed.



2. Configure virtual processors, network adapters, and virtual hard drive settings.
3. Select **Apply** to save the settings and then select **OK** to close the settings page.

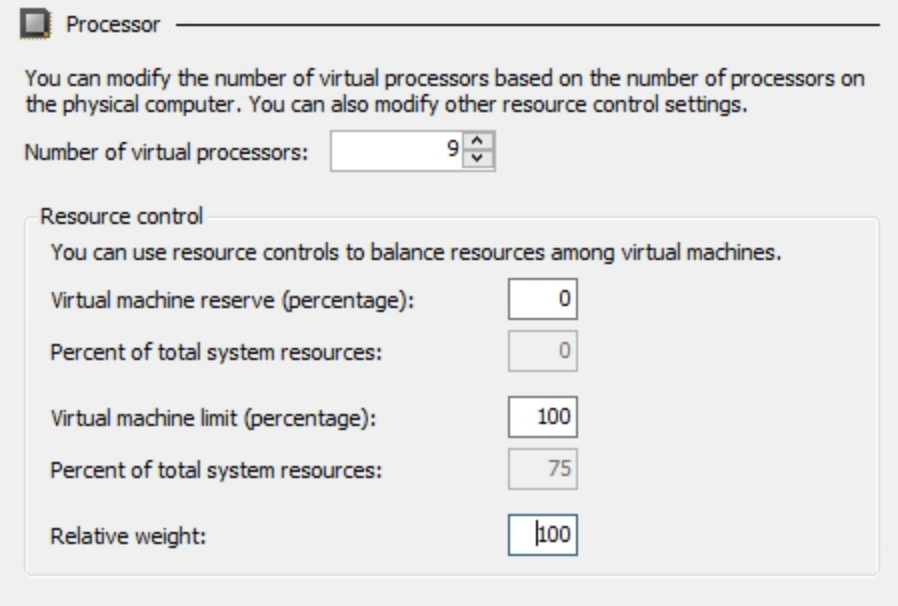
FortiGate VM virtual processors

You must configure FortiGate VM virtual processors in the server settings page. The number of processors is dependent on your server environment.

Configure FortiGate VM virtual processors:

1. In the **Settings** page, select **Processor** from the **Hardware** menu.

   The **Processor** page is displayed.



2. Configure the number of virtual processors for the FortiGate VM virtual machine. Optionally, you can use resource controls to balance resources among virtual machines.
3. Select **Apply** to save the settings.

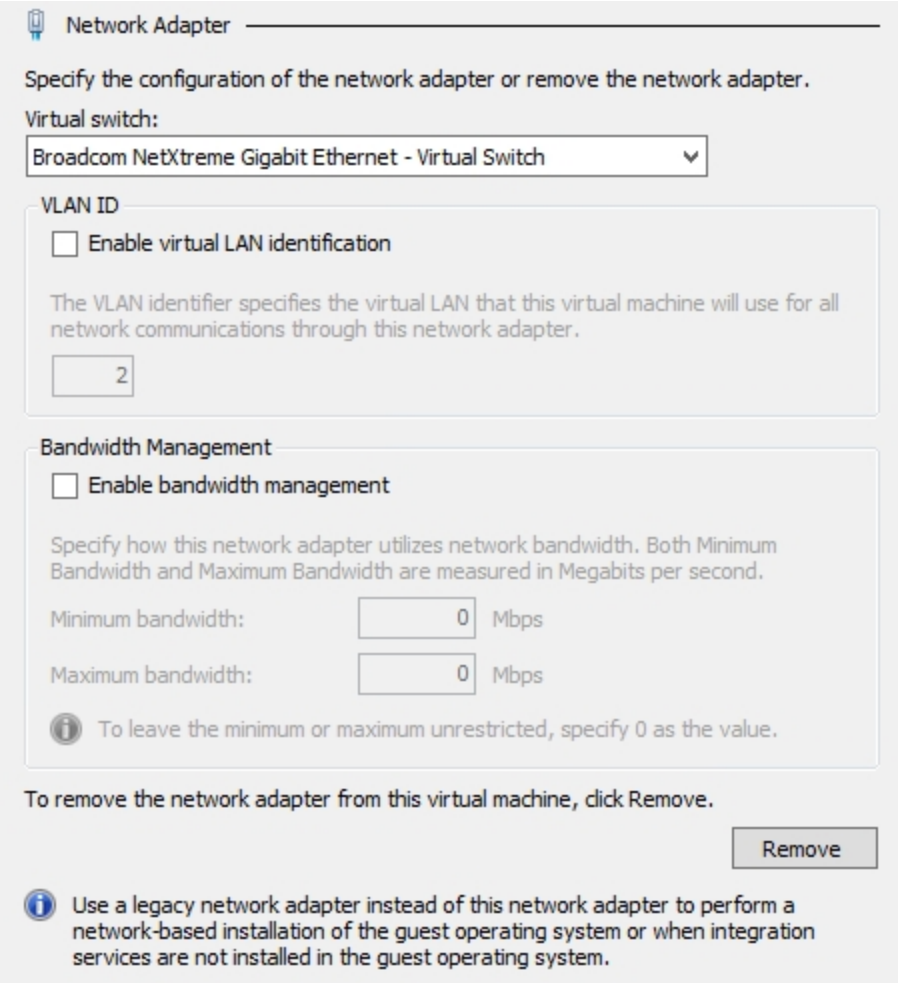
FortiGate VM network adapters

You must configure FortiGate VM network adapters in the server settings page. FortiGate VM supports four network adapters.

Configure FortiGate VM network adapters:

1. In the **Settings** page, select **Add Hardware** from the **Hardware** menu, select **Network Adapter** in the device list, and select the **Add** button.

The **Network Adapter** page is displayed.



1. You must manually configure four network adapters for FortiGate VM in the settings page. For each network adapter, select the virtual switch from the drop-down list.
2. Select **Apply** to save the settings.

FortiGate VM virtual hard disk

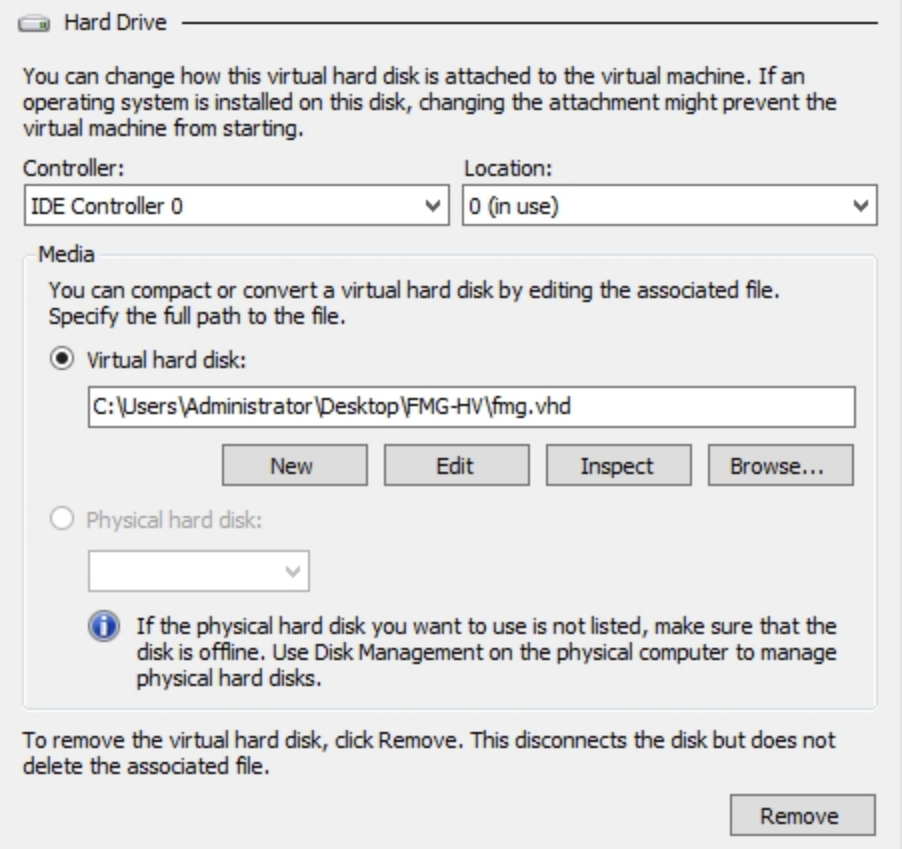
You must configure the FortiGate VM virtual hard disk in the server settings page.

If you know your environment will expand in the future, it is recommended to increase the hard disk size beyond 30GB. The VM license limit is 2TB.

Configure a FortiGate VM virtual hard drive:

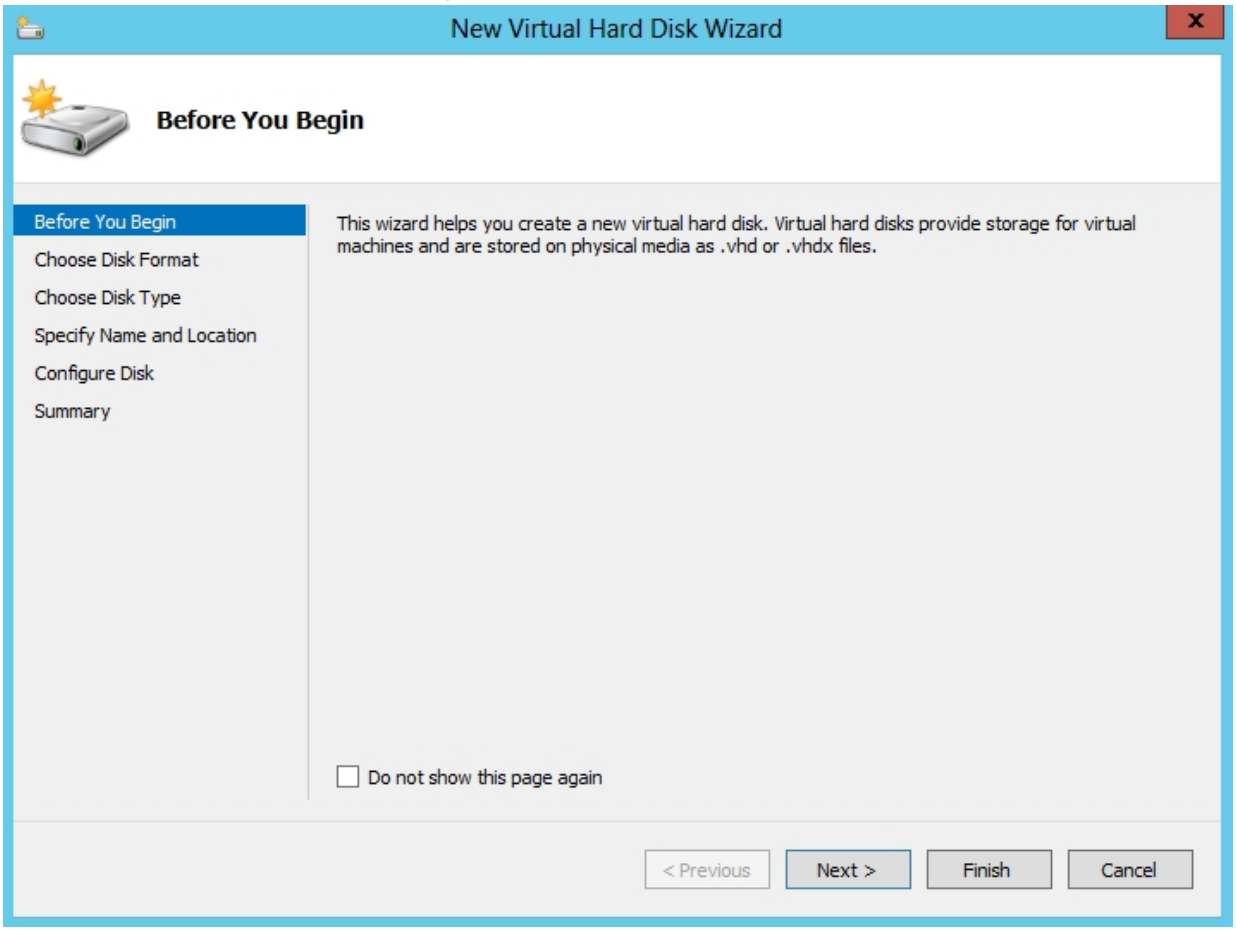
1. In the **Settings** page, select **IDE Controller 0 > Hard Drive** from the **Hardware** menu.

   The **Hard Drive** page is displayed.



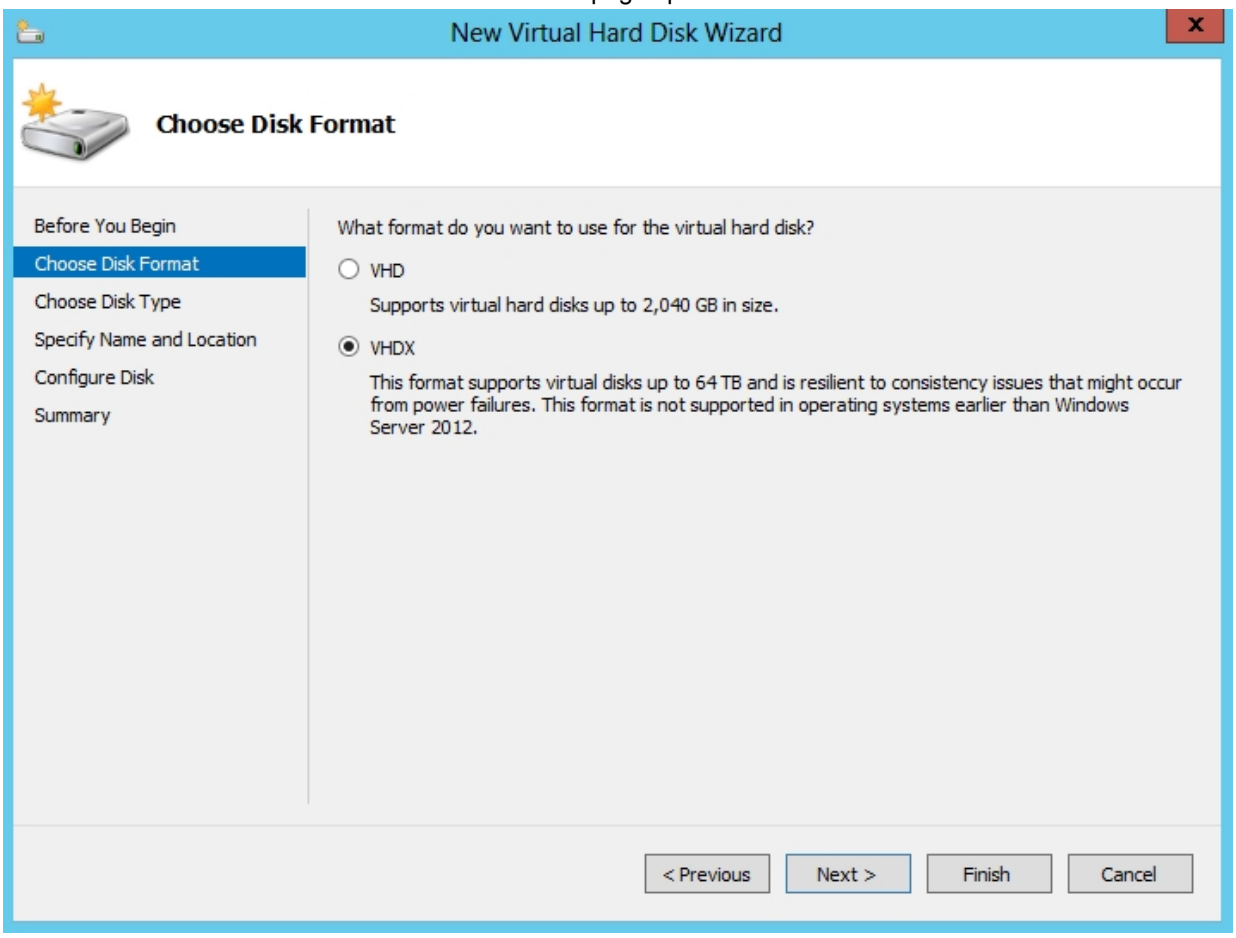
2. Select **New** to create a new virtual hard disk.

The **New Virtual Hard Disk Wizard** opens.



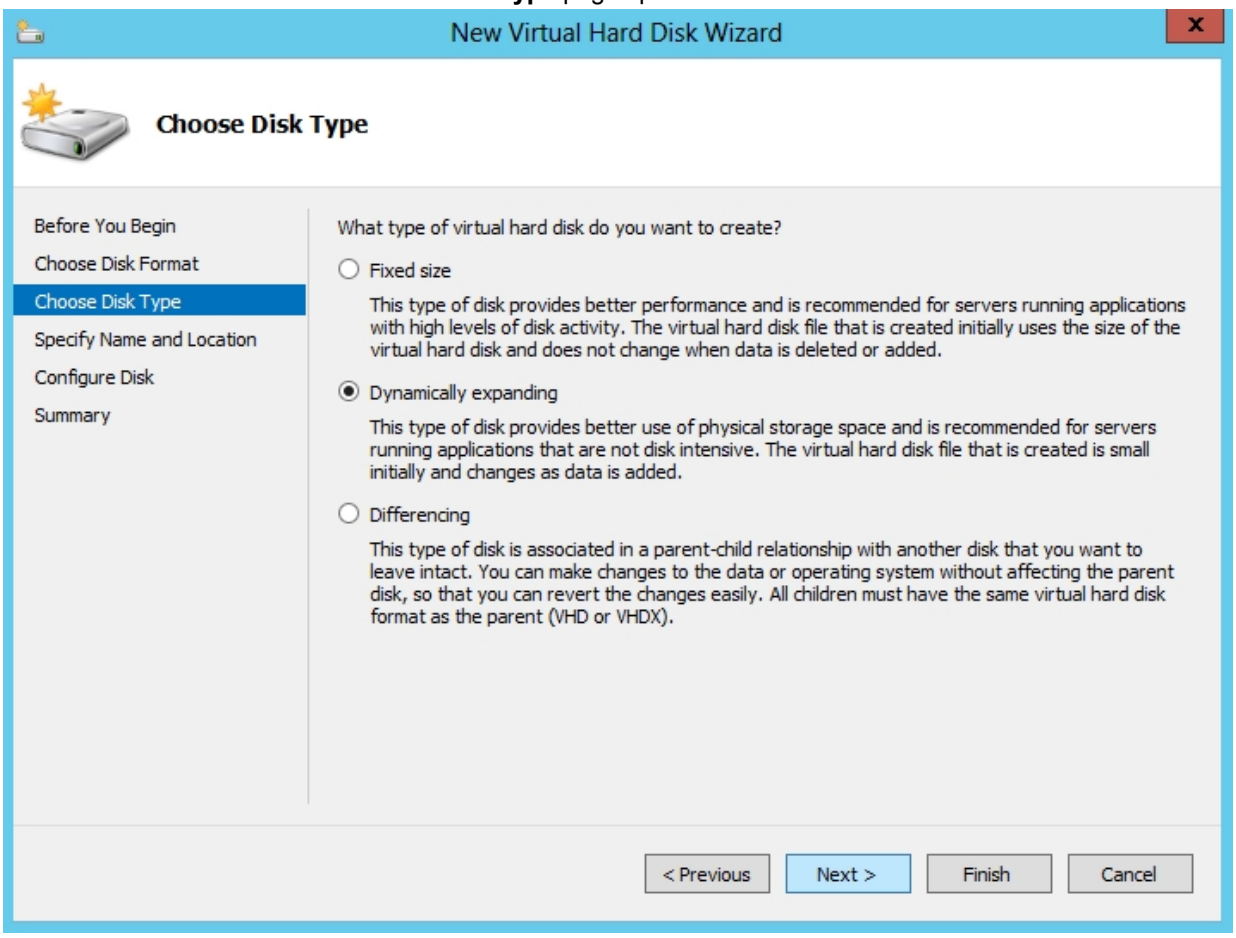
3. This wizard helps you to create a new virtual hard disk.

Select **Next** to continue. The **Choose Disk Format** page opens.



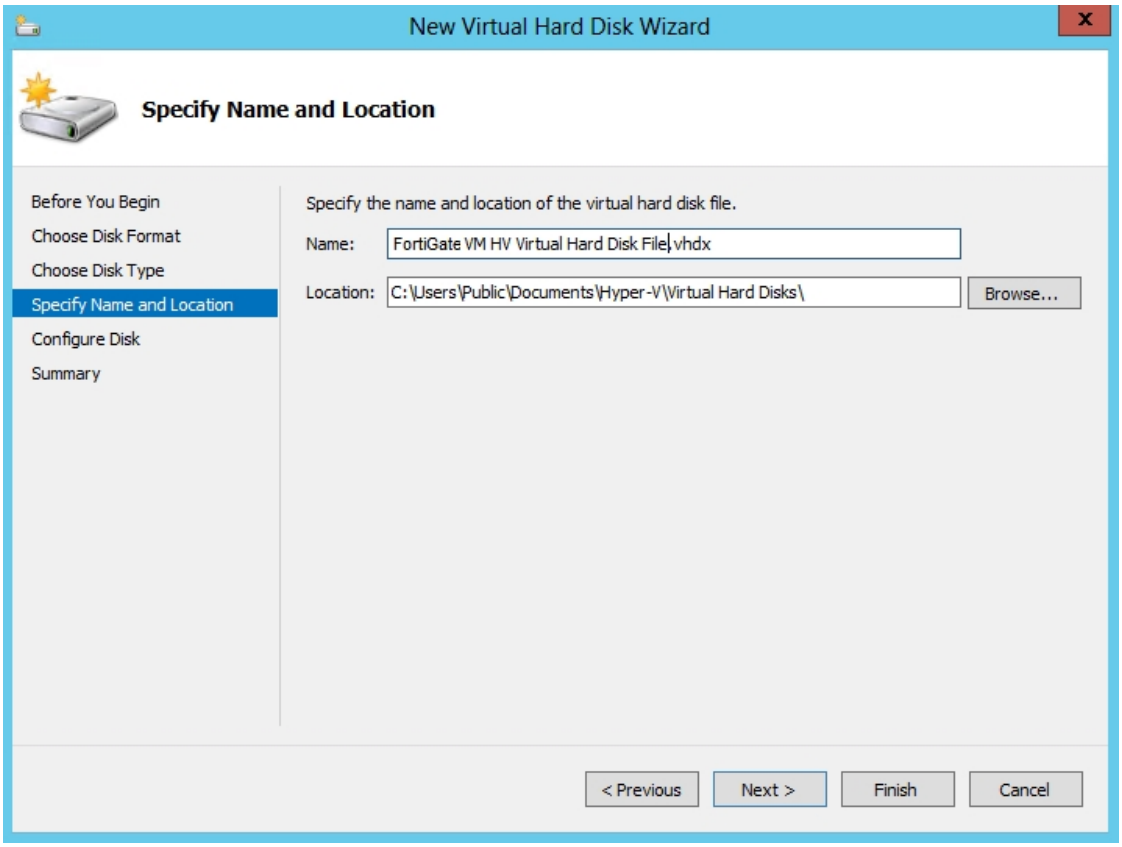
4. Select to use VHDX format virtual hard disks. This format supports virtual disks up to 64TB and is resilient to consistency issues that might occur from power failures. This format is not supported in operating systems earlier than Windows Server 2012. Note that FortiGate-VM does not support hard disks larger than 2TB.

Select **Next** to continue. The **Choose Disk Type** page opens.



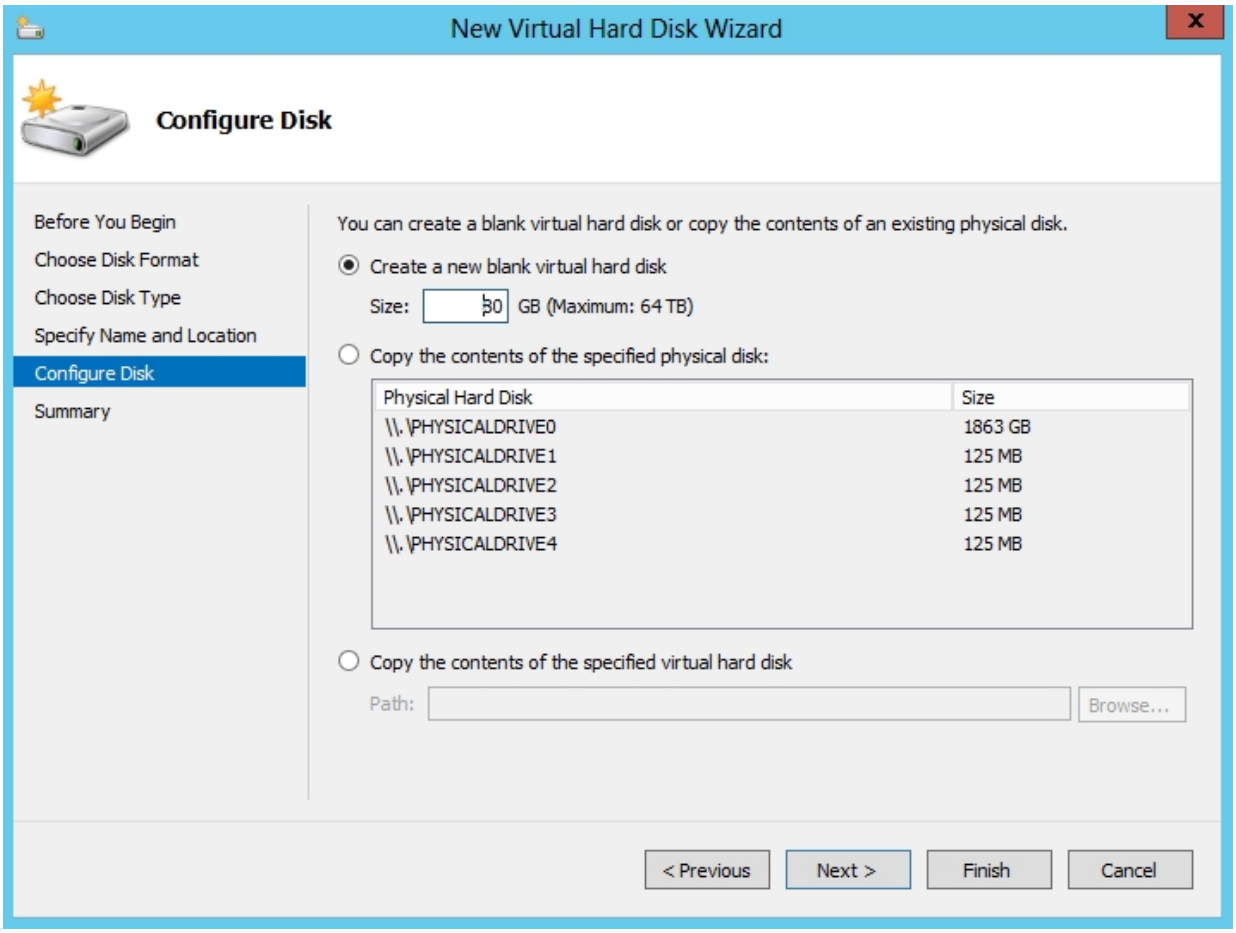
5. Select the type of virtual disk you want to use. Select one of the following disk types:
   - Fixed size: This type of disk provides better performance and is recommended for servers running applications with high levels of disk activity. The virtual hard disk file that is created initially uses the size of the virtual hard disk and does not change when data is deleted or added.
   - Dynamic expanding: This type of disk provides better use of physical storage space and is recommended for servers running applications that are not disk intensive. The virtual disk file that is created is small initially and changes as data is added.
   - Differencing: This type of disk is associated in a parent-child relationship with another disk that you want to leave intact. You can make changes to the data or operating system without affecting the parent disk, so that you can revert the changes easily. All children must have the same virtual hard disk format as the parent (VHD or VHDX).

   Select **Next** to continue. The **Specify Name and Location** page opens.



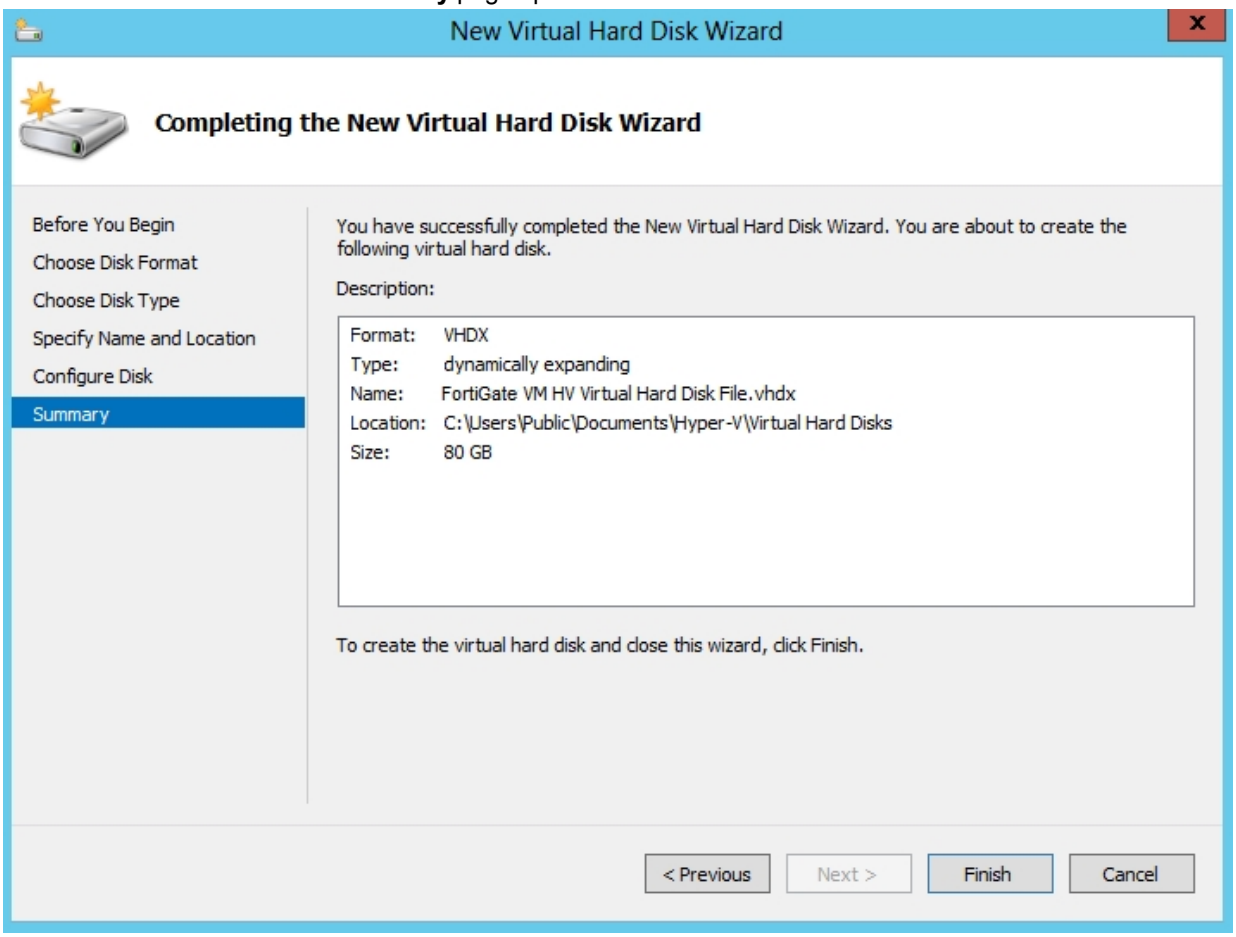
6. Specify the name and location of the virtual hard disk file. Use the **Browse** button to select a specific file folder on your server.

   Select **Next** to continue. The **Configure Disk** page opens.



7. Select to **Create a new blank virtual hard disk** and enter the size of the disk in GB. The maximum size is dependent on your server environment.

Select **Next** to continue. The **Summary** page opens.



8. The summary page provides details of the virtual hard disk. Select **Finish** to create the virtual hard disk.
9. Select **Apply** to save the settings and select **OK** to exit the settings page.

High Availability Hyper-V configuration

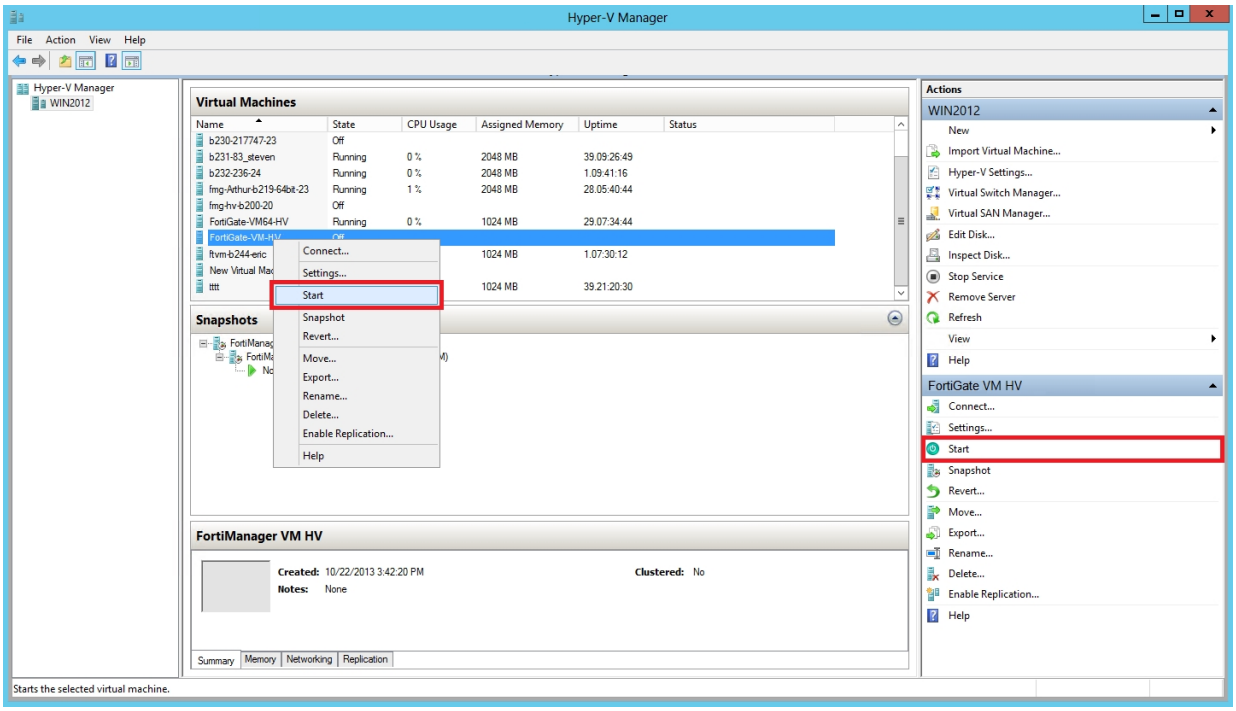
Promiscuous mode and support for MAC address spoofing is required for FortiGate-VM for Hyper-V to support FortiGate Clustering Protocol (FGCP) high availability (HA). By default the FortiGate-VM for Hyper-V has promiscuous mode enabled in the XML configuration file in the FortiGate-VM Hyper-V image. If you have problems with HA mode, confirm that this is still enabled.

In addition, because the FGCP applies virtual MAC addresses to FortiGate data interfaces and because these virtual MAC addresses mean that matching interfaces of different FortiGate-VM instances will have the same virtual MAC addresses you have to configure Hyper-V to allow MAC spoofing. But you should only enable MAC spoofing for FortiGate-VM data interfaces. You should not enable MAC spoofing for FortiGate HA heartbeat interfaces.

With promiscuous mode enabled and the correct MAC spoofing settings you should be able to configure HA between two or more FortiGate-VM for Hyper-V instances.

Start the FortiGate VM

You can now proceed to power on your FortiGate VM. Select the name of the FortiGate VM in the list of virtual machines, right-click, and select **Start** in the menu. Optionally, you can select the name of the FortiGate VM in the list of virtual machines and select **Start** in the **Actions** menu.



Deployment example – KVM

Once you have downloaded the FORTINET.out.kvm.zip file and extracted virtual hard drive image file fortios.qcow2, you can create the virtual machine in your KVM environment.

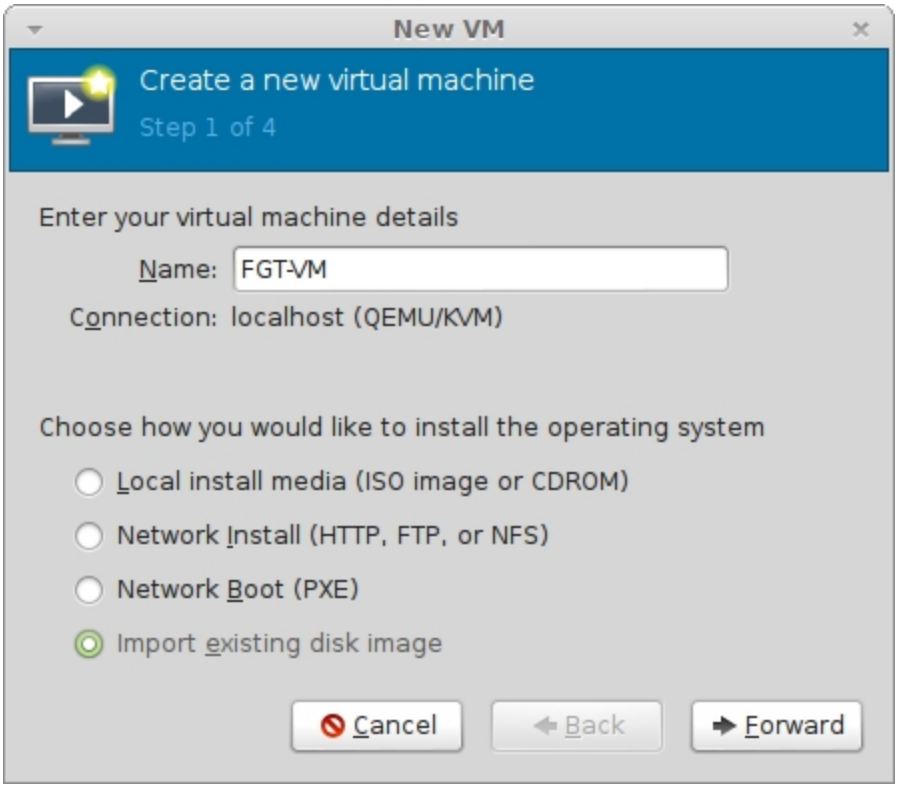
The following topics are included in this section:

Create the FortiGate VM virtual machine

To create the FortiGate VM virtual machine:

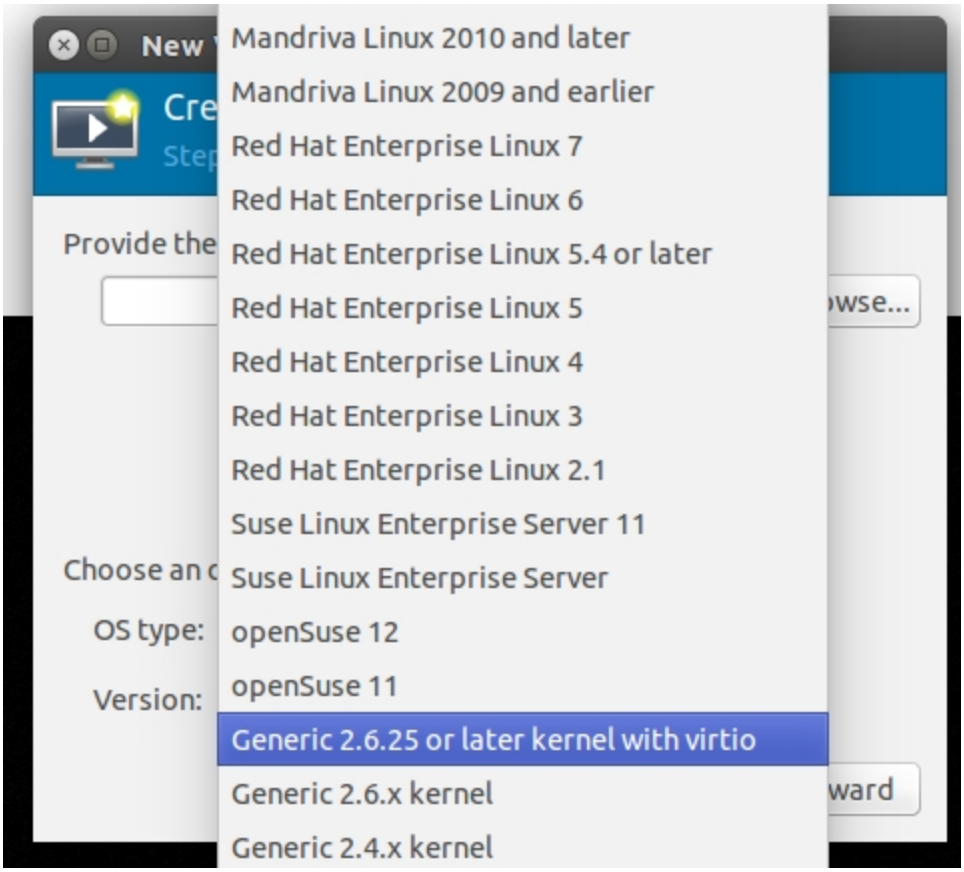
1. Launch Virtual Machine Manager (virt-manager) on your KVM host server.

   The **Virtual Machine Manager** home page opens.
2. In the toolbar, select **Create a new virtual machine**.



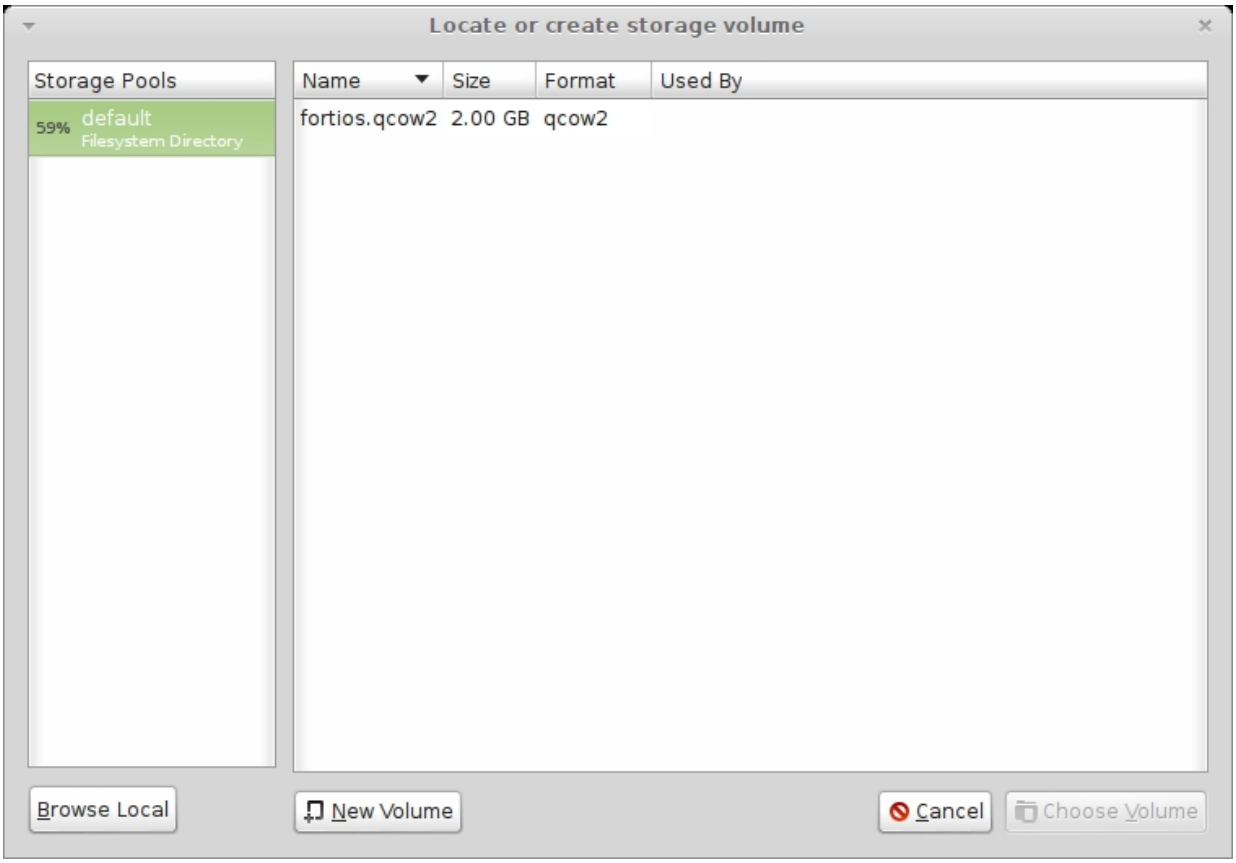
3. Enter a **Name** for the VM, FGT-VM for example.
4. Ensure that **Connection** is localhost. (This is the default.)
5. Select **Import existing disk image**.

6. Select **Forward**.



7. In **OS Type** select **Linux**.
8. In **Version**, select a Generic version with virtio.

9. Select **Browse**.



10. If you copied the fortios.qcow2 file to `/var/lib/libvirt/images`, it will be visible on the right. If you saved it somewhere else on your server, select Browse Local and find it.
11. Choose **Choose Volume**.
12. Select **Forward**.
13. Specify the amount of memory and number of CPUs to allocate to this virtual machine. The amounts must not exceed your license limits. See FortiGate VM Overview on page 3277.
14. Select **Forward**.
15. Expand **Advanced options**. A new virtual machine includes one network adapter by default. Select a network adapter on the host computer. Optionally, set a specific MAC address for the virtual network interface. Set **Virt Type** to **virtio** and **Architecture** to **qcow2**.
16. Select **Finish**.

Configure FortiGate VM hardware settings

Before powering on your FortiGate VM you must add the log disk and configure the virtual hardware of your FortiGate VM.

To configure settings for FortiGate VM on the server:

1. In the Virtual Machine Manager, locate the name of the virtual machine and then select Open from the toolbar.
2. Select **Add Hardware**. In the **Add Hardware** window select **Storage**.
3. Select **Create a disk image on the computer's harddrive** and set the size to 30GB.

If you know your environment will expand in the future, it is recommended to increase the hard disk size beyond 30GB. The VM license limit is 2TB.

4. Enter:

Device type	Virtio disk
Cache mode	Default
Storage format	raw

Even though raw is the storage format listed, the qcow2 format is also supported.

5. Select **Network** to configure add more the network interfaces. The **Device type** must be **Virtio**.

   A new virtual machine includes one network adapter by default. You can add more through the Add Hardware window. FortiGate VM requires four network adapters. You can configure network adapters to connect to a virtual switch or to network adapters on the host computer.
6. Select **Finish**.

Start the FortiGate VM

You can now proceed to power on your FortiGate VM. Select the name of the FortiGate VM in the list of virtual machines. In the toolbar, select **Console** and then select **Start**.

Deployment example – OpenXen

Once you have downloaded the FORTINET.out.OpenXen.zip file and extracted virtual hard drive image file fortios.qcow2, you can create the virtual machine in your OpenXen environment.

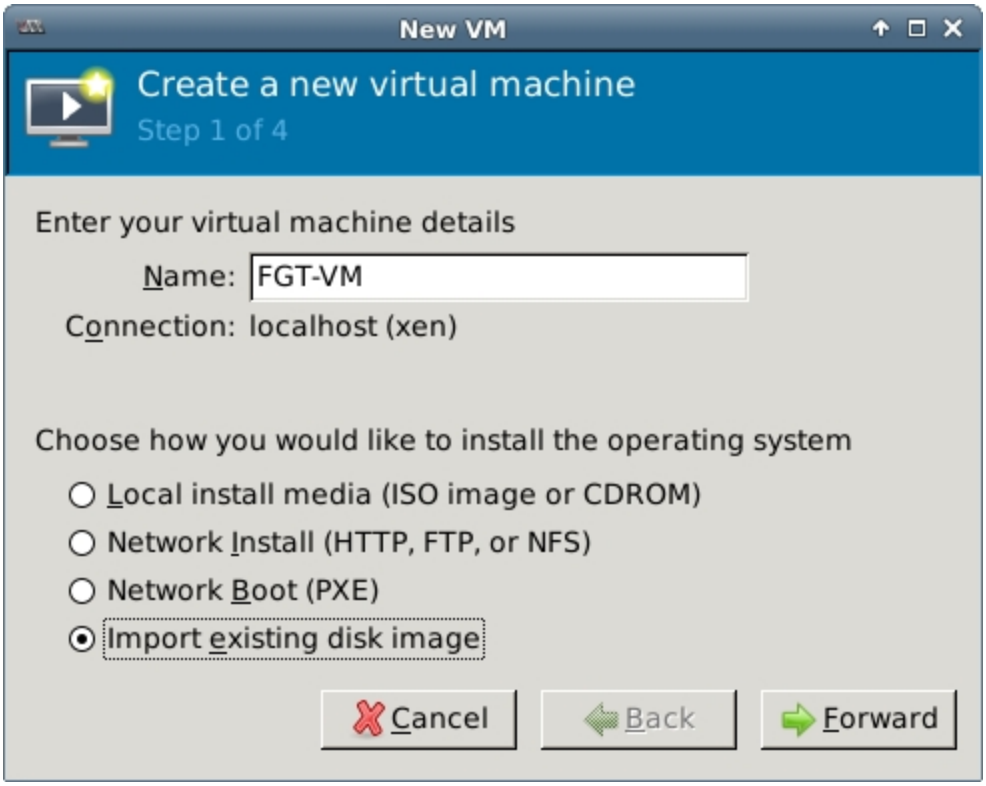
The following topics are included in this section:

Create the FortiGate VM virtual machine (VMM)

To create the FortiGate VM virtual machine:

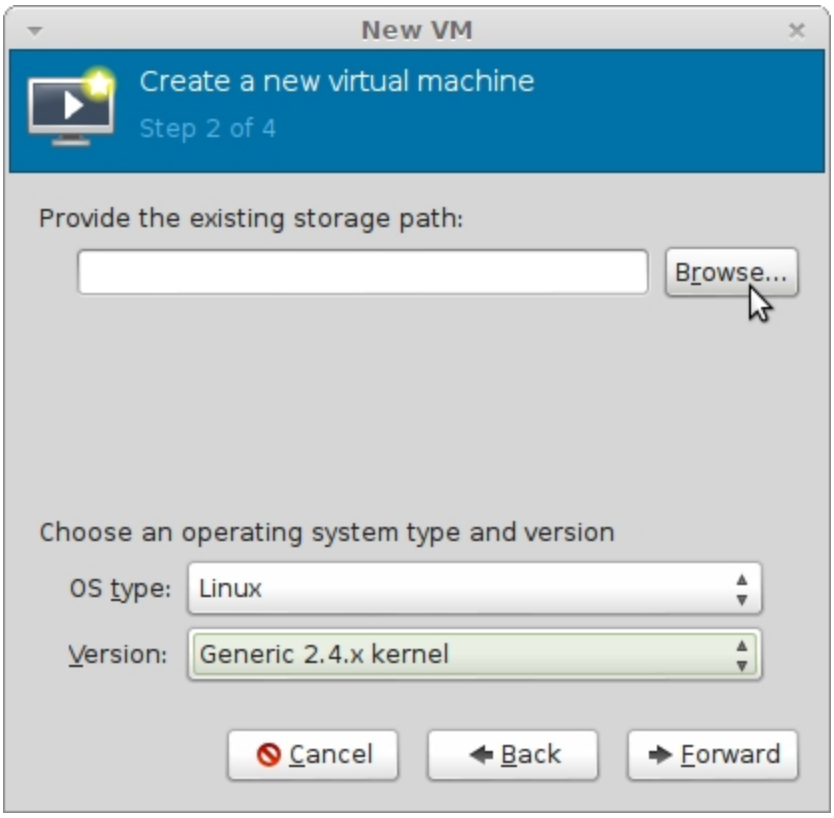
1. Launch Virtual Machine Manager (virt-manager) on your OpenXen host server.

   The **Virtual Machine Manager** home page opens.
2. In the toolbar, select **Create a new virtual machine**.



3. Enter a **Name** for the VM, FGT-VM for example.
4. Ensure that **Connection** is localhost. (This is the default.)
5. Select **Import existing disk image**.

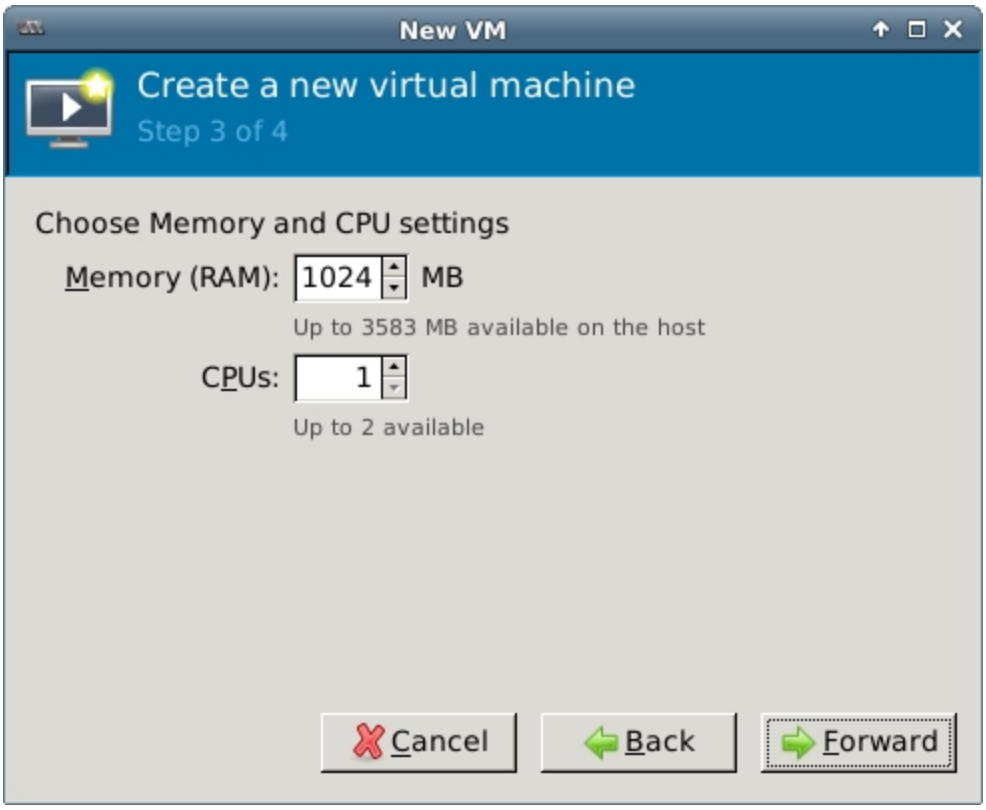
6. Select **Forward**.



7. In **OS Type** select **Linux**.
8. In **Version**, select **Generic 2.4.x.kernel**.
9. Select **Browse**.

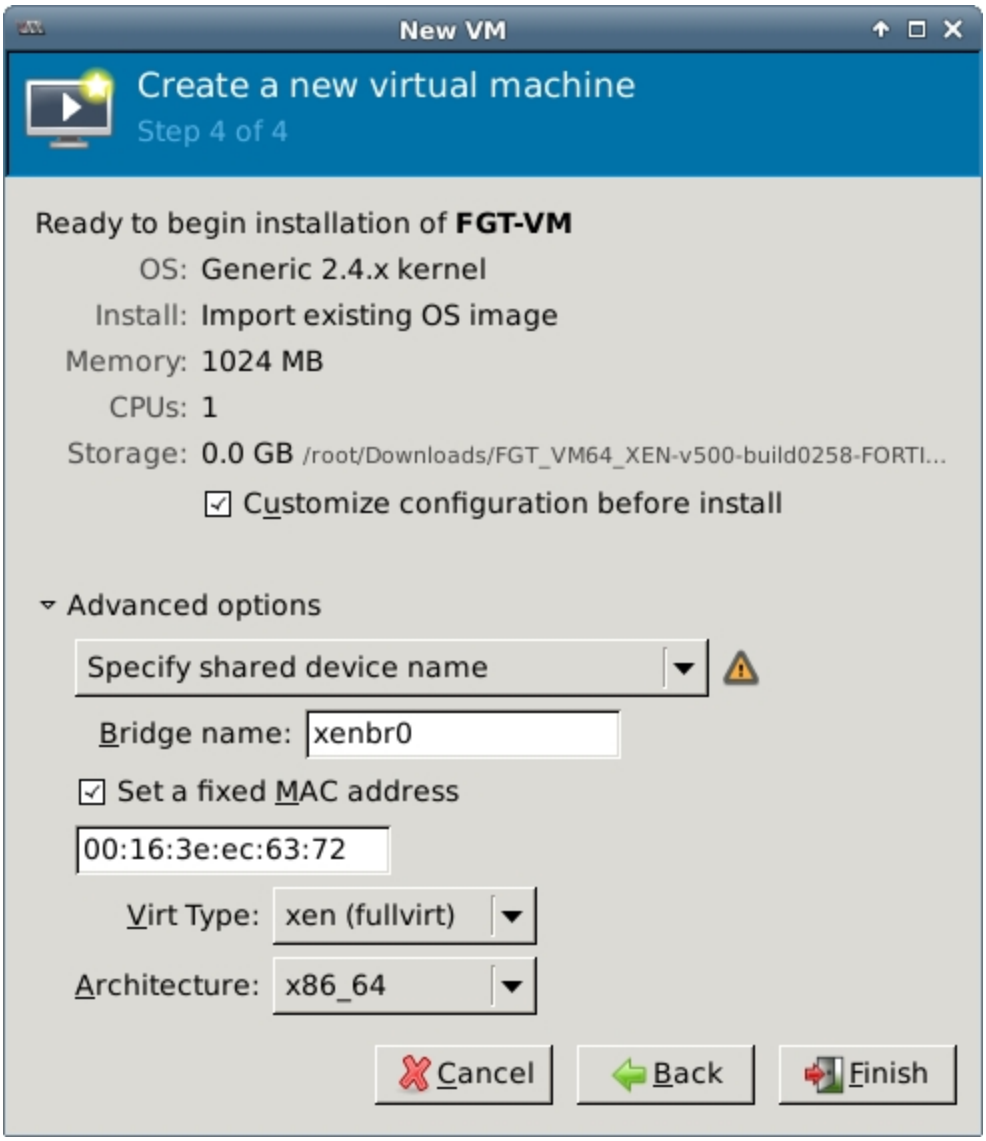
   The **Locate or create storage volume** window opens.
10. Select **Browse Local,** find the fortios.qcow2 disk image file.
11. Select fortios.qcow2 and select **Choose Volume**.

12. Select **Forward**.



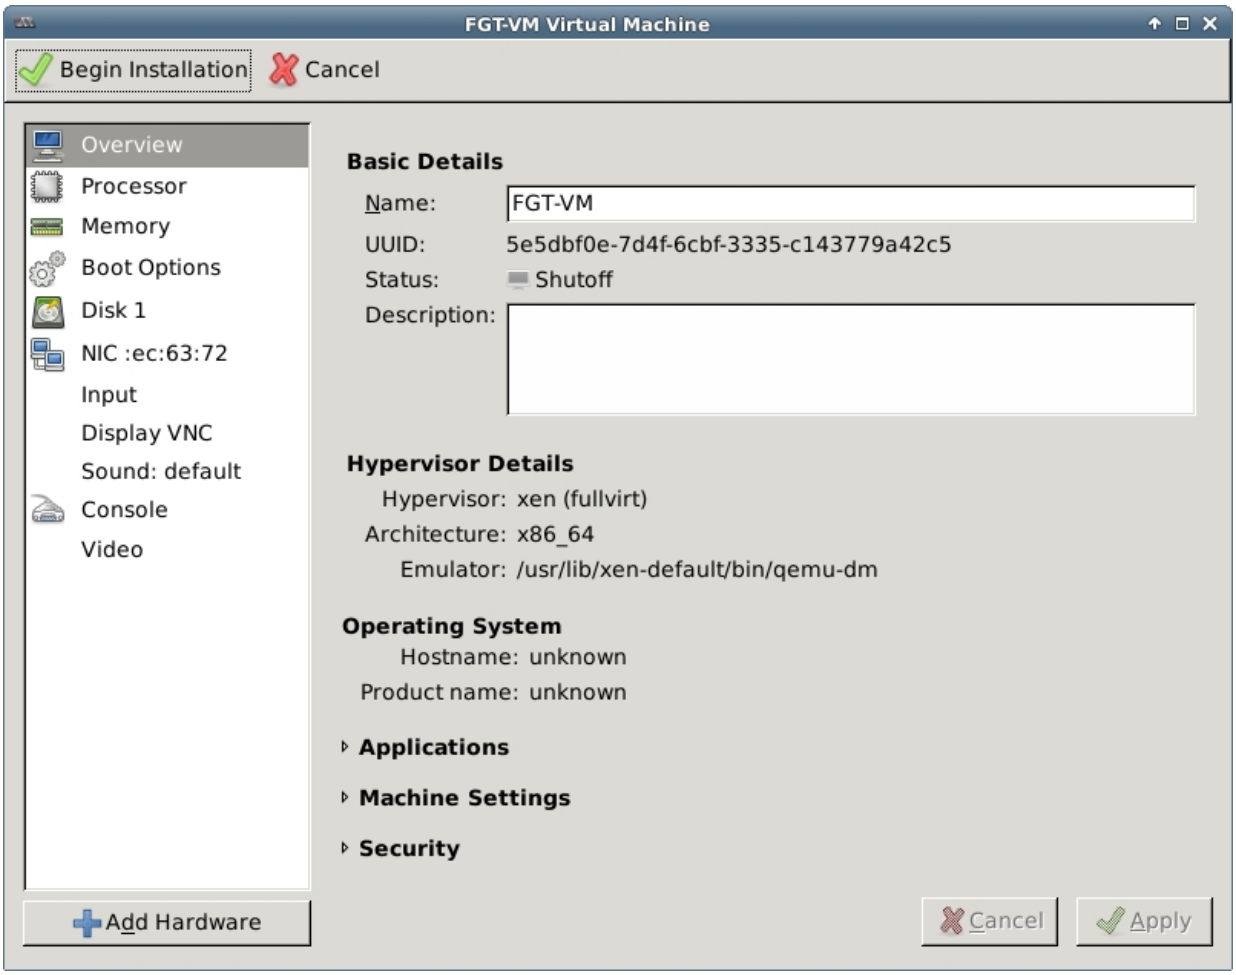
13. Specify the amount of memory and number of CPUs to allocate to this virtual machine. The amounts must not exceed your license limits.

14. Select **Forward**.



15. Select **Customize configuration before install**. This enables you to make some hardware configuration changes before VM creation is started.
16. Expand **Advanced options**. A new virtual machine includes one network adapter by default. Select **Specify shared device name** and enter the name of the bridge interface on the OpenXen host. Optionally, set a specific MAC address for the virtual network interface. **Virt Type** and **Architecture** are set by default and should be correct.
17. Select **Finish**.

    The virtual machine hardware configuration window opens.



You can use this window to add hardware such as network interfaces and disk drives.

18. Select **Add Hardware**. In the **Add Hardware** window select **Storage**.
19. Select **Create a disk image on the computer's harddrive** and set the size to 30GB.

If you know your environment will expand in the future, it is recommended to increase the hard disk size beyond 30GB. The VM license limit is 2TB.

20. Enter:

Device type	Virtio disk
Cache mode	Default
Storage format	raw

21. Select **Network** to configure add more the network interfaces. The **Device type** must be **Virtio**.

A new virtual machine includes one network adapter by default. You can add more through the Add Hardware window. FortiGate VM requires four network adapters. You can configure network adapters to connect to a virtual

switch or to network adapters on the host computer.

22. Select **Finish**.
23. Select **Begin Installation**. After the installation completes successfully, the VM starts and the console window opens.

Deployment example – Citrix XenServer

Once you have downloaded the FORTINET.out.CitrixXen.zip file and extracted the files, you can create the virtual machine in your Citrix Xen environment.

The following topics are included in this section:

Create the FortiGate VM virtual machine (XenCenter)

To create the FortiGate VM virtual machine from the OVF file

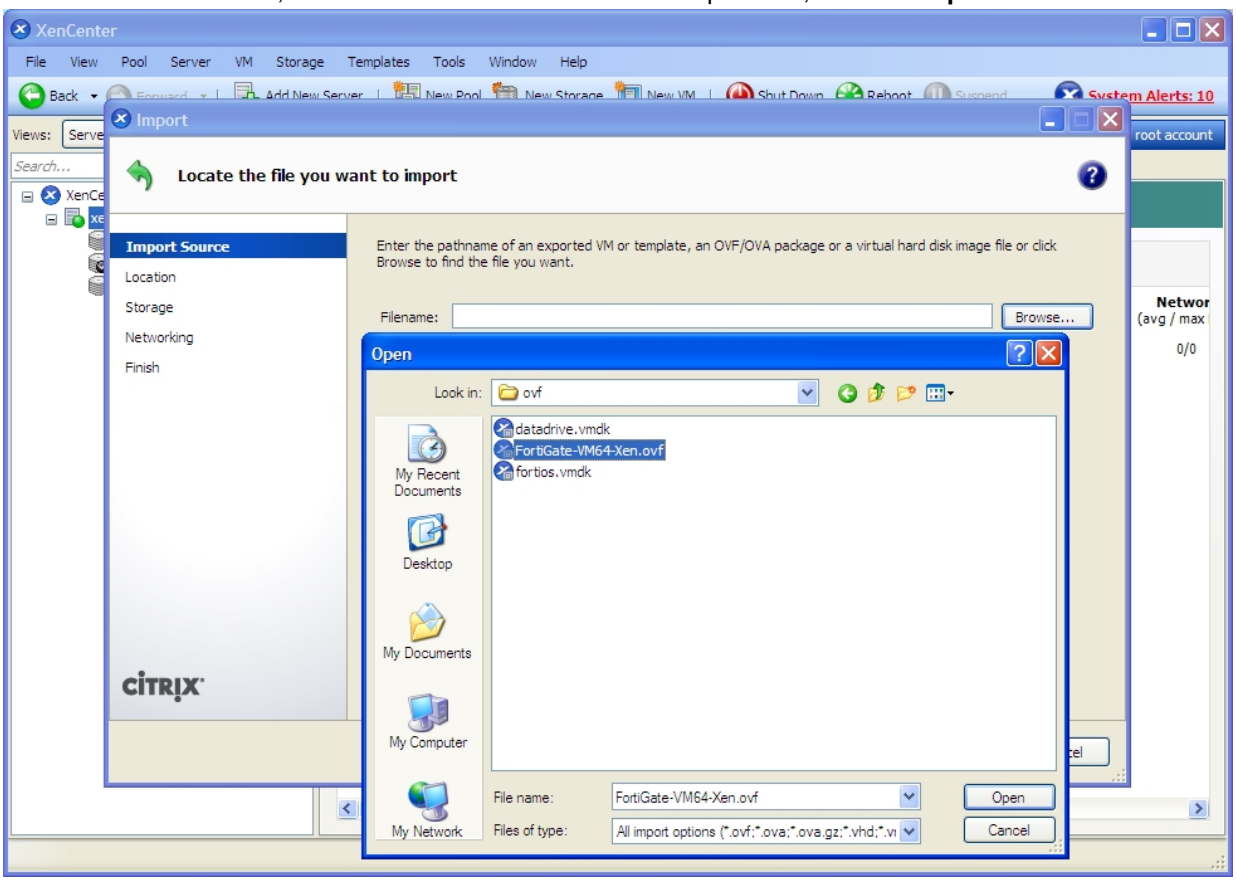
1. Launch XenCenter on your management computer.

   The management computer can be any computer that can run Citrix XenCenter, a Windows application.
2. If you have not already done so, select **ADD a server**. Enter your Citrix XenServer IP address and the root logon credentials required to manage that server.

   Your Citrix XenServer is added to the list in the left pane.

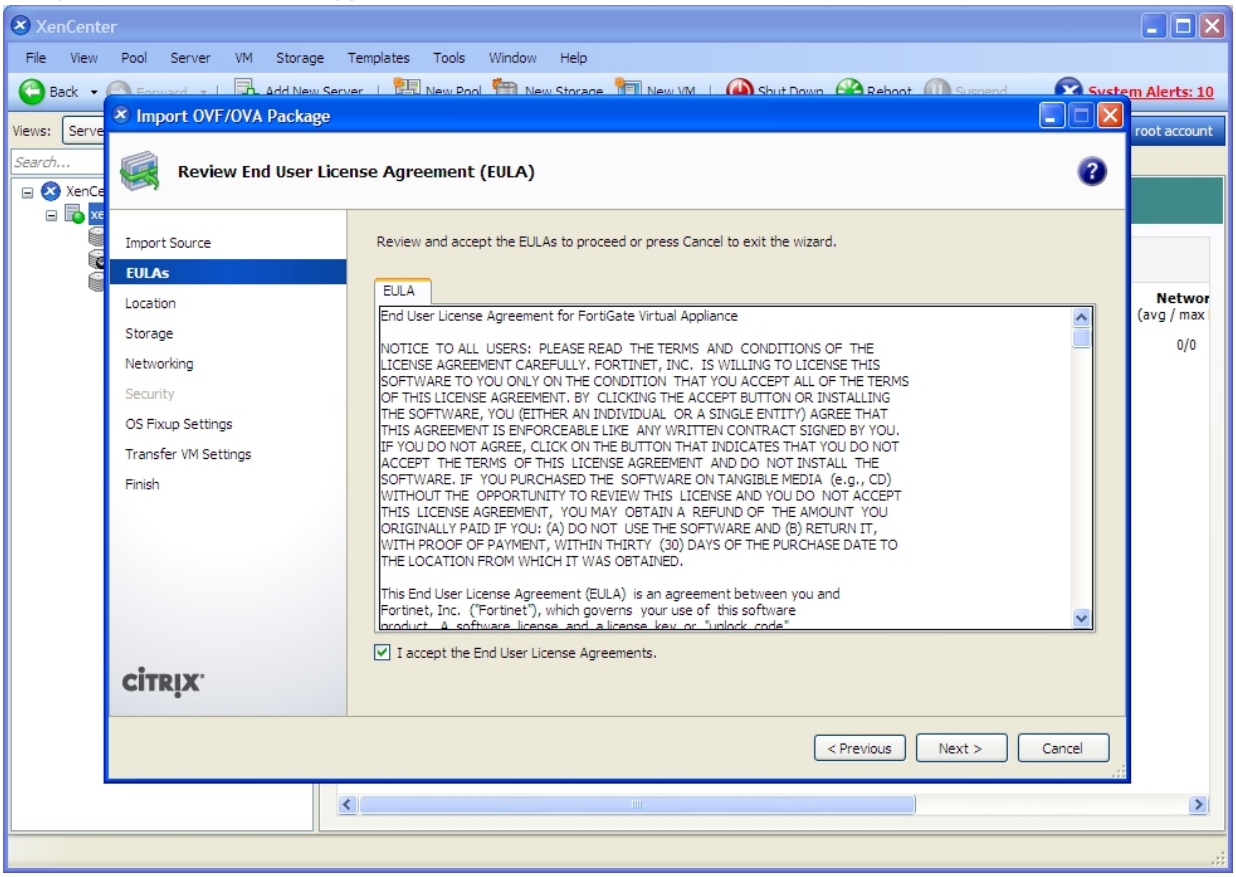
   The **Virtual Machine Manager** home page opens.
3. Go to **File > Import**. An import dialog will appear.

4. Click the **Browse** button, find the FortiGate-VM64-Xen.ovf template file, then click **Open**.



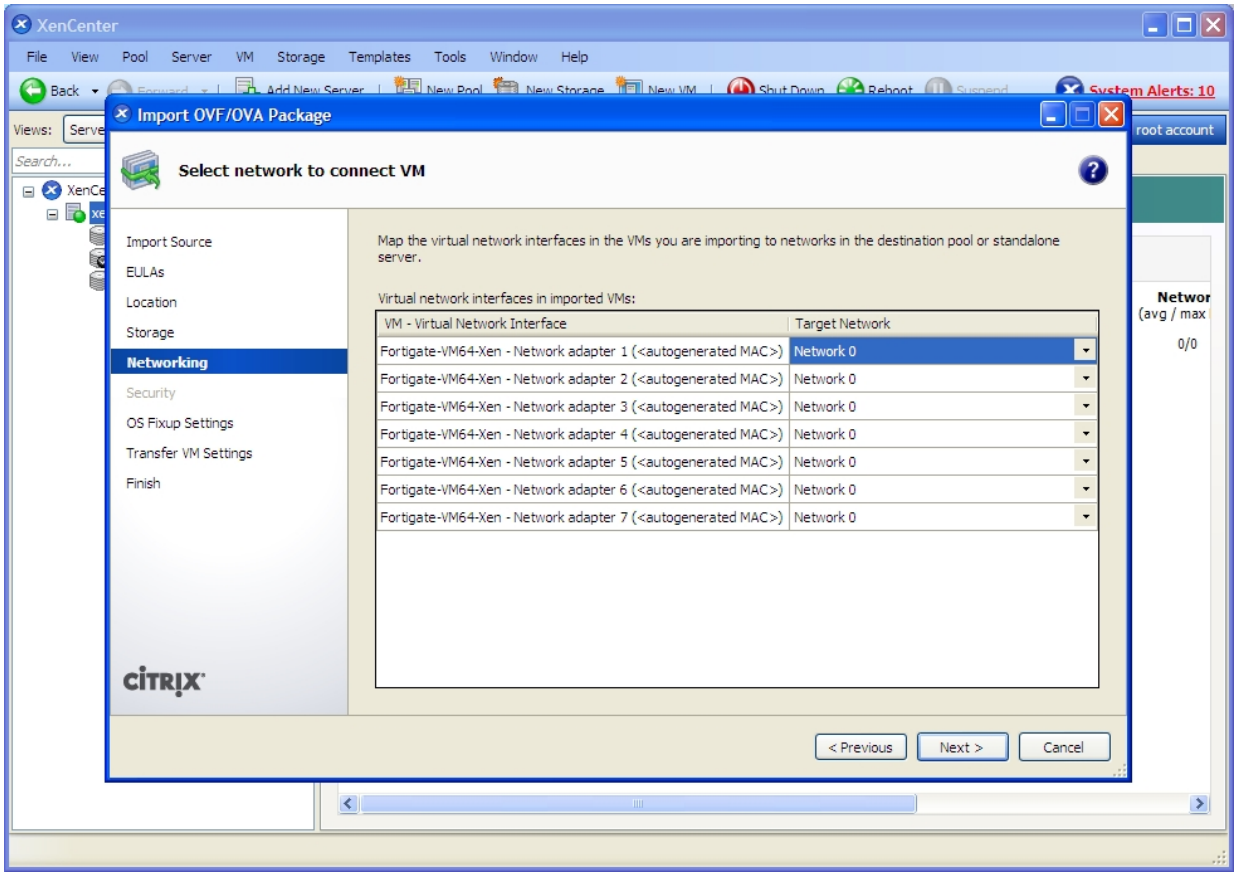
5. Select **Next**.

6. Accept the FortiGate Virtual Appliance EULA, then select **Next**.



7. Choose the pool or standalone server that will host the VM, then select **Next**.
8. Select the storage location for FortiGate VM disk drives or accept the default. Select **Next**.

9. Configure how each vNIC (virtual network adapter) in FortiGate VM will be mapped to each vNetwork on the Citrix XenServer, then click **Next**.



10. Click **Next** to skip OS fixup.
11. Select **Next** to use the default network settings for transferring the VM to the host.
12. Select **Finish**.

The Citrix XenServer imports the FortiGate VM files and configures the VM as specified in the OVF template. Depending on your computer's hardware speed and resource load, and also on the file size and speed of the network connection, this might take several minutes to complete.

When VM import is complete, the XenCenter left pane includes the FortiGate VM in the list of deployed VMs for your Citrix XenServer.

Configure virtual hardware

Before you start your FortiGate-VM for the first time, you need to adjust your virtual machine's virtual hardware settings to meet your network requirements.

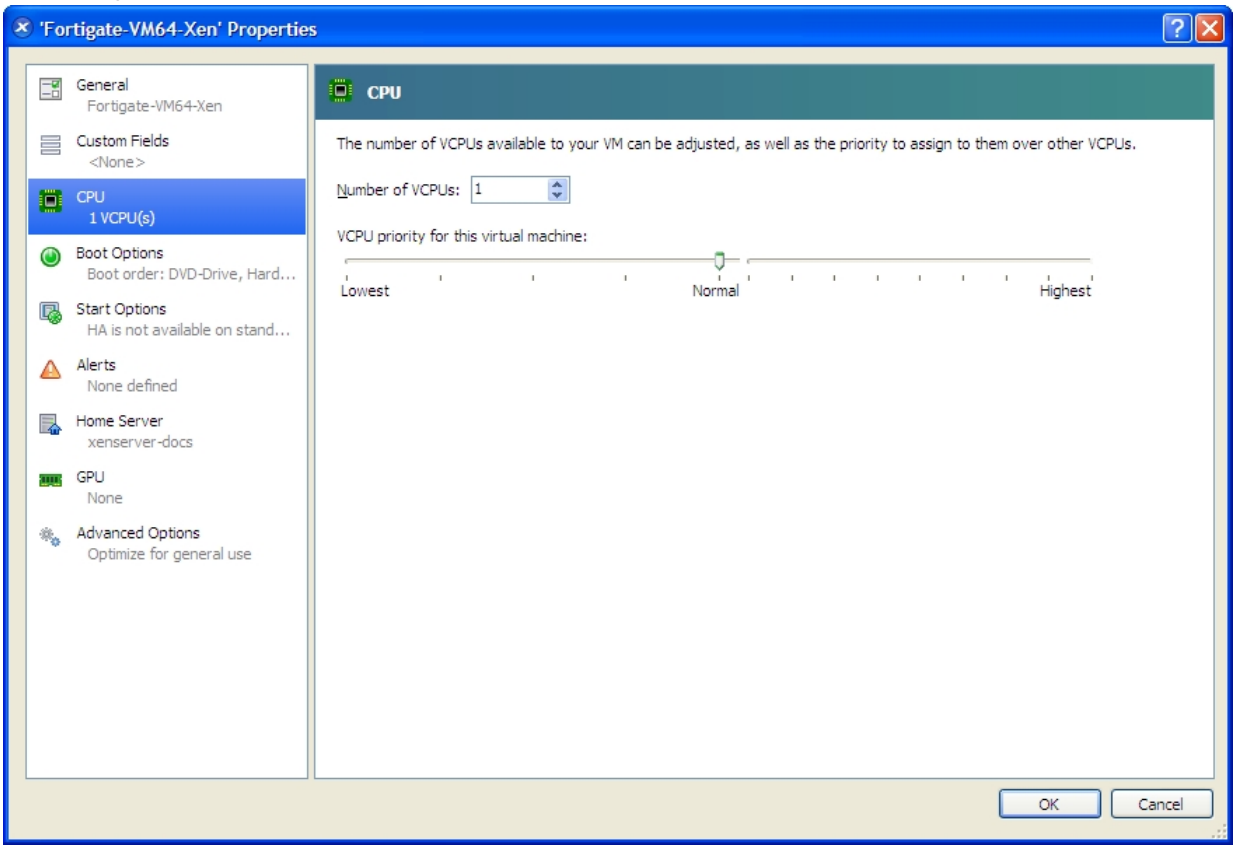
Configuring number of CPUs and memory size

Your FortiGate-VM license limits the number CPUs and amount of memory that you can use. The amounts you allocate must not exceed your license limits.

To access virtual machine settings

1. Open XenCenter.
2. Select your FortiGate VM in the left pane.
   The tabs in the right pane provide access to the virtual hardware configuration. The Console tab provides access to the FortiGate console.

1. To set the number of CPUs
2. In the XenCenter left pane, right-click the FortiGate VM and select Properties.
   The Properties window opens.
3. In the left pane, select CPU.



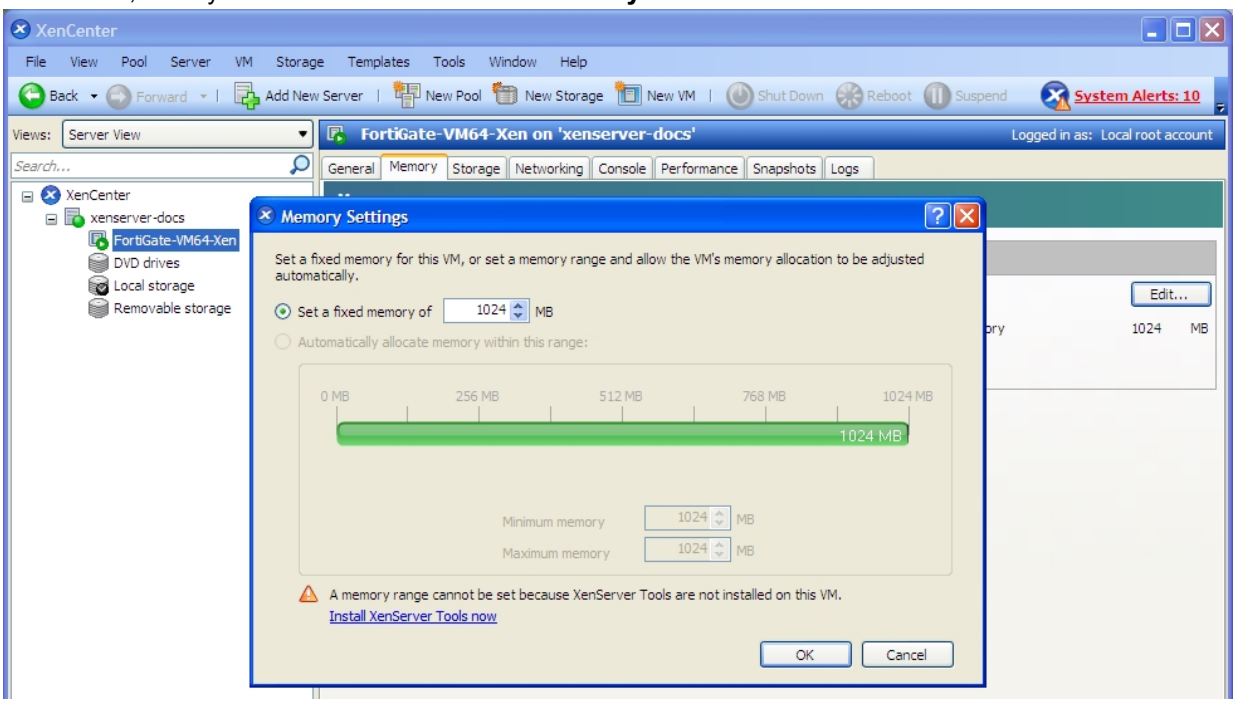
4. Adjust **Number of CPUs** and then select **OK**.

   XenCenter will warn if you select more CPUs than the Xen host computer contains. Such a configuration might reduce performance.

To set memory size

1. In the XenCenter left pane, select the FortiGate VM.
2. In the right pane, select the **Memory** tab.

3. Select **Edit**, modify the value in the **Set a fixed memory of** field and select **OK**.



Configuring disk storage

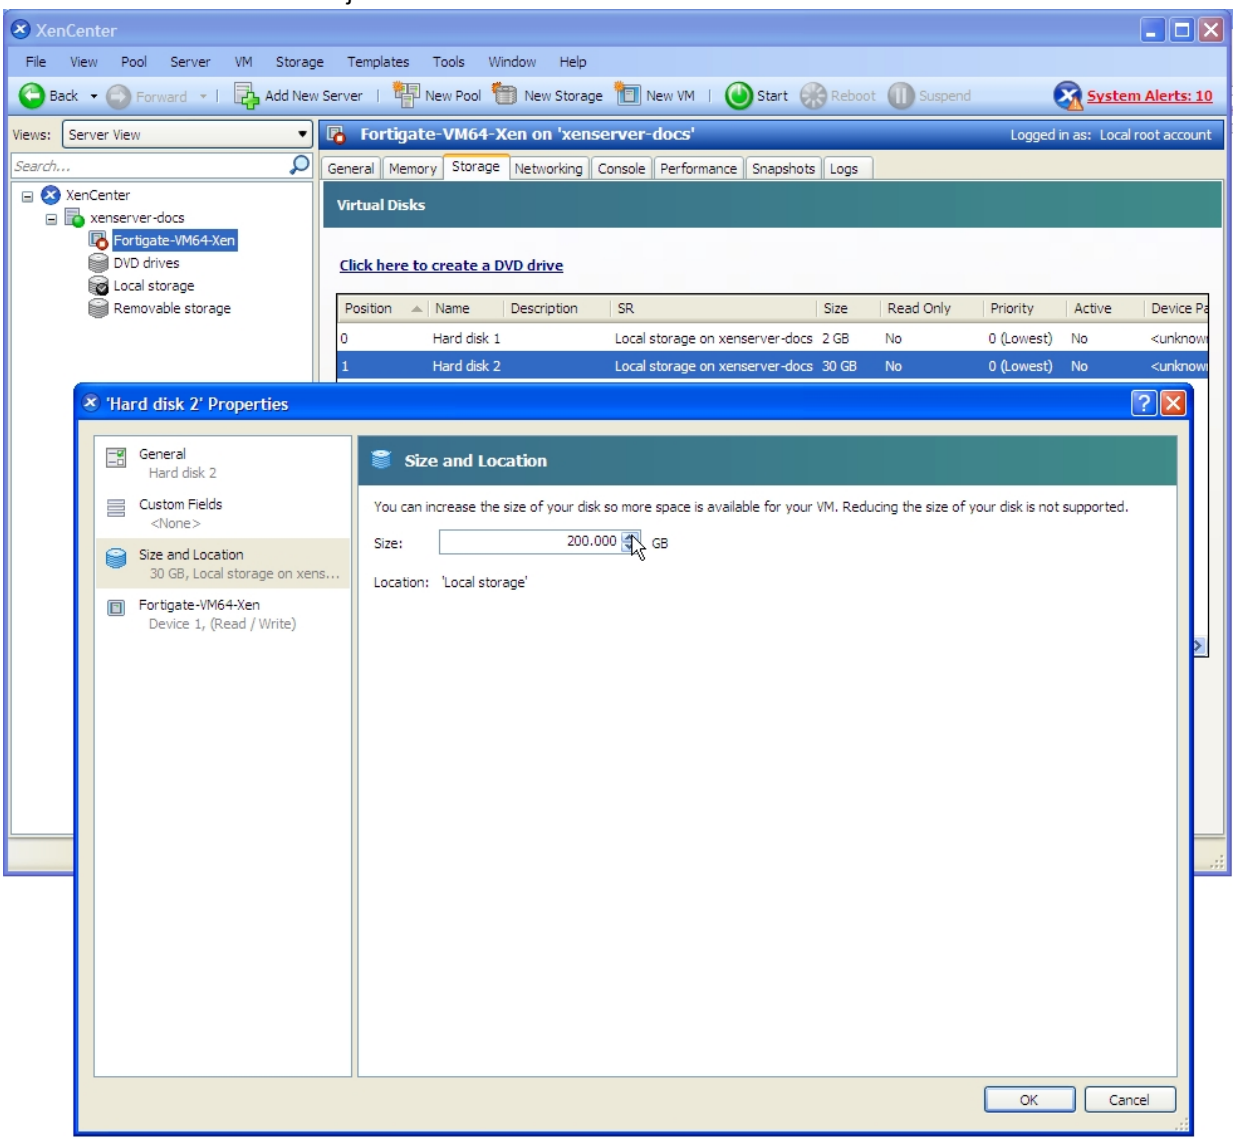
By default the FortiGate VM data disk 30GB. You will probably want to increase this. Disk resizing must be done before you start the VM for the first time.

To resize the FortiGate data disk

1. In the XenCenter left pane, select the FortiGate VM.
2. Select the **Storage** tab. Select **Hard disk 2** (the 30GB drive), then select **Properties**.

   The **'Hard disk 2' Properties** window opens.

3. Select **Size and Location**. Adjust **Size** and select **OK**.



FortiGate VM Initial Configuration

Before you can connect to the FortiGate VM web-based manager you must configure a network interface in the FortiGate VM console. Once an interface with administrative access is configured, you can connect to the FortiGate VM web-based Manager and upload the FortiGate VM license file that you downloaded from the Customer Service & Support website.

The following topics are included in this section:

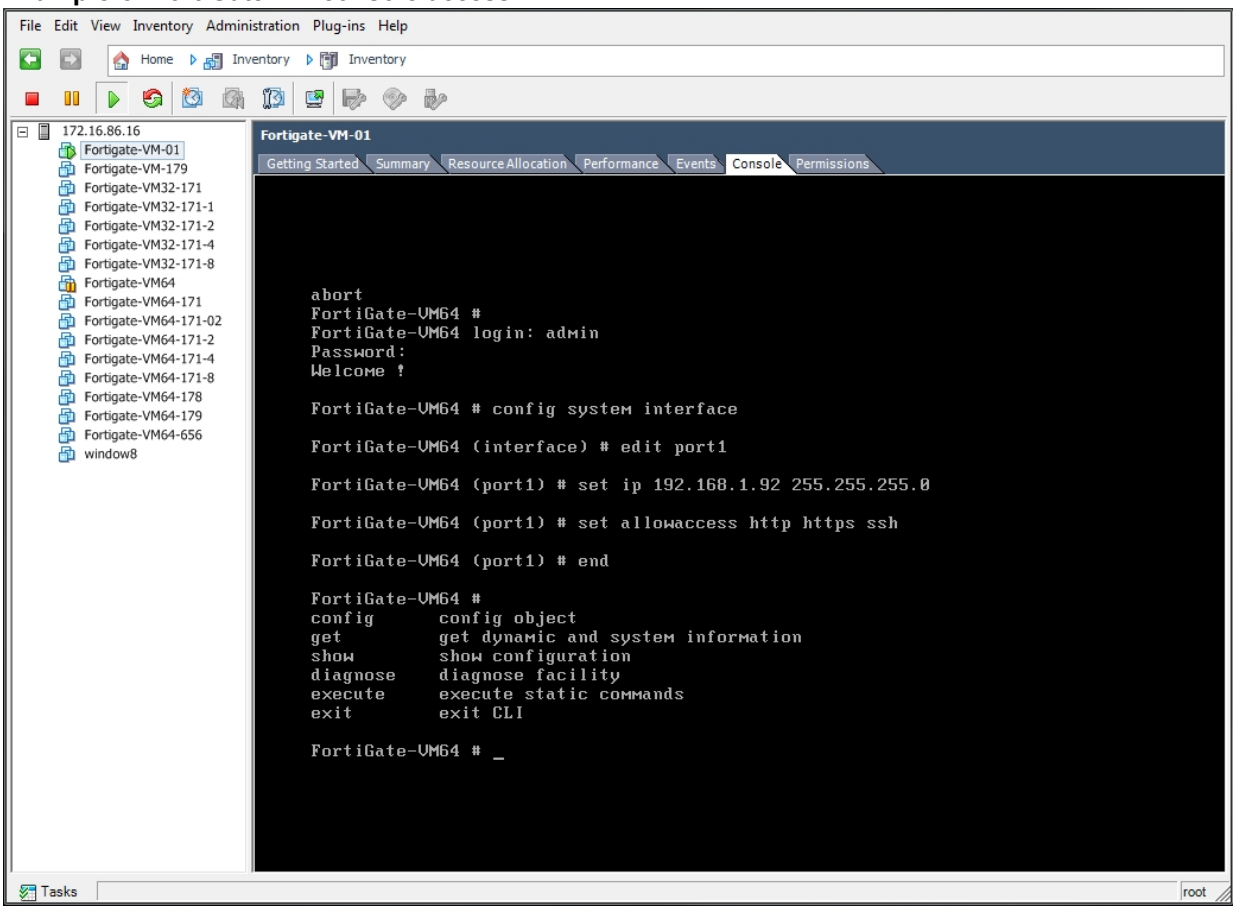
Set FortiGate VM port1 IP address

Hypervisor management environments include a guest console window. On the FortiGate VM, this provides access to the FortiGate console, equivalent to the console port on a hardware FortiGate unit. Before you can access the Web-based manager, you must configure FortiGate VM port1 with an IP address and administrative access.

To configure the port1 IP address:

1. In your hypervisor manager, start the FortiGate VM and access the console window.
   You might need to press Return to see a login prompt.

   Example of FortiGate VM console access:



2. At the FortiGate VM login prompt enter the username `admin`. By default there is no password. Just press Return.
3. Using CLI commands, configure the port1 IP address and netmask. Also, HTTP access must be enabled because until it is licensed the FortiGate VM supports only low-strength encryption. HTTPS access will not work.

   For example:

```
config system interface
  edit port1
    set ip 192.168.0.100 255.255.255.0
    append allowaccess http
  end
```

You can also use the `append allowaccess` CLI command to enable other access protocols, such as `auto-ipsec`, `http`, `probe-response`, `radius-acct`, `snmp`, and `telnet`. The `ping`, `https`, `ssh`, and `fgfm` protocols are enabled on the `port1` interface by default.

4. To configure the default gateway, enter the following CLI commands:

```
config router static
   edit 1
      set device port1
      set gateway <class_ip>
end
```

You must configure the default gateway with an IPv4 address. FortiGate VM needs to access the Internet to contact the FortiGuard Distribution Network (FDN) to validate its license.

5. To configure your DNS servers, enter the following CLI commands:

```
config system dns
   set primary <Primary DNS server>
   set secondary <Secondary DNS server>
end
```

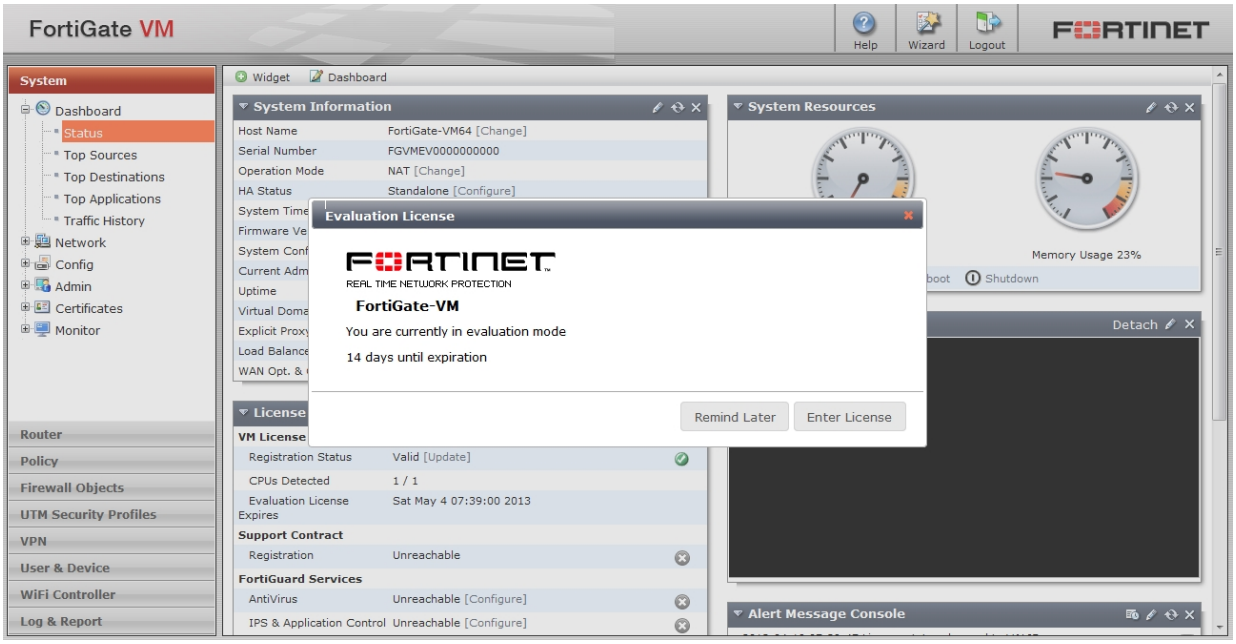
The default DNS servers are `208.91.112.53` and `208.91.112.52`.

6. To upload the FortiGate VM license from an FTP or TFTP server, use the following CLI command:

```
execute restore vmlicense {ftp | tftp} <VM license file name> <Server IP or FQDN>
    [:server port]
```

You can also upload the license in the FortiGate VM Web-based Manager. See Set FortiGate VM port1 IP address on page 3327.

Web-based Manager and Evaluation License dialog box



Connect to the FortiGate VM Web-based Manager

When you have configured the port1 IP address and netmask, launch a web browser and enter the IP address that you configured for port1. At the login page, enter the username `admin` and password field and select **Login**. The default password is no password. The Web-based Manager will appear with an **Evaluation License** dialog box.

Due to low encryption on the FortiGate side of the connection, some modern browsers will not allow the connection. If that is the case, the adjusting of the browser settings is unlikely to make a difference. There are two options:

- Use FTP or TFTP to apply the license
- Make sure that the interface on the port being accessed has been configured to allow HTTP/HTTPS access

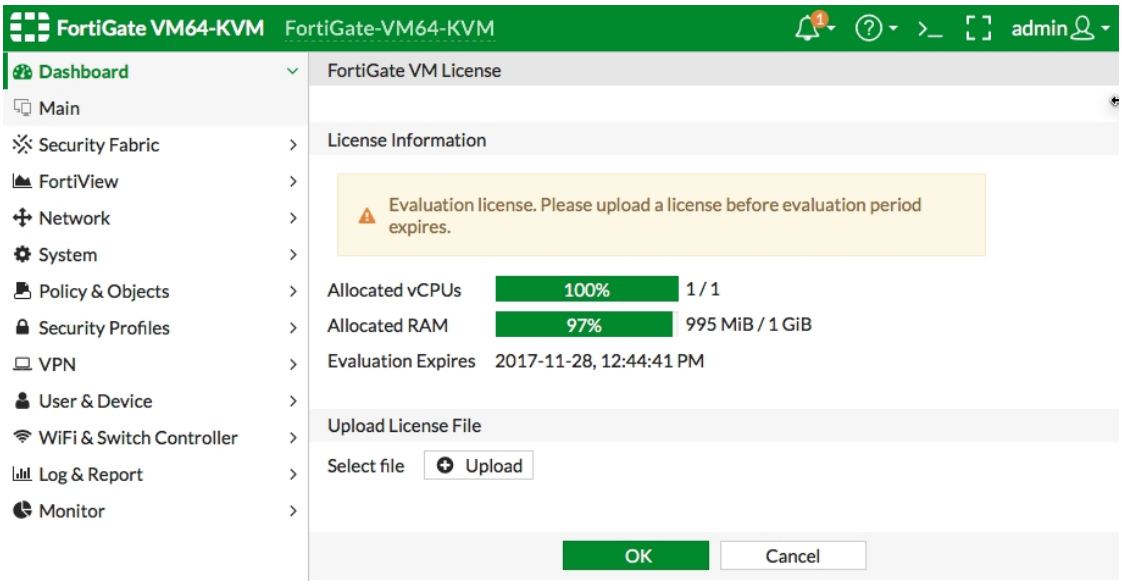
Upload the FortiGate VM license file

Every Fortinet VM includes a 15-day trial license. During this time the FortiGate VM operates in evaluation mode. Before using the FortiGate VM you must enter the license file that you downloaded from the Customer Service & Support website upon registration.

To upload the FortiGate VM licence file:

1. In the **Evaluation License** dialog box, select **Enter License**.
   The license upload page opens.

   License upload page:



2. Select **Upload** and locate the license file (`.lic`) on your computer. Select **OK** to upload the license file.
3. Refresh the browser to login.
4. Enter `admin` in the Name field and select **Login**. The VM registration status appears as valid in the License Information widget once the license has been validated by the FortiGuard Distribution Network (FDN) or FortiManager for closed networks.

Modern browsers can have an issue with allowing connecting to a FortiGate if the encryption on the device is too low. Adjusting browser settings does not normally mitigate the issue. If this happens, Admins must use a FTP/TFTP server to apply the license.

CLI

You can also upload the license file via the CLI using the following CLI command:

```
execute restore vmlicense [ftp | tftp] <filenmame string> <ftp server>[:ftp port]
```

Example:

The following is an example output when using a tftp server to install license.

```
exec restore vmlicense tftp license.lic 10.0.1.2
This operation will overwrite the current VM license!Do you want to continue? (y/n)y
Please wait...Connect to tftp server 10.0.1.2 ...
Get VM license from tftp server OK.
VM license install succeeded.
Rebooting firewall.
```

The command has the side effect of rebooting the firewall without giving you a chance to back out or delay the reboot, so becareful about the timing of using the command.

Validate the FortiGate VM license with FortiManager

You can validate your FortiGate VM license with some models of FortiManager. To determine whether your FortiManager unit has the VM Activation feature, see Features section of the FortiManager Product Data sheet.

To validate your FortiGate VM with your FortiManager:

1. To configure your FortiManager as a closed network, enter the following CLI command on your FortiManager:

```
config fmupdate publicnetwork
   set status disable
   end
```

2. To configure FortiGate VM to use FortiManager as its override server, enter the following CLI commands on your FortiGate VM:

```
config system central-management
   set mode normal
   set type fortimanager
   set include-default-servers disable
   set vdom <Enter the name of the VDOM to use when communicating with the FortiManager
       device>
   config server-list
      edit 1
         set server-type update rating
         set server-address <your FMG IP>
      next
   end
end
```

3. Load the FortiGate VM license file in the Web-based Manager.
   - Go to **System > Dashboard > Status**.
   - In the **License Information** widget, in the **Registration Status** field, select **Update**. Browse for the `.lic` license file and select **OK**.

4. To activate the FortiGate VM license, enter the following CLI command on your FortiGate VM:

```
execute update-now
```

5. To check the FortiGate VM license status, enter the following CLI commands on your FortiGate VM:

```
get system status
```

The following output is displayed:

```
Version: Fortigate-VM v5.0,build0099,120910 (Interim)
Virus-DB: 15.00361(2011-08-24 17:17)
Extended DB: 15.00000(2011-08-24 17:09)
Extreme DB: 14.00000(2011-08-24 17:10)
IPS-DB: 3.00224(2011-10-28 16:39)
FortiClient application signature package: 1.456(2012-01-17 18:27)
Serial-Number: FGVM02Q105060000
License Status: Valid
BIOS version: 04000002
Log hard disk: Available

diagnose hardware sysinfo vm full
   The following output is displayed:
UUID: 564db33a29519f6b1025bf8539a41e92
valid: 1
status: 1
code: 200 (If the license is a duplicate, code 401 will be displayed)
warn: 0
copy: 0
received: 45438
warning: 0
recv: 201201201918
dup:
```

Licensing timeout

In closed environments without Internet access, it is mandatory to perform offline licensing of the virtual FortiGate using a FortiManager as a license server. If the FortiGate-VM cannot perform license validation within the license timeout period, which is 30 days, the FortiGate will discard all packets and effectively ceasing operation as a firewall.

The status of the licence will go through some status changes before it times out.

Status	Description
Valid	The FortiGate can connect and validate against a FortiManager or FDS
Warning	The FortiGate ***cannot*** connect and validate against a FortiManager or FDS. A check is made against how many days the Warning status has been continuous. If the number is less the 30 days the status does not change.
Invalid	The FortiGate ***cannot*** connect and validate against a FortiManager or FDS. A check is made against how many days the Warning status has been continuous. If the number is 30 days or more, the status changes to Invalid.The firewall ceases to function properly.

There is only a single log entry after the virtual FortiGate cannot access the license server for the license expiration period. This means that when you go searching the logs for a reason for the FortiGate being offline there will not be a long list of error logs that draw attention to the issue. There will only be the one entry.

Configure your FortiGate VM

Once the FortiGate VM license has been validated you can begin to configure your device. You can use the **Wizard** located in the top toolbar for basic configuration including enabling central management, setting the

admin password, setting the time zone, and port configuration.

For more information on configuring your FortiGate VM see the FortiOS Handbook at http://docs.fortinet.com.

Chapter 35 - VoIP Solutions: SIP

This FortiOS Handbook chapter contains the following sections:

Inside FortiOS: VoIP Protection introduces FortiOS VoIP Protection

FortiGate VoIP solutions: SIP introduces FortiGate SIP support.

Common SIP VoIP configurations describes some common SIP configurations.

SIP messages and media protocols describes SIP messages and some common SIP media protocols.

The SIP session helper describes how the SIP session helper works and how to configure SIP support using the SIP session helper.

The SIP ALG describes how the SIP Application Layer Gateway (ALG) works and how to configure SIP support using the SIP ALG.

Conflicts between the SIP ALG and the session helper describes how to sort out conflicts between the SIP session helper and the ALG.

Stateful SIP tracking, call termination, and session inactivity timeout describes how the SIP ALG performs SIP stateful tracking, call termination and session actitivity timeouts.

SIP and RTP/RTCP describes how SIP relates to RTP and RTCP.

How the SIP ALG creates RTP pinholes describes how the SIP ALG creates pinholes.

Configuration example: SIP in Transparent Mode describes how to configure a FortiGate in Transparent mode to support SIP.

RTP enable/disable (RTP bypass) describes RTP bypass.

Opening and closing SIP register, contact, via and record-route pinholes describes how FortiOS opens and closes these pinholes.

Accepting SIP register responses describes how to enable accepting SIP register responses.

How the SIP ALG performs NAT describes how the SIP ALG performs NAT.

Enhancing SIP pinhole security describes how to open smaller pinholes.

Hosted NAT traversal describes SIP hosted NAT traversal and how to configure it.

SIP over IPv6 describes how to configure SIP over IPv6.

Deep SIP message inspection describes how deep SIP message inspection works.

Blocking SIP request messages describes how to block SIP request messages to prevent some common SIP attacks.

SIP rate limiting includes more options for preventing SIP attacks.

SIP logging describes how to enable SIP logging.

Inspecting SIP over SSL/TLS (secure SIP) describes how to inspection encrypted SIP traffic.

SIP and HA–session failover and geographic redundancy describes how to use FGCP HA to support SIP geographic redundancy.

SIP and IPS describes how to turn on IPS for SIP sessions.

SIP debugging describes some tools for debugging your SIP configuration.

Inside FortiOS: Voice over IP (VoIP) Protection

The FortiOS SIP Application Layer Gateway (ALG) allows SIP calls to pass through a FortiGate by opening SIP and RTP pinholes and performing source and destination IP address and port translation for SIP and RTP packets.

There are a large number of SIP-related Internet Engineering Task Force (IETF) documents (Request for Comments) that define behavior of SIP and related applications. FortiOS completly support RFC 3261 for SIP, RFC 4566 for SDP and RFC 3262 for Provisional Response Acknowledgment (PRACK). FortiOS also supports other SIP and SIP-related RFCs and performs Deep SIP message inspection for SIP statements defined in other SIP RFCs.

Advanced Voice over IP Protection

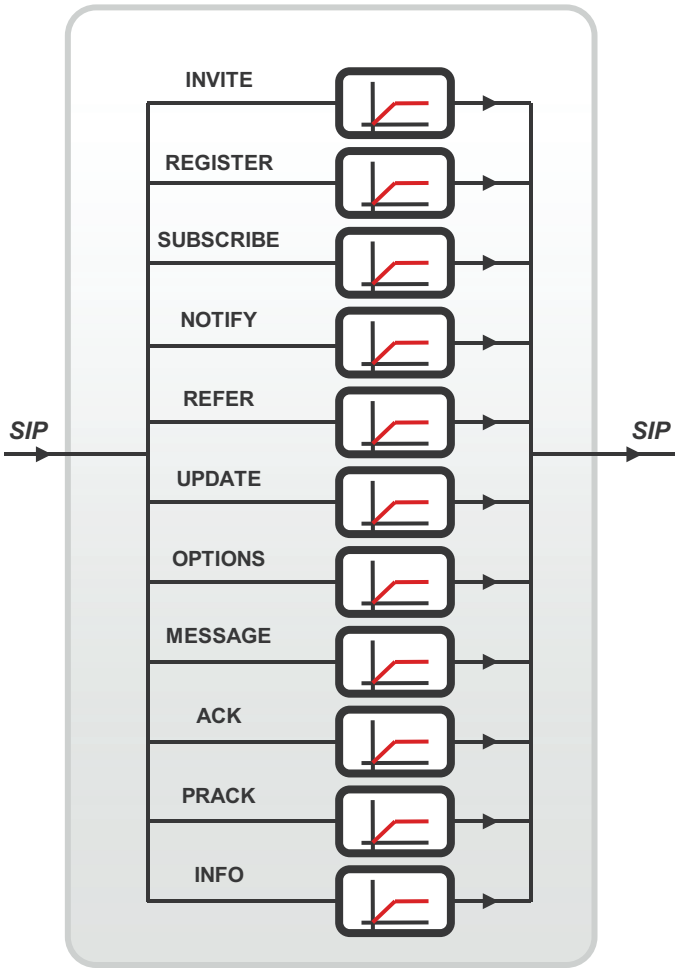
The FortiOS SIP Application Level Gateway (ALG) protects Voice over IP (SIP and SDP) services in Unified Communication and NGN/IMS networks with the following advanced VoIP defense mechanisms.

Deep SIP message inspection (also called deep SIP header inspection)

Verifies SIP and SDP header syntax and protects SIP servers from potential SIP Fuzzing attacks. When a violation is detected, FortiOS can impose counter measures and can also send automatic SIP response messages to offload processing from the SIP server.

SIP message rate limiting

Allows rate limiting of SIP messages per SIP request method. This prevents a SIP server from overload or from DoS attacks using particular SIP methods. For example, FortiOS can protect SIP servers from a flood of SIP REGISTER or INVITE messages, which can be caused by a DoS attack or a flash crowd.



RTP and RTCP pinholing

RTP pinholing only forwards RTP/RTCP packets that conform to the particular session description of the associated SIP dialog. If a SIP dialog is finished, FortiOS automatically closes the pinhole. RTP/RTCP pinholing is supported by FortiASIC acceleration and achieves high packet throughput at low jitter and delay.

Stateful SIP dialog tracking

FortiOS tracks SIP message sequences and prevents unwanted SIP messages that are not related to a particular SIP dialog. For instance, FortiOS can detect malicious SIP BYE messages that do not conform with the associated context of the SIP dialog.

Inspecting SIP over SSL/TLS (secure SIP)

Some SIP phones and SIP servers use SSL or TLS to encrypt SIP signalling traffic. To allow SIP over SSL/TLS calls to pass through the FortiGate unit, the encrypted signalling traffic has to be unencrypted and inspected. FortiOS intercepts and unencrypts and inspects the SIP packets. Allowed packets are then re-encrypted and forwarded to their destination.

Inspecting SIP on multiple ports

FortiOS can detect and inspect SIP and SDP UDP and TCP sessions and SIP SSL sessions and ou can configure the ports that the SIP ALG monitors for these sessions. In addition you can configure two different ports for SIP UDP sessions and two different ports for SIP TCP sessions. The port configuration can be changed without affecting other parts of the SIP configuration.

Carrier Grade protection

To protect VoIP infrastructure in carrier networks, FortiOS complies with typical carrier requirements for availability and robustness.

High Availability

FortiOS supports a hot failover configuration with an active and a standby FortiGate device. FortiOS dynamically updates the context on the standby unit with SIP and RTP related data. This enables the standby unit to takeover stable voice calls in case of a planned or unplanned outage or failover of the active unit.

Geographical Redundancy of SIP servers

In FortiOS SIP server cluster configurations the active and standby units can be deployed in different geographical locations. This configuration prevents a total outage of a SIP server infrastructure if one location goes offline. FortiOS supports the detection of SIP server outages (loss of heartbeats) and a redirect of SIP messages to the redundant SIP server location.

Logging and Reporting

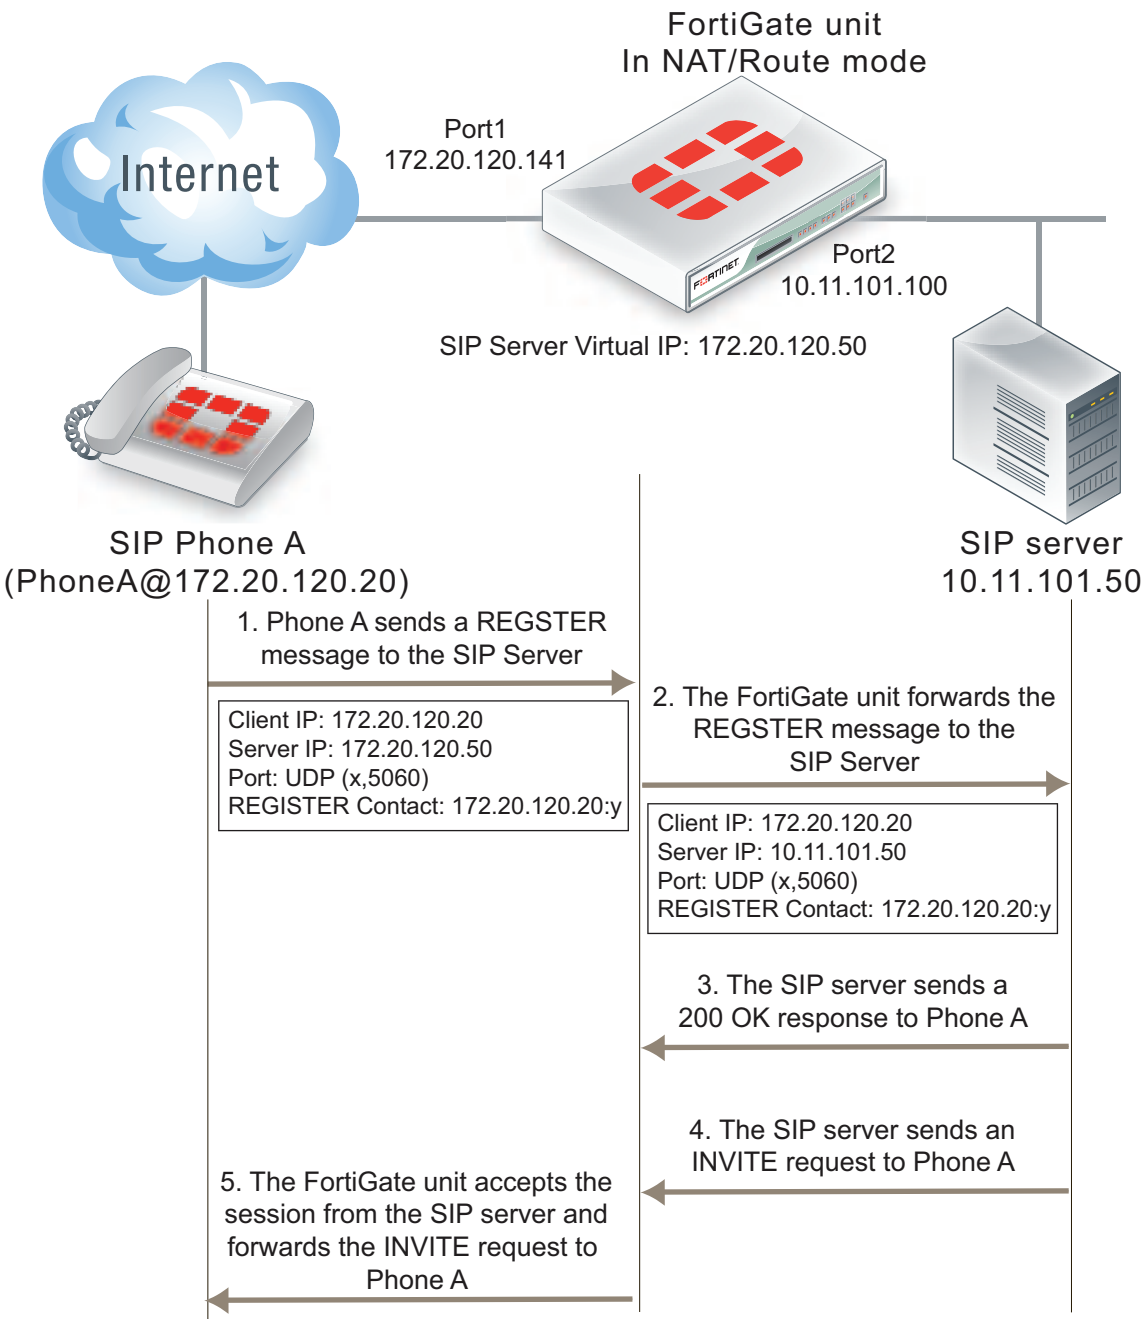
FortiOS can log call related information internally or to an external SYSLOG or FortiAnalyzer unit. This includes event logs that show particular SIP-related attacks or syntax violations with SIP messages or logs that summarize call statistics.

NAT/NAPT

FortiOS performs configurable network address translation for IP addresses in the SIP and SDP header. The SIP ALG follows the configured NAT addresses in firewall virtual IPs and changes SIP header IP addresses accordingly. RTP NAT is controlled by SIP/SDP and the firewall policy. This allows translating an unlimited number of IP addresses without adding specific RTP policies.

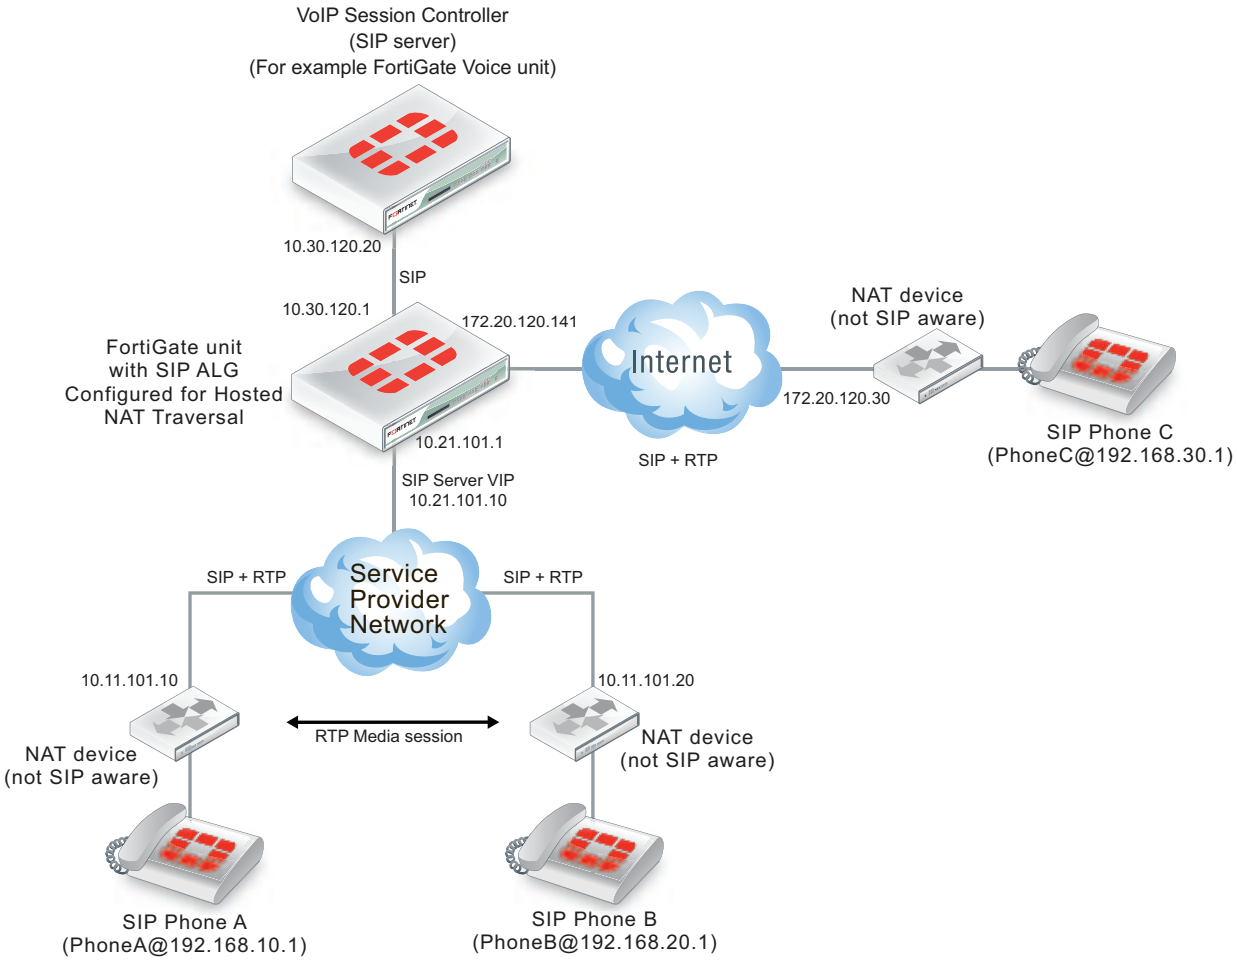
Header Manipulation

FortiOS SIP and SDP header manipulation supports SIP Network Address Translation (NAT) through FortiGate units configured as NAT firewalls.



Hosted NAT traversal (HNT)

In many service provider networks, CPE firewall devices provide NAT without application awareness. This causes issues for SIP/SDP and RTP traffic, since UAC IP address information references to the internal network behind the far end firewall. VoIP calls cannot be connected successfully. FortiOS mitigates far end NAT issues (called Hosted NAT traversal) by probing the first RTP packet from the UAC and learning the far end NA(P)T binding. FortiOS then updates the internal NAT binding for RTP accordingly.

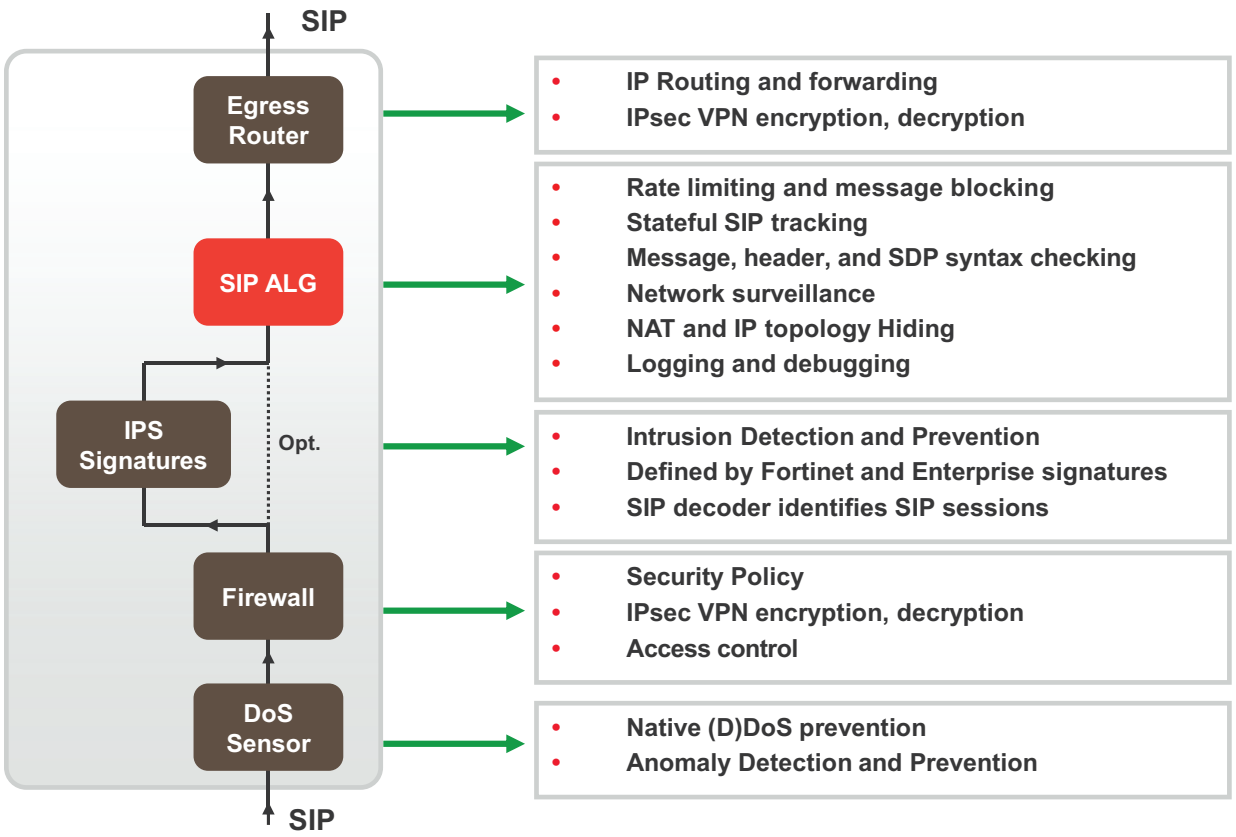


IP Address conservation for NAT

In case of SIP and RTP NAT IP the original address information can get lost after translating to the provisioned IP addresses. This IP address information is sometimes required for detailed billing records or debugging purposes. FortiOS can maintain the original IP address information in a translated SIP header by adding it to the SIP/SDP info line (i=) or by adding it to the original attribute (o=). Either option can be selected depending on the SIP billing environment.

SIP ALG activation

The FortiOS SIP ALG is applied to SIP traffic accepted by a firewall policy that includes a VoIP profile. The VoIP profile controls how the SIP ALG processes SIP sessions. FortiOS also includes a high-performance SIP session helper that provides limited SIP functionality. In most cases the SIP ALG should be used because the SIP ALG supports the complete range of FortiOS SIP features.



SIP over IPv6

FortiOS, operating in NAT/Route and in Transparent mode supports SIP over IPv6. The SIP ALG can process SIP messages that use IPv6 addresses in the headers, bodies, and in the transport stack. The SIP ALG cannot modify the IPv6 addresses in the SIP headers so FortiGate units cannot perform SIP or RTP NAT over IPv6 and also cannot translate between IPv6 and IPv4 addresses.

Platform support and hardware acceleration

FortiOS supports VoIP protection with the SIP ALG on all FortiGate hardware platforms. Whenever a FortiGate unit provides FortiASIC or SPM HW acceleration, the SIP ALG will use this option to fast-path RTP/RTCP traffic.

As well, since the SIP ALG is proxy-based, SIP control packets are not offloaded to NP4 or NP6 processors. But actual voice or other media traffic can be offloaded to NP4 or NP6 processors after the SIP session is established. Many FortiGate units also support low latencey hardware acceleration configurations that also enhance SIP voice transmission.

FortiGate hardware acceleration provides a high throughput solution at very low jitter and delay. FortiOS provides efficient and highly scalable protection for VoIP in emerging Enterprise and Carrier network. This complements Fortinet's NGFW and UTM offerings. VoIP protection can be easily added to any firewall policy just by adding a VoIP profile.

VoIP protection is supported in FortiAnalyzer and FortiManager. Centralized logging and management are essential for carrier and MSSP service provider and are influencing business case calculations.

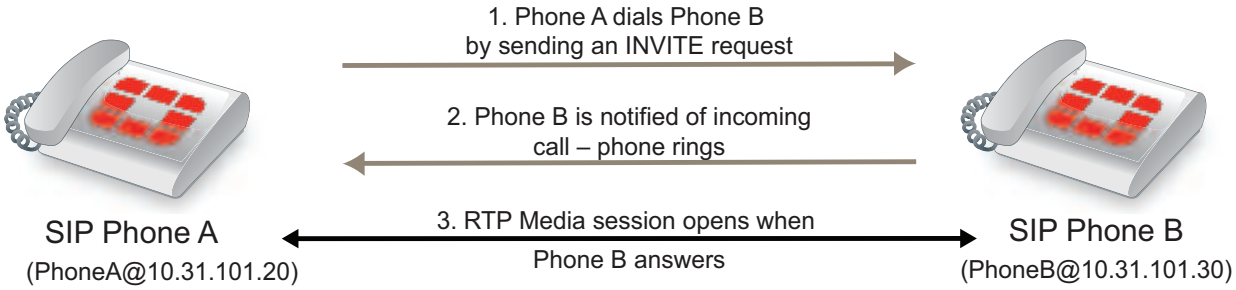
Common SIP VoIP configurations

This section describes some common SIP VoIP configurations and simplified SIP dialogs for these configurations. This section also shows some examples of how adding a FortiGate affects SIP processing.

Peer to peer configuration

In the peer to peer configuration shown below, two SIP phones (in the example, FortiFones) communicate directly with each other. The phones send SIP request and response messages back and forth between each other to establish the SIP session.

SIP peer to peer configuration

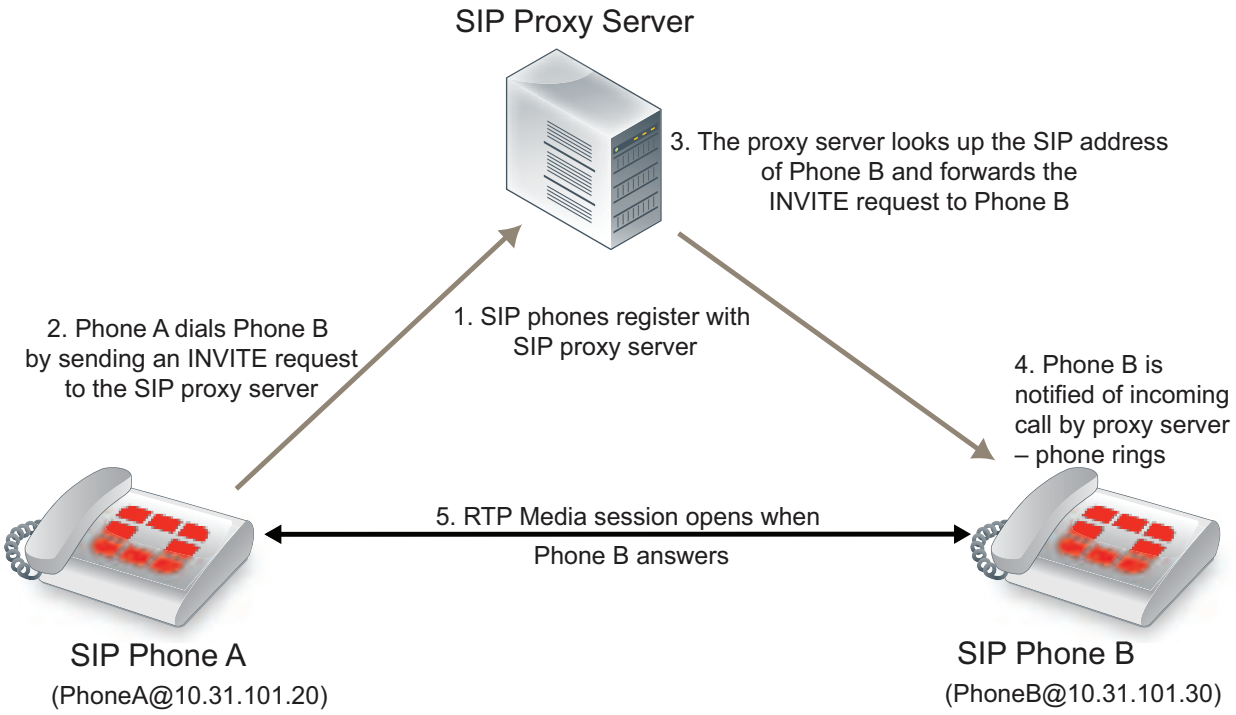


Peer to peer configurations are not very common because they require the SIP phones to keep track of the names and addresses of all of the other SIP phones that they can communicate with. In most cases a SIP proxy or re-direct server maintains addresses of a large number of SIP phones and a SIP phone starts a call by contacting the SIP proxy server.

SIP proxy server configuration

A SIP proxy server act as intermediary between SIP phones and between SIP phones (for example, two FortiFones) and other SIP servers. As shown below, SIP phones send request and response messages the SIP proxy server. The proxy server forwards the messages to other clients or to other SIP proxy servers. Proxy servers can hide SIP phones by proxying the signaling messages. To the other users on the VoIP network, the signaling invitations look as if they come from the SIP proxy server.

SIP in proxy mode

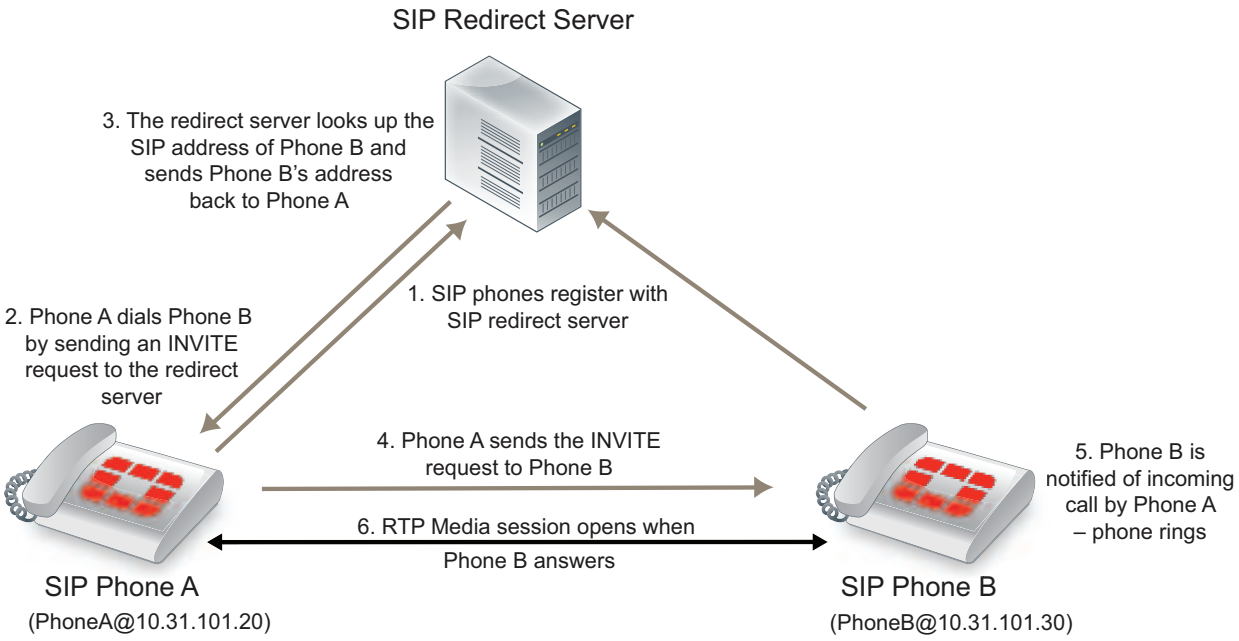


A common SIP configuration would include multiple networks of SIP phones. Each of the networks would have its own SIP server. Each SIP server would proxy the communication between phones on its own network and between phones in different networks.

SIP redirect server configuration

A SIP redirect server accepts SIP requests, maps the addresses in the request into zero or more new addresses and returns those addresses to the client. The redirect server does not initiate SIP requests or accept calls. As shown below, SIP clients send INVITE requests to the redirect server, which then looks up the destination address. The redirect server returns the destination address to the client. The client uses this address to send the INVITE request directly to the destination SIP client.

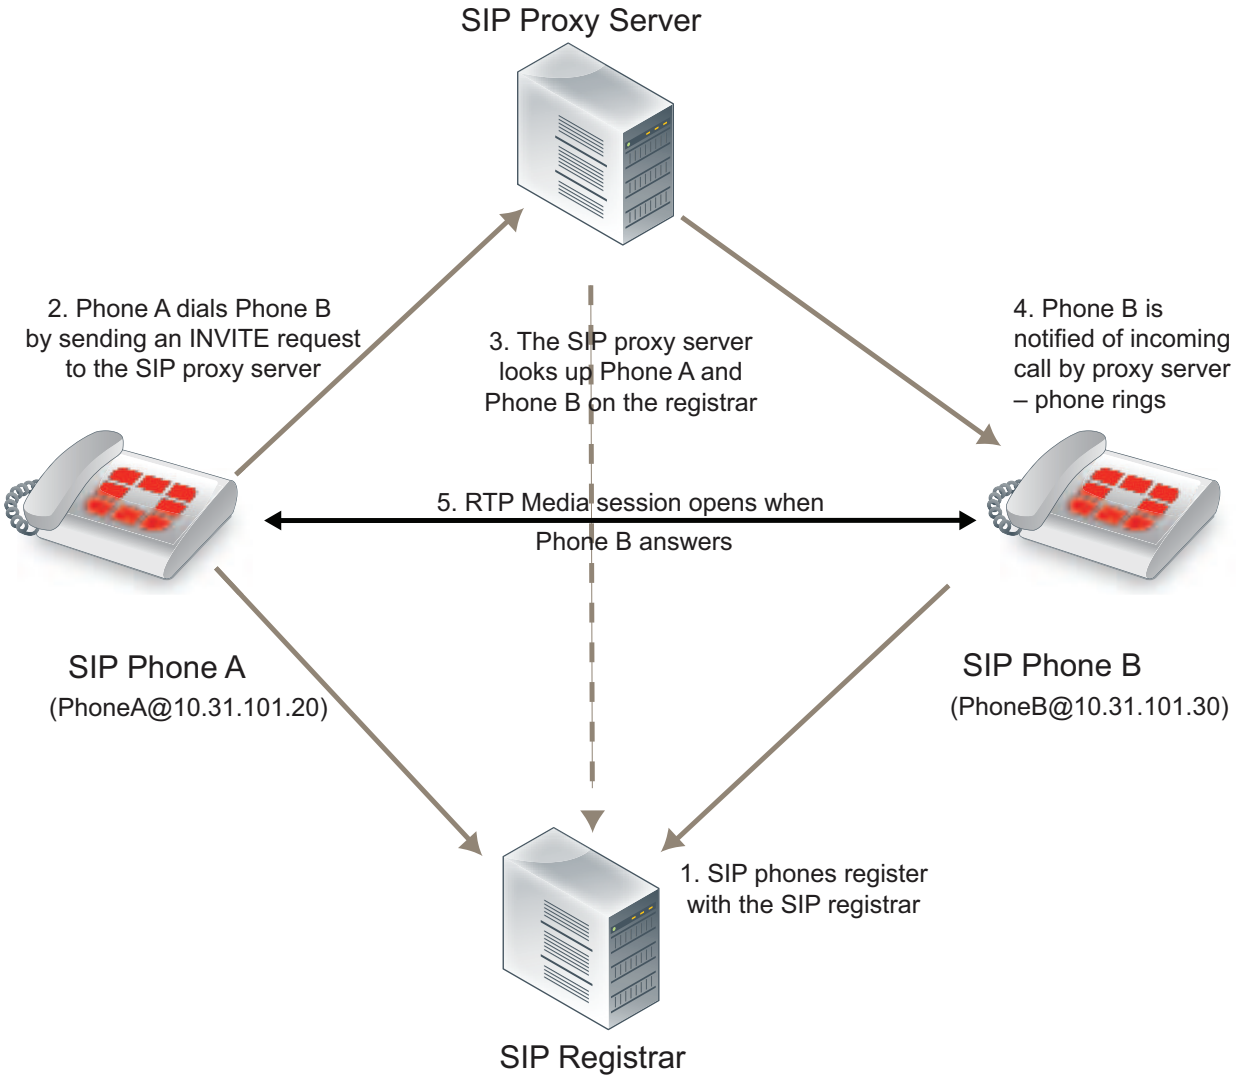
SIP in redirect model



SIP registrar configuration

A SIP registrar accepts SIP REGISTER requests from SIP phones for the purpose of updating a location database with this contact information. This database can then become a SIP location service that can be used by SIP proxy severs and redirect servers to locate SIP clients. As shown below, SIP clients send REGISTER requests to the SIP registrar.

SIP registrar and proxy servers

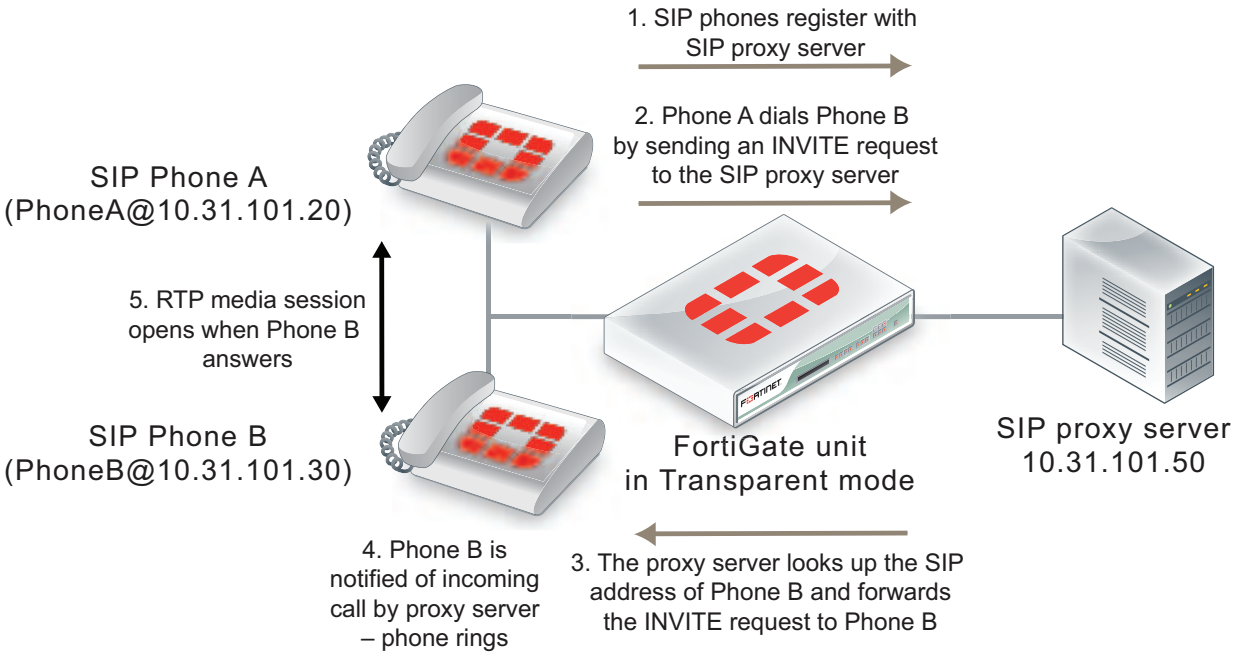


SIP with a FortiGate

Depending on your security requirements and network configuration FortiGates may be in many different places in a SIP configuration. This section shows a few examples.

The diagram below shows a FortiGate installed between a SIP proxy server and SIP phones on the same network. The FortiGate is operating in Transparent mode so both the proxy server and the phones are on the same subnet. In this configuration, called SIP inspection without address translation, the FortiGate could be protecting the SIP proxy server on the private network by implementing SIP security features for SIP sessions between the SIP phones and the SIP proxy server.

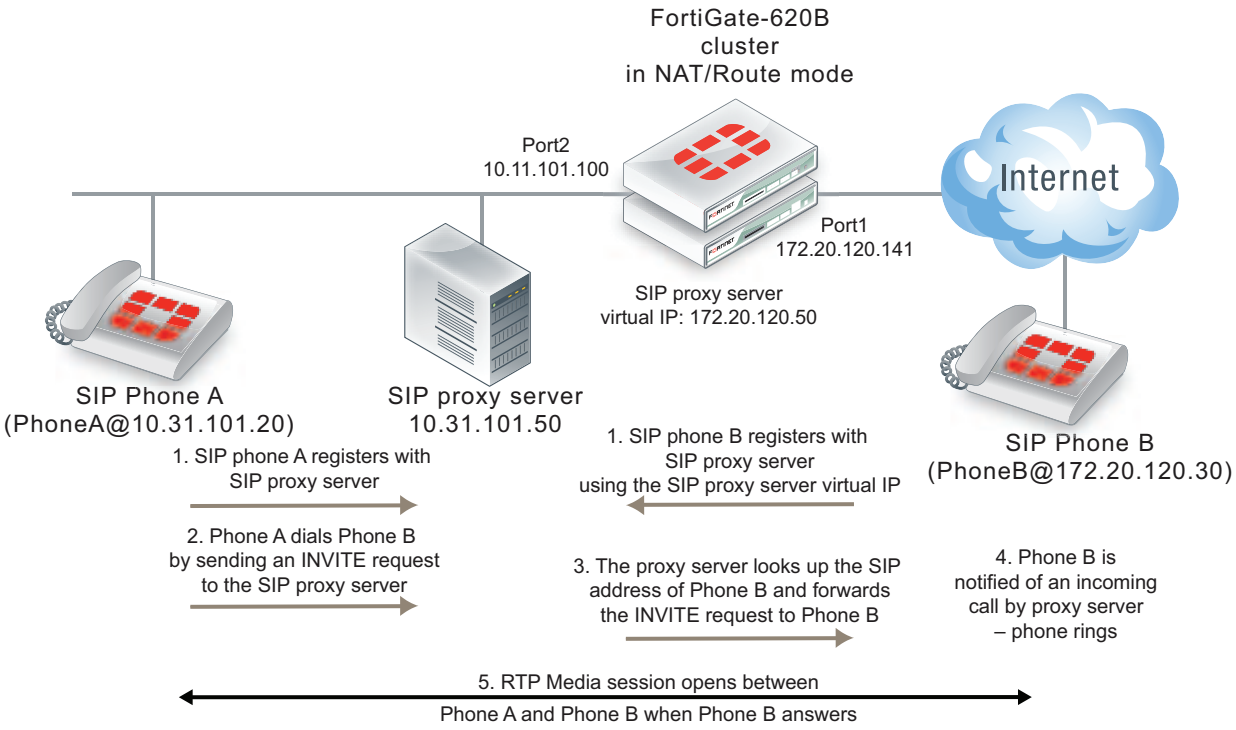
SIP network with FortiGate in Transparent mode



The phones and server use the same SIP dialogs as they would if the FortiGate was not present. However, the FortiGate can be configured to control which devices on the network can connect to the SIP proxy server and can also protect the SIP proxy server from SIP vulnerabilities.

The following diagram shows a FortiGate operating in NAT/Route mode and installed between a private network and the Internet. Some SIP phones and the SIP proxy server are connected to the private network and some SIP phones are connected to the Internet. The SIP phones on the Internet can connect to the SIP proxy server through the FortiGate and communication between SIP phones on the private network and SIP phones on the Internet must pass through the FortiGate.

SIP network with FortiGate in NAT/Route mode



The phones and server use the same SIP dialog as they would if the FortiGate was not present. However, the FortiGate can be configured to control which devices on the network can connect to the SIP proxy server and can also protect the SIP proxy server from SIP vulnerabilities. In addition, the FortiGate has a firewall virtual IP that forwards packets sent to the SIP proxy server Internet IP address (172.20.120.50) to the SIP proxy server internal network IP address (10.31.101.30).

Since the FortiGate is operating in NAT/Route mode it must translate packet source and destination IP addresses (and optionally ports) as the sessions pass through the FortiGate. Also, the FortiGate must translate the addresses contained in the SIP headers and SDP body of the SIP messages. As well the FortiGate must open SIP and RTP pinholes through the FortiGate. SIP pinholes allow SIP signaling sessions to pass through the FortiGate between phones and between phones and SIP servers. RTP pinholes allow direct RTP communication between the SIP phones once the SIP dialog has established the SIP call. Pinholes are opened automatically by the FortiGate. Administrators do not add security policies for pinholes or for RTP sessions. All that is required is a security policy that accepts SIP traffic.

Opening an RTP pinhole means opening a port on a FortiGate interface to allow RTP traffic to use that port to pass through the FortiGate between the SIP phones on the Internet and SIP phones on the internal network. A pinhole only accepts packets from one RTP session. Since a SIP call involves at least two media streams (one from Phone A to Phone B and one from Phone B to Phone A) the FortiGate opens two RTP pinholes. Phone A sends RTP packets through a pinhole in port2 and Phone B sends RTP packets through a pinhole in port1. The FortiGate opens the pinholes when required by the SIP dialog and closes the pinholes when the SIP call is completed. The FortiGate opens new pinholes for each SIP call.

Each RTP pinhole actually includes two port numbers. The RTP port number as defined in the SIP message and an RTCP port number, which is the RTP port number plus 1. For example, if the SIP call used RTP port 3346 the FortiGate would create a pinhole for ports 3346 and 3347.

SIP messages and media protocols

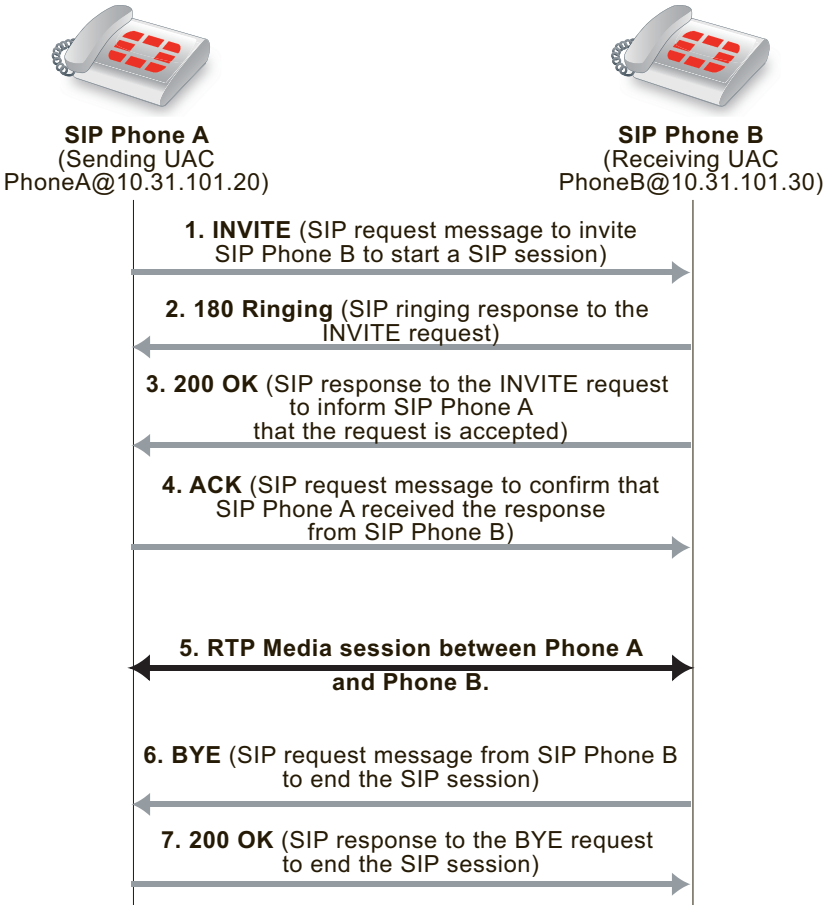
This section provides an overview of SIP messages and how they communicate information about SIP sessions and how SDP, RTP, and RTCP fits in with SIP communications.

SIP uses clear text messages to start, maintain, and end media sessions between SIP user agent clients (UACs) and user agent servers (UASs). These messages form a SIP dialog. A typical SIP dialog begins with an INVITE request message sent from a UAC to another UAC or to a UAS. The first INVITE request message attempts to start a SIP call and includes information about the sending UAC and the receiving UAC as well as information about the communication session.

If only two UACs are involved as shown below, the receiving UAC (Phone B) responds with a 180 Ringing and then a 200 OK SIP response message that informs Phone A that Phone B received and accepted the request. Phone A then sends an ACK message to notify Phone B that the SIP response was received. Phone A and Phone B can then participate in the RTP media session set up by the SIP messages.

When the phone call is complete, one of the UACs (in the example Phone B) hangs up sending a BYE request message to Phone A. Phone A then sends a 200 OK response to Phone B acknowledging that the session has ended.

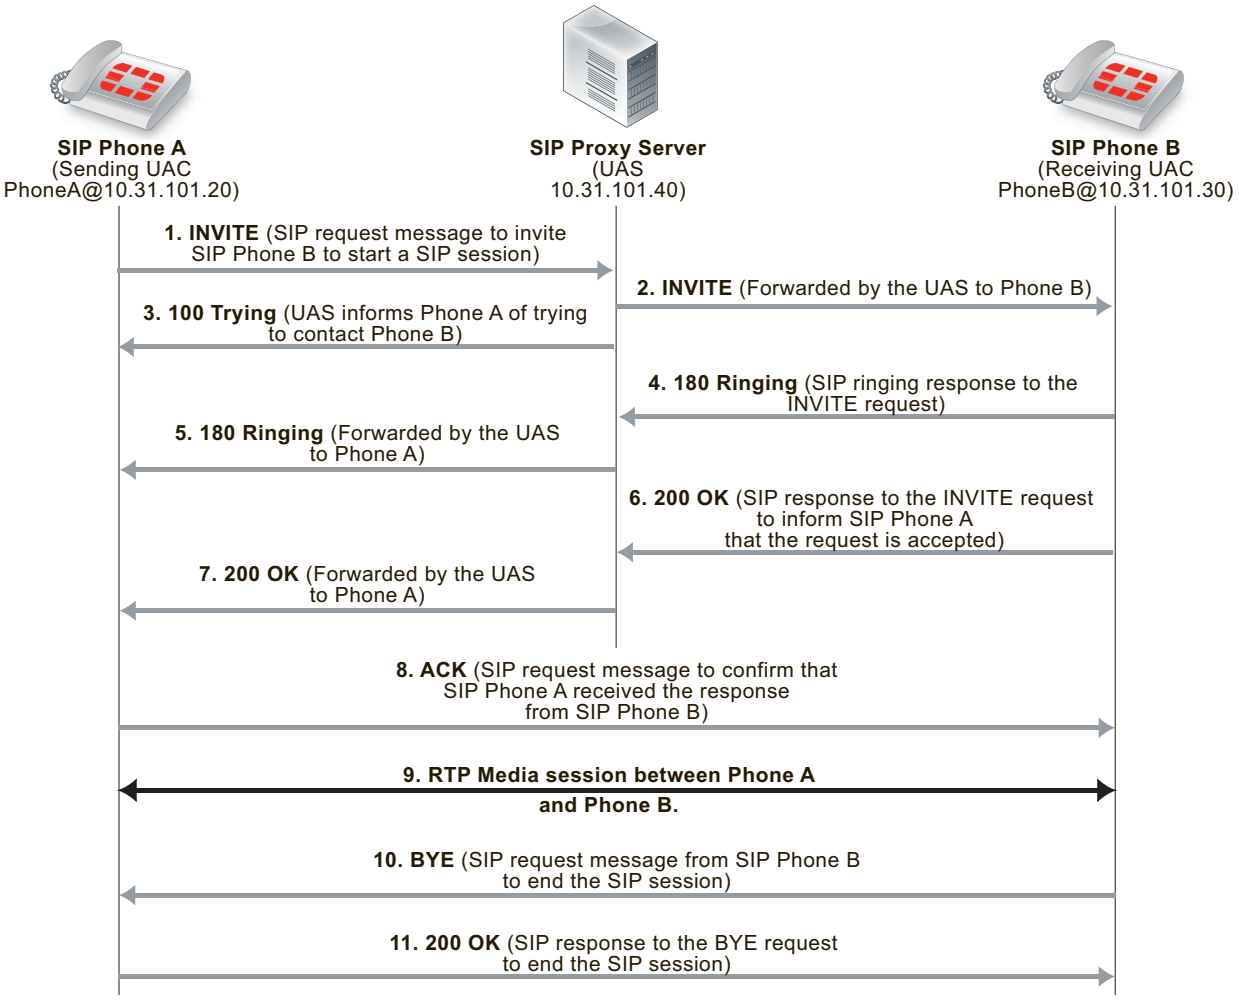
Basic SIP dialog between two UACs



If a UAS in the form of a SIP proxy server is involved, similar messages are sent and received, but the proxy server participates as an intermediary in the initial call setup. In the example below the SIP proxy server receives the INVITE request from Phone A and forwards it to Phone B. The proxy server then sends a 100 Trying response to Phone A. Phone B receives the INVITE request and responds with a 180 Ringing and then a 200 OK SIP response message. These messages are received by the proxy server and forwarded to Phone A to notify Phone A that Phone B received and accepted the request. Phone A then sends an ACK message to notify Phone B that the SIP response was received. This response is received by the proxy server and forwarded to Phone B. Phone A and Phone B can then participate in the media session independently of the proxy server.

When the phone call is complete Phone B hangs up sending a BYE request message to Phone A. Phone A then sends a 200 OK response to Phone B acknowledging that the session has ended.

Basic SIP dialog between UACs with a SIP proxy server UAS



The SIP messages include SIP headers that contain names and addresses of Phone A, Phone B and the proxy server. This addressing information is used by the UACs and the proxy server during the call set up.

The SIP message body includes Session Description Protocol (SDP) statements that Phone A and Phone B use to establish the media session. The SDP statements specify the type of media stream to use for the session (for example, audio for SIP phone calls) and the protocol to use for the media stream (usually the Real Time Protocol (RTP) media streaming protocol).

Phone A includes the media session settings that it would like to use for the session in the INVITE message. Phone B includes its response to these media settings in the 200 OK response. Phone A's ACK response confirms the settings that Phone A and Phone B then use for the media session.

Hardware accelerated RTP processing

FortiGates can offload RTP packet processing to network processor (NP) interfaces. This acceleration greatly enhances the overall throughput and resulting in near speed RTP performance.

SIP request messages

SIP sessions always start with a SIP request message (also just called a SIP request). SIP request messages also establish, maintain, and terminate SIP communication sessions. The following table lists some common SIP request message types.

Common SIP request message types

Message Type	Description
INVITE	A client sends an INVITE request to invite another client to participate in a multimedia session. The INVITE request body usually contains the description of the session.
ACK	The originator of an INVITE message sends an ACK request to confirm that the final response to an INVITE request was received. If the INVITE request did not contain the session description, it must be included in the ACK request.
PRACK	In some cases, SIP uses provisional response messages to report on the progress of the response to a SIP request message. The provisional response messages are sent before the final SIP response message. Similar to an ACK request message, a PRACK request message is sent to acknowledge that a provisional response message has been received.
OPTIONS	The UA uses OPTIONS messages to get information about the capabilities of a SIP proxy. The SIP proxy server replies with a description of the SIP methods, session description protocols, and message encoding that are supported.
BYE	A client sends a BYE request to end a session. A BYE request from either end of the SIP session terminates the session.
CANCEL	A client sends a CANCEL request to cancel a previous INVITE request. A CANCEL request has no effect if the SIP server processing the INVITE sends a final response to the INVITE before receiving the CANCEL.
REGISTER	A client sends a REGISTER request to a SIP registrar server with information about the current location (IP address and so on) of the client. A SIP registrar server saves the information it receives in REGISTER requests and makes this information available to any SIP client or server attempting to locate the client.

Message Type	Description
Info	For distributing mid-session signaling information along the signaling path for a SIP call. I
Subscribe	For requesting the current state and state updates of a remote node.
Notify	Informs clients and servers of changes in state in the SIP network.
Refer	Refers the recipient (identified by the Request-URI) to a third party according to the contact information in the request.
Update	Opens a pinhole for new or updated SDP information.
Response codes (1xx, 202, 2xx, 3xx, 4xx, 5xx, 6xx)	Indicates the status of a transaction. For example: 200 OK, 202 Accepted, or 400 Bad Request.

SIP response messages

SIP response messages (often just called SIP responses) provide status information in response to SIP request messages. All SIP response messages include a response code and a reason phrase. There are five SIP response message classes. They are described below.

There are also two types of SIP response messages, provisional and final. Final response messages convey the result of the request processing, and are sent reliably. Provisional responses provide information on the progress of the request processing, but may not be sent reliably. Provisional response messages start with 1xx and are also called informational response messages.

Informational (or provisional)

Informational or provisional responses indicate that a request message was received and imply that the endpoint is going to process the request. Information messages may not be sent reliably and may not require an acknowledgement.

If the SIP implementation uses Provisional Response Acknowledgment (PRACK) (RFC 3262) then informational or provisional messages are sent reliably and require a PRACK message to acknowledge that they have been received.

Informational responses can contain the following reason codes and reason phrases:

```
100 Trying
180 Ringing
181 Call is being forwarded
182 Queued
183 Session progress
```

Success

Success responses indicate that a request message was received, understood, and accepted. Success responses can contain the following reason codes and reason phrases:

```
200 OK
```

```
202 Accepted
```

Redirection

Redirection responses indicate that more information is required for the endpoint to respond to a request message. Redirection responses can contain the following reason codes and reason phrases:

```
300 Multiple choices
301 Moved permanently
302 Moved temporarily
305 Use proxy
380 Alternative service
```

Client error

Client error responses indicate that a request message was received by a server that contains syntax that the server cannot understand (i.e. contains a syntax error) or cannot comply with. Client error responses include the following reason codes and reason phrases:

```
400 Bad request                401 Unauthorized
402 Payment required           403 Forbidden
404 Not found                  405 Method not allowed
406 Not acceptable             407 Proxy authentication required
408 Request time-out           409 Conflict
410 Gone                       411 Length required
413 Request entity too large   414 Request-URL too large
415 Unsupported media type     420 Bad extension
480 Temporarily not available
481 Call leg/transaction does not exist
482 Loop detected
484 Address incomplete         483 Too many hops
486 Busy here                  485 Ambiguous
488 Not acceptable here        487 Request canceled
```

Server error

Server error responses indicate that a server was unable to respond to a valid request message. Server error responses include the following reason codes and reason phrases:

```
500 Server internal error
501 Not implemented
502 Bad gateway
502 Service unavailable
504 Gateway time-out
505 SIP version not supported
```

Global failure

Global failure responses indicate that there are no servers available that can respond to a request message. Global failure responses include the following reason codes and reason phrases:

```
600 Busy everywhere
603 Decline
604 Does not exist anywhere
606 Not acceptable
```

SIP message start line

The first line in a SIP message is called the start line. The start line in a request message is called the request-line and the start line in a response message is called the status-line.

Request-line	The first line of a SIP request message. The request-line includes the SIP message type, the SIP protocol version, and a Request URI that indicates the user or service to which this request is being addressed. The following example request-line specifies the INVITE message type, the address of the sender of the message (`inviter@example.com`), and the SIP version: `INVITE sip:inviter@example.com SIP/2.0`
Status-line	The first line of a SIP response message. The status-line includes the SIP protocol version, the response code, and the reason phrase. The example status-line includes the SIP version, the response code (`200`) and the reason phrase (`OK`). `SIP/2.0 200 OK`

SIP headers

Following the start line, SIP messages contain SIP headers (also called SIP fields) that convey message attributes and to modify message meaning. SIP headers are similar to HTTP header fields and always have the following format:

```
<header_name>:<value>
```

SIP messages can include the SIP headers listed in the following table:

SIP headers

SIP Header	Description
Allow	Lists the set of SIP methods supported by the UA generating the message. All methods, including ACK and CANCEL, understood by the UA MUST be included in the list of methods in the Allow header field, when present. For example: `Allow: INVITE, ACK, OPTIONS, CANCEL, BYE`
Call-ID	A globally unique identifier for the call, generated by the combination of a random string and the sender's host name or IP address. The combination of the To, From, and Call-ID headers completely defines a peer-to-peer SIP relationship between the sender and the receiver. This relationship is called a SIP dialog. `Call-ID: ddeg45e793@10.31.101.30`

SIP Header	Description
Contact	Included in SIP request messages, the Contact header contains the SIP URI of the sender of the SIP request message. The receiver uses this URI to contact the sender. For example: `Contact: Sender <sip:sender@10.31.100.20>t`
Content-Length	The number of bytes in the message body (in bytes). `Content-Length: 126`
Content-Type	In addition to SIP headers, SIP messages include a message body that contains information about the content or communication being managed by the SIP session. The Content-Type header specifies what the content of the SIP message is. For example, if you are using SIP with SDP, the content of the SIP message is SDP code. `Content-Type: application/sdp`
CSeq	The command sequence header contains a sequence integer that is increased for each new SIP request message (but is not incremented in the response message). This header also incudes the request name found in the request message request-line. For example: `CSeq: 1 INVITE`
Expires	Gives the relative time after which the message (or content) expires. The actual time and how the header is used depends on the SIP method. For example: `Expires: 5`
From	Identifies the sender of the message. Responses to a message are sent to the address of the sender. The following example includes the sender's name (`Sender`) and the sender's SIP address (`sender@10.31.101.20.`): `From: Sender <sip:sender@10.31.101.20>`
Max-forwards	An integer in the range 0-255 that limits the number of proxies or gateways that can forward the request message to the next downstream server. Also called the number of hops, this value is decreased every time the message is forwarded. This can also be useful when the client is attempting to trace a request chain that appears to be failing or looping in mid-chain. `For example: Max-Forwards: 30`
P-Asserted-Identity	The P-Asserted-Identity header is used among trusted SIP entities to carry the identity of the user sending a SIP message as it was verified by authentication. See RFC 3325. The header contains a SIP URI and an optional display-name, for example: `P-Asserted-Identity: "Example Person" <sip:10.31.101.50>`

SIP Header	Description
RAck	Sent in a PRACK request to support reliability of information or provisional response messages. It contains two numbers and a method tag. For example: `RAck: 776656 1 INVITE`
Record-Route	Inserted into request messages by a SIP proxy to force future requests to be routed through the proxy. In the following example, the host at IP address 10.31.101.50 is a SIP proxy. The `lr` parameter indicates the URI of a SIP proxy in Record-Route headers. `Record-Route: <sip:10.31.101.50;lr>`
Route	Forces routing for a request message through one or more SIP proxies. The following example includes two SIP proxies: `Route: <sip:172.20.120.10;lr>, <sip:10.31.101.50;lr>`
RSeq	The RSeq header is used in information or provisional response messages to support reliability of informational response messages. The header contains a single numeric value. For example: `RSeq: 33456`
To	Identifies the receiver of the message. The address in this field is used to send the message to the receiver. The following example includes the receiver's name (`Receiver`) and the receiver's SIP address (`receiver@10.31.101.30.`): `To: Receiver <sip:receiver@10.31.101.30>`
Via	Indicates the SIP version and protocol to be used for the SIP session and the address to which to send the response to the message that contains the Via field. The following example Via field indicates to use SIP version 2, UDP for media communications, and to send the response to 10.31.101.20 using port 5060. `Via: SIP/2.0/UDP 10.31.101.20:5060`

The SIP message body and SDP session profiles

The SIP message body describes the session to be initiated. For example, in a SIP phone call the body usually includes audio codec types, sampling rates, server IP addresses and so on. For other types of SIP session the body could contain text or binary data of any type which relates in some way to the session. The message body is included in request and response messages.

Two possible SIP message body types:

- Session Description Protocol (SDP), most commonly used for SIP VoIP.
- Multipurpose Internet Mail Extensions (MIME)

SDP is most often used for VoIP and FortiGates support SDP content in SIP message bodies. SDP is a text-based protocol used by SIP to control media sessions. SDP does not deliver media but provides a session profile

that contains media details, transport addresses, parameter negotiation, and other session description metadata for the participants in a media session. The participants use the information in the session profile to negotiate how to communicate and to manage the media session. SDP is described by RFC 4566.

An SDP session profile always contains session information and may contain media information. Session information appears at the start of the session profile and media information (using the `m=` attribute) follows.

SDP session profiles can include the attributes listed in the following table.

SDP session profile attributes

Attribute	Description
a=	Attributes to extend SDP in the form `a=<attribute>` or `a=<attribute>:<value>`.
b=	Contains information about the bandwidth required for the session or media in the form `b=<bandwidth_type>:<bandwidth>`.
c=	Connection data about the session including the network type (usually IN for Internet), address type (IPv4 or IPv6), the connection source address, and other optional information. For example: `c=IN IPv4 10.31.101.20`
i=	A text string that contains information about the session. For example: `i=A audio presentation about SIP`
k=	Can be used to convey encryption keys over a secure and trusted channel. For example: `k=clear:444gdduudjffdee`

Attribute	Description

m=	Media information, consisting of one or more lines all starting with `m=` and containing details about the media including the media type, the destination port or ports used by the media, the protocol used by the media, and a media format description.
	
	`m=audio 49170 RTP 0 3`
	`m-video 3345/2 udp 34`
	`m-video 2910/2 RTP/AVP 3 56`
	
	Multiple media lines are needed if SIP is managing multiple types of media in one session (for example, separate audio and video streams).
	
	Multiple ports for a media stream are indicated using a slash. `3345/2` udp means UDP ports 3345 and 3346. Usually RTP uses even-numbered ports for data with the corresponding one-higher odd ports used for the RTCP session belonging to the RTP session. So `2910/2 RTP/AVP` means ports 2910 and 2912 are used for RTP and 2911 and 2913 are used for RTCP.
	
	Media types include `udp` for an unspecified protocol that uses UDP, `RTP` or `RTP/AVP` for standard RTP and `RTP/SAVP` for secure RTP.

o=	The sender's username, a session identifier, a session version number, the network type (usually IN for Internet), the address type (for example, IPv4 or IPv6), and the sending device's IP address. The `o=` field becomes a universal identifier for this version of this session description. For example: `o=PhoneA 5462346 332134 IN IP4 10.31.101.20`
r=	Repeat times for a session. Used if a session will be repeated at one or more timed intervals. Not normally used for VoIP calls. The times can be in different formats. For example: `r=7d 1h 0 25h r=604800 3600 0 90000`
s=	Any text that describes the session or s= followed by a space. For example: `s=Call from inviter`
t=	The start and stop time of the session. Sessions with no time restrictions (most VoIP calls) have a start and stop time of 0. `t=0 0`
v=	SDP protocol version. The current SDP version is 0 so the v= field is always: `v=0`
z=	Time zone adjustments. Used for scheduling repeated sessions that span the time between changing from standard to daylight savings time. `z=2882844526 -1h 2898848070 0`

Example SIP messages

The following example SIP INVITE request message was sent by PhoneA to PhoneB. The first nine lines are the SIP headers. The SDP profile starts with v=0 and the media part of the session profile is the last line, starting with m=.

```
INVITE sip:PhoneB@172.20.120.30 SIP/2.0
Via: SIP/2.0/UDP 10.31.101.50:5060
From: PhoneA <sip:PhoneA@10.31.101.20>
To: PhoneB <sip:PhoneB@172.20.120.30>
Call-ID: 314159@10.31.101.20
CSeq: 1 INVITE
Contact: sip:PhoneA@10.31.101.20
Content-Type: application/sdp
Content-Length: 124
v=0
o=PhoneA 5462346 332134 IN IP4 10.31.101.20
s=Let's Talk
t=0 0
c=IN IP4 10.31.101.20
m=audio 49170 RTP 0 3
```

The following example shows a possible 200 OK SIP response message in response to the previous INVITE request message. The response includes `200 OK` which indicates success, followed by an echo of the original SIP INVITE request followed by PhoneB's SDP profile.

```
SIP/2.0 200 OK
Via: SIP/2.0/UDP 10.31.101.50:5060
From: PhoneA <sip:PhoneA@10.31.101.20>
To: PhoneB <sip:PhoneB@172.20.120.30>
Call-ID: 314159@10.31.101.20
CSeq: 1 INVITE
Contact: sip:PhoneB@10.31.101.30
Content-Type: application/sdp
Content-Length: 107
v=0
o=PhoneB 124333 67895 IN IP4 172.20.120.30
s=Hello!
t=0 0
c=IN IP4 172.20.120.30
m=audio 3456 RTP 0
```

SIP can support multiple media streams for a single SIP session. Each media steam will have its own c= and m= lines in the body of the message. For example, the following message includes three media streams:

```
INVITE sip:PhoneB@172.20.120.30 SIP/2.0
Via: SIP/2.0/UDP 10.31.101.20:5060
From: PhoneA <sip:PhoneA@10.31.101.20>
To: PhoneB <sip:PhoneB@172.20.120.30>
Call-ID: 314159@10.31.101.20
CSeq: 1 INVITE
Contact: sip:PhoneA@10.31.101.20
Content-Type: application/sdp
Content-Length: 124
v=0
o=PhoneA 5462346 332134 IN IP4 10.31.101.20
s=Let's Talk
t=0 0
```

```
c=IN IP4 10.31.101.20
m=audio 49170 RTP 0 3
c=IN IP4 10.31.101.20
m=audio 49172 RTP 0 3
c=IN IP4 10.31.101.20
m=audio 49174 RTP 0 3
```

The SIP session helper

The SIP session-helper is a high-performance solution that provides basic support for SIP calls passing through the FortiGate by opening SIP and RTP pinholes and by performing NAT of the addresses in SIP messages.

The SIP session helper:

- Understands SIP dialog messages.
- Keeps the states of the SIP transactions between SIP UAs and SIP servers.
- Translates SIP header and SDP information to account for NAT operations performed by the FortiGate.
- Opens up and closes dynamic SIP pinholes for SIP signalling traffic.
- Opens up and closes dynamic RTP and RTSP pinholes for RTP and RTSP media traffic.
- Provides basic SIP security as an access control device.
- Uses the intrusion protection (IPS) engine to perform basic SIP protocol checks.

SIP session helper configuration overview

By default FortiOS uses the SIP ALG for SIP traffic. If you want to use the SIP session helper you need to enter the following command:

```
config system settings
   set default-voip-alg-mode kernel-helper-based
end
```

The SIP session helper is set to listen for SIP traffic on TCP or UDP port 5060. SIP sessions using port 5060 accepted by a security policy that does not include a VoIP profile are processed by the SIP session helper.

You can enable and disable the SIP session helper, change the TCP or UDP port that the session helper listens on for SIP traffic, and enable or disable SIP NAT tracing. If the FortiGate is operating with multiple VDOMs, each VDOM can have a different SIP session helper configuration.

To have the SIP session helper process SIP sessions you need to add a security policy that accepts SIP sessions on the configured SIP UDP or TCP ports. The security policies can have service set to ANY, or to the SIP pre-defined firewall service, or a custom firewall service. The SIP pre-defined firewall service restricts the security policy to only accepting sessions on UDP port 5060.

If NAT is enabled for security policies that accept SIP traffic, the SIP session helper translates addresses in SIP headers and in the RDP profile and opens up pinholes as required for the SIP traffic. This includes security policies that perform source NAT and security policies that contain virtual IPs that perform destination NAT and port forwarding. No special SIP configuration is required for this address translation to occur, it is all handled automatically by the SIP session helper according to the NAT configuration of the security policy that accepts the SIP session.

To use the SIP session helper you must not add a VoIP profile to the security policy. If you add a VoIP profile, SIP traffic bypasses the SIP session helper and is processed by the SIP ALG.

In most cases you would want to use the SIP ALG since the SIP session helper provides limited functionality. However, the SIP session helper is available and can be useful for high-performance solutions where a high level of SIP security is not a requirement.

Disabling and enabling the SIP session helper

You can use the following steps to disable the SIP session helper. You might want to disable the SIP session helper if you don't want the FortiGate to apply NAT or other SIP session help features to SIP traffic. With the SIP session helper disabled, the FortiGate can still accept SIP sessions if they are allowed by a security policy, but the FortiGate will not be able to open pinholes or NAT the addresses in the SIP messages.

To disable the sip session helper

1. Enter the following command to find the sip session helper entry in the session-helper list:

```
show system session-helper
   .
   .
   .
edit 13
   set name sip
   set port 5060
   set protocol 17
next
   .
   .
   .
```

   This command output shows that the sip session helper listens in UDP port 5060 for SIP sessions.

2. Enter the following command to delete session-helper list entry number 13 to disable the sip session helper:

```
config system session-helper
   delete 13
end
```

If you want to use the SIP session helper you can verify whether it is enabled or disabled using the `show system session-helper` command.

You do not have to disable the SIP session helper to use the SIP ALG.

If the SIP session helper has been disabled by being removed from the session-helper list you can use the following command to enable the SIP session helper by adding it back to the session helper list:

```
config system session-helper
   edit 0
      set name sip
      set port 5060
      set protocol 17
end
```

Changing the port numbers that the SIP session helper listens on

You can use the following command to change the port number that the SIP session helper listens on for SIP traffic to 5064. The SIP session helper listens on the same port number for UDP and TCP SIP sessions. In this example, the SIP session helper is session helper 13:

```
config system session-helper
   edit 13
      set port 5064
   end
```

The `config system settings` options `sip-tcp-port`, `sip-udp-port`, and `sip-ssl-port` control the ports that the SIP ALG listens on for SIP sessions. See Changing the port numbers that the SIP ALG listens on on page 3369.

Your FortiGate may use a different session helper number for SIP. Enter the following command to view the session helpers:

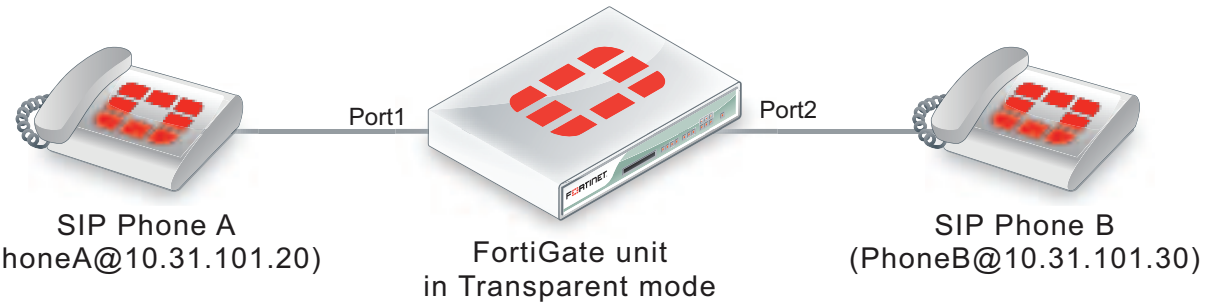
```
show system session-helper
   .
   .
   .
   edit 13
      set name sip
      set port 5060
      set protocol 17
   end
   .
   .
   .
```

Configuration example: SIP session helper in Transparent Mode

The figure below shows an example SIP network consisting of a FortiGate operating in Transparent mode between two SIP phones. Since the FortiGate is operating in Transparent mode both phones are on the same network and the FortiGate and the SIP session helper does not perform NAT. Even though the SIP session helper is not performing NAT you can use this configuration to apply SIP session helper security features to the SIP traffic.

The FortiGate requires two security policies that accept SIP packets. One to allow SIP Phone A to start a session with SIP Phone B and one to allow SIP Phone B to start a session with SIP Phone A.

SIP network with FortiGate in Transparent mode



General configuration steps

The following general configuration steps are required for this SIP configuration that uses the SIP session helper. This example includes security policies that specifically allow SIP sessions using UDP port 5060 from Phone A to Phone B and from Phone B to Phone A. In most cases you would have more than two phones so would use more general security policies. Also, you can set the firewall service to ANY to allow traffic other than SIP on UDP port 5060.

This example assumes that you have entered the following command to enable using the SIP session helper:

```
config system settings
   set default-voip-alg-mode kernel-helper-based
end
```

1. Add firewall addresses for Phone A and Phone B.
2. Add a security policy that accepts SIP sessions initiated by Phone A.
3. Add a security policy that accepts SIP sessions initiated by Phone B.

Configuration steps - GUI

To add firewall addresses for the SIP phones

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New > Address** to add the following addresses for Phone A and Phone B:

Category	Address
Name	Phone_A
Type	IP/Netmask
Subnet / IP Range	10.31.101.20/255.255.255.255
Interface	port1

Category	Address
Name	Phone_B
Type	IP/Netmask
Subnet / IP Range	10.31.101.30/255.255.255.255
Interface	port2

To add security policies to accept SIP sessions

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select **Create New** to add a security policy.
3. Add a security policy to allow Phone A to send SIP request messages to Phone B:

Incoming Interface	port1
Outgoing Interface	port2
Source	Phone_A
Destination Address	Phone_B
Schedule	always
Service	SIP
Action	ACCEPT

4. Select **OK**.
5. Add a security policy to allow Phone B to send SIP request messages to Phone A:

Incoming Interface	port2
Outgoing Interface	port1
Source Address	Phone_B
Destination Address	Phone_A
Schedule	always
Service	SIP
Action	ACCEPT

6. Select **OK**.

Configuration steps - CLI

To add firewall addresses for Phone A and Phone B and security policies to accept SIP sessions

1. Enter the following command to add firewall addresses for Phone A and Phone B.

```
config firewall address
   edit Phone_A
      set associated interface port1
      set type ipmask
      set subnet 10.31.101.20 255.255.255.255
   next
   edit Phone_B
      set associated interface port2
      set type ipmask
      set subnet 10.31.101.30 255.255.255.255
   end
```

2. Enter the following command to add security policies to allow Phone A to send SIP request messages to Phone B and Phone B to send SIP request messages to Phone A.

```
config firewall policy
   edit 0
      set srcintf port1
```

```
    set dstintf port2
    set srcaddr Phone_A
    set dstaddr Phone_B
    set action accept
    set schedule always
    set service SIP
  next
  edit 0
    set srcintf port2
    set dstintf port1
    set srcaddr Phone_B
    set dstaddr Phone_A
    set action accept
    set schedule always
    set service SIP
    set utm-status enable
  end
```

SIP session helper diagnose commands

You can use the `diagnose sys sip` commands to display diagnostic information for the SIP session helper.

Use the following command to set the debug level for the SIP session helper. Different debug masks display different levels of detail about SIP session helper activity.

```
diagnose sys sip debug-mask <debug_mask_int>
```

Use the following command to display the current list of SIP dialogs being processed by the SIP session help. You can also use the `clear` option to delete all active SIP dialogs being processed by the SIP session helper.

```
diagnose sys sip dialog {clear | list}
```

Use the following command to display the current list of SIP NAT address mapping tables being used by the SIP session helper.

```
diagnose sys sip mapping list
```

Use the following command to display the current SIP session helper activity including information about the SIP dialogs, mappings, and other SIP session help counts. This command can be useful to get an overview of what the SIP session helper is currently doing.

```
diagnose sys sip status
```

The SIP ALG

In most cases you should use the SIP Application Layer Gateway (ALG) for processing SIP sessions. The SIP ALG provides the same basic SIP support as the SIP session helper. Additionally, the SIP ALG provides a wide range of features that protect your network from SIP attacks, apply rate limiting to SIP sessions, check the syntax of SIP and SDP content of SIP messages, and provide detailed logging and reporting of SIP activity.

By default all SIP traffic is processed by the SIP ALG. If the policy that accepts the SIP traffic includes a VoIP profile the SIP traffic is processed by that profile. If the policy does not include a SIP profile the SIP traffic is processed by the SIP ALG using the default VoIP profile.

If a FortiGate or a VDOM has been configured to use the SIP session helper, you can change this behavior to the default configuration of using the SIP ALG with the following command:

```
config system settings
```

```
    set default-voip-alg-mode proxy-based
end
```

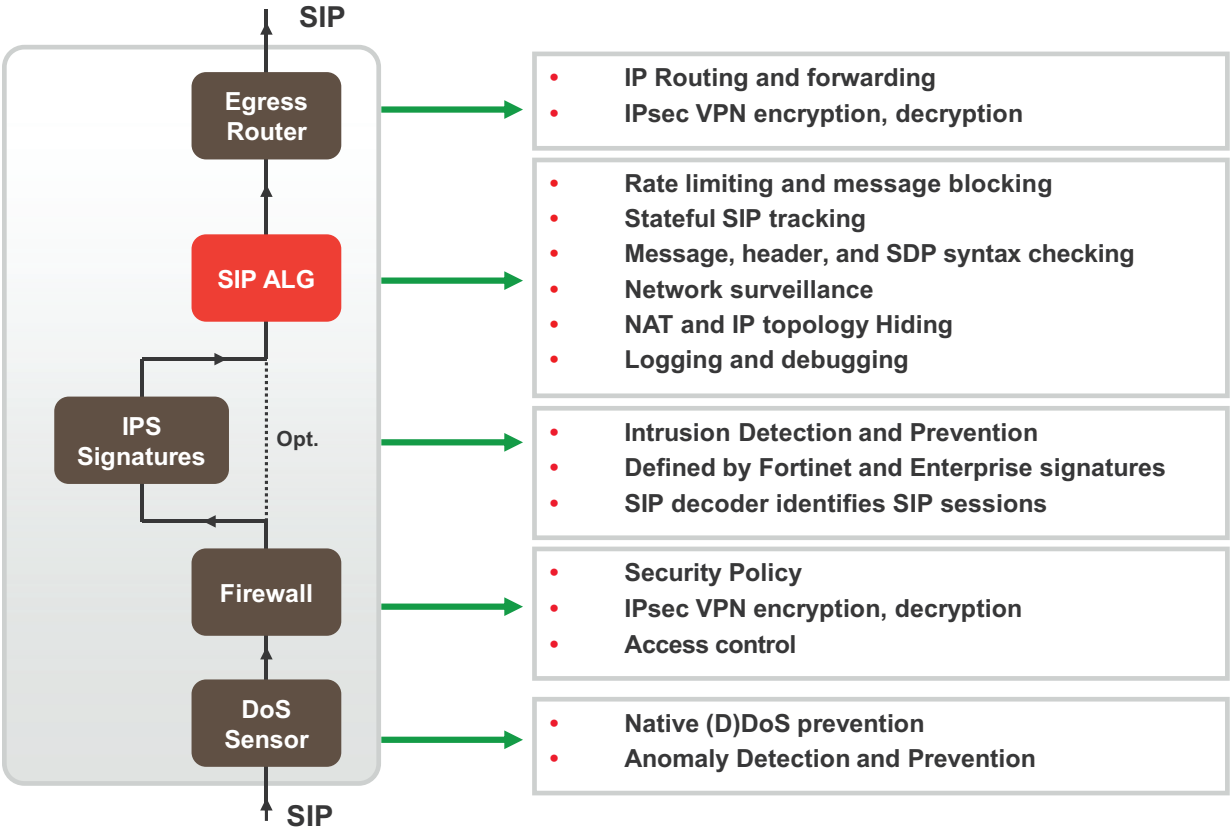
From the GUI you can only configure VoIP security profiles and add them to security policies if VoIP is turned on under **System > Feature Select** and if the **Inspection Mode** is set to **Proxy-based**. However, you can always configure VoIP profiles and add them to security profiles from the CLI. And if the `default-voip-alg` mode is set to `proxy-based` the default SIP profile will still be used even if VoIP security profiles are not visible from the GUI.

As shown in the figure below, the FortiGate SIP ALG intercepts SIP packets after they have been routed by the routing module, accepted by a security policy and passed through DoS and IPS Sensors (if DoS and IPS are enabled). The ALG raises SIP packets to the application layer, analyzes the SIP and SDP addressing information in the SIP messages, makes adjustments (for example, NAT) to this addressing if required, and then sends the packets out the egress interface to their destination.

The SIP ALG provides:

- All the same features as the SIP session helper including NAT and SIP and RTP Pinholes.
- In addition for the ALG you can enable or disable RTP pinholing, SIP register pinholing and SIP contact pinholing. In a signaling only environment where the RTP stream bypasses the FortiGate, you can disable RTP pinholing to improve performance.
- SIP TCP and UDP support
- SIP Message order checking
- Configurable Header line length maximums

The SIP ALG works at the application level after ingress packets are accepted by a security policy



- Message fragment assembly (TCP)
- If SIP messages are fragmented across multiple packets, the FortiGate assembles the fragments, does inspection and pass the message in its entirety to the SIP server as one packet. This offloads the server from doing all the TCP processing of fragments.
- L4 Protocol Translation
- Message Flood Protection
- Protects a SIP server from intentional or unintentional DoS of flooding INVITE, REGISTER, and other SIP methods by allowing control of the rate that these massages pass through the FortiGate.
- SIP message type filtering
- The FortiGate can prevent specified SIP message types from passing through the FortiGate to a SIP server. For example In a voice only SIP implementation, there may be no need to permit a SUBSCRIBE message to ever make it's way to the SIP call processor. Also, if a SIP server cannot process some SIP message types you can use SIP message type filtering to block them. For example, a SIP server could have a bug that prevents it from processing certain SIP messages. In this case you can temporarily block these message types until problem with the SIP server has been fixed.
- SIP statistics and logging
- SIP over IPv6
- SIP over SSL/TLS
- Deep SIP message syntax checking (also called deep SIP header inspection or SIP fuzzing protection). Prevents attacks that use malformed SIP messages. Can check many SIP headers and SDP statements. Configurable bypass and modification options.

- Hosted NAT traversal, Resolves IP address issue in SIP and SDP lines due to NAT-PT in far end firewall. Important feature for VoIP access networks.
- SIP High Availability (HA), including active-passive clustering and session pickup (session failover) for SIP sessions.
- Geographical Redundancy. In an HA configuration, if the active SIP server fails (missing SIP heartbeat messages or SIP traffic) SIP sessions can be redirected to a secondary SIP server in another location.
- SIP per request method message rate limitation with configurable threshold for SIP message rates per request method. Protects SIP servers from SIP overload and DoS attacks.
- RTP Bypass, Supports configurations with and without RTP pinholing. May inspect and protect SIP signaling only.
- SIP NAT with IP address conservation. Performs SIP and RTP aware IP Network Address translation. Preserves the lost IP address information in the SDP profile i= line for later processing/debugging in the SIP server. See NAT with IP address conservation on page 3398.
- IP topology hiding
- The IP topology of a network can be hidden through NAT and NAPT manipulation of IP and SIP level addressing. For example, see SIP NAT scenario: source address translation (source NAT) on page 3384.
- SIP inspection without address translation
- The SIP ALG inspects SIP messages but addresses in the messages are not translated. This feature can be applied to a FortiGate operating in Transparent mode or in NAT/Route mode. In Transparent mode you add normal Transparent mode security policies that enable the SIP ALG and include a VoIP profile that causes the SIP ALG to inspect SIP traffic as required. For an example configuration, see Configuration example: SIP in Transparent Mode on page 3374.
- For a FortiGate operating in NAT/Route mode, if SIP traffic can pass between different networks without requiring NAT because is supported by the routing configuration, you can add security policies that accept SIP traffic without enabling NAT. In the VoIP profile you can configure the SIP ALG to inspect SIP traffic as required.

Enabling VoIP support from the GUI

Before you begin to configure VoIP security profiles, including SIP, from the GUI you should go to **System > Feature Select** and turn on **VoIP** (under **Additional Features**).

Also, VoIP security profiles are only available if the FortiGate or current VDOM **Inspection Mode** is set to **Proxy-based** in the **System Information** Dashboard widget. If the Inspection mode is set to Flow-based the inspection mode will not be visible from the System Information Dashboard widget. You must use the following CLI command to change the Inspection mode to proxy:

```
config system settings
   set inspection-mode proxy
end
```

SIP ALG configuration overview

To apply the SIP ALG, you add a SIP VoIP profile to a security policy that accepts SIP sessions. All SIP sessions accepted by the security policy will be processed by the SIP ALG using the settings in the VoIP profile. The VoIP profile contains settings that are applied to SIP, Session Initiation Protocol for Instant Messaging and Presence Leveraging Extensions (SIMPLE) and Skinny Call Control Protocol (SCCP) sessions. All SCCP sessions accepted by the security policy are also processed by the ALG. You configure SIP and SCCP settings separately. SIP settings also apply to SIMPLE sessions.

VoIP profiles

You can customize the default VoIP profile or add new VoIP profiles.

To add a new VoIP profile from the GUI go to **Security Profiles > VoIP** and select **Create New** (the + button).

For SIP, from the GUI you can configure the VoIP profile to limit the number of SIP REGISTER and INVITE requests. Many additional options for configuring how the ALG processes SIP sessions are available from the CLI.

For SCCP you can limit the call setup time. Additional SCCP options are available from the CLI.

Use the following command to add a VoIP profile named VoIP_Pro_1 from the CLI:

```
config voip profile
   edit VoIP_Pro_1
end
```

FortiGates include two pre-defined VoIP profiles. On the GUI these profiles look identical. However, the CLI-only settings result in the following functionality.

default	The most commonly used VoIP profile. This profile enables both SIP and SCCP and places the minimum restrictions on what calls will be allowed to negotiate. This profile allows normal SCCP, SIP and RTP sessions and enables the following security settings: • `block-long-lines` to block SIP messages with lines that exceed maximum line lengths. • `block-unknown` to block unrecognized SIP request messages. • `open-record-route-pinhole` to open pinholes for Record-Route messages. • `log-violations` to write log messages that record SIP violations. • `log-call-summary` to write log messages that record SIP call progress (similar to DLP archiving). • `nat-trace` (see NAT with IP address conservation on page 3398). • `contact-fixup` perform NAT on the IP addresses and port numbers in SIP headers in SIP CONTACT messages even if they don't match the session's IP address and port numbers. • `ips-rtp` to enable IPS in security policies that also accept SIP sessions to protect the SIP traffic from SIP-based attacks.
strict	This profile is available for users who want to validate SIP messages and to only allow SIP sessions that are compliant with RFC 3261. In addition to the settings in the default VoIP profile, the strict profile sets all SIP deep message inspection header checking options to `discard`. So the strict profile blocks and drops SIP messages that contain malformed SIP or SDP lines that can be detected by the ALG. For more information about SIP deep header inspection, see Deep SIP message inspection on page 3412.

Neither of the default profiles applies SIP rate limiting. To apply more ALG features to SIP sessions you can clone (copy) the pre-defined VoIP profiles and make your own modifications to them. You can clone VoIP profiles from the GUI or the CLI. For example, from the CLI, to clone the default profile and configure the limit for SIP NOTIFY request messages to 1000 messages per second per security policy and block SIP INFO request messages.

```
config voip profile
   clone default to my_voip_pro
   edit my_voip_pro
      config sip
         set notify-rate 1000
         set block-info enable
      end
   end
```

Changing the port numbers that the SIP ALG listens on

Most SIP configurations use TCP or UDP port 5060 for SIP sessions and port 5061 for SIP SSL sessions. If your SIP network uses different ports for SIP sessions you can use the following command to configure the SIP ALG to listen on a different TCP, UDP, or SSL ports. For example, to change the TCP port to 5064, the UDP port to 5065, and the SSL port to 5066.

```
config system settings
   set sip-tcp-port 5064
   set sip-udp-port 5065
   set sip-ssl-port 5066
end
```

You also configure the SIP ALG to listen in two different TCP ports and two different UDP ports for SIP sessions. For example, if you receive SIP TCP traffic on port 5060 and 5064 and UDP traffic on ports 5061 and 5065 you can enter the following command to receive the SIP traffic on all of these ports:

```
config system settings
   set sip-tcp-port 5060 5064
   set sip-udp-port 5061 5065
end
```

Disabling the SIP ALG in a VoIP profile

SIP is enabled by default in a VoIP profile. If you are just using the VoIP profile for SCCP you can use the following command to disable SIP in the VoIP profile.

```
config voip profile
   edit VoIP_Pro_2
      config sip
      set status disable
   end
```

SIP ALG diagnose commands

You can use the `diagnose sys sip-proxy` command to display diagnostic information for the SIP ALG. A number of options are available including:

Use the following command to list all active SIP calls being processed by the SIP ALG. You can also use the `clear` option to delete all active SIP calls being processed by the SIP ALG, the idle option to list idle SIP calls, and the invite option to list SIP invite transactions.

```
diagnose sys sip-proxy calls {clear | list | idle | invite}
```

Use the following commands to employ filters to display specific information about the SIP ALG and the session that it is processing. You can build up a filter by including a number of options such as source address, VoIP profile, policy, and so on.

```
diagnose sys sip-proxy filter <filter_options>
```

```
diagnose sys sip-proxy log-filter <filter_options>
```

Use the following command to display the active SIP rate limiting meters and their current settings.

```
diagnose sys sip-proxy meters list
```

Use the following command to display status information about the SIP sessions being processed by the SIP ALG. You can also clear all SIP ALG statistics.

```
diagnose sys sip-proxy stats {clear | list}
```

Conflicts between the SIP ALG and the session helper

If you suspect that the SIP session helper is being used instead of the ALG, you can use the `diagnose sys sip` command to determine if the SIP session helper is processing SIP sessions. For example, the following command displays the overall status of the SIP sessions being processed by the SIP session helper:

The `diagnose sys sip` command only displays current status information. To see activity the SIP session helper has to actually be processing SIP sessions when you enter the command. For example, if the SIP session helper had been used for processing calls that ended 5 minutes ago, the command output would show no SIP session helper activity.

```
diagnose sys sip status
dialogs: max=32768, used=0
mappings: used=0
dialog hash by ID: size=2048, used=0, depth=0
dialog hash by RTP: size=2048, used=0, depth=0
mapping hash: size=2048, used=0, depth=0
count0: 0
count1: 0
count2: 0
count3: 0
count4: 0
```

This command output shows that the session helper is not processing SIP sessions because all of the used and count fields are 0. If any of these fields contains non-zero values then the SIP session helper may be processing SIP sessions.

Also, you can check to see if some ALG-only features are not being applied to all SIP sessions. For example, FortiView pages displays statistics for SIP and SCCP calls processed by the ALG but not for calls processed by the session helper. So if you see fewer calls than expected the session helper may be processing some of them.

Finally, you can check the policy usage and session information dashboard widgets to see if SIP sessions are being accepted by the wrong security policies.

Stateful SIP tracking, call termination, and session inactivity timeout

The SIP ALG tracks SIP dialogs over their lifespan between the first INVITE message and the Final 200 OK and ACK messages. For every SIP dialog, stateful SIP tracking reviews every SIP message and makes adjustment to SIP tracking tables as required. These adjustments include source and destination IP addresses, address translation, dialog expiration information, and media stream port changes. Such changes can also result in

dynamically opening and closing pinholes. You can use the `diagnose sys sip-proxy stats list` and the `diagnose sys sip-proxy filter` command to view the SIP call data being tracked by the SIP ALG.

The SIP ALG uses the SIP Expires header line to time out a SIP dialog if the dialog is idle and a Re-INVITE or UPDATE message is not received. The SIP ALG gets the Session-Expires value, if present, from the 200 OK response to the INVITE message. If the SIP ALG receives an INVITE before the session times out, all timeout values are reset to the settings in the new INVITE message or to default values. As a precautionary measure, the SIP ALG uses hard timeout values to set the maximum amount of time a call can exist. This ensures that the FortiGate is protected if a call ends prematurely.

When a SIP dialog ends normally, the SIP ALG deletes the SIP call information and closes open pinholes. A SIP call can also end abnormally due to an unexpected signaling or transport event that cuts off the call. When a call ends abnormally the SIP messages to end the call may not be sent or received. A call can end abnormally for the following reasons:

- Phones or servers crash during a call and a BYE message is not received.
- To attack a SIP system, a malicious user never send a BYE message.
- Poor implementations of SIP fail to process Record-Route messages and never send a BYE message.
- Network failures prevent a BYE message from being received.

Any phone or server in a SIP call can cancel the call by sending a CANCEL message. When a CANCEL message is received by the FortiGate, the SIP ALG closes open pinholes. Before terminating the call, the ALG waits for the final 200 OK message.

The SIP ALG can be configured to terminate SIP calls if the SIP dialog message flow or the call RTP (media) stream is interrupted and does not recover. You can use the following commands to configure terminating inactive SIP sessions and to set timers or counters to control when the call is terminated by the SIP ALG.

Adding a media stream timeout for SIP calls

Use the following command in a VoIP profile to terminate SIP calls accepted by a security policy containing the VoIP profile when the RTP media stream is idle for 100 seconds.

```
config voip profile
   edit VoIP_Pro_Name
      config sip
         set call-keepalive 100
      end
   end
```

You can adjust this setting between 1 and 10,080 seconds. The default call keepalive setting of 0 disables terminating a call if the media stream is interrupted. Set call keepalive higher if your network has latency problems that could temporarily interrupt media streams. If you have configured call keepalive and the FortiGate terminates calls unexpectedly you can increase the call keepalive time to resolve the problem.

Call keep alive should be used with caution because enabling this feature results in extra FortiGate CPU overhead and can cause delay/jitter for the VoIP call. Also, the FortiGate terminates the call without sending SIP messages to end the call. And if the SIP endpoints send SIP messages to terminate the call they will be blocked by the FortiGate if they are sent after the FortiGate terminates the call.

Adding an idle dialog setting for SIP calls

Use the following command in a VoIP profile to terminate SIP calls when for a single security policy, when the configured number of SIP calls (or dialogs) has stopped receiving SIP messages or has not received legitimate SIP messages. Using this command you can configure how many dialogs that have been accepted by a security policy that the VoIP profile is added to become idle before the SIP ALG deletes the oldest ones. The following command sets the maximum number of idle dialogs to 200:

```
config voip profile
   edit VoIP_Pro_Name
      config sip
         set max-idle-dialogs 200
      end
end
```

Idle dialogs would usually be dialogs that have been interrupted because of errors or problems or as the result of a SIP attack that opens a large number of SIP dialogs without closing them. This command provides a way to remove these dialogs from the dialog table and recover memory and resources being used by these open and idle dialogs.

You can adjust this setting between 1 and a very high number. The default maximum idle dialogs setting of 0 disables this feature. Set maximum dialogs higher if your network has latency problems that could temporarily interrupt SIP messaging. If you have configured max idle dialogs and the FortiGate terminates calls unexpectedly you can increase the max idle dialogs number to resolve the problem.

Changing how long to wait for call setup to complete

In some cases and some configurations your SIP system may experience delays during call setup. If this happens, some SIP ALG timers may expire before call setup is complete and drop the call. In some cases you may also want to reduce the amount of time the SIP ALG allows for call setup to complete.

You can use the `provisional-invite-expiry-time` SIP VoIP profile option to control how long the SIP ALG waits for provisional INVITE messages before assuming that the call setup has been interrupted and the SIP call should be dropped. The default value for this timer is 210 seconds. You can change it to between 10 and 3600 seconds.

Use the following command to change the expiry time to 100 seconds.

```
config voip profile
   edit Profile_name
      config sip
         set provisional-invite-expiry-time 100
      end
end
```

SIP and RTP/RTCP

FortiGates support the Real Time Protocol (RTP) application layer protocol for the VoIP call audio stream. RTP uses dynamically assigned port numbers that can change during a call. SIP control messages that start a call and that are sent during the call inform callers of the port number to use and of port number changes during the call.

During a call, each RTP session will usually have a corresponding Real Time Control Protocol (RTCP) session. By default, the RTCP session port number is one higher than the RTP port number.

The RTP port number is included in the `m=` part of the SDP profile. In the example above, the SIP INVITE message includes RTP port number is 49170 so the RTCP port number would be 49171. In the SIP response message the RTP port number is 3456 so the RTCP port number would be 3457.

How the SIP ALG creates RTP pinholes

The SIP ALG requires the following information to create a pinhole. The SIP ALG finds this information in SIP messages and some is provided by the SIP ALG:

Protocol	UDP (Extracted from SIP messages by the SIP ALG.)
Source IP	Any
Source port	Any
Destination IP	The SIP ALG extracts the destination IP address from the c= line in the SDP profile. The c= line can appear in either the session or media part of the SDP profile. The SIP ALG uses the IP address in the c= line of the media part of the SDP profile first. If the media part does not contain a c= line, the SIP ALG checks the c= line in the session part of the SDP profile. If the session part of the profile doesn't contain a c= line the packet is dropped. Pinholes for RTP and RTCP sessions share the same destination IP address.
Destination port	The SIP ALG extracts the destination port number for RTP from the m= field and adds 1 to this number to get the RTCP port number.
Lifetime	The length of time during which the pinhole will be open. When the lifetime ends, the SIP ALG removes the pinhole.

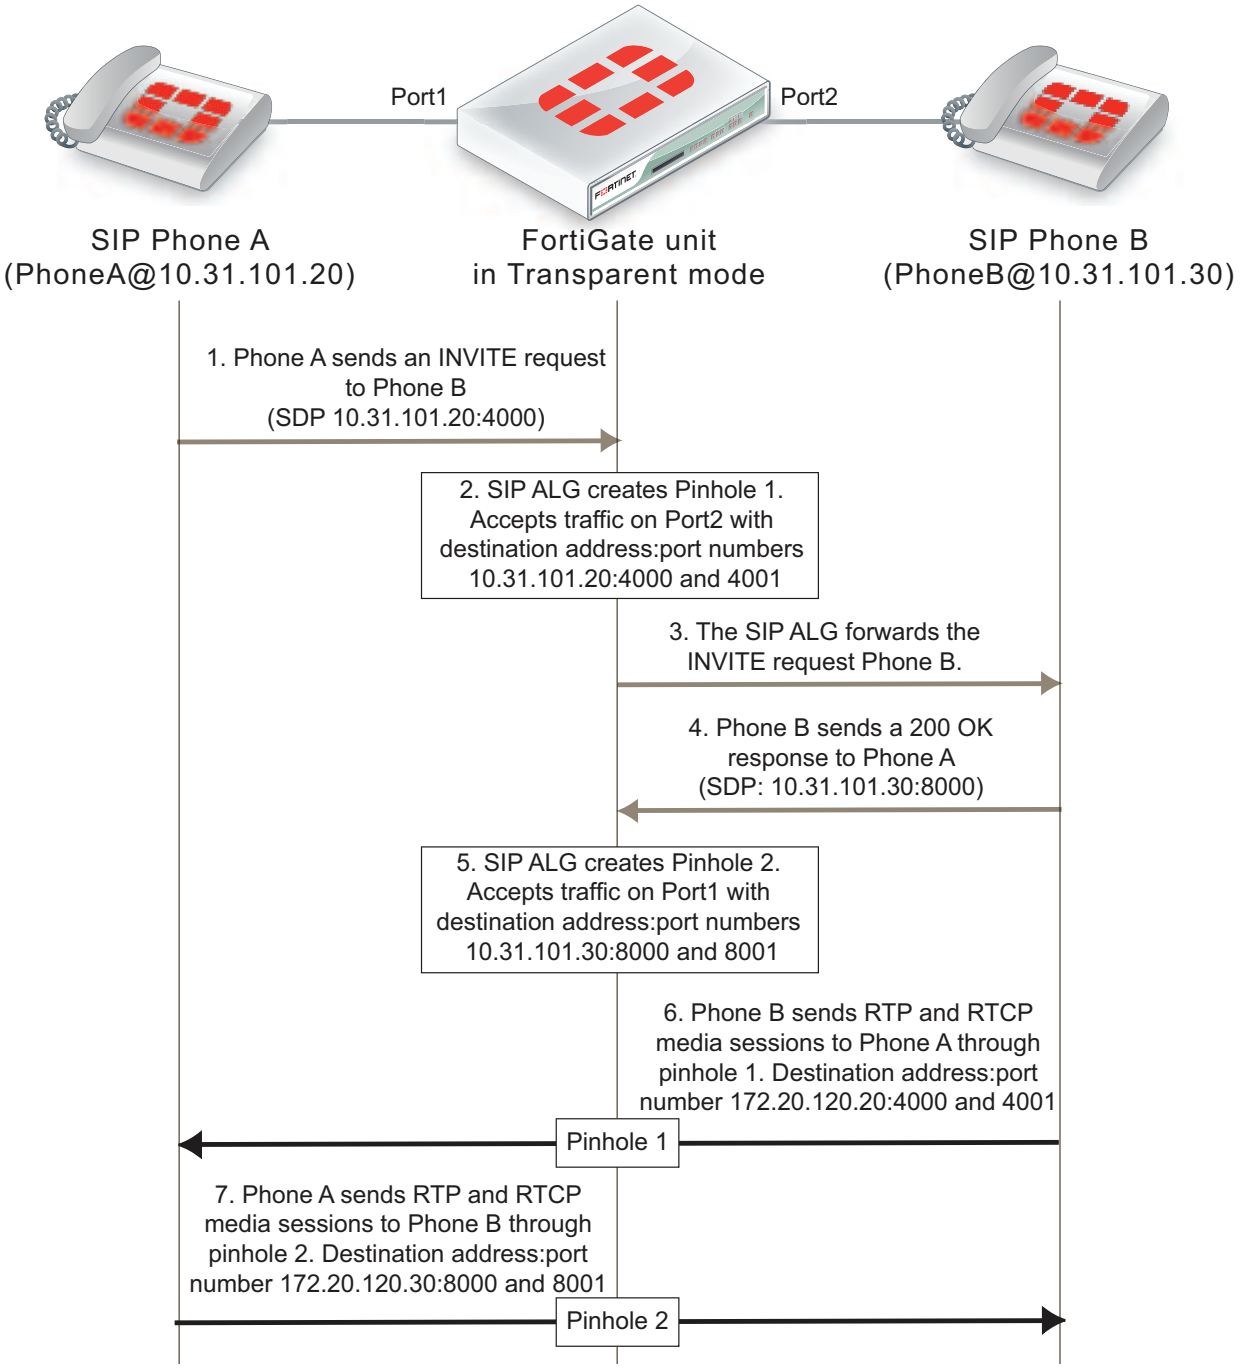
The SIP ALG keeps RTP pinholes open as long as the SIP session is alive. When the associated SIP session is terminated by the SIP ALG or the SIP phones or servers participating in the call, the RTP pinhole is closed.

The figure below shows a simplified call setup sequence that shows how the SIP ALG opens pinholes. Phone A and Phone B are installed on either side of a FortiGate operating in Transparent mode. Phone A and Phone B are on the same subnet. The FortiGate includes a security policy that accepts SIP sessions from port1 to port2 and from port2 to port1. The FortiGate does not require an RTP security policy, just the SIP policy.

You can see from this diagram that the SDP profile in the INVITE request from Phone A indicates that Phone A is expecting to receive a media stream sent to its IP address using port 4000 for RTP and port 4001 for RTCP. The SIP ALG creates pinhole 1 to allow this media traffic to pass through the FortiGate. Pinhole 1 is opened on the Port2 interface and will accept media traffic sent from Phone B to Phone A.

When Phone B receives the INVITE request from Phone A, Phone B will know to send media streams to Phone A using destination IP address 10.31.101.20 and ports 4000 and 4001. The 200 OK response sent from Phone B indicates that Phone B is expecting to receive a media stream sent to its IP address using ports 8000 and 8001. The SIP ALG creates pinhole 2 to allow this media traffic to pass through the FortiGate. Pinhole 2 is opened on the Port1 interface and will accept media traffic sent from Phone A to Phone B.

SIP call setup with a FortiGate in Transparent mode



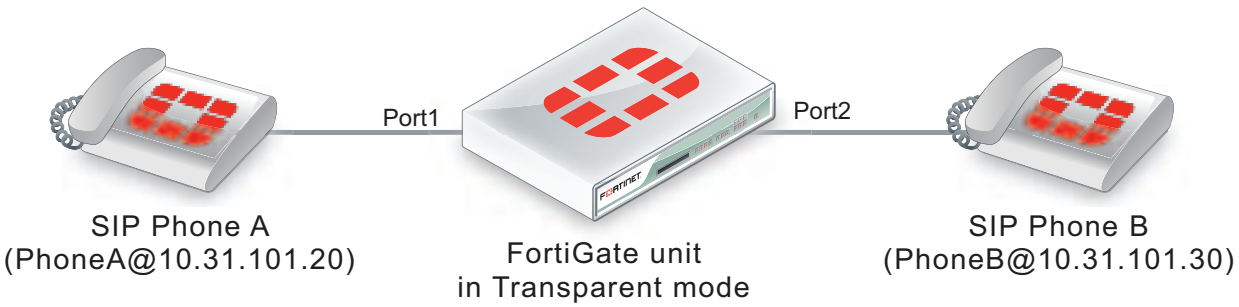
Configuration example: SIP in Transparent Mode

The figure below shows an example SIP network consisting of a FortiGate operating in Transparent mode between two SIP phones. Since the FortiGate is operating in Transparent mode both phones are on the same

network and the FortiGate and the SIP ALG does not perform NAT. Even though the SIP ALG is not performing NAT you can use this configuration to apply SIP security features to the SIP traffic.

The FortiGate requires two security policies that accept SIP packets. One to allow SIP Phone A to start a session with SIP Phone B and one to allow SIP Phone B to start a session with SIP Phone A.

SIP network with FortiGate in Transparent mode



General configuration steps

The following general configuration steps are required for this SIP configuration. This example uses the default VoIP profile. The example also includes security policies that specifically allow SIP sessions using UDP port 5060 from Phone A to Phone B and from Phone B to Phone A. In most cases you would have more than two phones so would use more general security policies. Also, you can set the security service to ANY to allow traffic other than SIP on UDP port 5060.

1. Add firewall addresses for Phone A and Phone B.
2. Add a security policy that accepts SIP sessions initiated by Phone A and includes the default VoIP profile.
3. Add a security policy that accepts SIP sessions initiated by Phone B and includes the default VoIP profile.

Configuration steps - GUI

Before you begin this procedure you may have to go to **System > Feature Select** and turn on VoIP.

To add firewall addresses for the SIP phones

1. Go to **Policy & Objects > Addresses**.
2. Add the following addresses for Phone A and Phone B:

Category	Address
Name	Phone_A
Type	IP/Netmask
Subnet / IP Range	10.31.101.20/255.255.255.255
Interface	port1

Category	Address
Name	Phone_B
Type	IP/Netmask
Subnet / IP Range	10.31.101.30/255.255.255.255
Interface	port2

To add security policies to apply the SIP ALG to SIP sessions

1. Go to **Policy & Objects > IPv4 Policy**.
2. Add a security policy to allow Phone A to send SIP request messages to Phone B:

Incoming Interface	port1
Outgoing Interface	port2
Source	Phone_A
Destination Address	Phone_B
Schedule	always
Service	SIP
Action	ACCEPT

3. Turn on **VoIP** and select the **default** VoIP profile.
4. Select **OK**.
5. Add a security policy to allow Phone B to send SIP request messages to Phone A:

Incoming Interface	port2
Outgoing Interface	port1
Source	Phone_B
Destination Address	Phone_A
Schedule	always
Service	SIP
Action	ACCEPT

6. Turn on **VoIP** and select the **default** VoIP profile.
7. Select **OK**.

Configuration steps - CLI

To add firewall addresses for Phone A and Phone B and security policies to apply the SIP ALG to SIP sessions

1. Enter the following command to add firewall addresses for Phone A and Phone B.

```
config firewall address
   edit Phone_A
      set associated-interface port1
      set type ipmask
      set subnet 10.31.101.20 255.255.255.255
   next
   edit Phone_B
      set associated-interface port2
      set type ipmask
      set subnet 10.31.101.30 255.255.255.255
   end
```

2. Enter the following command to add security policies to allow Phone A to send SIP request messages to Phone B and Phone B to send SIP request messages to Phone A.

```
config firewall policy
   edit 0
      set srcintf port1
      set dstintf port2
      set srcaddr Phone_A
      set dstaddr Phone_B
      set action accept
      set schedule always
      set service SIP
      set utm-status enable
      set voip-profile default
   next
   edit 0
      set srcintf port2
      set dstintf port1
      set srcaddr Phone_B
      set dstaddr Phone_A
      set action accept
      set schedule always
      set service SIP
      set utm-status enable
      set voip-profile default
   end
```

RTP enable/disable (RTP bypass)

You can configure the SIP ALG to stop from opening RTP pinholes. Called RTP bypass, this configuration can be used when you want to apply SIP ALG features to SIP signalling messages but do not want the RTP media streams to pass through the FortiGate. The FortiGate only acts as a signalling firewall and RTP media session bypass the FortiGate and no pinholes need to be created.

Enter the following command to enable RTP bypass in a VoIP profile by disabling opening RTP pinholes:

```
config voip profile
   edit VoIP_Pro_1
      config sip
         set rtp disable
      end
end
```

Opening and closing SIP register, contact, via and record-route pinholes

You can use the `open-register-pinhole`, `open-contact-pinhole`, `open-via-port`, and `open-record-route-pinhole` VoIP profile CLI options to control whether the FortiGate opens various pinholes.

If `open-register-pinhole` is enabled (the default setting) the FortiGate opens pinholes for SIP Register request messages. You can disable `open-register-pinhole` so that the FortiGate does not open pinholes for SIP Register request messages.

If `open-contact-pinhole` is enabled (the default setting) the FortiGate opens pinholes for non-Register SIP request messages. You can disable `open-contact-pinhole` so that the FortiGate does not open pinholes for non-register requests. Non-register pinholes are usually opened for SIP INVITE requests.

If `open-via-pinhole` is disabled (the default setting) the FortiGate does not open pinholes for Via messages. You can enable `open-via-pinhole` so that the FortiGate opens pinholes for Via messages.

If `open-record-route-pinhole` is enabled (the default setting) the FortiGate opens pinholes for Record-Route messages. You can disable `open-record-route-pinhole` so that the FortiGate does not open pinholes for Record-Route messages.

Usually you would want to open these pinholes. Keeping them closed may prevent SIP from functioning properly through the FortiGate. They can be disabled, however, for interconnect scenarios (where all SIP traffic is between proxies and traveling over a single session). In some cases these settings can also be disabled in access scenarios if it is known that all users will be registering regularly so that their contact information can be learned from the register request.

You might want to prevent pinholes from being opened to avoid creating a pinhole for every register or non-register request. Each pinhole uses additional system memory, which can affect system performance if there are hundreds or thousands of users, and requires refreshing which can take a relatively long amount of time if there are thousands of active calls.

To configure a VoIP profile to prevent opening register and non-register pinholes:

```
config voip profile
   edit VoIP_Pro_1
      config sip
         set open-register-pinhole disable
         set open-contact-pinhole disable
      end
end
```

In some cases you may not want to open pinholes for the port numbers specified in SIP Contact headers. For example, in an interconnect scenario when a FortiGate is installed between two SIP servers and the only SIP traffic through the FortiGate is between these SIP servers pinholes may not need to be opened for the port numbers specified in the Contact header lines.

If you disable `open-register-pinhole` then pinholes are not opened for ports in Contact header lines in SIP Register messages. If you disable `open-contact-pinhole` then pinholes are not opened for ports in Contact header lines in all SIP messages except SIP Register messages.

Accepting SIP register responses

You can enable the VoIP profile `open-via-pinhole` options to accept a SIP Register response message from a SIP server even if the source port of the Register response message is different from the destination port.

Most SIP servers use 5060 as the source port in the SIP register response. Some SIP servers, however, may use a different source port. If your SIP server uses a different source port, you can enable `open-via-pinhole` and the SIP ALG will create a temporary pinhole when the Register request from a SIP client includes a different source port. The FortiGate will accept a SIP Register response with any source port number from the SIP server.

Enter the following command to enable accepting any source port from a SIP server:

```
config voip profile
   edit VoIP_Pro_1
      config sip
         set open-via-pinhole enable
      end
end
```

How the SIP ALG performs NAT

In most Network Address Translation (NAT) configurations, multiple hosts in a private network share a single public IP address to access the Internet. For sessions originating on the private network for the Internet, NAT replaces the private IP address of the PC in the private subnet with the public IP address of the NAT device. The NAT device converts the public IP address for responses from the Internet back into the private address before sending the response over the private network to the originator of the session.

Using NAT with SIP is more complex because of the IP addresses and media stream port numbers used in SIP message headers and bodies. When a caller on the private network sends a SIP message to a phone or SIP server on the Internet, the SIP ALG must translate the private network addresses in the SIP message to IP addresses and port numbers that are valid on the Internet. When the response message is sent back to the caller, the SIP ALG must translate these addresses back to valid private network addresses.

In addition, the media streams generated by the SIP session are independent of the SIP message sessions and use varying port numbers that can also change during the media session. The SIP ALG opens pinholes to accept these media sessions, using the information in the SIP messages to determine the pinholes to open. The ALG may also perform port translation on the media sessions.

When an INVITE message is received by the SIP ALG, the FortiGate extracts addressing and port number information from the message header and stores it in a SIP dialog table. Similar to an IP session table the data in the dialog table is used to translate addresses in subsequent SIP messages that are part of the same SIP call.

When the SIP ALG receives a response to the INVITE message arrives, (for example, an ACK or 200 OK), the SIP ALG compares the addresses in the message fields against the entries in the SIP dialog table to identify the call context of the message. The SIP ALG then translates addresses in the SIP message before forwarding them to their destination.

The addressing and port number information in SDP fields is used by the ALG to reserve ports for the media session and create a NAT mapping between them and the ports in the SDP fields. Because SDP uses sequential ports for the RTP and RTCP channels, the ALG provides consecutive even-odd ports.

SIP ALG source address translation

When a SIP call is started by a phone on a private network destined for a phone on the Internet, only source address translation is required. The phone on the private network attempts to contact the actual IP address of the phone on the Internet. However, the source address of the phone on the private network is not routable on the Internet so the SIP ALG must translate all private IP addresses in the SIP message into public IP addresses.

To configure the FortiGate for source address translation you add security policy that accepts sessions from the internal network destined for the Internet. You must enable NAT for the security policy and add a VoIP profile.

When a SIP request is received from the internal to the external network, the SIP ALG replaces the private network IP addresses and port numbers in the SIP message with the IP address of the FortiGate interface connected to the Internet. Depending on the content of the message, the ALG translates addresses in the Via:, Contact:, Route:, and Record-Route: SIP header fields. The message is then forwarded to the destination (either a VoIP phone or a SIP server on the Internet).

The VoIP phone or server in the Internet sends responses to these SIP messages to the external interface of the FortiGate. The addresses in the response messages are translated back into private network addresses and the response is forwarded to the originator of the request.

For the RTP communication between the SIP phones, the SIP ALG opens pinholes to allow media through the FortiGate on the dynamically assigned ports negotiated based on information in the SDP and the Via:, Contact:, and Record-Route: header fields. The pinholes also allow incoming packets to reach the Contact:, Via:, and Record-Route: IP addresses and ports. When processing return traffic, the SIP ALG inserts the original Contact:, Via:, Route:, and Record-Route: SIP fields back into the packets.

SIP ALG destination address translation

Incoming calls are directed from a SIP phone on the Internet to the interface of the FortiGate connected to the Internet. To receive these calls you must add a security policy to accept SIP sessions from the Internet. The security policy requires a firewall virtual IP. SIP INVITE messages from the Internet connect to the external IP address of the virtual IP. The SIP ALG uses the destination address translation defined in the virtual IP to translated the addresses in the SIP message to addresses on the private network.

When a 200 OK response message arrives from the private network, the SIP ALG translates the addresses in the message to Internet addresses and opens pinholes for media sessions from the private network to the Internet.

When the ACK message is received for the 200 OK, it is also intercepted by the SIP ALG. If the ACK message contains SDP information, the SIP ALG checks to determine if the IP addresses and port numbers are not changed from the previous INVITE. If they are, the SIP ALG deletes pinholes and creates new ones as required. The ALG also monitors the Via:, Contact:, and Record-Route: SIP fields and opens new pinholes as required.

SIP Call Re-invite messages

SIP Re-INVITE messages can dynamically add and remove media sessions during a call. When new media sessions are added to a call the SIP ALG opens new pinholes and update SIP dialog data. When media sessions are ended, the SIP ALG closes pinholes that are no longer needed and removes SIP dialog data.

How the SIP ALG translates IP addresses in SIP headers

The SIP ALG applies NAT to SIP sessions by translating the IP addresses contained in SIP headers. For example, the following SIP message contains most of the SIP fields that contain addresses that need to be translated:

```
INVITE PhoneB@172.20.120.30 SIP/2.0
Via: SIP/2.0/UDP 172.20.120.50:5434
From: PhoneA@10.31.101.20
To: PhoneB@172.20.120.30
Call-ID: a12abcde@172.20.120.50
Contact: PhoneA@10.31.101.20:5434
Route: <sip:example@172.20.120.50:5060>
Record-Route: <sip:example@172.20.120.50:5060>
```

How IP address translation is performed depends on whether source NAT or destination NAT is applied to the session containing the message:

Source NAT translation of IP addresses in SIP messages

Source NAT translation occurs for SIP messages sent from a phone or server on a private network to a phone or server on the Internet. The source addresses in the SIP header fields of the message are typically set to IP addresses on the private network. The SIP ALG translates these addresses to the address the FortiGate interface connected to the Internet.

Source NAT translation of IP addresses in SIP request messages

SIP header	NAT action
To:	None
From:	Replace private network address with IP address of FortiGate interface connected to the Internet.
Call-ID:	Replace private network address with IP address of FortiGate interface connected to the Internet.
Via:	Replace private network address with IP address of FortiGate interface connected to the Internet.
Request-URI:	None
Contact:	Replace private network address with IP address of FortiGate interface connected to the Internet.
Record-Route:	Replace private network address with IP address of FortiGate interface connected to the Internet.
Route:	Replace private network address with IP address of FortiGate interface connected to the Internet.

Response messages from phones or servers on the Internet are sent to the FortiGate interface connected to the Internet where the destination addresses are translated back to addresses on the private network before forwarding the SIP response message to the private network.

Source NAT translation of IP addresses in SIP response messages

SIP header	NAT action
To:	None
From:	Replace IP address of FortiGate interface connected to the Internet with private network address.
Call-ID:	Replace IP address of FortiGate interface connected to the Internet with private network address.
Via:	Replace IP address of FortiGate interface connected to the Internet with private network address.
Request-URI:	N/A
Contact:	None
Record-Route:	Replace IP address of FortiGate interface connected to the Internet with private network address.
Route:	Replace IP address of FortiGate interface connected to the Internet with private network address.

Destination NAT translation of IP addresses in SIP messages

Destination NAT translation occurs for SIP messages sent from a phone or server on the Internet to a firewall virtual IP address. The destination addresses in the SIP header fields of the message are typically set to the virtual IP address. The SIP ALG translates these addresses to the address of a SIP server or phone on the private network on the other side of the FortiGate.

Destination NAT translation of IP addresses in SIP request messages

SIP header	NAT action
To:	Replace VIP address with address on the private network as defined in the firewall virtual IP.
From:	None
Call-ID:	None
Via:	None

SIP header	NAT action
Request-URI:	Replace VIP address with address on the private network as defined in the firewall virtual IP.
Contact:	None
Record-Route:	None
Route:	None

SIP response messages sent in response to the destination NAT translated messages are sent from a server or a phone on the private network back to the originator of the request messages on the Internet. These reply messages are accepted by the same security policy that accepted the initial request messages, The firewall VIP in the original security policy contains the information that the SIP ALG uses to translate the private network source addresses in the SIP headers into the firewall virtual IP address.

Destination NAT translation of IP addresses in SIP response messages

SIP header	NAT action
To:	None
From:	Replace private network address with firewall VIP address.
Call-ID:	None
Via:	None
Request-URI:	N/A
Contact:	Replace private network address with firewall VIP address.
Record-Route:	Replace private network address with firewall VIP address.
Route:	None

How the SIP ALG translates IP addresses in the SIP body

The SDP session profile attributes in the SIP body include IP addresses and port numbers that the SIP ALG uses to create pinholes for the media stream.

The SIP ALG translates IP addresses and port numbers in the o=, c=, and m= SDP lines. For example, in the following lines the ALG could translate the IP addresses in the o= and c= lines and the port number (49170) in the m= line.

```
o=PhoneA 5462346 332134 IN IP4 10.31.101.20
c=IN IP4 10.31.101.20
m=audio 49170 RTP 0 3
```

If the SDP session profile includes multiple RTP media streams, the SIP ALG opens pinholes and performs the required address translation for each one.

The two most important SDP attributes for the SIP ALG are c= and m=. The c= attribute is the connection information attribute. This field can appear at the session or media level. The syntax of the connection attribute is:

```
c=IN {IPV4 | IPV6} <destination_ip_address>
```

Where

- `IN` is the network type. FortiGates support the `IN` or Internet network type.
- `{IPV4 | IPV6}` is the address type. FortiGates support IPv4 or IPv6 addresses in SDP statements. However, FortiGates do not support all types of IPv6 address translation. See SIP over IPv6 on page 3411.
- `<destination_IP_address>` is the unicast numeric destination IP address or domain name of the connection in either IPv4 or IPv6 format.

The syntax of the media attribute is:

```
m=audio <port_number> RTP <format_list>
```

Where

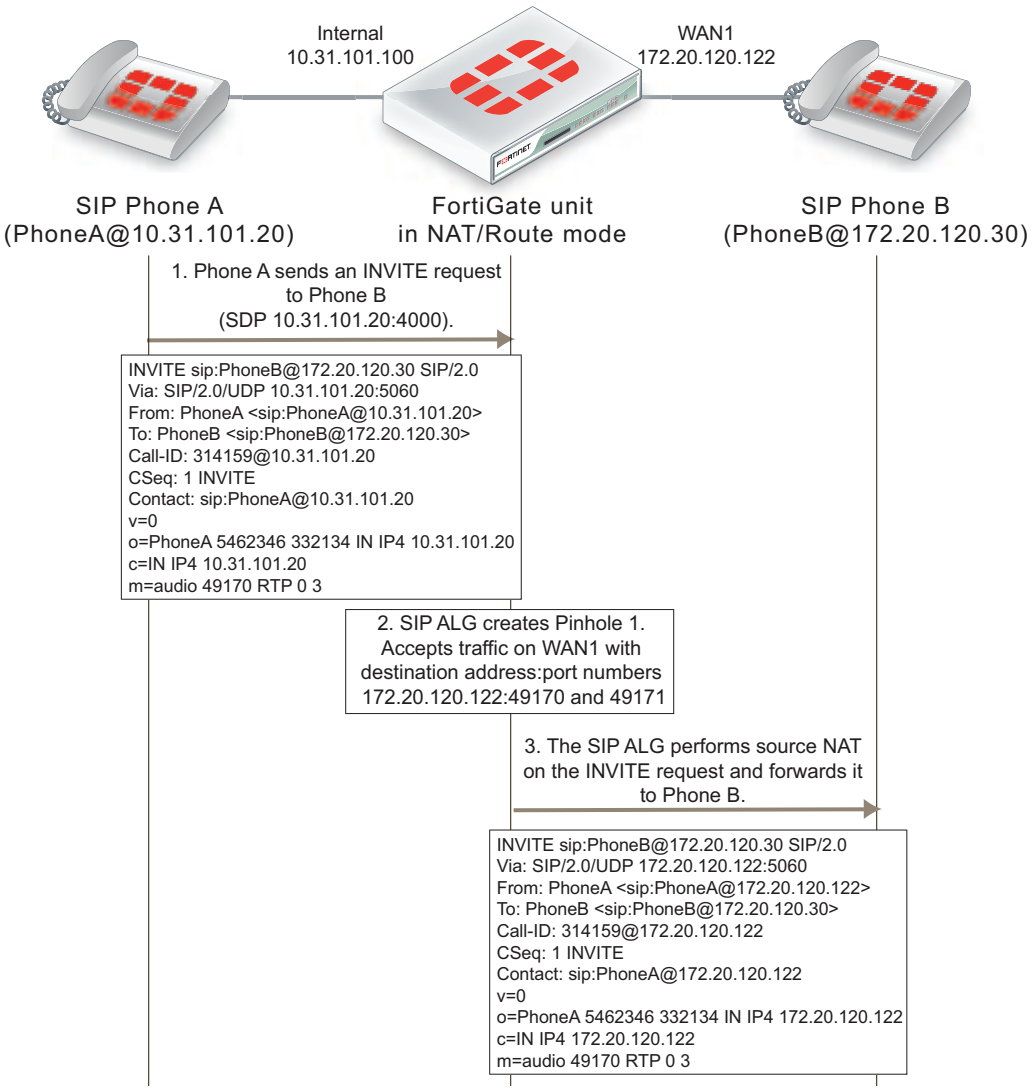
- `audio` is the media type. FortiGates support the `audio` media type.
- `<port_number>` is the destination port number used by the media stream.
- `RTP` is the application layer transport protocol used for the media stream. FortiGates support the Real Time Protocol (RTP) transport protocol.
- `<format_list>` is the format list that provides information about the application layer protocol that the media uses.

SIP NAT scenario: source address translation (source NAT)

The following figures show a source address translation scenario involving two SIP phones on different networks, separated by a FortiGate. In the scenario, SIP Phone A sends an INVITE request to SIP Phone B and SIP Phone B replies with a 200 OK response and then the two phones start media streams with each other.

To simplify the diagrams, some SIP messages are not included (for example, the Ringing and ACK response messages) and some SIP header lines and SDP profile lines have been removed from the SIP messages.

SIP source NAT scenario part 1: INVITE request sent from Phone A to Phone B



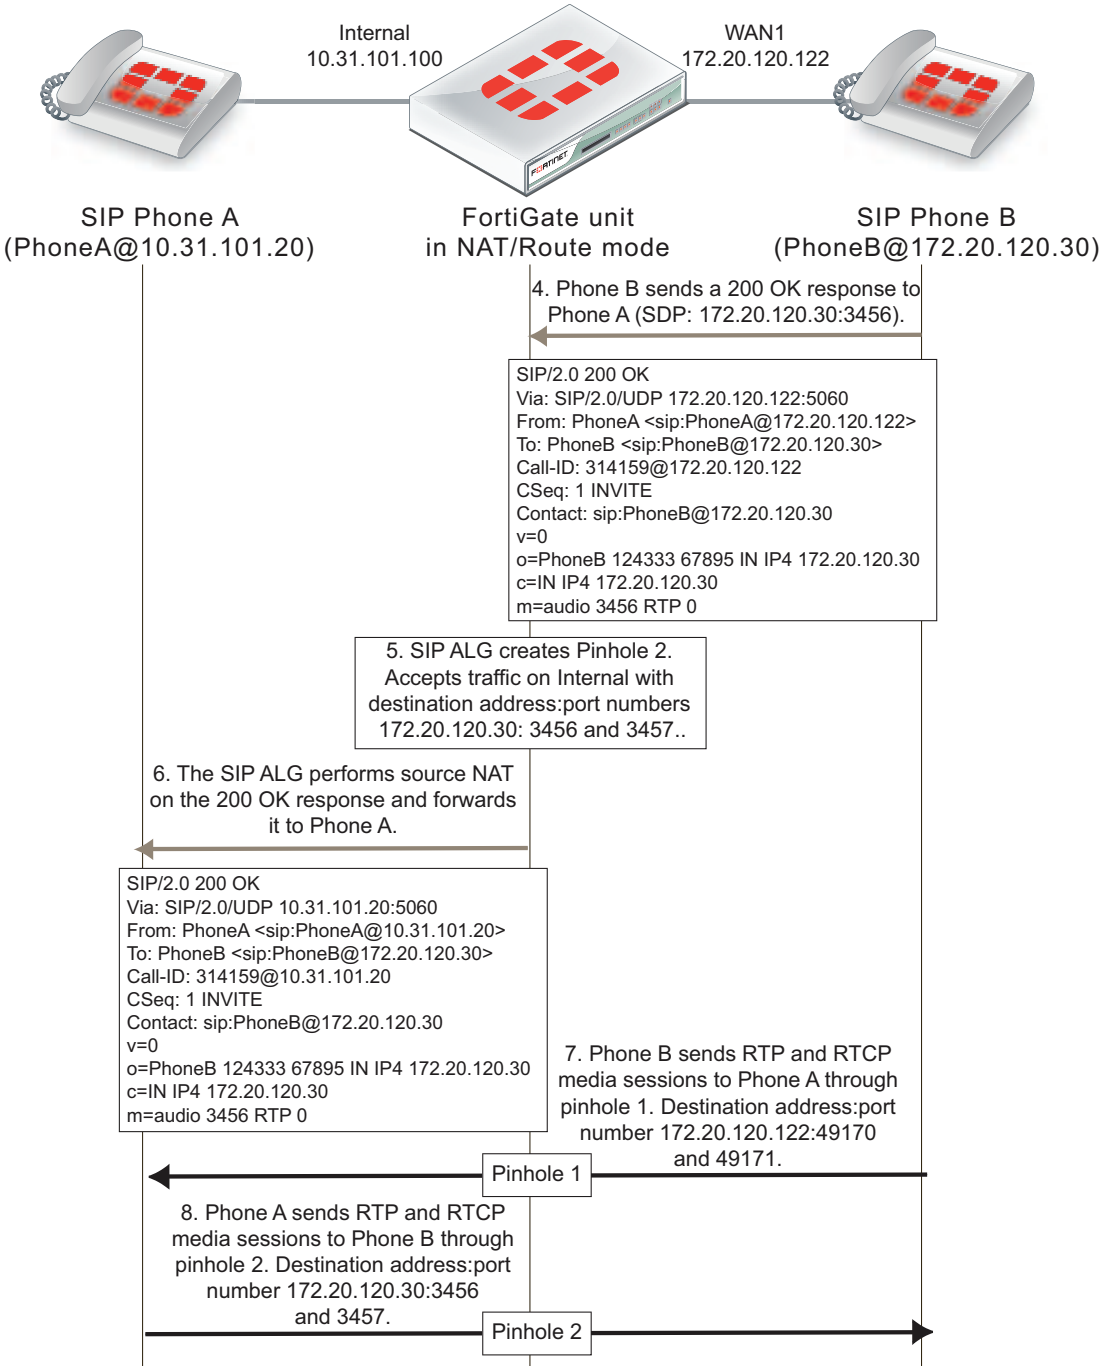
For the replies to SIP packets sent by Phone A to be routable on Phone Bs network, the FortiGate uses source NAT to change their source address to the address of the WAN1 interface. The SIP ALG makes similar changes the source addresses in the SIP headers and SDP profile. For example, the original INVITE request from Phone A includes the address of Phone A (10.31.101.20) in the from header line. After the INVITE request passes through the FortiGate, the address of Phone A in the From SIP header line is translated to 172.20.120.122, the address of the FortiGate WAN1 interface. As a result, Phone B will reply to SIP messages from Phone A using the WAN1 interface IP address.

The FortiGate also opens a pinhole so that it can accept media sessions sent to the WAN1 IP address using the port number in the m= line of the INVITE request and forward them to Phone A after translating the destination address to the IP address of Phone A.

Phone B sends the 200 OK response to the INVITE message to the WAN1 interface. The SDP profile includes the port number that Phone B wants to use for its media stream. The FortiGate forwards 200 OK response to Phone A after translating the addresses in the SIP and SDP lines back to the IP address of Phone A. The SIP ALG also

opens a pinhole on the Internal interface that accepts media stream sessions from Phone A with destination address set to the IP address of Phone B and using the port that Phone B added to the SDP m= line.

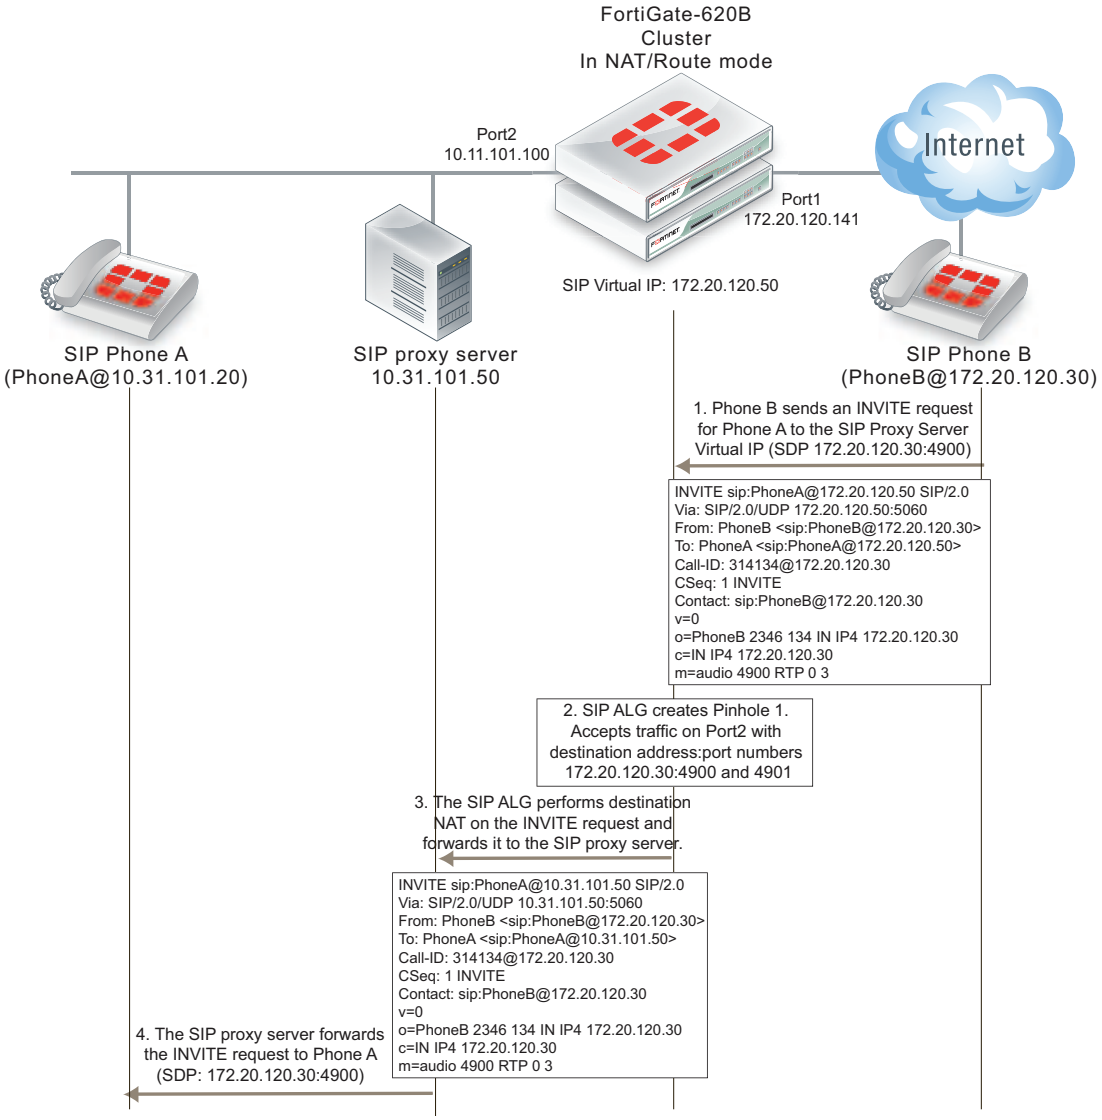
SIP source NAT scenario part 2: 200 OK returned and media streams established



SIP NAT scenario: destination address translation (destination NAT)

The following figures show how the SIP ALG translates addresses in a SIP INVITE message sent from SIP Phone B on the Internet to SIP Phone A on a private network using the SIP proxy server. Because the addresses on the private network are not visible from the Internet, the security policy on the FortiGate that accepts SIP sessions includes a virtual IP. Phone A sends SIP the INVITE message to the virtual IP address. The FortiGate accepts the INVITE message packets and using the virtual IP, translates the destination address of the packet to the IP address of the SIP proxy server and forwards the SIP message to it.

SIP destination NAT scenario part 1: INVITE request sent from Phone B to Phone A



To simplify the diagrams, some SIP messages are not included (for example, the Ringing and ACK response messages) and some SIP header lines and SDP profile lines have been removed from the SIP messages.

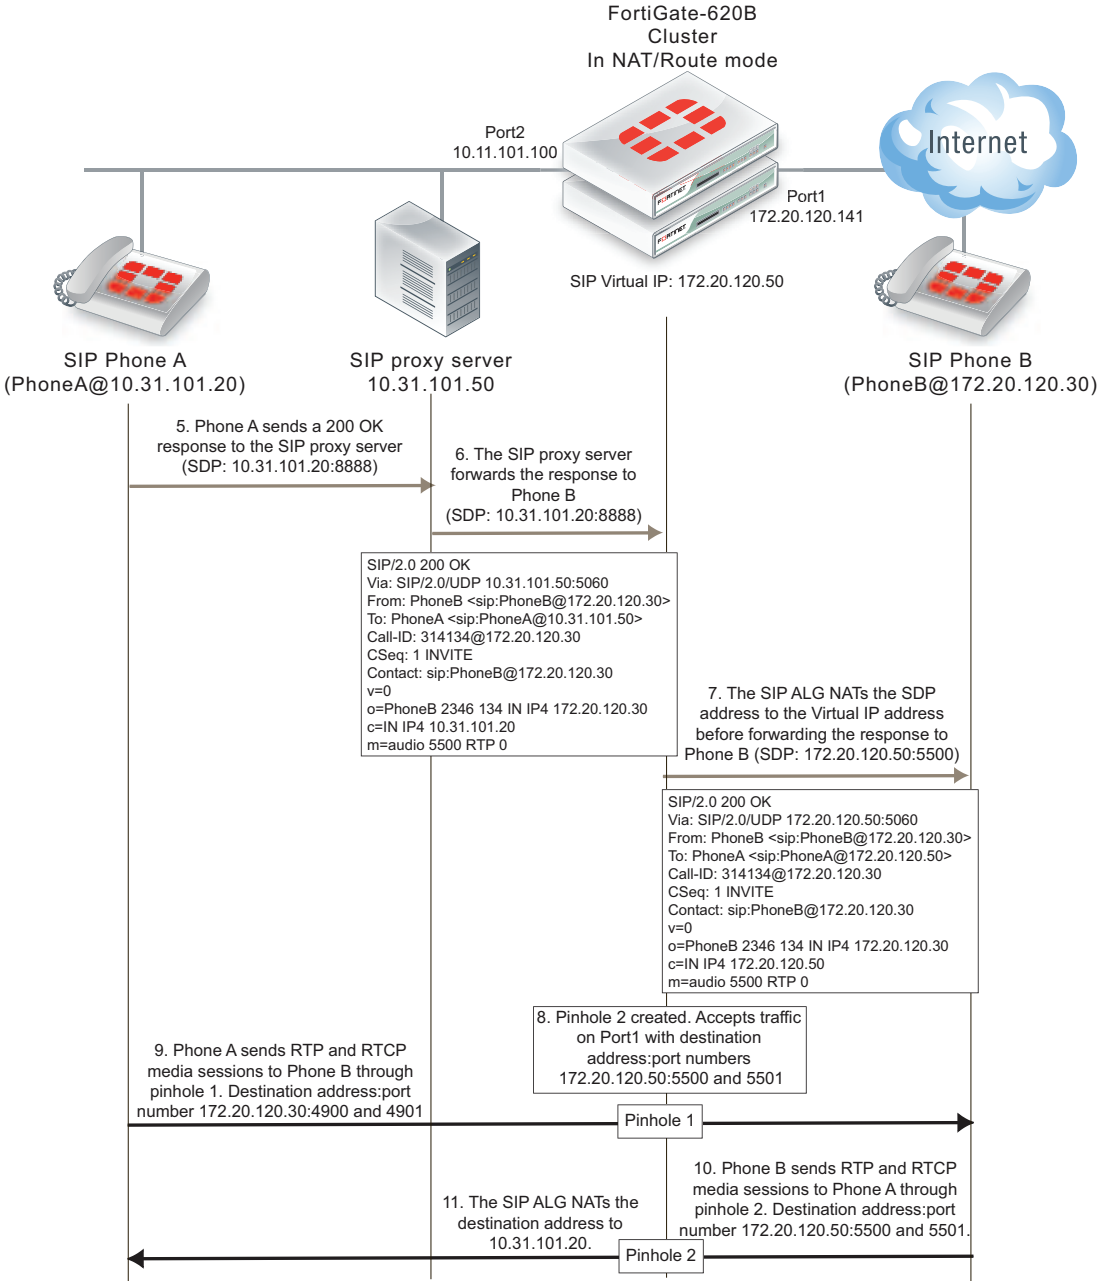
The SIP ALG also translates the destination addresses in the SIP message from the virtual IP address (172.20.120.50) to the SIP proxy server address (10.31.101.50). For this configuration to work, the SIP proxy

server must be able to change the destination addresses for Phone A in the SIP message from the address of the SIP proxy server to the actual address of Phone A.

The SIP ALG also opens a pinhole on the Port2 interface that accepts media sessions from the private network to SIP Phone B using ports 4900 and 4901.

Phone A sends a 200 OK response back to the SIP proxy server. The SIP proxy server forwards the response to Phone B. The FortiGate accepts the 100 OK response. The SIP ALG translates the Phone A addresses back to the SIP proxy server virtual IP address before forwarding the response back to Phone B. The SIP ALG also opens a pinhole using the SIP proxy server virtual IP which is the address in the o= line of the SDP profile and the port number in the m= line of the SDP code.

SIP destination NAT scenario part 2: 200 OK returned to Phone B and media streams established

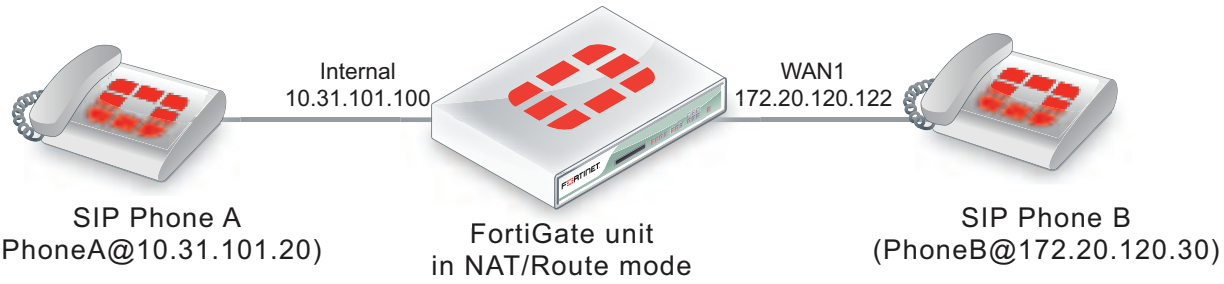


The media stream from Phone A is accepted by pinhole one and forwarded to Phone B. The source address of this media stream is changed to the SIP proxy server virtual IP address. The media stream from Phone B is accepted by pinhole 2 and forwarded to Phone B. The destination address of this media stream is changed to the IP address of Phone A.

SIP NAT configuration example: source address translation (source NAT)

This configuration example shows how to configure the FortiGate to support the source address translation scenario shown below. The FortiGate requires two security policies that accept SIP packets. One to allow SIP Phone A to start a session with SIP Phone B and one to allow SIP Phone B to start a session with SIP Phone A. Both of these policies must include source NAT. In this example the networks are not hidden from each other so destination NAT is not required.

SIP source NAT configuration



General configuration steps

The following general configuration steps are required for this SIP configuration. This example uses the default VoIP profile. The example also includes security policies that specifically allow SIP sessions using UDP port 5060 from Phone A to Phone B and from Phone B to Phone A. In most cases you would have more than two phones so would use more general security policies. Also, you can set the firewall service to ANY to allow traffic other than SIP on UDP port 5060.

1. Add firewall addresses for Phone A and Phone B.
2. Add a security policy that accepts SIP sessions initiated by Phone A and includes the default VoIP profile.
3. Add a security policy that accepts SIP sessions initiated by Phone B and includes the default VoIP profile.

Configuration steps - GUI

To add firewall addresses for the SIP phones

1. Go to **Policy & Objects > Addresses**.
2. Add the following addresses for Phone A and Phone B:

Category	Address
Name	Phone_A
Type	IP/Netmask

Subnet / IP Range	10.31.101.20/255.255.255.255
Interface	Internal

Category	Address
Name	Phone_B
Type	IP/Netmask
Subnet / IP Range	172.20.120.30/255.255.255.255
Interface	wan1

To add security policies to apply the SIP ALG to SIP sessions

1. Go to **Policy & Objects > Policy > IPv4**.
2. Add a security policy to allow Phone A to send SIP request messages to Phone B:

Incoming Interface	internal
Outgoing Interface	wan1
Source	Phone_A
Destination Address	Phone_B
Schedule	always
Service	SIP
Action	ACCEPT

3. Turn on **NAT** and select **Use Outgoing Interface Address**.
4. Turn on **VoIP** and select the **default** VoIP profile.
5. Select **OK**.
6. Add a security policy to allow Phone B to send SIP request messages to Phone A:

Incoming Interface	wan1
Outgoing Interface	internal
Source	Phone_B
Destination Address	Phone_A
Schedule	always
Service	SIP
Action	ACCEPT

7. Turn on **NAT** and select **Use Outgoing Interface Address**.
8. Turn on **VoIP** and select the **default** VoIP profile.
9. Select **OK**.

Configuration steps - CLI

To add firewall addresses for Phone A and Phone B and security policies to apply the SIP ALG to SIP sessions

1. Enter the following command to add firewall addresses for Phone A and Phone B.

```
config firewall address
   edit Phone_A
      set associated interface internal
      set type ipmask
      set subnet 10.31.101.20 255.255.255.255
   next
   edit Phone_B
      set associated interface wan1
      set type ipmask
      set subnet 172.20.120.30 255.255.255.255
   end
```

2. Enter the following command to add security policies to allow Phone A to send SIP request messages to Phone B and Phone B to send SIP request messages to Phone A.

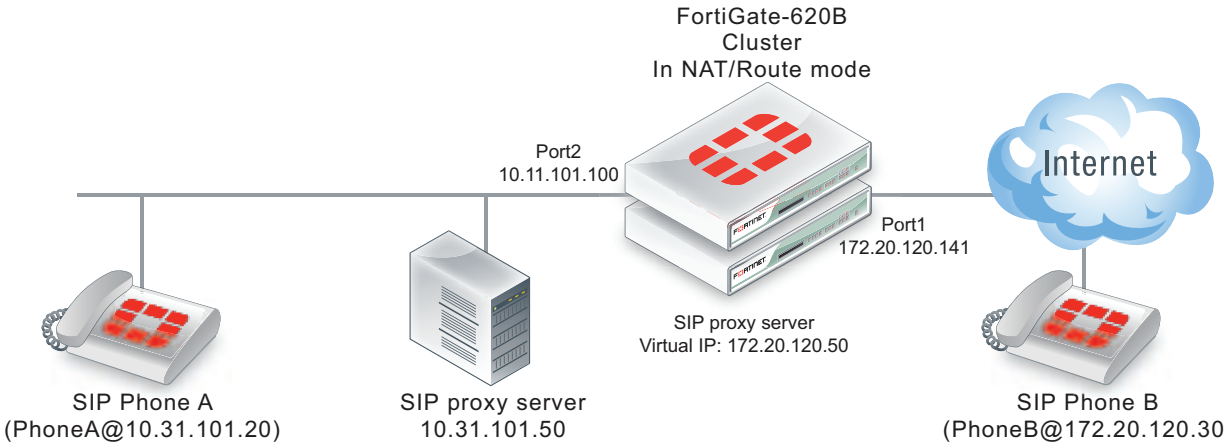
```
config firewall policy
   edit 0
      set srcintf internal
      set dstintf wan1
      set srcaddr Phone_A
      set dstaddr Phone_B
      set action accept
      set schedule always
      set service SIP
      set nat enable
      set utm-status enable
      set voip-profile default
   next
   edit 0
      set srcintf wan1
      set dstintf internal
      set srcaddr Phone_B
      set dstaddr Phone_A
      set action accept
      set schedule always
      set service SIP
      set nat enable
      set utm-status enable
      set voip-profile default
   end
```

SIP NAT configuration example: destination address translation (destination NAT)

This configuration example shows how to configure the FortiGate to support the destination address translation scenario shown in the figure below. The FortiGate requires two SIP security policies:

- A destination NAT security policy that allows SIP messages to be sent from the Internet to the private network. This policy must include destination NAT because the addresses on the private network are not routable on the Internet.
- A source NAT security policy that allows SIP messages to be sent from the private network to the Internet.

SIP destination NAT scenario part two: 200 OK returned to Phone B and media streams established



General configuration steps

The following general configuration steps are required for this destination NAT SIP configuration. This example uses the default VoIP profile.

1. Add the SIP proxy server firewall virtual IP.
2. Add a firewall address for the SIP proxy server on the private network.
3. Add a destination NAT security policy that accepts SIP sessions from the Internet destined for the SIP proxy server virtual IP and translates the destination address to the IP address of the SIP proxy server on the private network.
4. Add a security policy that accepts SIP sessions initiated by the SIP proxy server and destined for the Internet.

Configuration steps - GUI

To add the SIP proxy server firewall virtual IP

1. Go to **Policy & Objects > Virtual IPs**.
2. Add the following SIP proxy server virtual IP.

VIP Type	IPv4
Name	SIP_Proxy_VIP
Interface	port1
Type	Static NAT
External IP Address/Range	172.20.120.50
Mapped IP Address/Range	10.31.101.50

To add a firewall address for the SIP proxy server

1. Go to **Policy & Objects > Addresses**.
2. Add the following for the SIP proxy server:

Address Name	SIP_Proxy_Server
Type	Subnet
Subnet/IP Range	10.31.101.50/255.255.255.255
Interface	port2

To add the security policies

1. Go to **Policy & Objects > IPv4 Policy**.
2. Add a destination NAT security policy that includes the SIP proxy server virtual IP that allows Phone B (and other SIP phones on the Internet) to send SIP request messages to the SIP proxy server.

Incoming Interface	port1
Outgoing Interface	port2
Source	all
Destination Address	SIP_Proxy_VIP
Schedule	always
Service	SIP
Action	ACCEPT

3. Turn on **NAT** and select **Use Outgoing Interface Address**.
4. Turn on **VoIP** and select the **default** VoIP profile.
5. Select **OK**.
6. Add a source NAT security policy to allow the SIP proxy server to send SIP request messages to Phone B and the Internet:

Incoming Interface	port2
Destination Address	all
Source	SIP_Proxy_Server
Schedule	always
Service	SIP
Action	ACCEPT

7. Turn on **NAT** and select **Use OutgingInterface Address**.
8. Turn on **VoIP** and select the **default** VoIP profile.

9. Select **OK**.

Configuration steps - CLI

To add the SIP proxy server firewall virtual IP and firewall address

1. Enter the following command to add the SIP proxy server firewall virtual IP.

```
config firewall vip
   edit SIP_Proxy_VIP
      set type static-nat
      set extip 172.20.120.50
      set mappedip 10.31.101.50
      set extintf port1
   end
```

2. Enter the following command to add the SIP proxy server firewall address.

```
config firewall address
   edit SIP_Proxy_Server
      set associated interface port2
      set type ipmask
      set subnet 10.31.101.50 255.255.255.255
   end
```

To add security policies

1. Enter the following command to add a destination NAT security policy that includes the SIP proxy server virtual IP that allows Phone B (and other SIP phones on the Internet) to send SIP request messages to the SIP proxy server.

```
config firewall policy
   edit 0
      set srcintf port1
      set dstintf port2
      set srcaddr all
      set dstaddr SIP_Proxy_VIP
      set action accept
      set schedule always
      set service SIP
      set nat enable
      set utm-status enable
      set voip-profile default
   end
```

2. Enter the following command to add a source NAT security policy to allow the SIP proxy server to send SIP request messages to Phone B and the Internet:

```
config firewall policy
   edit 0
      set srcintf port2
      set dstintf port1
      set srcaddr SIP_Proxy_Server
      set dstaddr all
      set action accept
      set schedule always
      set service SIP
      set nat enable
      set utm-status enable
      set voip-profile default
```

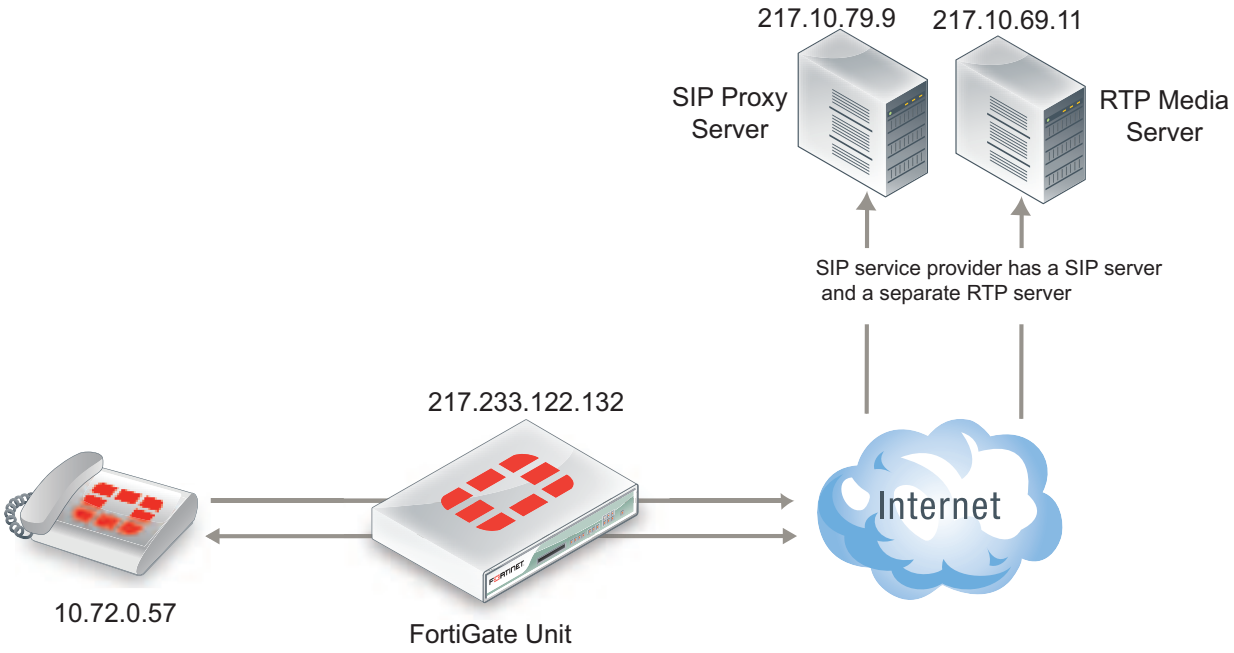
```
end
```

SIP and RTP source NAT

In the source NAT scenario shown below, a SIP phone connects to the Internet through a FortiGate with and IP address configured using PPPoE. The SIP ALG translates all private IPs in the SIP contact header into public IPs.

You need to configure an internal to external SIP security policy with NAT selected, and include a VoIP profile with SIP enabled.

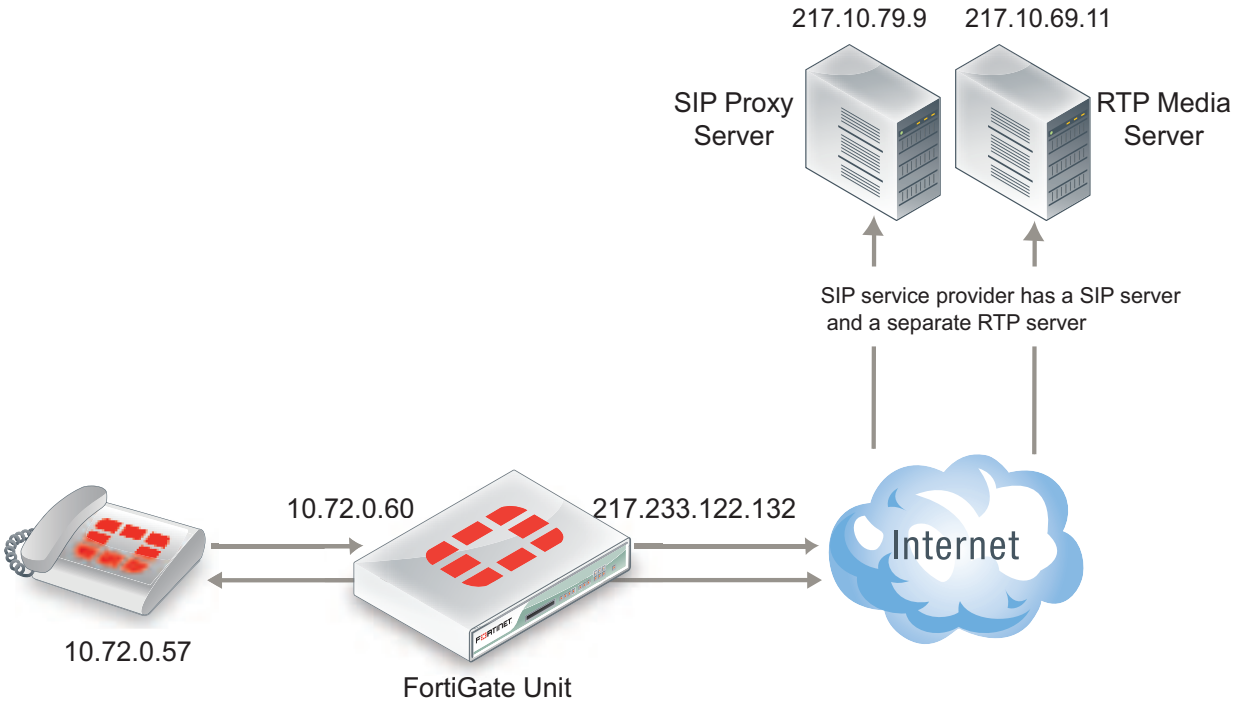
SIP source NAT



SIP and RTP destination NAT

In the following destination NAT scenario, a SIP phone can connect through the FortiGate to private IP address using a firewall virtual IP (VIP). The SIP ALG translates the SIP contact header to the IP of the real SIP proxy server located on the Internet.

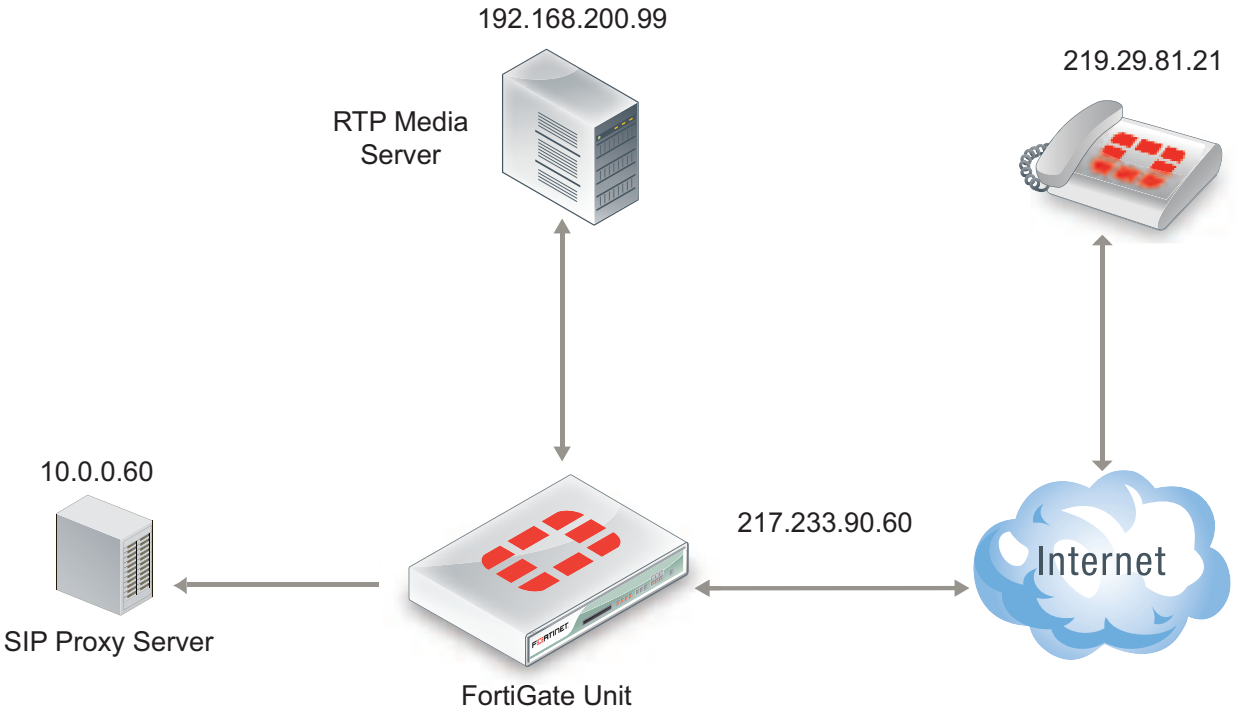
SIP destination NAT



In the scenario, shown above, the SIP phone connects to a VIP (10.72.0.60). The SIP ALG translates the SIP contact header to 217.10.79.9, opens RTP pinholes, and manages NAT.

The FortiGate also supports a variation of this scenario where the RTP media server's IP address is hidden on a private network or DMZ.

SIP destination NAT-RTP media server hidden



In the scenario shown above, a SIP phone connects to the Internet. The VoIP service provider only publishes a single public IP. The FortiGate is configured with a firewall VIP. The SIP phone connects to the FortiGate (217.233.90.60) and using the VIP the FortiGate translates the SIP contact header to the SIP proxy server IP address (10.0.0.60). The SIP proxy server changes the SIP/SDP connection information (which tells the SIP phone which RTP media server IP it should contact) also to 217.233.90.60.

Source NAT with an IP pool

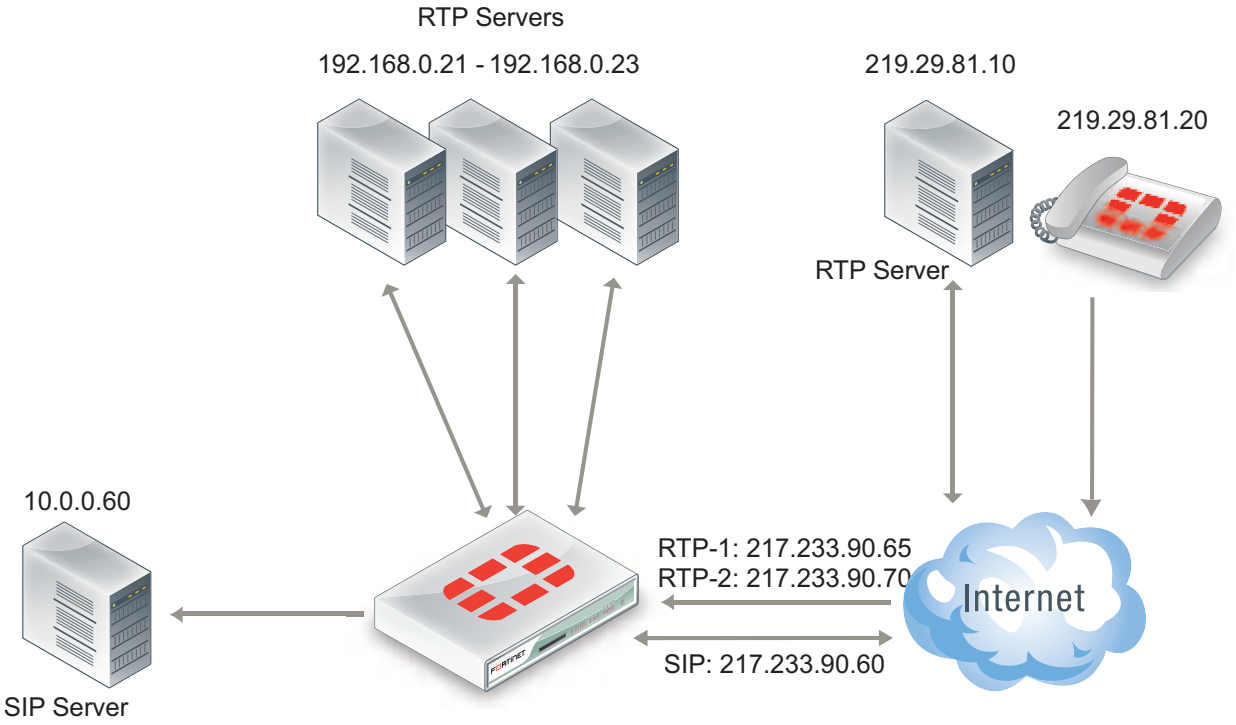
You can choose **NAT** with the **Dynamic IP Pool** option when configuring a security policy if the source IP of the SIP packets is different from the interface IP. The FortiGate ALG interprets this configuration and translates the SIP header accordingly.

This configuration also applies to destination NAT.

Different source and destination NAT for SIP and RTP

This is a more complex scenario that a SIP service provider may use. It can also be deployed in large-scale SIP environments where RTP has to be processed by the FortiGate and the RTP server IP has to be translated differently than the SIP serverIP.

Different source and destination NAT for SIP and RTP



In this scenario, shown above, assume there is a SIP server and a separate media gateway. The SIP server is configured so that the SIP phone (219.29.81.20) will connect to 217.233.90.60. The media gateway (RTP server: 219.29.81.10) will connect to 217.233.90.65.

What happens is as follows:

1. The SIP phone connects to the SIP VIP. The FortiGate ALG translates the SIP contact header to the SIP server: 219.29.81.20 > 217.233.90.60 (> 10.0.0.60).
2. The SIP server carries out RTP to 217.233.90.65.
3. The FortiGate ALG opens pinholes, assuming that it knows the ports to be opened.
4. RTP is sent to the RTP-VIP (217.233.90.65.) The FortiGate ALG translates the SIP contact header to 192.168.0.21.

NAT with IP address conservation

In a source or destination NAT security policy that accepts SIP sessions, you can configure the SIP ALG or the SIP session helper to preserve the original source IP address of the SIP message in the i= line of the SDP profile. NAT with IP address conservation (also called SIP NAT tracing) changes the contents of SIP messages by adding the source IP address of the originator of the message into the SDP i= line of the SIP message. The SDP i= line is used for free-form text. However, if your SIP server can retrieve information from the SDP i= line, it can be useful for keeping a record of the source IP address of the originator of a SIP message when operating in a NAT environment. You can use this feature for billing purposes by extracting the IP address of the originator of the message.

Configuring SIP IP address conservation for the SIP ALG

You can use the following command to enable or disable SIP IP address conservation in a VoIP profile for the SIP ALG. SIP IP address conservation is enabled by default in a VoIP profile.

```
config voip profile
   edit VoIP_Pro_1
      config sip
         set nat-trace disable
      end
   end
```

If the SIP message does not include an i= line and if the original source IP address of the traffic (before NAT) was 10.31.101.20 then the FortiGate would add the following i= line.

```
i=(o=IN IP4 10.31.101.20)
```

You can also use the `preserve-override` option to configure the SIP ALG to either add the original o= line to the end of the i= line or replace the i= line in the original message with a new i= line in the same form as above for adding a new i= line.

By default, `preserver-override` is disabled and the SIP ALG adds the original o= line to the end of the original i= line. Use the following command to configure the SIP ALG to replace the original i= line:

```
config voip profile
   edit VoIP_Pro_1
      config sip
         set preserve-override enable
      end
   end
```

Configuring SIP IP address conservation for the SIP session helper

You can use the following command to enable or disable SIP IP address conservation for the SIP session helper. IP address conservation is enabled by default for the SIP session helper.

```
config system settings
   set sip-nat-trace disable
end
```

If the SIP message does not include an i= line and if the original source IP address of the traffic (before NAT) was 10.31.101.20 then the FortiGate would add the following i= line.

```
i=(o=IN IP4 10.31.101.20)
```

Controlling how the SIP ALG NATs SIP contact header line addresses

You can enable `contact-fixup` so that the SIP ALG performs normal SIP NAT translation to SIP contact headers as SIP messages pass through the FortiGate.

Disable `contact-fixup` if you do not want the SIP ALG to perform normal NAT translation of the SIP contact header if a Record-Route header is also available. If `contact-fixup` is disabled, the FortiGate ALG does the following with contact headers:

- For Contact in Requests, if a Record-Route header is present and the request comes from the external network, the SIP Contact header is not translated.
- For Contact in Responses, if a Record-Route header is present and the response comes from the external network, the SIP Contact header is not translated.

If `contact-fixup` is disabled, the SIP ALG must be able to identify the external network. To identify the external network, you must use the `config system interface` command to set the `external` keyword to `enable` for the interface that is connected to the external network.

Enter the following command to perform normal NAT translation of the SIP contact header:

```
config voip profile
   edit VoIP_Pro_1
      config sip
         set contact-fixup enable
      end
   end
```

Controlling NAT for addresses in SDP lines

You can use the `no-sdp-fixup` option to control whether the FortiGate performs NAT on addresses in SDP lines in the SIP message body.

The `no-sdp-fixup` option is disabled by default and the FortiGate performs NAT on addresses in SDP lines. Enable this option if you don't want the FortiGate to perform NAT on the addresses in SDP lines.

```
config voip profile
   edit VoIP_Pro_1
      config sip
         set no-sdp-fixup enable
      end
   end
```

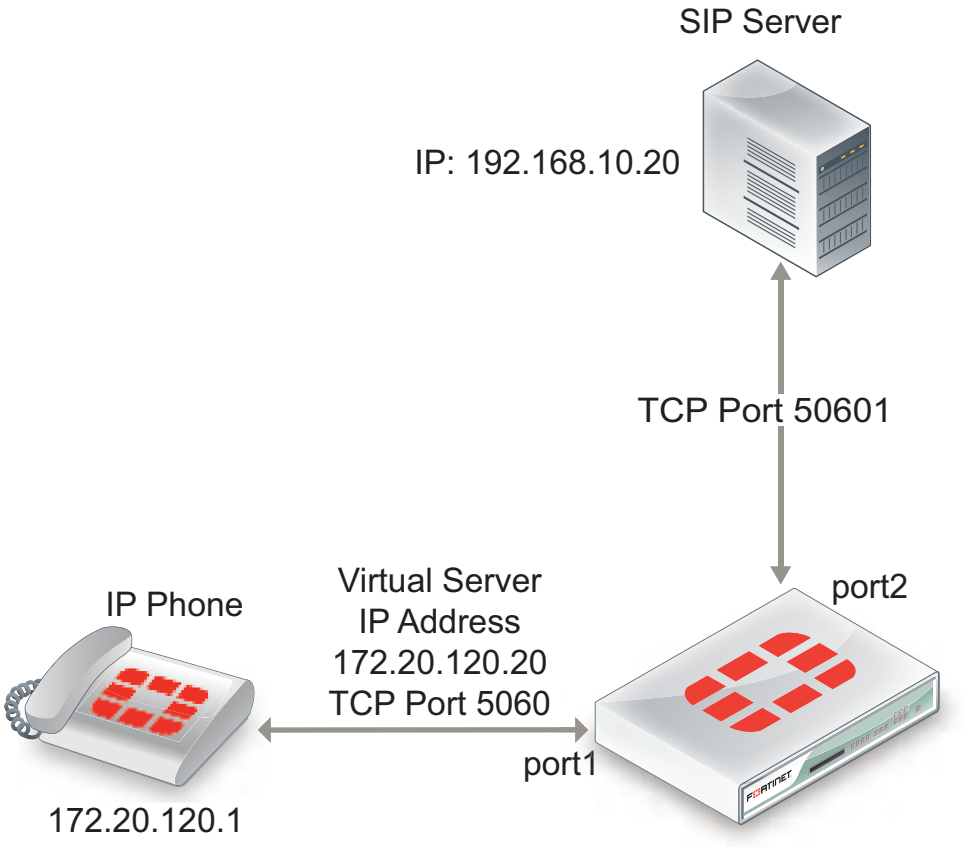
Translating SIP session destination ports

Using port forwarding virtual IPs you can change the destination port of SIP sessions as they pass through the FortiGate.

Translating SIP sessions to a different destination port

To configure translating SIP sessions to a different destination port you must add a static NAT virtual IP that translates tie SIP destination port to another port destination. In the example the destination port is translated from 5060 to 50601. This configuration can be used if SIP sessions uses different destination ports on different networks.

Example translating SIP sessions to a different destination port



To translate SIP sessions to a different destination port

1. Add the static NAT virtual IP.

   This virtual IP forwards traffic received at the port1 interface for IP address 172.20.120.20 and destination port 5060 to the SIP server at IP address 192.168.10.20 with destination port 5061.

```
config firewall vip
   edit "sip_port_trans_vip"
      set type static-nat
      set portforward enable
      set protocol tcp
      set extip 172.20.120.20
      set extport 5060
      set extintf "port1"
      set mappedip 192.168.10.20
      set mappedport 50601
      set comment "Translate SIP destination port"
   end
```

2. Add a security policy that includes the virtual IP and the default VoIP profile.

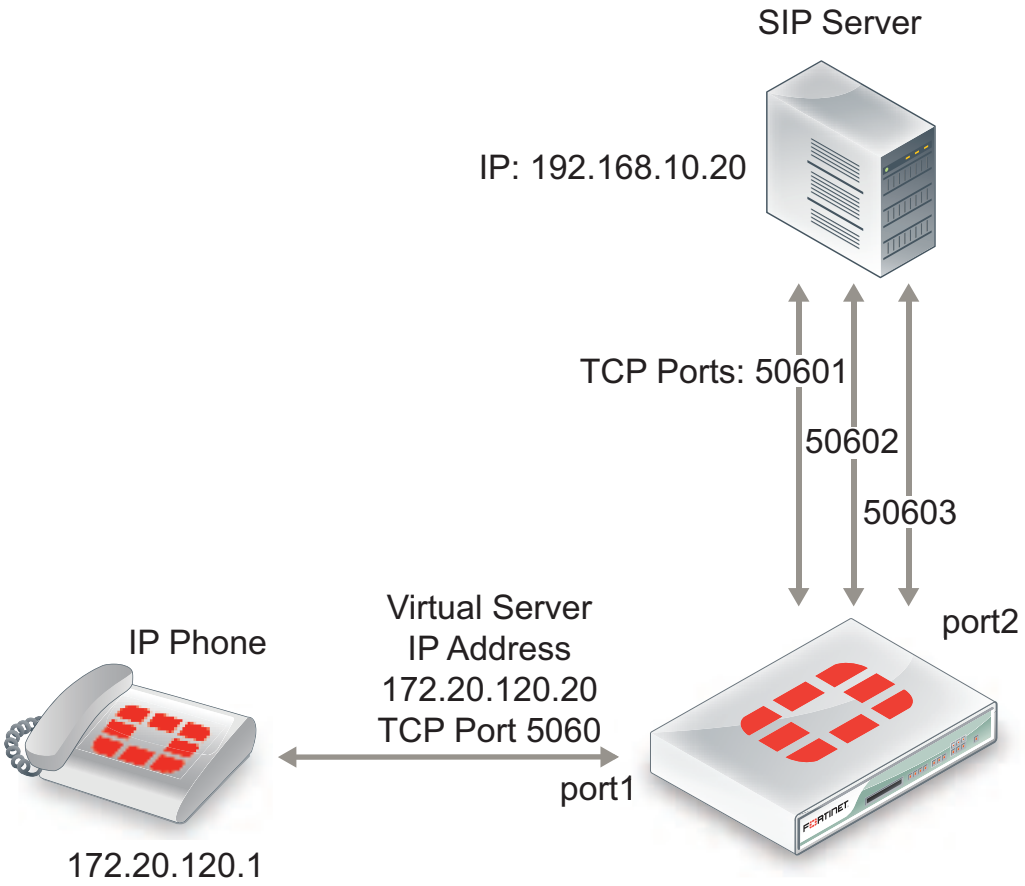
```
config firewall policy
   edit 1
      set srcintf "port1"
      set dstintf "port2"
      set srcaddr "all"
```

```
    set dstaddr "sip_port_trans_vip"
    set action accept
    set schedule "always"
    set service "ANY"
    set utm-status enable
    set profile-protocol-options default
    set comments "Translate SIP destination port"
end
```

Translating SIP sessions to multiple destination ports

You can use a load balance virtual IP to translate SIP session destination ports to a range of destination ports. In this example the destination port is translated from 5060 to the range 50601 to 50603. This configuration can be used if your SIP server is configured to receive SIP traffic on multiple ports.

Example translating SIP traffic to multiple destination ports



To translated SIP sessions to multiple destination ports

1. Add the load balance virtual IP.

   This virtual IP forwards traffic received at the port1 interface for IP address 172.20.120.20 and destination port 5060 to the SIP server at IP address 192.168.10.20 with destination port 5061.

   ```
   config firewall vip
   ```

```
edit "sip_port_ldbl_vip"
   set type load-balance
   set portforward enable
   set protocol tcp
   set extip 172.20.120.20
   set extport 5060
   set extintf "port1"
   set mappedip 192.168.10.20
   set mappedport 50601-50603
   set comment "Translate SIP destination port range"
end
```

2. Add a security policy that includes the virtual IP and VoIP profile.

```
config firewall policy
   edit 1
      set srcintf "port1"
      set dstintf "port2"
      set srcaddr "all"
      set dstaddr "sip_port_ldbl_vip"
      set action accept
      set schedule "always"
      set service "ANY"
      set utm-status enable
      set voip-profile default
      set comments "Translate SIP destination port"
   end
```

Adding the original IP address and port to the SIP message header after NAT

In some cases your SIP configuration may require that the original IP address and port from the SIP contact request is kept after NAT. For example, the original SIP contact request could include the following:

```
Contact: <sip:0150302438@172.20.120.110:5060>;
```

After the packet goes through the FortiGate and NAT is performed, the contact request could normally look like the following (the IP address translated to a different IP address and the port to a different port):

```
Contact: <sip:0150302438@10.10.10.21:33608>;
```

You can enable `register-contact-trace` in a VoIP profile to have the SIP ALG add the original IP address and port in the following format:

```
Contact: <sip:0150302438@<nated-ip>:<nated-port>;o=<original-ip>: <original-port>>;
```

So the contact line after NAT could look like the following:

```
Contact: <sip:0150302438@10.10.10.21:33608;o=172.20.120.110:5060>;
```

Enter the following command to enable keeping the original IP address and port:

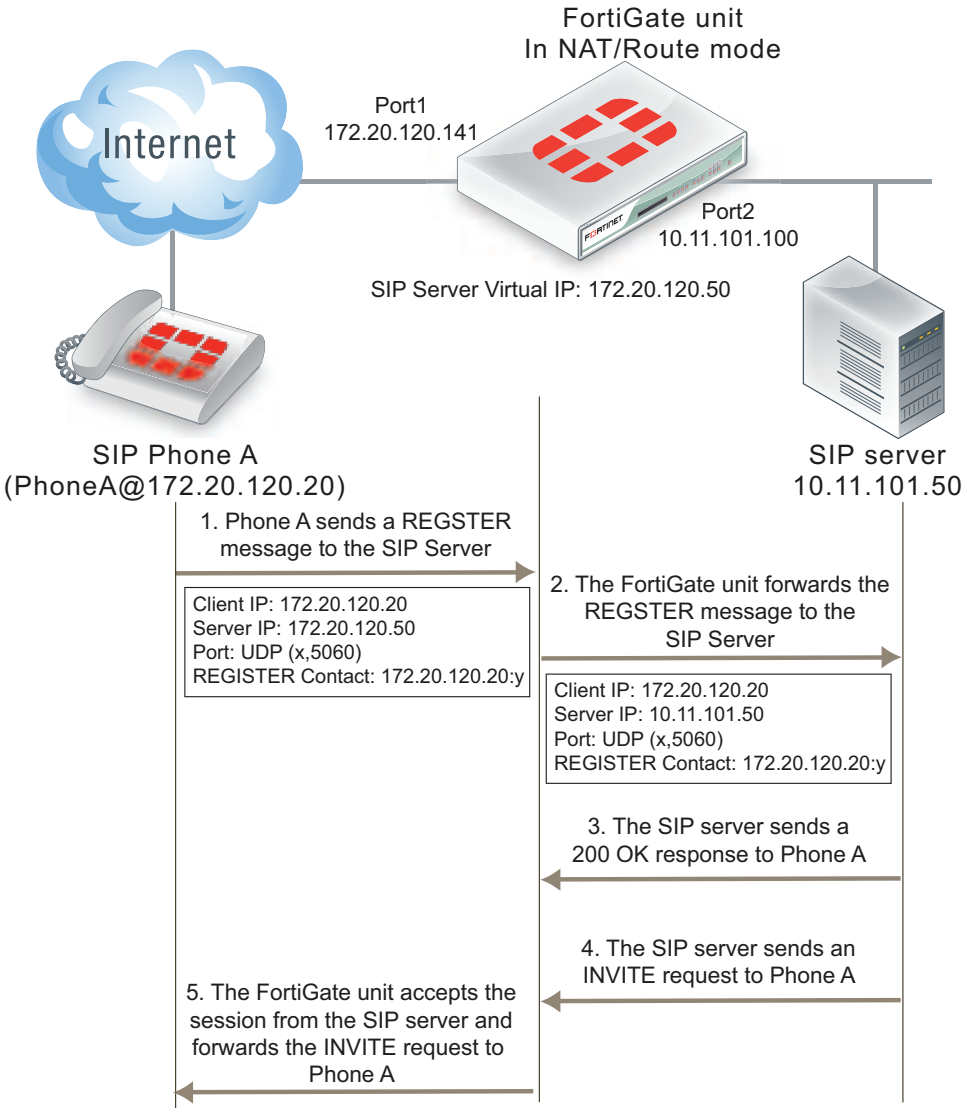
```
config voip profile
   edit Profile_name
      config sip
         set register-contract-trace enable
   end
```

Enhancing SIP pinhole security

You can use the `strict-register` option in a SIP VoIP profile to open smaller pinholes.

As shown below, when FortiGate is protecting a SIP server on a private network, the FortiGate does not have to open a pinhole for the SIP server to send INVITE requests to a SIP Phone on the Internet after the SIP Phone has registered with the server.

FortiGate protecting a SIP server on a private network



In the example, a client (SIP Phone A) sends a REGISTER request to the SIP server with the following information:

```
Client IP: 10.31.101.20
Server IP: 10.21.101.50
Port: UDP (x,5060)
REGISTER Contact: 10.31.101.20:y
```

Where `x` and `y` are ports chosen by Phone A.

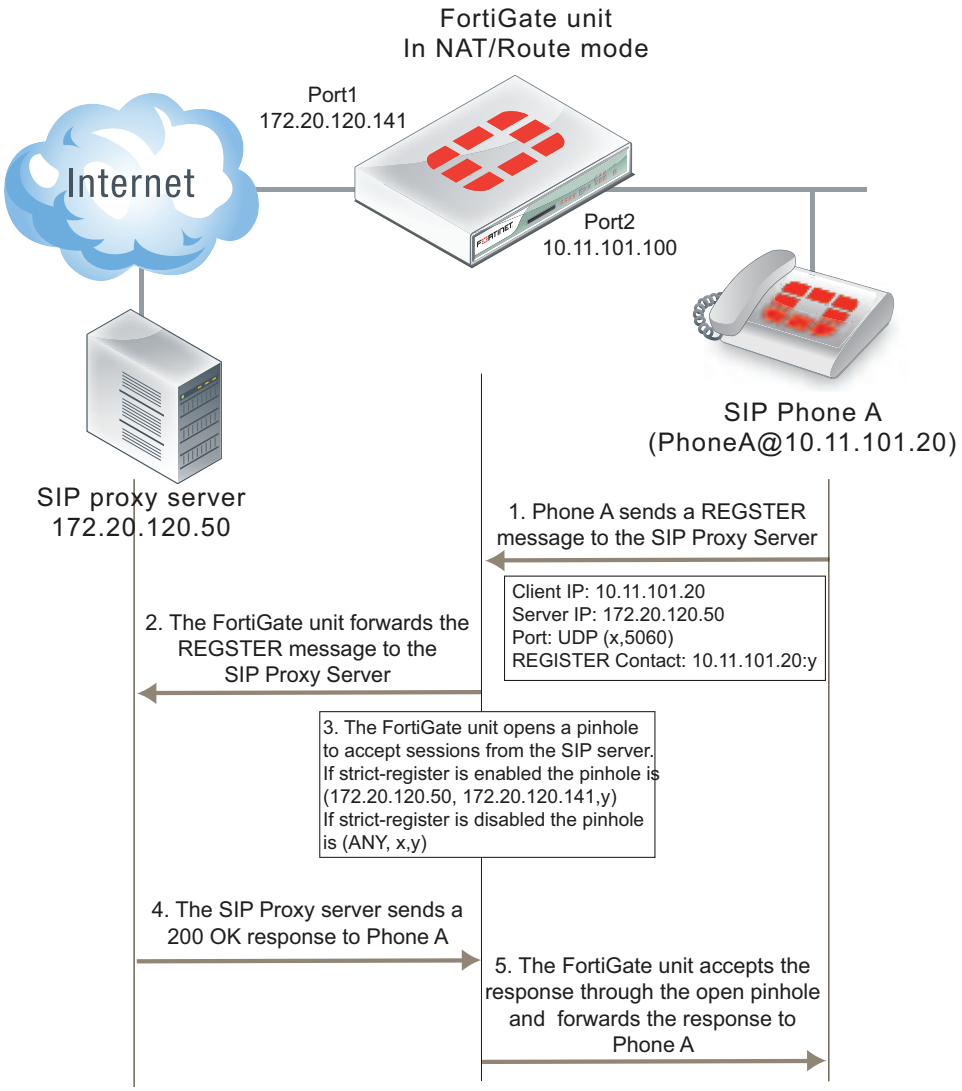
As soon as the server sends the 200 OK reply it can forward INVITE requests from other SIP phones to SIP Phone A. If the SIP proxy server uses the information in the REGISTER message received from SIP Phone A the INVITE messages sent to Phone A f will only get through the FortiGate if an policy has been added to allow the server to

send traffic from the private network to the Internet. Or the SIP ALG must open a pinhole to allow traffic from the server to the Internet. In most cases the FortiGate is protecting the SIP server so there is no reason not to add a security policy to all the SIP server to send outbound traffic to the Internet.

In a typical SOHO scenario, shown below, SIP Phone A is being protected from the Internet by a FortiGate. In most cases the FortiGate would not allow incoming traffic from the Internet to reach the private network. So the only way that an INVITE request from the SIP server can reach SIP Phone A is if the SIP ALG creates an incoming pinhole. All pinholes have three attributes:

```
(source address, destination address, destination port)
```

SOHO configuration, FortiGate protecting a network with SIP phones



The more specific a pinhole is the more secure it is because it will accept less traffic. In this situation, the pinhole would be more secure if it only accepted traffic from the SIP server. This is what happens if `strict-register` is enabled in the VoIP profile that accepts the REGISTER request from Phone A.

```
(SIP server IP address, client IP address, destination port)
```

If `strict-register` is disabled (the default configuration) the pinhole is set up with the following attributes

```
(ANY IP address, client IP address, destination port)
```

This pinhole allows connections through the FortiGate from ANY source address which is a much bigger and less secure pinhole. In most similar network configurations you should enable `strict-register` to improve pinhole security.

Enabling `strict-register` can cause problems when the SIP registrar and SIP proxy server are separate entities with separate IP addresses.

Enter the following command to enable `strict-register` in a VoIP profile.

```
config voip profile
   edit Profile_name
      config sip
         set strict-register enable
   end
```

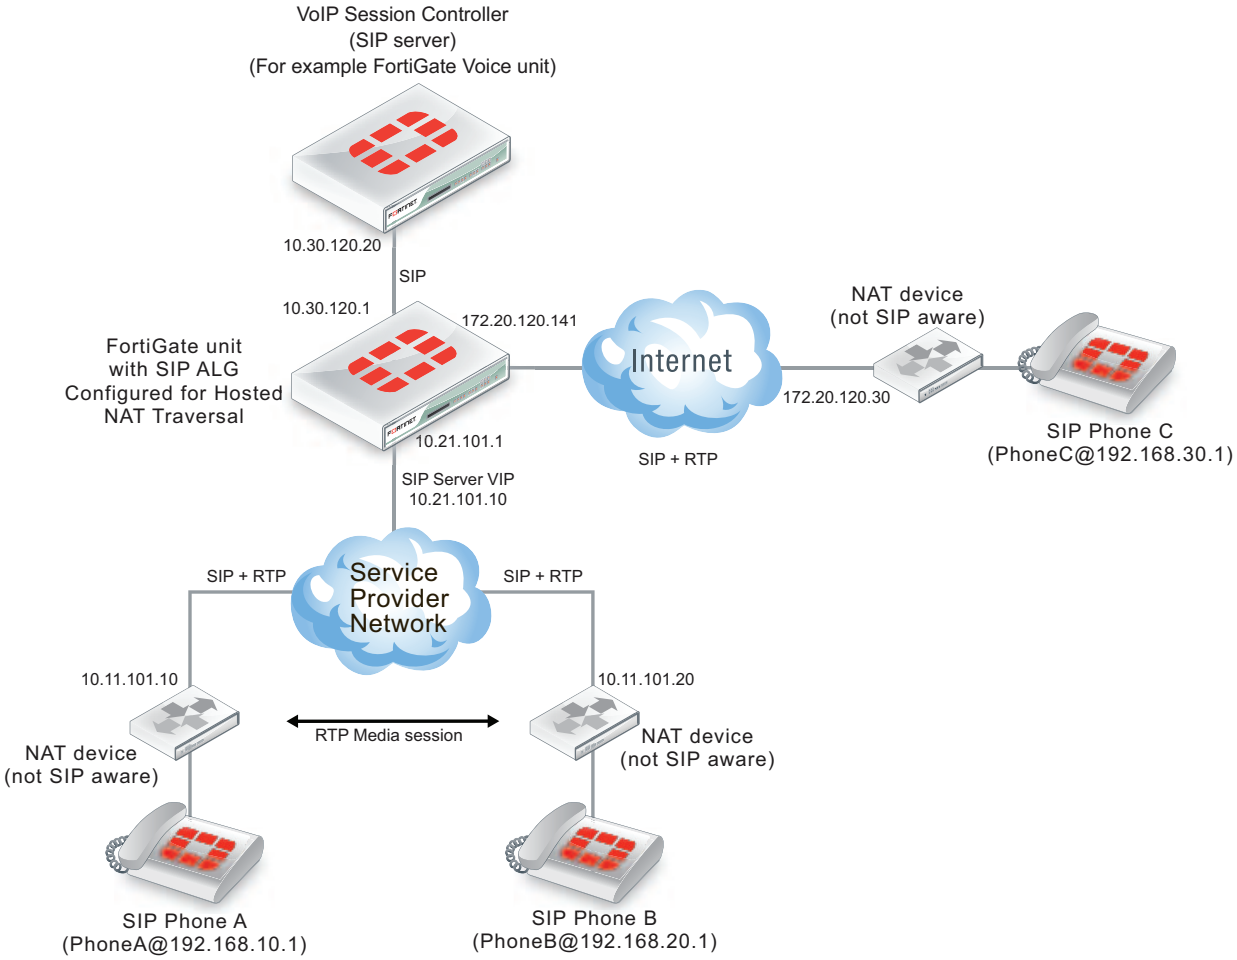
Hosted NAT traversal

With the increase in the use of VoIP and other media traffic over the Internet, service provider network administrators must defend their networks from threats while allowing voice and multimedia traffic to flow transparently between users and servers and among users. A common scenario could involve providing SIP VoIP services for customers with SIP phones installed behind NAT devices that are not SIP aware. NAT devices that are not SIP aware cannot translate IP addresses in SIP headers and SDP lines in SIP packets but can and do perform source NAT on the source or addresses of the packets. In this scenario the user's SIP phones would communicate with a SIP proxy server to set up calls between SIP phones. Once the calls are set up RTP packets would be communicated directly between the phones through each user's NAT device.

The problem with this configuration is that the SIP headers and SDP lines in the SIP packets sent from the phones and received by the SIP proxy server would contain the private network addresses of the VoIP phones that would not be routable on the service provider network or on the Internet. One solution could be to for each customer to install and configure SIP aware NAT devices. If this is not possible, another solution requires implement hosted NAT traversal.

In a hosted NAT traversal (HNT) configuration, a FortiGate is installed between the NAT device and the SIP proxy server and configured with a VoIP profile that enables SIP hosted NAT traversal. Security policies that include the VoIP profile also support destination NAT using a firewall virtual IP. When the SIP phones connect to the SIP server IP address the security policy accepts the SIP packets, the virtual IP translates the destination addresses of the packets to the SIP server IP address, and the SIP ALG NAT traversal configuration translates the source IP addresses on the SIP headers and SDP lines to the source address of the SIP packets (which would be the external IP address of the NAT devices). The SIP server then sees the SIP phone IP address as the external IP address of the NAT device. As a result SIP and RTP media sessions are established using the external IP addresses of the NAT devices instead of the actual IP addresses of the SIP phones.

FortiGate SIP Hosted NAT Traversal configuration



Configuration example: Hosted NAT traversal for calls between SIP Phone A and SIP Phone B

The following address translation takes place to allow a SIP call from SIP Phone A to SIP Phone B in the above diagram.

1. SIP Phone A sends a SIP Invite message to the SIP server. Packet source IP address: 192.168.10.1, destination IP address: 10.21.101.10.
2. The SIP packets are received by the NAT device which translates the source address of the SIP packets from 192.168.10.1 to 10.11.101.20.
3. The SIP packets are received by the FortiGate which translates the packet destination IP address to 10.30 120.20. The SIP ALG also translates the IP address of the SIP phone in the SIP header and SDP lines from 192.168.10.1 to 10.11.101.20.
4. The SIP server accepts the Invite message and forwards it to SIP Phone B at IP address10.11.101.20. The SIP server has this address for SIP Phone B because SIP packets from SIP Phone B have also been translated using the hosted NAT traversal configuration of the SIP ALG.
5. When the SIP call is established, the RTP session is between 10.11.101.10 and 10.11.101.20 and does not pass through the FortiGate. The NAT devices translated the destination address of the RTP packets to the private IP addresses of the SIP phones.

General configuration steps

The following general configuration steps are required for this destination NAT SIP configuration. This example uses the default VoIP profile.

1. Add a VoIP profile that enables hosted NAT translation.
2. Add a SIP proxy server firewall virtual IP.
3. Add a firewall address for the SIP proxy server on the private network.
4. Add a destination NAT security policy that accepts SIP sessions from the Internet destined for the SIP proxy server virtual IP and translates the destination address to the IP address of the SIP proxy server on the private network.
5. Add a security policy that accepts SIP sessions initiated by the SIP proxy server and destined for the Internet.

Configuration steps - GUI

To add the SIP proxy server firewall virtual IP

1. Go to **Policy & Objects > Virtual IPs.**
2. Add the SIP proxy server virtual IP.

Name	SIP_Proxy_VIP
External Interface	port1
Type	Static NAT
External IP Address/Range	172.20.120.50
Mapped IP Address/Range	10.31.101.50

To add a firewall address for the SIP proxy server

1. Go to **Policy & Objects > Addresses**.
2. Add the following for the SIP proxy server:

Category	Address
Name	SIP_Proxy_Server
Type	Subnet
Subnet / IP Range	10.31.101.50/255.255.255.255
Interface	port2

To add the security policies

1. Go to **Policy & Objects > IPv4 Policy**.
2. Add a destination NAT security policy that includes the SIP proxy server virtual IP that allows Phone B (and other SIP phones on the Internet) to send SIP request messages to the SIP proxy server.

Incoming Interface	port1
Outgoing Interface	port2
Source	all
Destination Address	SIP_Proxy_VIP
Schedule	always
Service	SIP
Action	ACCEPT

3. TUrn on **NAT** and select **Use Outgoing Interface Address**.
4. Turn on **VoIP** and select the **default** VoIP profile.
5. Select **OK**.
6. Add a source NAT security policy to allow the SIP proxy server to send SIP request messages to Phone B and the Internet:

Incoming Interface	port2
Outgoing Interface	port1
Source	SIP_Proxy_Server
Destination Address	all
Schedule	always
Service	SIP
Action	ACCEPT

7. Tuen on **NAT** and select **Use Outgoing Interface Address**.
8. Turn on **VoIP** and select the **default** VoIP profile.
9. Select **OK**.

Configuration steps - CLI

To add a VoIP profile that enables hosted NAT translation

1. Enter the following command to add a VoIP profile named HNT that enables hosted NAT traversal. This command shows how to clone the default VoIP profile and enable hosted NAT traversal.

```
config voip profile
   clone default to HNT
   edit HNT
      config sip
         set hosted-nat-traversal enable
      end
   end
```

To add the SIP proxy server firewall virtual IP and firewall address

1. Enter the following command to add the SIP proxy server firewall virtual IP.

```
config firewall vip
   edit SIP_Proxy_VIP
      set type static-nat
      set extip 10.21.101.10
      set mappedip 10.30.120.20
      set extintf port1
   end
```

2. Enter the following command to add the SIP proxy server firewall address.

```
config firewall address
   edit SIP_Proxy_Server
      set associated interface port2
      set type ipmask
      set subnet 10.30.120.20 255.255.255.255
   end
```

To add security policies

1. Enter the following command to add a destination NAT security policy that includes the SIP proxy server virtual IP that allows Phone A to send SIP request messages to the SIP proxy server.

```
config firewall policy
   edit 0
      set srcintf port1
      set dstintf port2
      set srcaddr all
      set dstaddr SIP_Proxy_VIP
      set action accept
      set schedule always
      set service SIP
      set nat enable
      set utm-status enable
      set profile-protocol-options default
      set voip-profile HNT
   end
```

2. Enter the following command to add a source NAT security policy to allow the SIP proxy server to send SIP request messages to Phone B:

```
config firewall policy
   edit 0
      set srcintf port2
      set dstintf port1
      set srcaddr SIP_Proxy_Server
      set dstaddr all
      set action accept
      set schedule always
      set service SIP
      set nat enable
      set utm-status enable
      set profile-protocol-options default
      set voip-profile default
   end
```

Hosted NAT traversal for calls between SIP Phone A and SIP Phone C

The following address translation takes place to allow a SIP call from SIP Phone A to SIP Phone C in the previous diagram.

1. SIP Phone A sends a SIP Invite message to the SIP server. Packet source IP address: 192.168.10.1 and destination IP address: 10.21.101.10.
2. The SIP packets are received by the NAT device which translates the source address of the SIP packets from 192.168.10.1 to 10.11.101.20.
3. The SIP packets are received by the FortiGate which translates the packet destination IP address to 10.30 120.20. The SIP ALG also translates the IP address of the SIP phone in the SIP header and SDP lines from 192.168.10.1 to 10.11.101.20.
4. The SIP server accepts the Invite message and forwards it to SIP Phone C at IP address 172.20.120.30. The SIP server has this address for SIP Phone C because SIP packets from SIP Phone C have also been translated using the hosted NAT traversal configuration of the SIP ALG.
5. When the SIP call is established, the RTP session is between 10.11.101.10 and 172.20.120.30. The packets pass through the FortiGate which performs NAT as required.

Restricting the RTP source IP

Use the following command in a VoIP profile to restrict the RTP source IP to be the same as the SIP source IP when hosted NAT traversal is enabled.

```
config voip profile
   edit VoIP_HNT
      config sip
         set hosted-nat-traversal enable
         set hnt-restrict-source-ip enable
      end
   end
```

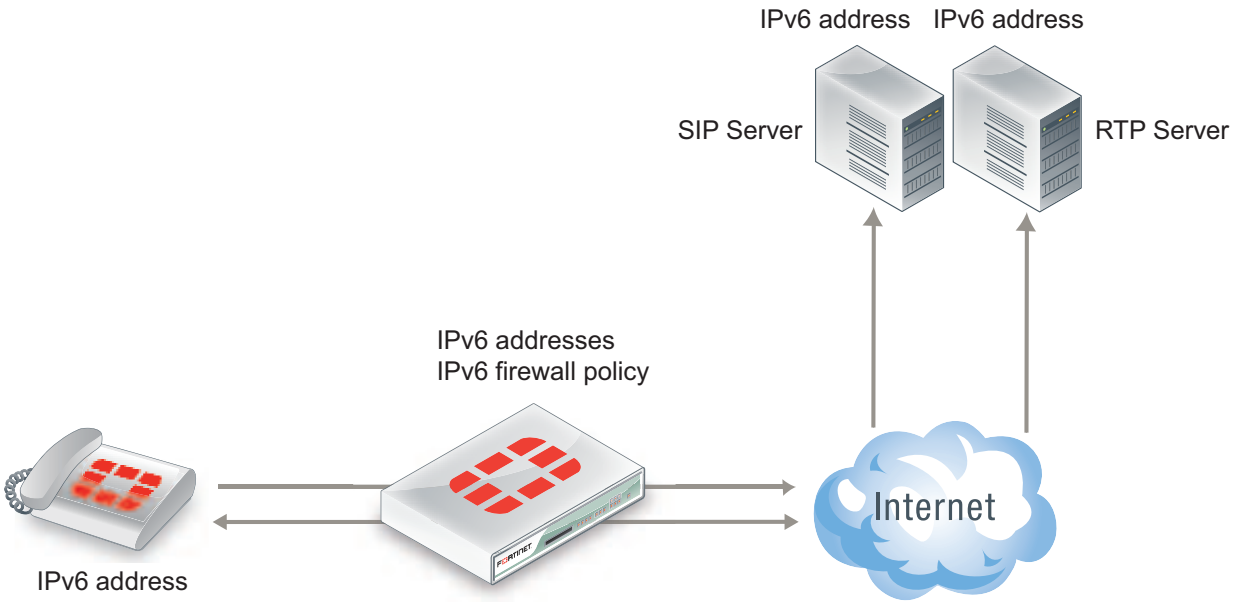
SIP over IPv6

FortiGates operating in NAT/Route and in Transparent mode support SIP over IPv6. The SIP ALG can process SIP messages that use IPv6 addresses in the headers, bodies, and in the transport stack. The SIP ALG cannot modify the IPv6 addresses in the SIP headers so FortiGates cannot perform SIP or RTP NAT over IPv6 and also cannot translate between IPv6 and IPv4 addresses.

In the scenario shown inthe figure below, a SIP phone connects to the Internet through a FortiGate operating. The phone and the SIP and RTP servers all have IPv6 addresses.

The FortiGate has IPv6 security policies that accept SIP sessions. The SIP ALG understands IPv6 addresses and can forward IPv6 sessions to their destinations. Using SIP application control features the SIP ALG can also apply rate limiting and other settings to SIP sessions.

SIP support for IPv6

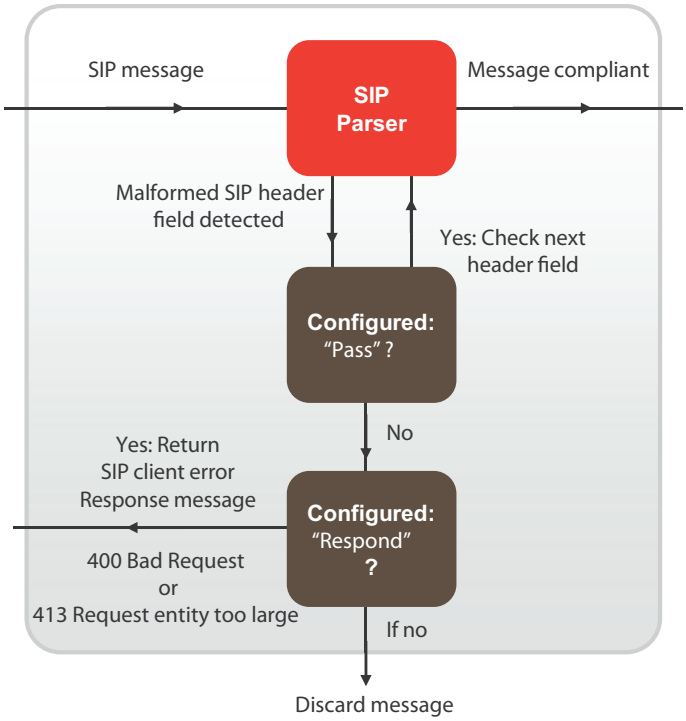


To enable SIP support for IPv6 add an IPv6 security policy that accepts SIP packets and includes a VoIP profile.

Deep SIP message inspection

Deep SIP message syntax inspection (also called Deep SIP header inspection or SIP fuzzing protection) provides protection against malicious SIP messages by applying SIP header and SDP profile syntax checking. SIP Fuzzing attacks can be used by attackers to discover and exploit vulnerabilities of a SIP entity (for example a SIP proxy server). Most often these attacks could crash or compromise the SIP entity.

Deep SIP message inspection



- **Checks the SIP request message Request-line**
- **Checks the following SIP header fields:**
  - **Allow, Call-id, Contact, Content-length, Content-type, CSeq, Expires, From, Max-Forwards, P-asserted-identity, Rack, Record-Route, Route, Rseq, To, Via**
- **Checks all SDP profile lines**
- **Configurable header and body length checks**
- **Optional logging of message violations**

Deep SIP message inspection checks the syntax of each SIP header and SDP profile line to make sure they conform to the syntax defined in the relevant RFC and IETF standard. You can also configure the SIP ALG to inspect for:

- Unknown SIP message types (message types not defined in a SIP RFC) this option is enabled by default and can be disabled. When enabled unknown message types are discarded. Configured using the `block-unknown` option.
- Unknown line types (message line types that are not defined in any SIP or SDP RFC). Configured using the `unknown-header` option.
- Messages that are longer than a configured maximum size. Configured using the `max-body-length` option.
- Messages that contain one or more lines that are longer that a set maximum line length (default 998 characters). Configured using the `max-line-length` option.

Actions taken when a malformed message line is found

When a malformed message line or other error is found the SIP ALG can be configured to discard the message containing the error, pass the message without any other actions, or responding to the message with a 400 Bad Request or 413 Request entity too large client error SIP response message and then discard the message. (For information about client error SIP response messages, see Client error on page 3352.)

If a message line is longer than the configured maximum, the SIP ALG sends the following message:

```
SIP/2.0 413 Request Entity Too Large, <optional_info>
```

If a message line is incorrect or in an unknown message line is found, the SIP ALG sends the following message:

```
SIP/2.0 400 Bad Request, <optional_info>
```

The `<optional_info>` provides more information about why the message was rejected. For example, if the SIP ALG finds a malformed Via header line, the response message may be:

```
SIP/2.0 400 Bad Request, malformed Via header
```

If the SIP ALG finds a malformed message line, and the action for this message line type is discard, the message is discarded with no further checking or responses. If the action is pass, the SIP ALG continues parsing the SIP message for more malformed message lines. If the action is respond, the SIP ALG sends the SIP response message and discards the message containing the malformed line with no further checking or response. If only malformed message line types with action set to pass are found, the SIP ALG extracts as much information as possible from the message (for example for NAT and opening pinholes, and forwards the message to its destination).

If a SIP message containing a malformed line is discarded the SIP ALG will not use the information in the message for call processing. This could result in the call being terminated. If a malformed line in a SIP message includes information required for the SIP call that the SIP ALG cannot interpret (for example, if an IP address required for SIP NAT is corrupted) the SIP ALG may not be able to continue processing the call and it could be terminated. Discarded messages are counted by SIP ALG static message counters.

Logging and statistics

To record a log message each time the SIP ALG finds a malformed header, enable logging SIP violations in a VoIP profile. In all cases, when the SIP ALG finds an error the FortiGate records a malformed header log message that contains information about the error. This happens even if the action is set to pass.

If, because of recording log messages for deep message inspection, the CPU performance is affected by a certain amount, the FortiGate records a critical log message about this event and stops writing log messages for deep SIP message inspection.

The following information is recorded in malformed header messages:

- The type of message line in which the error was found.
- The content of the message line in which the error was found (it will be truncated if it makes the log message too long)
- The column or character number in which the error was found (to make it easier to determine what caused the error)

Deep SIP message inspection best practices

Because of the risks imposed by SIP header attacks or incorrect data being allowed and because selecting drop or respond does not require more CPU overhead that pass you would want to set all tests to drop or respond. However, in some cases malformed lines may be less of a threat or risk. For example, the SDP i= does not usually contain information that is parsed by any SIP device so a malformed i= line may not pose a threat.

You can also used the pre-defined VoIP profiles to apply different levels of deep message inspection. The default VoIP profile sets all deep message inspection options to pass and the strict VoIP profile sets all deep message inspection options to discard. From the CLI you can use the `clone` command to copy these pre-defined VoIP profiles and then customize them for your requirements.

Configuring deep SIP message inspection

You configure deep SIP message inspection in a VoIP profile. All deep SIP message inspection options are available only from the CLI.

Enter the following command to configure deep SIP message inspection to discard messages with malformed Request-lines (the first line in a SIP request message):

```
config voip profile
```

```
edit VoIP_Pro_Name
   config sip
      set malformed-request-line respond
   end
end
```

You cannot configure message inspection for the Status-line, which is the first line in a SIP response message.

The following table lists the SIP header lines that the SIP ALG can inspect and the CLI command for configuring the action for each line type. The table also lists the RFC that the header line is defined in.

SIP header lines that the SIP ALG can inspect for syntax errors

SIP Header line	VoIP profile option	RFC
Allow	malformed-header-allow	RFC 3261
Call-ID	malformed-header-call-id	RFC 3261
Contact	malformed-header-contact	RFC 3261
Content-Length	malformed-header-content-length	RFC 3261
Content-Type	malformed-header-content-type	RFC 3261
CSeq	malformed-header-cseq	RFC 3261
Expires	malformed-header-expires	RFC 3261
From	malformed-header-from	RFC 3261
Max-forwards	malformed-header-max-forwards	RFC 3261
P-Asserted-Identity	malformed-header-p-asserted-identity	RFC 3325
RAck	malformed-header-rack	RFC 3262
Record-Route	malformed-header-record-route	RFC 3261
Route	malformed-header-route	RFC 3261
RSeq	malformed-header-rseq	RFC 3262
To	malformed-header-to	RFC 3261
Via	malformed-header-via	RFC 3261

The table below lists the SDP profile lines that the SIP ALG inspects and the CLI command for configuring the action for each line type. SDP profile lines are defined by RFC 4566 and RFC 2327.

SDP profile lines that the SIP ALG can inspect for syntax errors

Attribute	VoIP profile option
a=	malformed-header-sdb-a
b=	malformed-header-sdp-b
c=	malformed-header-sdp-c
i=	malformed-header-sdp-i
k=	malformed-header-sdp-k
m=	malformed-header-sdp-m
o=	malformed-header-sdp-o
r=	malformed-header-sdp-r
s=	malformed-header-sdp-s
t=	malformed-header-sdp-t
v=	malformed-header-sdp-v
z=	malformed-header-sdp-z

Discarding SIP messages with some malformed header and body lines

Enter the following command to configure deep SIP message inspection to discard SIP messages with a malformed Via line, a malformed route line or a malformed m= line but to pass messages with a malformed i= line or a malformed Max-Forwards line

```
config voip profile
   edit VoIP_Pro_Name
      config sip
         set malformed-header-via discard
         set malformed-header-route discard
         set malformed-header-sdp-m discard
         set malformed-header-sdp-i pass
         set malformed-header-max-forwards pass
      end
   end
```

Discarding SIP messages with an unknown SIP message type

Enter the following command to discard SIP messages with an unknown SIP message line type as defined in all current SIP RFCs:

```
config voip profile
```

```
edit VoIP_Pro_Name
   config sip
      set unknown-header discard
   end
end
```

Discarding SIP messages that exceed a message size

Enter the following command to set the maximum size of a SIP message to 200 bytes. Messages longer than 200 bytes are discarded.

```
config voip profile
   edit VoIP_Pro_Name
      config sip
         set max-body-length 200
      end
   end
```

The `max-body-length` option checks the value in the SIP Content-Length header line to determine body length. The Content-Length can be larger than the actual size of a SIP message if the SIP message content is split over more than one packet. SIP message sizes vary widely. The size of a SIP message can also change with the addition of Via and Record-Route headers as the message is transmitted between users and SIP servers.

Discarding SIP messages with lines longer than 500 characters

Enter the following command to set the length of a SIP message line to 500 characters and to block messages that include lines with 500 or more characters:

```
config voip profile
   edit VoIP_Pro_Name
      config sip
         set max-line-length 500
         set block-long-lines enable
      end
   end
```

Blocking SIP request messages

You may want to block different types of SIP requests:

- to prevent SIP attacks using these messages.
- If your SIP server cannot process some SIP messages because of a temporary issue (for example a bug that crashes or compromises the server when it receives a message of a certain type).
- Your SIP implementation does not use certain message types.

When you enable message blocking for a message type in a VoIP profile, whenever a security policy containing the VoIP profile accepts a SIP message of this type, the SIP ALG silently discards the message and records a log message about the action.

Use the following command to configure a VoIP profile to block SIP CANCEL and Update request messages:

```
config voip profile
   edit VoIP_Pro_Name
      config sip
         set block-cancel enable
         set block-update enable
```

```
    end
end
```

SIP uses a variety of text-based messages or requests to communicate information about SIP clients and servers to the various components of the SIP network. Since SIP requests are simple text messages and since the requests or their replies can contain information about network components on either side of the FortiGate, it may be a security risk to allow these messages to pass through.

The following table lists all of the VoIP profile SIP request message blocking options. All of these options are disabled by default.

Blocking SIP OPTIONS messages may prevent a redundant configuration from operating correctly. See Supporting geographic redundancy when blocking OPTIONS messages on page 3426 for information about resolving this problem.

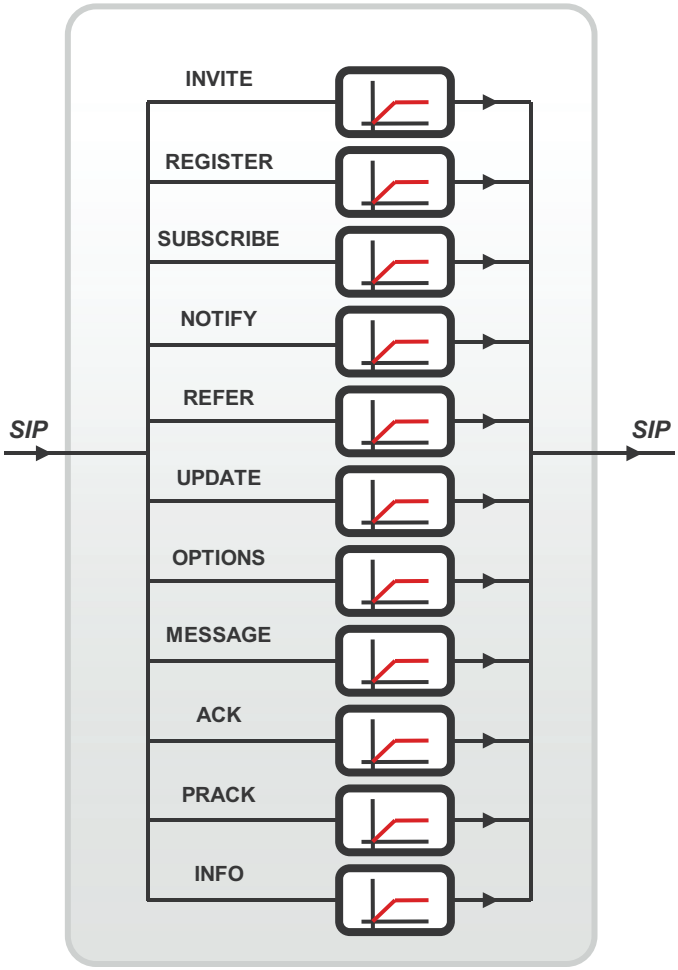
Options for blocking SIP request messages

SIP request message	SIP message blocking CLI Option
ACK	block-ack
BYE	block-bye
Cancel	block-cancel
INFO	block-info
INVITE	block-invite
Message	block-message
Notify	block-notify
Options	block-options
PRACK	block-prack
Publish	block-publish
Refer	block-refer
Register	block-register
Subscribe	block-subscribe
Update	block-update

SIP rate limiting

Configurable threshold for SIP message rates per request method. Protects SIP servers from SIP overload and DoS attacks.

SIP rate limiting



FortiGates support rate limiting for the following types of VoIP traffic:

- Session Initiation Protocol (SIP)
- Skinny Call Control Protocol (SCCP) (most versions)
- Session Initiation Protocol for Instant Messaging and Presence Leveraging Extensions (SIMPLE).

You can use rate limiting of these VoIP protocols to protect the FortiGate and your network from SIP and SCCP Denial of Service (DoS) attacks. Rate limiting protects against SIP DoS attacks by limiting the number of SIP REGISTER and INVITE requests that the FortiGate receives per second. Rate limiting protects against SCCP DoS attacks by limiting the number of SCCP call setup messages that the FortiGate receives per minute.

You configure rate limiting for a message type by specifying a limit for the number of messages that can be received per second. The rate is limited per security policy. When VoIP rate limiting is enabled for a message

type, if the a single security policy accepts more messages per second than the configured rate, the extra messages are dropped and log messages are written when the messages are dropped.

Use the following command to configure a VoIP profile to limit the number of INVITE messages accepted by each security policy that the VoIP profile is added to 100 INVITE messages a second:

```
config voip profile
   edit VoIP_Pro_Name
      config sip
         set invite-rate 100
      end
   end
```

If you are experiencing denial of service attacks from traffic using these VoIP protocols, you can enable VoIP rate limiting and limit the rates for your network. Limit the rates depending on the amount of SIP and SCCP traffic that you expect the FortiGate to be handling. You can adjust the settings if some calls are lost or if the amount of SIP or SCCP traffic is affecting FortiGate performance.

The table below lists all of the VoIP profile SIP rate limiting options. All of these options are set to 0 so are disabled by default.

Blocking SIP OPTIONS messages may prevent a redundant configuration from operating correctly. See Supporting geographic redundancy when blocking OPTIONS messages on page 3426 for information about resolving this problem.

Options for SIP rate limiting

SIP request message	Rate Limiting CLI Option
ACK	ack-rate
BYE	bye-rate
Cancel	cancel-rate
INFO	info-rate
INVITE	invite-rate
Message	message-rate
Notify	notify-rate
Options	options-rate
PRACK	prack-rate
Publish	publish-rate
Refer	refer-rate
Register	register-rate

SIP request message	Rate Limiting CLI Option
Subscribe	subscribe-rate
Update	update-rate

Limiting the number of SIP dialogs accepted by a security policy

In addition to limiting the rates for receiving SIP messages, you can use the following command to limit the number of SIP dialogs (or SIP calls) that the FortiGate accepts.

```
config voip profile
   edit VoIP_Pro_Name
      config sip
         set max-dialogs 2000
      end
   end
```

This command sets the maximum number of SIP dialogs that can be open for SIP sessions accepted by any security policy that you add the VoIP profile to. The default setting of 0 does not limit the number of dialogs. You can add a limit to control the number of open dialogs and raise and lower it as required. You might want to limit the number of open dialogs for protection against SIP-based attackers opening large numbers of SIP dialogs. Every dialog takes memory and FortiGate CPU resources to process. Limiting the number of dialogs may improve the overall performance of the FortiGate. Limiting the number of dialogs will not drop calls in progress but may prevent new calls from connecting.

SIP logging

You can enable SIP logging and logging of SIP violationsin a VoIP profile.

```
config voip profile
   edit VoIP_Pro_Name
      config sip
         set log-call-summary enable
         set log-violations enable
      end
   end
```

To view SIP log messages go to **Log & Report > Forward Traffic**.

Inspecting SIP over SSL/TLS (secure SIP)

Some SIP phones and SIP servers can communicate using SSL or TLS to encrypt the SIP signaling traffic. To allow SIP over SSL/TLS calls to pass through the FortiGate, the encrypted signaling traffic has to be unencrypted and inspected. To do this, the FortiGate SIP ALG intercepts and unencrypts and inspects the SIP packets. The packets are then re-encrypted and forwarded to their destination.

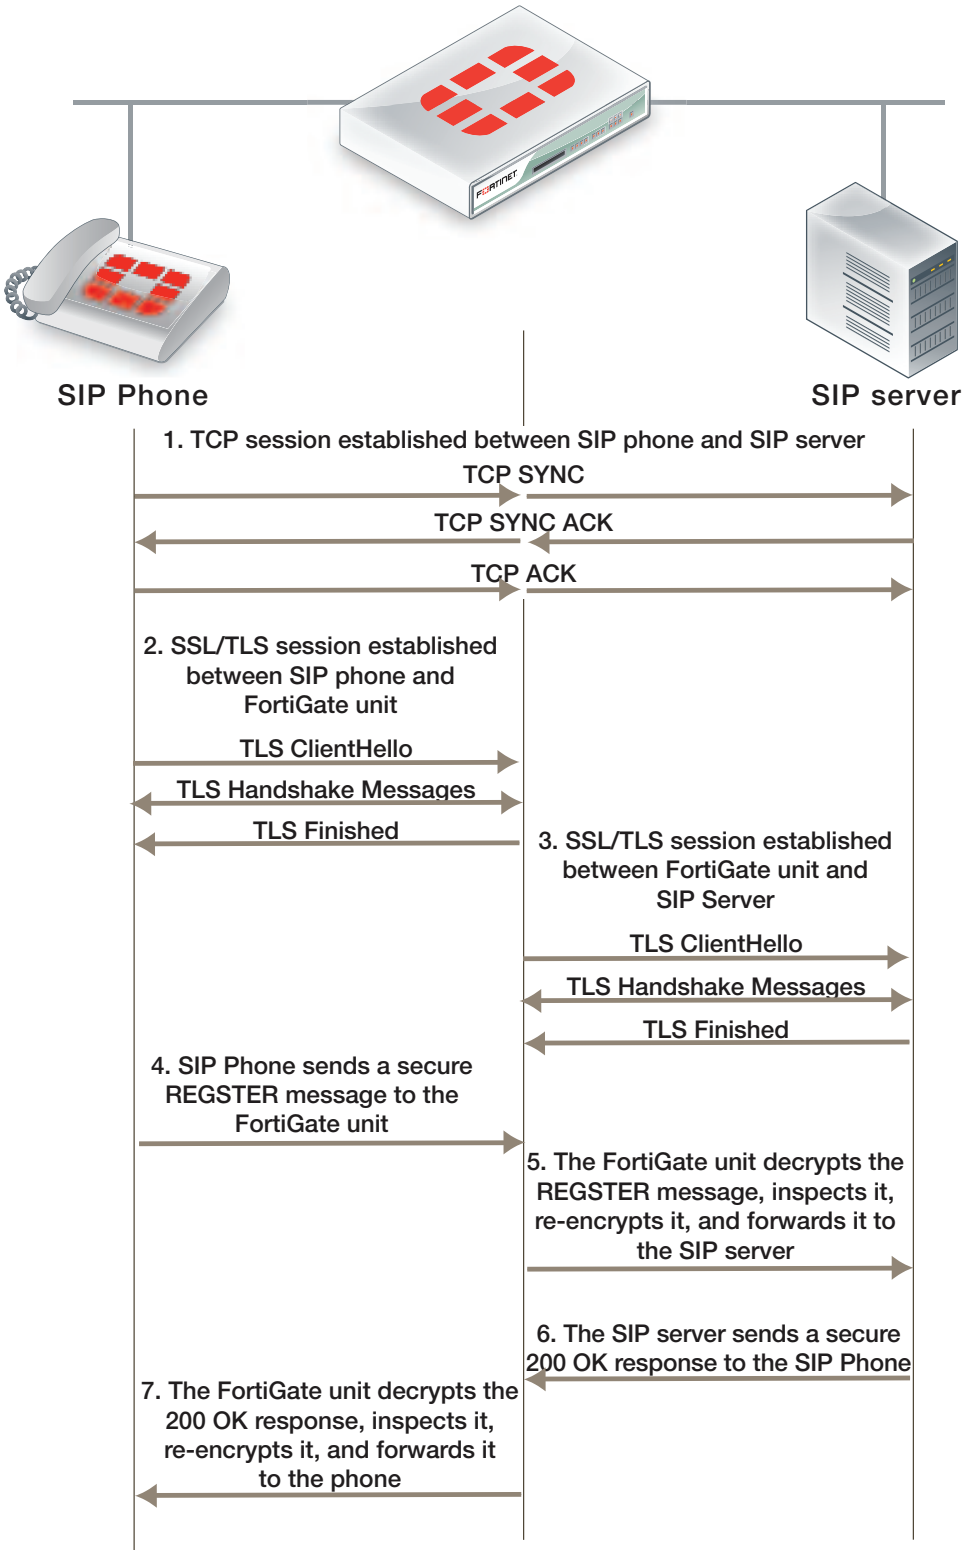
Normally SIP over SSL/TLS uses port 5061. You can use the following command to change the port that the FortiGate listens on for SIP over SSL/TLS sessions to port 5066:

```
config system settings
   set sip-ssl-port 5066
end
```

The SIP ALG supports full mode SSL/TLS only. Traffic between SIP phones and the FortiGate and between the FortiGate and the SIP server is always encrypted.

You enable SSL/TLS SIP communication by enabling SSL mode in a VoIP profile. You also need to install the SIP server and client certificates on your FortiGate and add them to the SSL configuration in the VoIP profile.

SIP over SSL/TLS between a SIP phone and a SIP server



Other than enabling SSL mode and making sure the security policies accept the encrypted traffic, the FortiGate configuration for SSL/TLS SIP is the same as any SIP configuration. SIP over SSL/TLS is supported for all supported SIP configurations.

Adding the SIP server and client certificates

A VoIP profile that supports SSL/TLS SIP requires one certification for the SIP server and one certificate that is used by all of the clients. Use the following steps to add these certificates to the FortiGate. Before you start, make sure the client and server certificate files and their key files are accessible from the management computer.

1. Go to **System > Certificates** and select **Import.**
2. Set **Type** to **Certificate**.
3. Browse to the **Certificate file** and the **Key file** and select **OK**.
4. Enter a password for the certificate and select **OK**.
   The certificate and key are uploaded to the FortiGate and added to the **Local Certificates** List.
5. Repeat to upload the other certificate.

The certificates are added to the list of Local Certificates as the filenames you uploaded. You can add comments to make it clear where its from and how it is intended to be used.

Adding SIP over SSL/TLS support to a VoIP profile

Use the following commands to add SIP over SSL/TLS support to the default VoIP profile. The following command enables SSL mode and adds the client and server certificates and passwords, the same ones you entered when you imported the certificates:

```
config voip profile
   edit default
      config sip
         set ssl-mode full
         set ssl-client-certificate "Client_cert"
         set ssl-server-certificate "Server_cert"
         set ssl-auth-client "check-server"
         set ssl-auth-server "check-server-group"
      end
   end
```

Other SSL mode options are also available:

`ssl-send-empty-frags {disable | enable}`	Enable to send empty fragments to avoid CBC IV attacks. Compatible with SSL 3.0 and TLS 1.0 only. Default is `enable`.
`ssl-client-renegotiation {allow | deny | secure}`	Control how the ALG responds when a client attempts to renegotiate the SSL session. You can allow renegotiation or block sessions when the client attempts to renegotiate. You can also select `secure` to reject an SSL connection that does not support RFC 5746 secure renegotiation indication. Default is `allow`.

`ssl-algorithm {high | low | medium}`	Select the relative strength of the algorithms that can be selected. You can select `high`, the default, to allow only AES or 3DES, `medium`, to allow AES, 3DES, or RC4 or `low`, to allow AES, 3DES, RC4, or DES.
`ssl-pfs {allow | deny | reqqure}`	Select whether to `allow`, `deny`, or `require` perfect forward secrecy (PFS). Default is `allow`.
`ssl-min-version {ssl-3.0 | tls-1.0 | tls-1.1}`	Select the minimum level of SSL support to allow. The default is `ssl-3.0`.
`ssl-max-version {ssl-3.0 | tls-1.0 | tls-1.1}`	Select the maximum level of SSL support to allow. The default is `tls-1.1`.

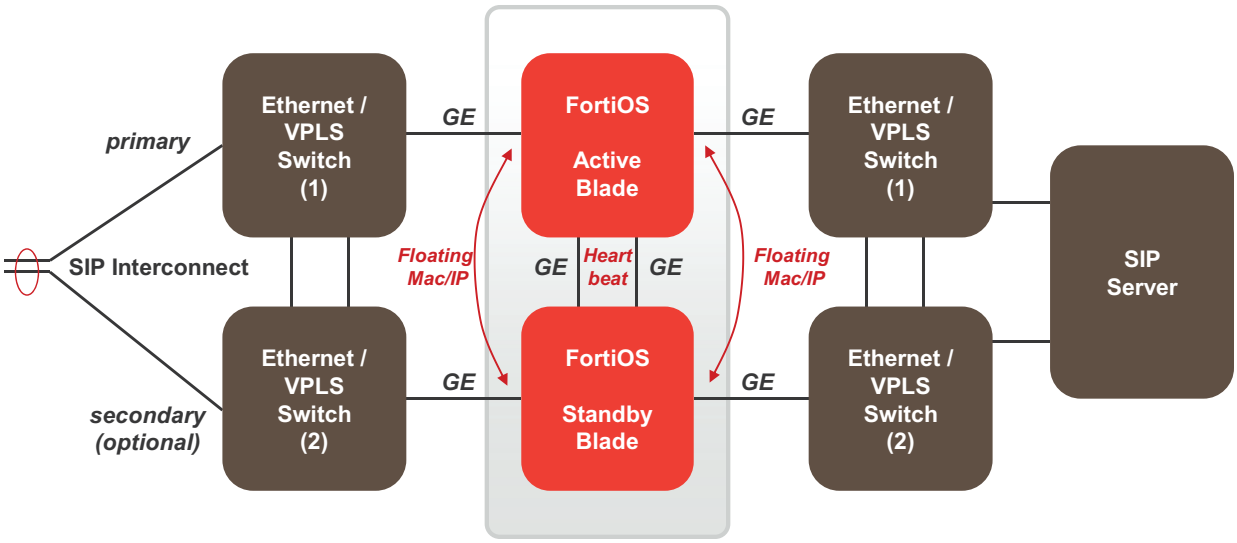
SIP and HA–session failover and geographic redundancy

FortiGate active-passive high availability (HA) supports SIP UDP session failover (also called stateful failover) if the SIP sessions are processed by the SIP ALG. To support SIP UDP session failover, create a standard HA configuration and select the enable **Session Pick-up** option.

SIP session failover replicates SIP states to all cluster units. If an HA failover occurs, all in-progress SIP UDP calls (setup complete) and their RTP flows are maintained and the calls continue after the failover with minimal or no interruption.

SIP calls being set up at the time of a failover may lose signaling messages. In most cases the SIP clients and servers should use message retransmission to complete the call setup after the failover has completed. As a result, SIP users may experience a delay if their calls are being set up when an HA failover occurs. But in most cases the call setup should be able to continue after the failover.

SIP HA session failover

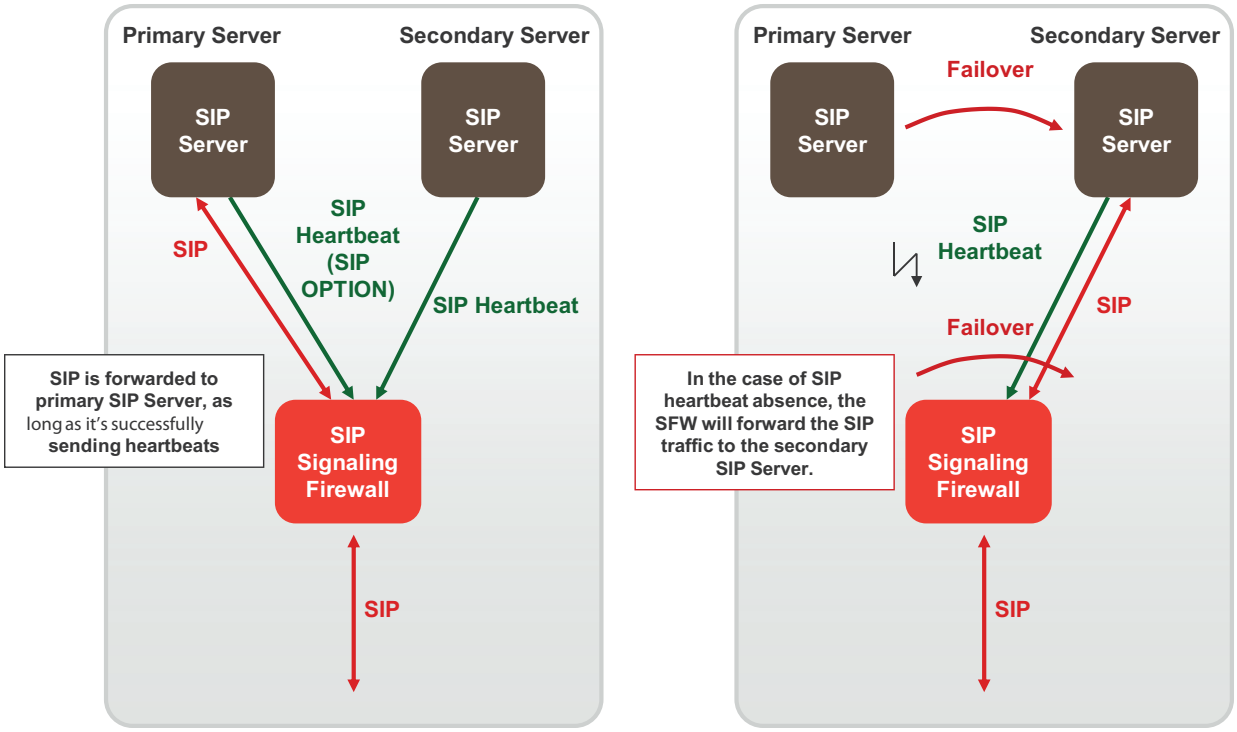


In some cases, failover during call tear down can result in hanging RTP connections that can accumulate over time and use up system memory. If this becomes a problem, you can set a time for the `call-keepalive` SIP VoIP profile setting. This setting causes the FortiGate to terminate calls with no activity after the time limit has exceeded. Range is 1 to 10,080 seconds. This options should be used with caution because it results in extra FortiGate CPU overhead and can cause delay and jitter for the VoIP call. Also, the FortiGate terminates the call without sending SIP messages to end the call. And if the SIP endpoints send SIP messages to terminate the call they will be blocked by the FortiGate if they are sent after the FortiGate terminates the call.

SIP geographic redundancy

Maintains a active-standby SIP server configuration, which even supports geographical distribution. If the active SIP server fails (missing SIP heartbeat messages or SIP traffic) FortiOS will redirect the SIP traffic to a secondary SIP server. No special configuration is required for geographic redundancy, just standard HA configuration.

Geographic redundancy



Supporting geographic redundancy when blocking OPTIONS messages

For some geographic redundant SIP configurations, the SIP servers may use SIP OPTIONS messages as heartbeats to notify the FortiGate that they are still operating (or alive). This is a kind of passive SIP monitoring mechanism where the FortiGate isn't actively monitoring the SIP servers and instead the FortiGate passively receives and analyzes OPTIONS messages from the SIP servers.

If FortiGates block SIP OPTIONS messages because `block-options` is enabled, the configuration may fail to operate correctly because the OPTIONS messages are blocked by one or more FortiGates.

However, you can work around this problem by enabling the `block-geo-red-options` application control list option. This option causes the FortiGate to refresh the local SIP server status when it receives an OPTIONS

message before dropping the message. The end result is the heartbeat signals between geographically redundant SIP servers are maintained but OPTIONS messages do not pass through the FortiGate.

Use the following command to block OPTIONS messages while still supporting geographic redundancy:

```
config voip profile
   edit VoIP_Pro_Name
      config sip
         set block-options disable
         set block-geo-red-options enable
      end
end
```

The `block-options` option setting overrides the `block-geo-red-options` option. If `block-options` is enabled the FortiGate only blocks SIP OPTIONS messages and does not refresh local SIP server status.

Support for RFC 2543-compliant branch parameters

RFC 3261 is the most recent SIP RFC, it obsoletes RFC 2543. However, some SIP implementations may use RFC 2543-compliant SIP calls.

The `rfc2543-branch` VoIP profile option allows the FortiGate to support SIP calls that include an RFC 2543-compliant branch parameter in the SIP Via header. This option also allows FortiGates to support SIP calls that include Via headers that are missing the branch parameter.

```
config voip profile
   edit VoIP_Pro_Name
      config sip
         set rfc2543-branch enable
      end
   end
```

SIP and IPS

You can enable IPS in security policies that also accept SIP sessions to protect the SIP traffic from SIP-based attacks. If you enable IPS in this way then by default the pinholes that the SIP ALG creates to allow RTP and RTCP to flow through the firewall will also have IPS enabled.

This inheritance of the IPS setting can cause performance problems if the RTP traffic volume is high since IPS checking may reduce performance in some cases. Also if you are using network processor (NP) interfaces to accelerate VoIP performance, when IPS is enabled for the pinhole traffic is diverted to the IPS and as a result is not accelerated by the network processors.

You can use the following CLI command to disable IPS for the RTP pinhole traffic.

```
config voip profile
   edit VoIP_Pro_Name
      config sip
         set ips-rtp disable
      end
   end
```

SIP debugging

This chapter includes some information to help with debugging SIP configurations.

SIP debug log format

Assuming that `diagnose debug console timestamp` is enabled then the following shows the debug that is generated for an INVITE if `diag debug appl sip -1` is enabled:

```
2010-01-04 21:39:59 sip port 26 locate session for 192.168.2.134:5061 ->
172.16.67.192:5060
2010-01-04 21:39:59 sip sess 0x979df38 found for 192.168.2.134:5061 ->
172.16.67.192:5060
2010-01-04 21:39:59 sip port 26 192.168.2.134:5061 -> 172.16.67.192:5060
2010-01-04 21:39:59 sip port 26 read [(0,515)

SIP-proxy filter per VDOM

You can use the `diagnose sys sip-proxy xxx` command in a VDOM to get info about how SIP is operating in each VDOM.

SIP-proxy filter command

Use the `diagnose system sip-proxy filter` to filter diagnose information for the SIP ALG. The following filters are available:

```
diag sys sip-proxy filter vd
diag sys sip-proxy filter dst-addr4
diag sys sip-proxy filter dst-addr6
diag sys sip-proxy filter dst-port
diag sys sip-proxy filter identity-policy
diag sys sip-proxy filter negate
diag sys sip-proxy filter policy
diag sys sip-proxy filter policy-type
diag sys sip-proxy filter profile-group
diag sys sip-proxy filter src-addr4
diag sys sip-proxy filter src-addr6
diag sys sip-proxy filter src-port
diag sys sip-proxy filter vd
diag sys sip-proxy filter voip-profile
```

You can clear, view and negate/invert the sense of a filter using these commands:

```
diag sys sip-proxy filter clear
diag sys sip-proxy filter list
diag sys sip-proxy filter negate
```

SIP debug setting

Control of the SIP debug output is governed by the following command

```
diagnose debug application sip <debug_level_int>
```

Where the `<debug_level_int>` is a bitmask and the individual values determine whether the listed items are logged or not. The `<debug_level_int>` can be:

1	Configuration changes, mainly addition/deletion/modification of virtual domains.
2	TCP connection accepts or connects, redirect creation.

4	Create or delete a session.
16	Any IO read or write.
32	An ASCII dump of all data read or written.
64	Include HEX dump in the above output.
128	Any activity related to the use of the FortiCarrier dynamic profile feature to determine the correct profile-group to use.
256	Log summary of interesting fields in a SIP call.
1024	Any activity related to SIP geo-redundancy.
2048	Any activity related to HA syncing of SIP calls.

Display SIP rate-limit data

You can use the `diagnose sys sip-proxy meters` command to display SIP rate limiting data.

For the following command output `rate 1` shows that the current (over last second) measured rate for INVITE/ACK and BYTE was 1 per second, the `peak 1` shows that the peak rate recorded is 1 per second, the `max 0` shows that there is no maximum limit set, the `count 18` indicates that 18 messages were received and `drop 0` indicates that none were dropped due to being over the limit.

```
diag sys sip-proxy meters
sip
sip vd: 0
sip policy: 1
sip identity-policy: 0
sip policy-type: IPv4
sip profile-group:
sip dialogs: 18
sip dialog-limit: 0
sip UNKNOWN: rate 0 peak 0 max 0 count 0 drop 0
sip ACK: rate 1 peak 1 max 0 count 18 drop 0
sip BYE: rate 1 peak 1 max 0 count 18 drop 0
sip CANCEL: rate 0 peak 0 max 0 count 0 drop 0
sip INFO: rate 0 peak 0 max 0 count 0 drop 0
sip INVITE: rate 1 peak 1 max 0 count 18 drop 0
sip MESSAGE: rate 0 peak 0 max 0 count 0 drop 0
sip NOTIFY: rate 0 peak 0 max 0 count 0 drop 0
sip OPTIONS: rate 0 peak 0 max 0 count 0 drop 0
sip PRACK: rate 0 peak 0 max 0 count 0 drop 0
sip PUBLISH: rate 0 peak 0 max 0 count 0 drop 0
sip REFER: rate 0 peak 0 max 0 count 0 drop 0
sip REGISTER: rate 0 peak 0 max 0 count 0 drop 0
sip SUBSCRIBE: rate 0 peak 0 max 0 count 0 drop 0
sip UPDATE: rate 0 peak 0 max 0 count 0 drop 0
sip PING: rate 0 peak 0 max 0 count 0 drop 0
sip YAHOOREF: rate 0 peak 0 max 0 count 0 drop 0
```

Chapter 36 - WAN Optimization, Web Cache, Explicit Proxy, and WCCP

You configure all of these features by creating security policies and adding WAN Optimization, web caching, and proxying to them. These same security policies can also include security profiles that apply UTM and NGFW features to WAN Optimization, web caching, and explicit proxy traffic.

Toggling Disk Usage for logging or wan-opt

Both logging and WAN Optimization use hard disk space to save data. For FortiOS 5.4 you cannot use the same hard disk for WAN Optimization and logging.

- If the FortiGate has one hard disk, then it can be used for either disk logging or WAN optimization, but not both. By default, the hard disk is used for disk logging.
- If the FortiGate has two hard disks, then one disk is always used for disk logging and the other disk is always used for WAN optimization.

On the FortiGate, go to **System > Advanced > Disk Settings** to switch between **Local Log** and **WAN Optimization**.

You can also change disk usage from the CLI using the following command:

```
configure system global
   set disk-usage {log | wanopt}
end
```

The Toggle Disk Usage feature is supported on all new "E" Series models, while support for "D" Series models may vary.

Please refer to the Feature Platform Matrix for more information.

Changing the disk setting formats the disk, erases current data stored on the disk and disables either disk logging or WAN Optimization.

You can configure WAN Optimization from the CLI or the GUI. To configure WAN Optimization from the GUI you must go to **System > Feature Select** and turn on WAN Optimization.

Remote logging (including logging to FortiAnalyzer and remote Syslog servers) is not affected by using the single local hard disk for WAN Optimization.

Enabling WAN Optimization affects more than just disk logging

In addition to affecting WAN Optimization, the following table shows other features affected by the FortiGate disk configuration.

Features affected by Disk Usage as per the number of internal hard disks on the FortiGate

Feature	Logging Only (1 hard disk)	WAN Opt. Only (1 hard disk)	Logging & WAN Opt. (2 hard disks)
Logging	Supported	Not supported	Supported
Report/Historical FortiView	Supported	Not supported	Supported
Firewall Packet Capture (Policy Capture and Interface Capture)	Supported	Not supported	Supported
AV Quarantine	Supported	Not supported	Supported
IPS Packet Capture	Supported.	Not supported	Supported
DLP Archive	Supported	Not supported	Supported
Sandbox DB & Results	FortiSandbox database and results are also stored on disk, but will not be affected by this feature.		

Distributing WAN optimization, explicit proxy, and web caching to multiple CPU Cores

By default WAN optimization, explicit proxy and web caching is handled by half of the CPU cores in a FortiGate unit. For example, if your FortiGate unit has 4 CPU cores, by default two will be used for WAN optimization, explicit proxy and web caching. You can use the following command to change the number of CPU cores that are used.

```
config system global
   set wad-worker-count <number>
end
```

The value for `<number>` can be between 1 and the total number of CPU cores in your FortiGate unit. Adding more cores may enhance WAN optimization, explicit proxy and web caching performance and reduce the performance of other FortiGate systems.

How this chapter is organized

The FortiOS Handbook chapter contains the following sections:

- Inside FortiOS: WAN Optimization highlights the features and benefits of FortiOS WAN optimizaton.
- Example network topologies provides an overview of FortiGate WAN optimization best practices and technologies and some of the concepts and rules for using them. We recommend that you begin with this chapter before attempting to configure your FortiGate unit to use WAN optimization.
- Configuring WAN optimization provides basic configuration for WAN optimization rules, including adding rules, organizing rules in the rule list and using WAN optimization addresses. This chapter also explains how WAN optimization accepts sessions, as well as how and when you can apply security profiles to WAN optimization traffic.
- Peers and authentication groups describes how to use WAN optimization peers and authentication groups to control access to WAN optimization tunnels.
- Configuration examples describes basic active-passive and peer-to-peer WAN optimization configuration examples. This chapter is a good place to start learning how to put an actual WAN optimization network together.
- Web caching and SSL offloading describes how web caching works to cache HTTP and HTTPS, how to use SSL offloading to improved performance of HTTPS websites, and includes web caching configuration examples.
- FortiClient WAN optimization describes how FortiGate and FortiClient WAN optimization work together and includes an example configuration.
- The FortiGate explicit web proxy describes how to configure the FortiGate explicit web proxy, how users connect to the explicit web proxy, and how to add web caching to the explicit web proxy.
- The FortiGate explicit FTP proxy describes how to configure the FortiGate explicit FTP proxy and how users connect to the explicit FTP proxy.
- FortiGate WCCP describes FortiGate WCCP and how to configure WCCP and the WCCP client.
- Diagnose commands describes get and diagnose commands available for troubleshooting WAN optimization, web cache, and WCCP.

Inside FortiOS: WAN Optimization

Enterprises deploying FortiOS can leverage WAN optimization to provide fast and secure application responses between locations on a Wide Area Network (WAN). The web caching component of FortiOS WAN optimization extends this protection and performance boost to cloud services.

Centralize without compromising your WAN performance

Many multi-location enterprise environments reduce costs and consolidate resources by centralizing applications or providing applications in the cloud. Efficient and high-speed communication between applications and their users is critical. Remote sites don't always have access to high bandwidth, but users at all sites expect consistent network performance. Minimizing user impact and improving performance is especially vital when applications designed for local area networks (LANs) are on the cloud.

Even applications that work fine on a local LAN, such as Windows File Sharing (CIFS), email exchange (MAPI), and many others, suffer from bandwidth limitations and latency issues when accessed over a WAN. This results in a loss of productivity and a perceived need for expensive network upgrades. FortiOS's WAN Optimization provides an inexpensive and easy way to deploy a solution to this problem.

FortiOS is commonly deployed in central offices, satellite offices, and in the cloud to provide secure communications across a WAN using IPsec or SSL VPN. This installed infrastructure can be leveraged to add more value by using WAN Optimization to accelerate WAN traffic and web caching to accelerate could services.

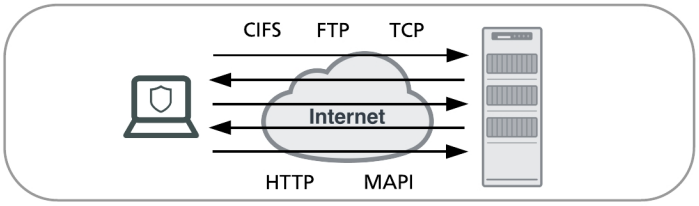
FortiOS WAN Optimization

FortiOS includes license-free WAN Optimization on most current FortiGate devices. WAN Optimization is a comprehensive solution that maximizes your WAN performance and provides intelligent bandwith management and unmatched consolidated security performance. WAN Optimization reduces your network overhead and removes unneccessary traffic for a better overall performance experience. Efficient use of bandwidth and better application performance will remove the need for costly WAN link upgrades between data centers and other expensive solutions for your network traffic growth.

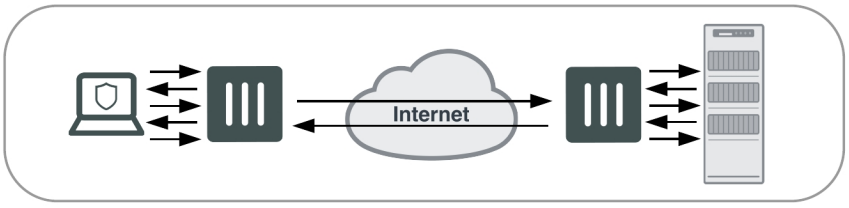
Protocol optimization

Protocol optimization is effective for applications designed for the LAN that do not function well on low bandwidth high latency networks. FortiOS protocol optimization improves the efficiency of CIFS, FTP, HTTP, MAPI, and general TCP sessions.

Regular bandwidth usage



Improved bandwidth usage with FortiGate protocol optimization



For example, CIFS, which is a fairly “chatty” protocol, requires many background transactions to successfully transfer a single file. When transferring the file, CIFS sends small chunks of data and waits sequentially for each chunk’s arrival and acknowledgment before sending the next. This large amount of request/acknowledgement traffic can delay transfers. FortiOS CIFS WAN Optimization removes this chatiness and gets on with the job of transferring the file.

TCP protocol optimization uses techniques such as SACK support, window scaling and window size adjustment, and connection pooling to remove common WAN TCP bottlenecks.

Web caching

In an enterprise environment, multiple users will often want to get the same content (for example, a sales spreadsheet, a corporate presentation or a PDF from a cloud service, or a software update). With FortiOS Web

caching, content from the cloud, from the web or from other sites on the WAN is download once and cached on the local FortiGate device. When other uses access the same content they download it from the cache. The result is less bandwidth use and reduced latency for the file requester.

FortiOS web caching also recognizes requests for Windows or MS-Office updates and downloads the new update file in the background. Once downloaded to the cache, the new update file is available to all users and all subsequent requests for this update are rapidly downloaded from the cache.

Byte caching

Byte caching improves caching by accelerating the transfer of similar, but not identical content. Byte caching accelerates multiple downloads of different email messages with the same corporate disclaimer by downloading the disclaimer over the WAN once and then downloading all subsequent disclaimers from a local FortiGate unit. Byte caching reduces the amount of data crossing the WAN when multiple different emails with the same or similar attachments or different versions of an attachment are downloaded from a corporate email server to different locations over the WAN.

Dynamic data chunking

Dynamic data chunking detects and optimizes persistent data chunks in changed files or in data embedded in traffic that uses an unknown protocol. For example, dynamic chunking can cache data in Lotus notes traffic and make the data chunks available for email and other protocols.

Data Deduplication

Byte caching breaks large units of application data, like an email attachment or a file download, into manageable small chunks of data. Each chunk of data is labeled with a hash, and chunks with their respective hashes are stored in a database on the local FortiGate unit. When a remote user request a file, the WAN Optimization sends the hashes, rather than the actual data. The FortiGate unit at the other end of the WAN tunnel reassembles the data from its own hash database, only downloading chunks that it is missing. Deduplication, or the process of eliminating duplicate data, will reduce space consumption. In addition to reducing the amount of data downloaded across the WAN, byte caching is not application specific and assists by accelerating all of the protocols supported by WAN Optimization.

Server Monitoring and Management

The health and performance of real servers can be monitored from the FortiGate GUI. Virtual servers and their assigned real servers can be monitored for health status, if there have been any monitor events, number of active sessions, round trip time and number of bytes processed. Should a server become problematic and require administration, it can be gracefully removed from the Real Server pool to enable disruption free maintenance. When a removed real server is able to operate it can gracefully be added back to the virtual server.

SSL acceleration

SSL is used by many organizations to keep WAN communications private. WAN Optimization boosts SSL acceleration properties of FortiGate FortiASIC hardware by accelerating SSL traffic across the WAN. The FortiGate unit handles SSL encryption/decryption for corporate servers providing SSL encrypted connections over the WAN.

VPN replacement

FortiOS WAN optimization supports secure SSL-encrypted tunnels between FortiGate units on the WAN. Employing secure WAN Optimization tunnels can replace IPsec VPNs between sites. The result is a single, relatively simple configuration that supports optimization and privacy of communication across the WAN and uses FortiGate SSL acceleration to provide high performance.

Road warriors and home workers

The drive to give employees greater flexibility and reduce operational costs has led to more remote workers, both at home and on the road. Whether accessing the office from a hotel, public wireless hotspot, or home, the problem is the same: low bandwidth and high latency harming application performance. WAN Optimization is integrated into FortiClient, which can be installed on PCs and wireless devices to optimize communication between remote workers and their offices.

Reduce your...

- **Capital outlay:** Organizations only need to purchase a single device per location.
- **Licensing costs:** WAN Optimization is included with FortiOS. Additional licenses are not needed.
- **Network complexity:** Small offices that may not have the space or power connections for multiple devices do not need to worry: no additional devices are required.

What's new in FortiOS 5.4

Toggle Disk Usage for logging or wan-opt (290892)

Both logging and WAN Optimization use hard disk space to save data. For FortiOS 5.4 you cannot use the same hard disk for WAN Optimization and logging.

- If the FortiGate has one hard disk, then it can be used for either disk logging or WAN optimization, but not both. By default, the hard disk is used for disk logging.
- If the FortiGate has two hard disks, then one disk is always used for disk logging and the other disk is always used for WAN optimization.

WAN Optimization is **not** supported while the FortiGate is in **Flow-based** inspection.

On the FortiGate, go to **System > Advanced > Disk Settings** to switch between **Local Log** and **WAN Optimization**.

You can also change disk usage from the CLI using the following command:

```
configure system global
   set disk-usage {log | wanopt}
end
```

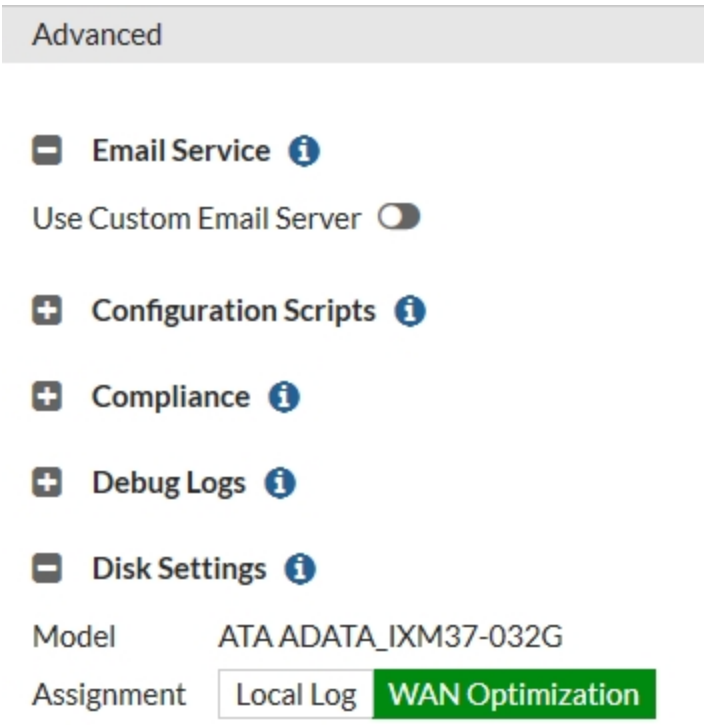
The Toggle Disk Usage feature is supported on all new "E" Series models, while support for "D" Series models may vary.

Please refer to the Feature Platform Matrix for more information.

Changing the disk setting formats the disk, erases current data stored on the disk and disables either disk logging or WAN Optimization.

You can configure WAN Optimization from the CLI or the GUI. To configure WAN Optimization from the GUI you must go to **System > Feature Select** and turn on WAN Optimization.

Remote logging (including logging to FortiAnalyzer and remote Syslog servers) is not affected by using the single local hard disk for WAN Optimization.



Enabling WAN Optimization affects more than just disk logging

In addition to affecting WAN Optimization, the following table shows other features affected by the FortiGate disk configuration.

Features affected by Disk Usage as per the number of internal hard disks on the FortiGate

Feature	Logging Only (1 hard disk)	WAN Opt. Only (1 hard disk)	Logging & WAN Opt. (2 hard disks)
Logging	Supported	Not supported	Supported
Report/Historical FortiView	Supported	Not supported	Supported
Firewall Packet Capture (Policy Capture and Interface Capture)	Supported	Not supported	Supported
AV Quarantine	Supported	Not supported	Supported
IPS Packet Capture	Supported.	Not supported	Supported
DLP Archive	Supported	Not supported	Supported

Feature	Logging Only (1 hard disk)	WAN Opt. Only (1 hard disk)	Logging & WAN Opt. (2 hard disks)
Sandbox DB & Results	FortiSandbox database and results are also stored on disk, but will not be affected by this feature.		

MAPI AV scanning is supported over WAN Optimization (267975)

AV works on MAPI when WAN Optimization is used.

New explicit proxy features

The following section describes new explicit web proxy features added to FortiOS 5.4.0 and FortiOS 5.4.1.

FortiOS 5.4.1

These features first appeared in FortiOS 5.4.1.

Support Kerberos and NTLM authentication (370489)

FortiGate now recognizes the client's authentication method from the token and selects the correct authentication scheme to authenticate successfully.

CLI syntax

```
config firewall explicit-proxy-policy
   edit <example>
      set active-auth-method [ntlm | basic | digest | negotiate | none]
   end
```

Explicit Web Proxy WISP support improvements (309388 309236)

The following Explicit Web Proxy WISP CLI syntax has been changed and added:

- Changed web-proxy wisp to table object and added outgoing-ip.

CLI syntax

```
config web-proxy
   set server-ip // WISP server IP address
   set server-port // WISP server port (1 - 65535)
```

- In the web filter profile, added WISP servers and WISP algorithm.

CLI syntax

```
config webfilter profile
edit <example>
set wisp-servers // WISP servers
set wisp-algorithm // WISP server selection algorithm
```

Improvements to explicit web proxy policy page (305817)

Explicit proxy URL categories show description next to their numerical values in the CLI. Also, all categories for **URL Category** are available in the GUI.

Explicit web proxy Kerberos authentication support (297503)

The following web proxy Kerberos authentication CLI syntax has been added:

CLI syntax

```
config user krb-keytab
edit <example>
set principal // Kerberos service principal
set ldap-server // LDAP server name
set keytab // base64 coded keytab
```

Explicit proxy, Web Caching, and WAN Optimization are not supported for Flow-based VDOMs (274748)

Explicit proxy, web caching, and WAN optimization have been removed from the GUI in a Flow-based VDOM.

Explicit proxy support for base64 encoded X-Authenticated-Groups and X-Authenticated-User HTTP headers (356979)

Data for http header-names X-Authenticated-Groups and X-Authenticated-User are decoded before further processing.

FortiOS 5.4.0

These features first appeared in FortiOS 5.4.0.

New explicit proxy firewall address types (284753)

New explicit proxy firewall address types improve granularity over header matching for explicit web proxy policies. You can enable this option using the **Show in Address List** button on the Address and Address Group New/Edit forms under **Policy & Objects > Addresses**.

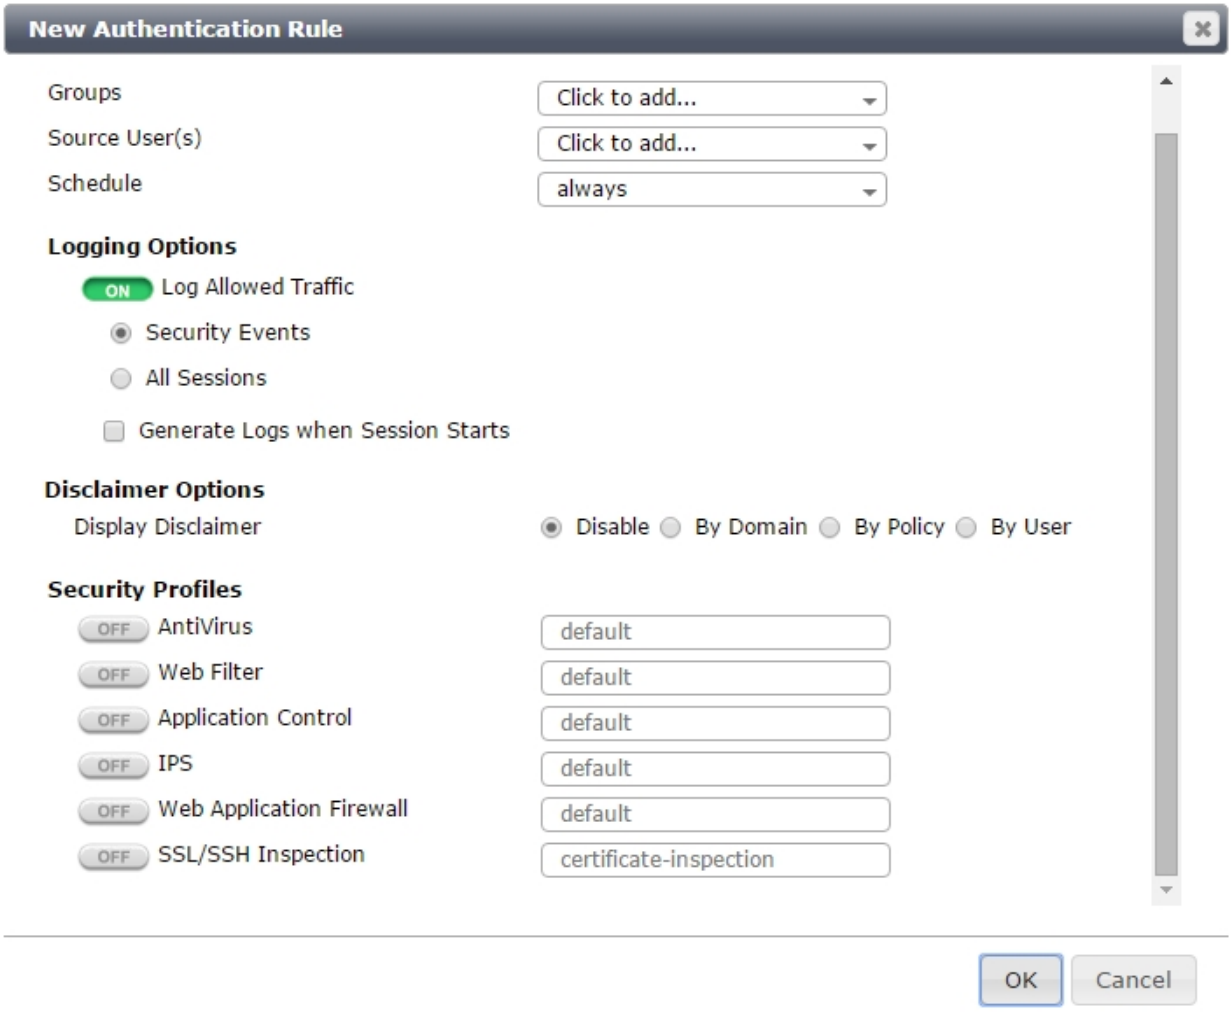
The following new address types have been added:

- **URL Pattern** - destination address
- **Host Regex Match** - destination address
- **URL Category** - destination address (URL filtering)
- **HTTP Method** - source address
- **User Agent** - source address
- **HTTP Header** - source address
- **Advanced (Source)** - source address (combines User Agent, HTTP Method, and HTTP Header)
- **Advanced (Destination)** - destination address (combines Host Regex Match and URL Category)

Disclaimer messages can be added to explicit proxy policies (273208)

Disclaimer options are now available for each explicit proxy policy or split policy of ID-based policy. This feature allows you to create user exceptions for specific URL categories (including warning messages) based on user groups.

The **Disclaimer Options** are configured under **Policy & Objects > Explicit Proxy Policy**. You can also configure a disclaimer for each Authentication Rule by setting **Action** to **Authenticate**.



Disclaimer explanations

- **Disable:** No disclaimer (default setting).
- **By Domain:** The disclaimer will be displayed on different domains. The explicit web proxy will check the referring header to mitigate the javascript/css/images/video/etc page.
- **By Policy:** The disclaimer will be displayed if the HTTP request matches a different explicit firewall policy.
- **By User:** The disclaimer will be displayed when a new user logs on.

Firewall virtual IPs (VIPs) can be used with Explicit Proxy policies (234974)

The explicit web-proxy will now accept VIP addresses for destination address. If an external IP matches a VIP policy, the IP is changed to the mapped-IP of the VIP.

Implement Botnet features for explicit policy (259580)

The option `scan-botnet-connections` has been added to the firewall explicit proxy policy.

Syntax:

```
config firewall explicit-proxy-policy
   edit <policyid>
      set scan-botnet-connections [disable/block/monitor]
end
```

where:

`disable` means do not scan connections to botnet servers.

`block` means block connections to botnet servers.

`monitor` means log connections to botnet servers.

Add HTTP.REFERRER URL to web filter logs (260538)

Added support for the referrer field in the HTTP header on webfilter log, this field along with others in the HTTP header are very useful in heuristic analysis /search for malware infected hosts.

Adding guest management to explicit web proxy (247566)

Allow user group with type **Guest** to be referenced in explicit-proxy-policy.

Example network topologies

FortiGate WAN optimization consists of a number of techniques that you can apply to improve the efficiency of communication across your WAN. These techniques include protocol optimization, byte caching, web caching, SSL offloading, and secure tunneling. Protocol optimization can improve the efficiency of traffic that uses the CIFS, FTP, HTTP, or MAPI protocol, as well as general TCP traffic. Byte caching caches files and other data on FortiGate units to reduce the amount of data transmitted across the WAN. Web caching stores web pages on FortiGate units to reduce latency and delays between the WAN and web servers. SSL offloading offloads SSL decryption and encryption from web servers onto FortiGate SSL acceleration hardware. Secure tunneling secures traffic as it crosses the WAN.

You can apply different combinations of these WAN optimization techniques to a single traffic stream depending on the traffic type. For example, you can apply byte caching and secure tunneling to any TCP traffic. For HTTP and HTTPS traffic, you can also apply protocol optimization and web caching.

You can configure a FortiGate unit to be an explicit web proxy server for both IPv4 and IPv6 traffic and an explicit FTP proxy server. Users on your internal network can browse the Internet through the explicit web proxy server or connect to FTP servers through the explicit FTP proxy server. You can also configure these proxies to protect access to web or FTP servers behind the FortiGate unit using a reverse proxy configuration.

Web caching can be applied to any HTTP or HTTPS traffic, this includes normal traffic accepted by a security policy, explicit web proxy traffic, and WAN optimization traffic.

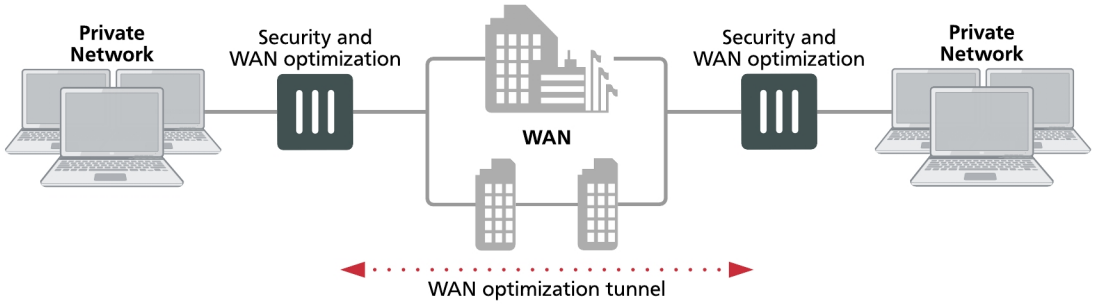
You can also configure a FortiGate unit to operate as a Web Cache Communication Protocol (WCCP) client or server. WCCP provides the ability to offload web caching to one or more redundant web caching servers.

FortiGate units can also apply security profiles to traffic as part of a WAN optimization, explicit web proxy, explicit FTP proxy, web cache and WCCP configuration. Security policies that include any of these options can also include settings to apply all forms of security profiles supported by your FortiGate unit.

Basic WAN optimization topology

The basic FortiGate WAN optimization topology consists of two FortiGate units operating as WAN optimization peers intercepting and optimizing traffic crossing the WAN between the private networks.

Security device and WAN optimization topology



FortiGate units can be deployed as security devices that protect private networks connected to the WAN and also perform WAN optimization. In this configuration, the FortiGate units are configured as typical security devices for

the private networks and are also configured for WAN optimization. The WAN optimization configuration intercepts traffic to be optimized as it passes through the FortiGate unit and uses a WAN optimization tunnel with another FortiGate unit to optimize the traffic that crosses the WAN.

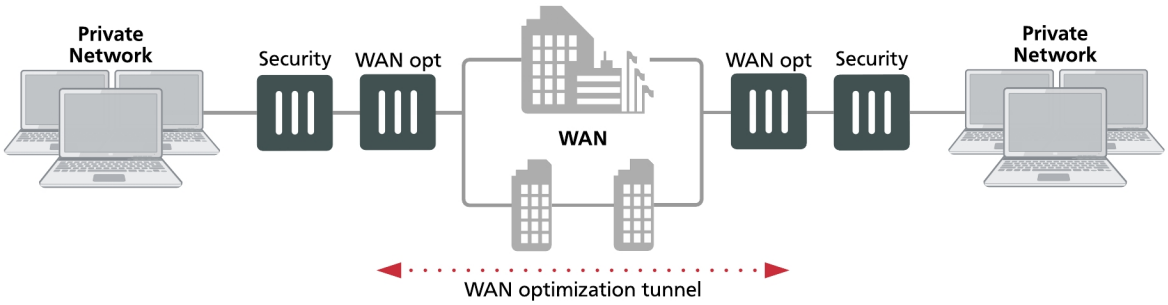
You can also deploy WAN optimization on single-purpose FortiGate units that only perform WAN optimization. In the out of path WAN optimization topology shown below, FortiGate units are located on the WAN outside of the private networks. You can also install the WAN optimization FortiGate units behind the security devices on the private networks.

The WAN optimization configuration is the same for FortiGate units deployed as security devices and for single-purpose WAN optimization FortiGate units. The only differences would result from the different network topologies.

Out-of-path WAN Optimization topology

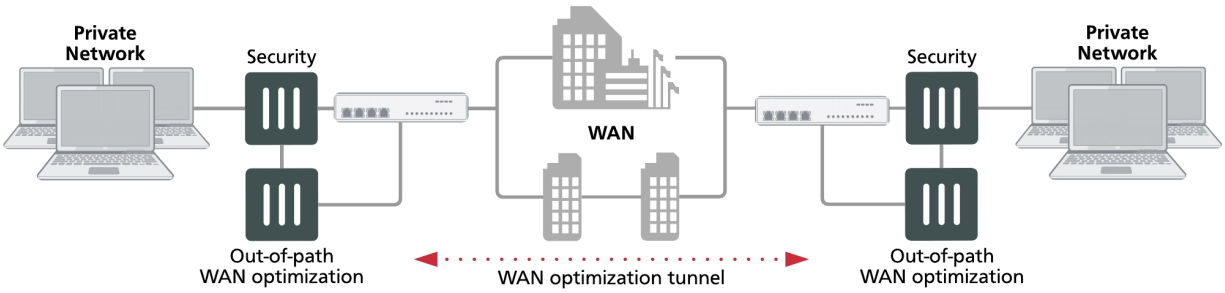
In an out-of-path topology, one or both of the FortiGate units configured for WAN optimization are not directly in the main data path. Instead, the out-of-path FortiGate unit is connected to a device on the data path, and the device is configured to redirect sessions to be optimized to the out-of-path FortiGate unit.

Single-purpose WAN optimization topology



The following out-of-path FortiGate units are configured for WAN optimization and connected directly to FortiGate units in the data path. The FortiGate units in the data path use a method such as policy routing to redirect traffic to be optimized to the out-of-path FortiGate units. The out-of-path FortiGate units establish a WAN optimization tunnel between each other and optimize the redirected traffic.

Out-of-path WAN optimization



One of the benefits of out-of-path WAN optimization is that out-of-path FortiGate units only perform WAN optimization and do not have to process other traffic. An in-path FortiGate unit configured for WAN optimization also has to process other non-optimized traffic on the data path.

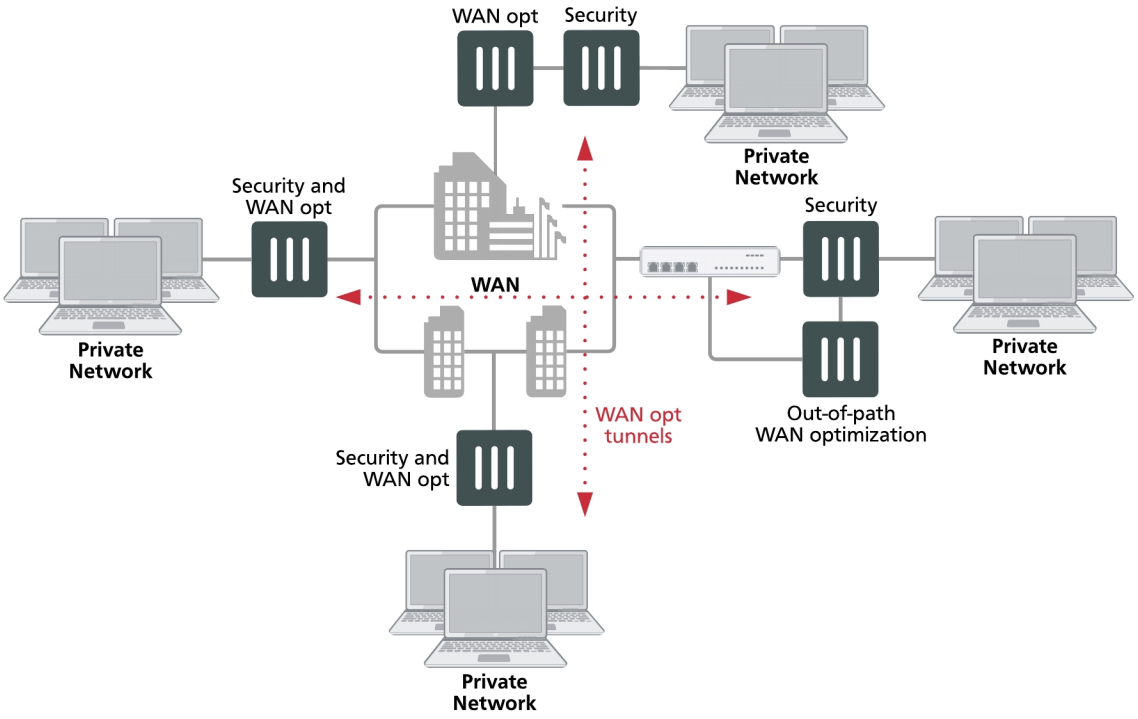
The out-of-path FortiGate units can operate in NAT/Route or Transparent mode.

Other out-of-path topologies are also possible. For example, you can install the out-of-path FortiGate units on the private networks instead of on the WAN. Also, the out-of-path FortiGate units can have one connection to the network instead of two. In a one-arm configuration such as this, security policies and routing have to be configured to send the WAN optimization tunnel out the same interface as the one that received the traffic.

Topology for multiple networks

As shown in below, you can create multiple WAN optimization configurations between many private networks. Whenever WAN optimization occurs, it is always between two FortiGate units, but you can configure any FortiGate unit to perform WAN optimization with any of the other FortiGate units that are part of your WAN.

WAN optimization among multiple networks

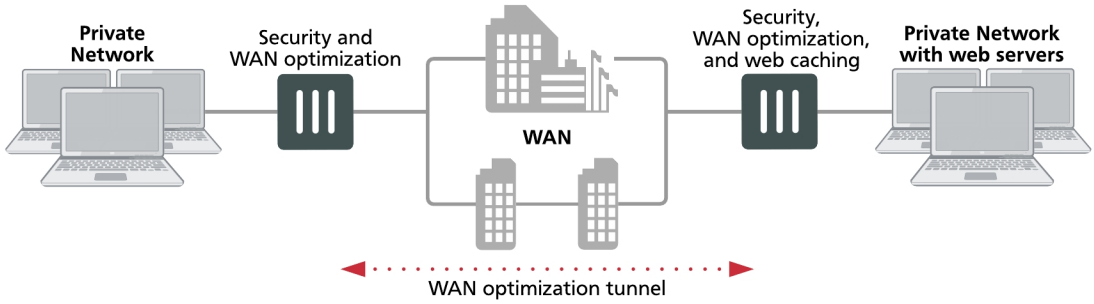


You can also configure WAN optimization between FortiGate units with different roles on the WAN. FortiGate units configured as security devices and for WAN optimization can perform WAN optimization as if they are single-purpose FortiGate units just configured for WAN optimization.

WAN optimization with web caching

You can add web caching to a WAN optimization topology when users on a private network communicate with web servers located across the WAN on another private network.

WAN optimization with web caching topology

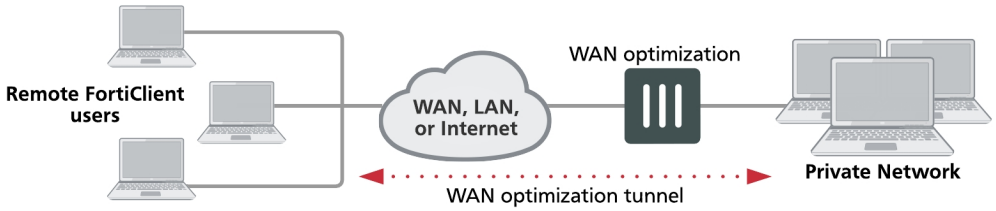


The topology above is the same as that shown in Basic WAN optimization topology on page 3443 with the addition of web caching to the FortiGate unit in front of the private network that includes the web servers. You can also add web caching to the FortiGate unit that is protecting the private network. In a similar way, you can add web caching to any WAN Optimization topology.

WAN optimization and web caching with FortiClient peers

FortiClient WAN optimization works with FortiGate WAN optimization to accelerate remote user access to the private networks behind FortiGate units. The FortiClient application requires a simple WAN optimization configuration to automatically detect if WAN optimization is enabled on the FortiGate unit. Once WAN optimization is enabled, the FortiClient application transparently makes use of the WAN optimization and web caching features available.

FortiClient WAN optimization topology



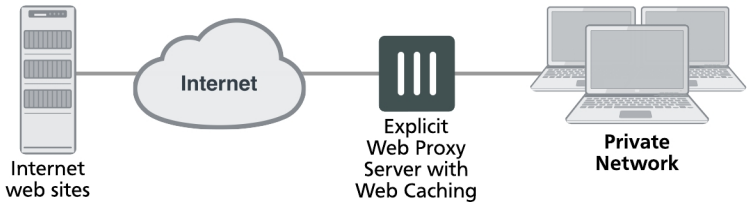
Explicit Web proxy topologies

You can configure a FortiGate unit to be an explicit web proxy server for Internet web browsing of IPv4 and IPv6 web traffic. To use the explicit web proxy, users must add the IP address of the FortiGate interface configured for the explicit web proxy to their web browser proxy configuration.

Explicit web proxy topology

If the FortiGate unit supports web caching, you can also add web caching to the security policy that accepts explicit web proxy sessions The FortiGate unit then caches Internet web pages on a hard disk to improve web browsing performance.

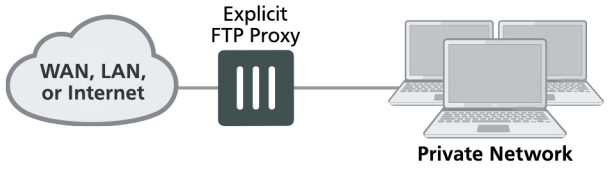
Explicit web proxy with web caching topology



Explicit FTP proxy topologies

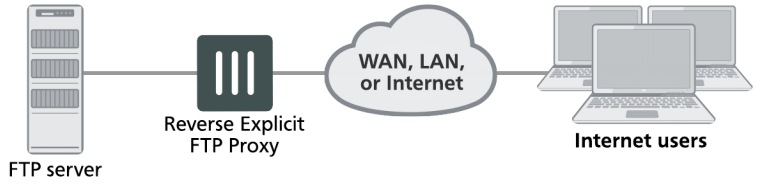
You can configure a FortiGate unit to be an explicit FTP proxy server for FTP users. To use the explicit web proxy, FTP users must connect to and authenticate with the explicit FTP proxy before connecting to an FTP server.

Explicit FTP proxy topology



You can also configure reverse explicit FTP proxy. In this configuration, users on the Internet connect to the explicit web proxy before connecting to an FTP server installed behind a FortiGate unit.

Reverse explicit FTP proxy topology



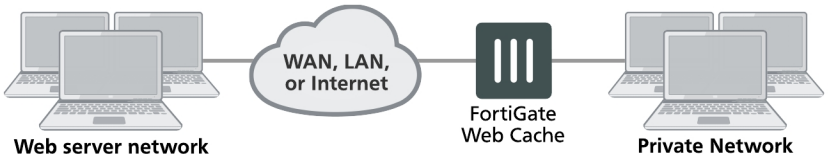
Web caching topologies

FortiGate web caching can be added to any security policy and any HTTP or HTTPS traffic accepted by that security policy can be cached on the FortiGate unit hard disk. This includes WAN optimization and explicit web proxy traffic. The network topologies for these scenarios are very similar. They involved a FortiGate unit installed between users and web servers with web caching enabled.

A typical web-caching topology includes one FortiGate unit that acts as a web cache server. Web caching is enabled in a security policy and the FortiGate unit intercepts web page requests accepted by the security policy, requests web pages from the web servers, caches the web page contents, and returns the web page contents to

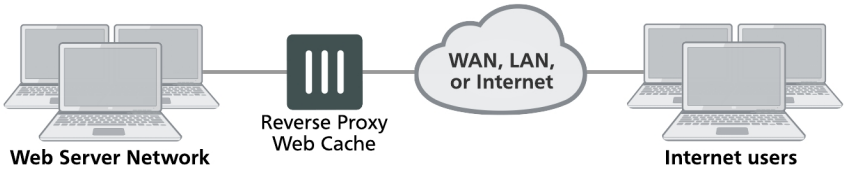
the users. When the FortiGate unit intercepts subsequent requests for cached web pages, the FortiGate unit contacts the destination web server just to check for changes.

Web caching topology



You can also configure reverse proxy web-caching. In this configuration, users on the Internet browse to a web server installed behind a FortiGate unit. The FortiGate unit intercepts the web traffic (HTTP and HTTPS) and caches pages from the web server. Reverse proxy web caching on the FortiGate unit reduces the number of requests that the web server must handle, leaving it free to process new requests that it has not serviced before.

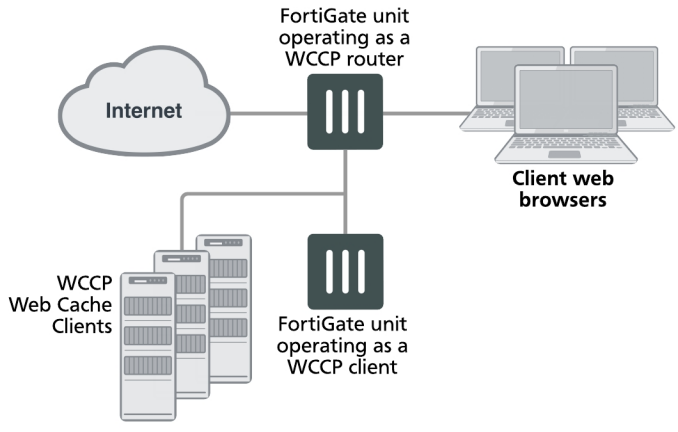
Reverse proxy web caching topology



WCCP topologies

You can operate a FortiGate unit as a Web Cache Communication Protocol (WCCP) router or cache engine. As a router, the FortiGate unit intercepts web browsing requests from client web browsers and forwards them to a WCCP cache engine. The cache engine returns the required cached content to the client web browser. If the cache server does not have the required content it accesses the content, caches it and returns the content to the client web browser.

WCCP topology



FortiGate units can also operate as WCCP cache servers, communicating with WCCP routers, caching web content and providing it to client web browsers as required.

WCCP is transparent to client web browsers. The web browsers do not have to be configured to use a web proxy.

Configuring WAN optimization

This chapter describes FortiGate WAN optimization client server architecture and other concepts you need to understand to be able to configure FortiGate WAN optimization.

Client/server architecture

Traffic across a WAN typically consists of clients on a client network communicating across a WAN with a remote server network. The clients do this by starting communication sessions from the client network to the server network. These communication sessions can be open text over the WAN or they can be encrypted by SSL VPN or IPsec VPN.

To optimize these sessions, you can add **WAN optimization security policies** to the **client-side FortiGate unit** to accept sessions from the client network that are destined for the server network. The client-side FortiGate unit is located between the client network and the WAN. WAN optimization security policies include **WAN optimization profiles** that control how the traffic is optimized.

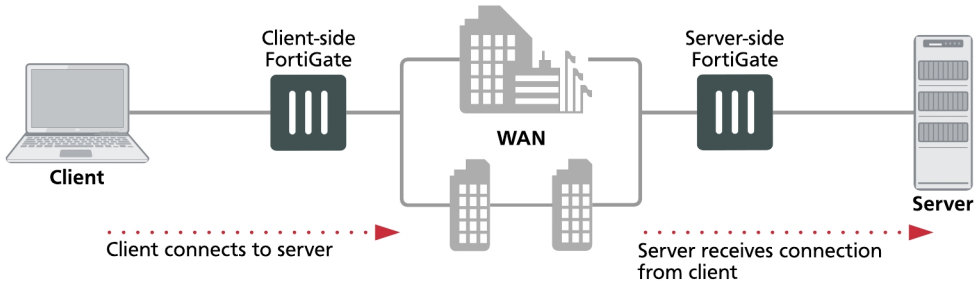
These same security policies can also include security profiles that apply UTM and NGFW features to WAN Optimization traffic.

The client-side FortiGate unit must also include the IP address of the **server-side FortiGate unit** in its WAN optimization **peer** configuration. The server-side FortiGate unit is located between the server network and the WAN, The peer configuration allows the client-side FortiGate unit to find the server-side FortiGate unit and attempt to establish a WAN optimization **tunnel** with it.

For the server-side FortiGate unit you must add a security policy with **wanopt** as the **Incoming Interface**. This security policy allows the FortiGate unit to accept WAN optimization sessions from the client-side FortiGate unit. For the server-side FortiGate unit to accept a WAN optimization connection it must have the client-side FortiGate unit in its WAN optimization peer configuration.

WAN optimization profiles are only added to the client-side WAN optimization security policy. The server-side FortiGate unit employs the WAN optimization settings set in the WAN optimization profile on the client-side FortiGate unit.

Client/server architecture



When both peers are identified the FortiGate units attempt to establish a WAN optimization **tunnel** between them. WAN optimization tunnels use port 7810. All optimized data flowing across the WAN between the client-

side and server-side FortiGate units use this tunnel. WAN optimization tunnels can be encrypted use SSL encryption to keep the data in the tunnel secure.

Any traffic can be sent through a WAN optimization tunnel. This includes SSL and IPsec VPN traffic. However, instead of configuring SSL or IPsec VPN for this communication you can add SSL encryption using the WAN optimization tunnel.

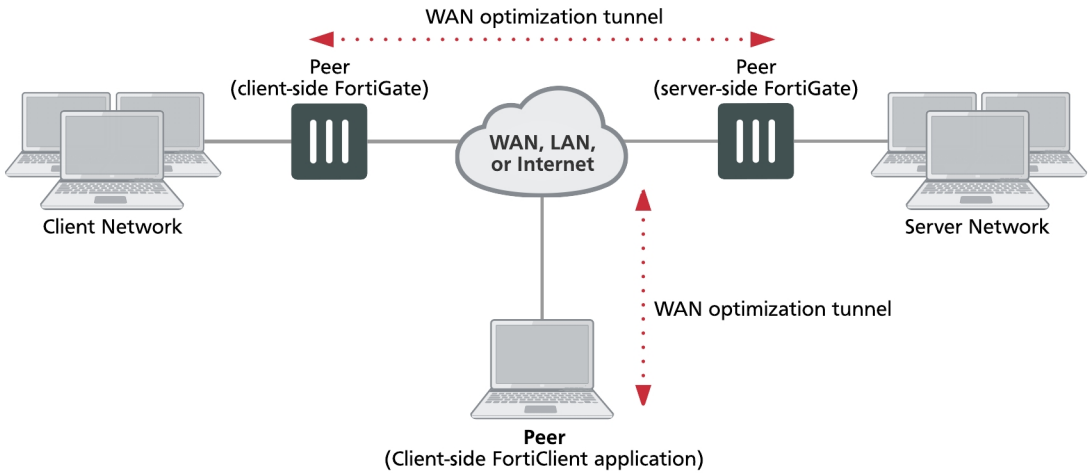
In addition to basic identification by peer host ID and IP address you can configure WAN optimization **authentication** using certificates and pre-shared keys to improve security. You can also configure FortiGate units involved in WAN optimization to accept connections from any identified peer or restrict connections to specific peers.

The FortiClient application can act in the same manner as a client-side FortiGate unit to optimize traffic between a computer running FortiClient and a FortiGate unit.

WAN optimization peers

The client-side and server-side FortiGate units are called WAN optimization peers because all of the FortiGate units in a WAN optimization network have the same peer relationship with each other. The client and server roles just relate to how a session is started. Any FortiGate unit configured for WAN optimization can be a client-side and a server-side FortiGate unit at the same time, depending on the direction of the traffic. Client-side FortiGate units initiate WAN optimization sessions and server-side FortiGate units respond to the session requests. Any FortiGate unit can simultaneously be a client-side FortiGate unit for some sessions and a server-side FortiGate unit for others.

WAN optimization peer and tunnel architecture



To identify all of the WAN optimization peers that a FortiGate unit can perform WAN optimization with, you add host IDs and IP addresses of all of the peers to the FortiGate unit configuration. The peer IP address is actually the IP address of the peer unit interface that communicates with the FortiGate unit.

Manual (peer-to-peer) and active-passive WAN optimization

You can create **manual** (peer-to-peer) and **active-passive** WAN optimization configurations.

In reality, because WAN optimization traffic can only be processed by one CPU core, it is not recommended to increase the number of manual mode peers on the FortiGate unit per VDOM.

Note that the maximum number of manual peers are restricted to 256 per VDOM. However, in Active-Passive configurations, there is no hard-limit to the maximum number of manual peers per VDOM.

Manual (peer to peer) configurations

Manual configurations allow for WAN optimization between one client-side FortiGate unit and one server-side FortiGate unit. To create a manual configuration you add a **manual mode** WAN optimization security policy to the client-side FortiGate unit. The manual mode policy includes the peer ID of a server-side FortiGate unit.

In a manual mode configuration, the client-side peer can only connect to the named server-side peer. When the client-side peer initiates a tunnel with the server-side peer, the packets that initiate the tunnel include extra information so that the server-side peer can determine that it is a peer-to-peer tunnel request. This extra information is required because the server-side peer does not require a WAN optimization policy; however, you need to add the client peer host ID and IP address to the server-side FortiGate unit peer list.

In addition, from the server-side FortiGate unit CLI you must and an Explicit Proxy security policy with `proxy` set to `wanopt` and the destination interface and network set to the network containing the servers that clients connect to over the WAN optimization tunnel. WAN optimization tunnel requests are accepted by the explicit proxy policy and if the client-side peer is in the server side peer's address list the traffic is forwarded to the servers on the destination network.

Manual mode client-side policy

You must configure manual mode client-side policies from the CLI. From the GUI a manual mode policy has WAN Optimization turned on and includes the following text beside the *WAN optimization* field: *Manual (Profile: <profile-name>. Peer: <peer-name>*.

Add a manual mode policy to the client-side FortiGate unit from the CLI. The policy enables WAN optimization, sets `wanopt-detection` to `off`, and uses the `wanopt-peer` option to specify the server-side peer. The following example uses the default WAN optimization profile.

```
config firewall policy
   edit 2
      set srcintf internal
      set dstintf wan1
      set srcaddr client-subnet
      set dstaddr server-subnet
      set action accept
      set schedule always
      set service ALL
      set wanopt enable
      set wanopt-detection off
      set wanopt-profile default
      set wanopt-peer server
   next
end
```

Manual mode server-side explicit proxy policy

The server-side explicit proxy policy allows connections from the WAN optimization tunnel to the server network by setting the proxy type to `wanopt`. You must add policies that set `proxy` to `wanopt` from the CLI and these policies do not appear on the GUI. The policy should look like the following:

```
configure firewall explicit-proxy-policy
   edit 3
      set proxy wanopt
      set dstintf internal
      set srcaddr all
      set dstaddr server-subnet
      set action accept
      set schedule always
      set service ALL
   next
end
```

Active-passive configurations

Active-passive WAN optimization requires an **active** WAN optimization policy on the client-side FortiGate unit and a **passive** WAN optimization policy on the server-side FortiGate unit. The server-side FortiGate unit also requires an explicit proxy policy with `proxy` set to `wanopt`.

You can use the passive policy to control WAN optimization address translation by specifying **transparent mode** or non-transparent mode. SeeWAN optimization transparent mode on page 3458. You can also use the passive policy to apply security profiles, web caching, and other FortiGate features at the server-side FortiGate unit. For example, if a server-side FortiGate unit is protecting a web server, the passive policy could enable web caching.

A single passive policy can accept tunnel requests from multiple FortiGate units as long as the server-side FortiGate unit includes their peer IDs and all of the client-side FortiGate units include the server-side peer ID.

Active client-side policy

Add an active policy to the client-side FortiGate unit by turning on **WAN Optimization** and selecting **active**. Then select a WAN optimization **Profile.** From the CLI the policy could look like the following:

```
config firewall policy
   edit 2
      set srcintf internal
      set dstintf wan1
      set srcaddr client-subnet
      set dstaddr server-subnet
      set action accept
      set schedule always
      set service ALL
      set wanopt enable
      set wanopt-detection active
      set wanopt-profile default
   next
end
```

Server-side tunnel policy

The server-side requires an explicit proxy policy that sets the `proxy` to `wanopt`. You must add this policy from the CLI and policies with `proxy` set to `wanopt` do not appear on the GUI. From the CLI the policy could look like

the following:

```
configure firewall explicit-proxy-policy
   edit 3
      set proxy wanopt
      set dstintf internal
      set srcaddr all
      set dstaddr server-subnet
      set action accept
      set schedule always
      set service ALL
   next
end
```

Server-side passive policy

Add a passive policy to the server-side FortiGate unit by selecting **Enable WAN Optimization** and selecting **passive**. Then set the **Passive Option** to **transparent**. From the CLI the policy could look like the following:

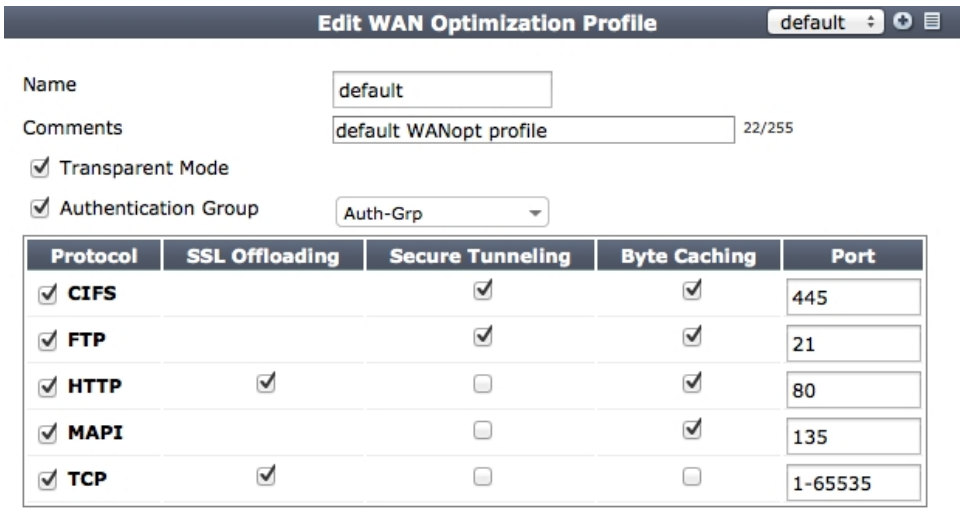
```
config firewall policy
edit 2
      set srcintf "wan1"
      set dstintf "internal"
      set srcaddr "all"
      set dstaddr "all"
      set action accept
      set schedule "always"
      set service "ANY"
      set wanopt enable
      set wanopt-detection passive
      set wanopt-passive-opt transparent
   next
```

WAN optimization profiles

Use WAN optimization profiles to apply WAN optimization techniques to traffic to be optimized. In a WAN optimization profile you can select the protocols to be optimized and for each protocol you can enable SSL offloading (if supported), secure tunneling, byte caching and set the port or port range the protocol uses. You can also enable transparent mode and optionally select an authentication group. You can edit the default WAN optimization profile or create new ones.

To configure a WAN optimization profile go to **WAN Opt. & Cache > Profiles** and edit a profile or create a new one.

Configuring a WAN optimization profile



From the CLI you can use the following command to configure a WAN optimization profile to optimize HTTP traffic.

```
config wanopt profile
   edit new-profile
      config http
         set status enable
   end
```

Transparent Mode	Servers receiving packets after WAN optimization "see" different source addresses depending on whether or not you select **Transparent Mode**. For more information, see WAN optimization transparent mode on page 3458.
Authentication Group	Select this option and select an authentication group so that the client and server-side FortiGate units must authenticate with each other before starting the WAN optimization tunnel. You must also select an authentication group if you select **Secure Tunneling** for any protocol. You must add identical authentication groups to both of the FortiGate units that will participate in the WAN optimization tunnel. For more information, see Configuring authentication groups on page 3470.
Protocol	Select CIFS, FTP, HTTP or MAPI to apply protocol optimization for the selected protocols. See Protocol optimization on page 3457. Select TCP if the WAN optimization tunnel accepts sessions that use more than one protocol or that do not use the CIFS, FTP, HTTP, or MAPI protocol.

SSL Offloading	Select to apply SSL offloading for HTTPS or other SSL traffic. You can use SSL offloading to offload SSL encryption and decryption from one or more HTTP servers to the FortiGate unit. If you enable this option, you must configure the security policy to accept SSL-encrypted traffic. If you enable SSL offloading, you must also use the CLI command `config firewall ssl-server` to add an SSL server for each HTTP server that you want to offload SSL encryption/decryption for. For more information, see Turning on web caching for HTTPS traffic on page 3496.
Secure Tunnelling	The WAN optimization tunnel is encrypted using SSL encryption. You must also add an authentication group to the profile. For more information, see Secure tunneling on page 3472.
Byte Caching	Select to apply WAN optimization byte caching to the sessions accepted by this rule. For more information, see "Byte caching".
Port	Enter a single port number or port number range. Only packets whose destination port number matches this port number or port number range will be optimized.

Processing non-HTTP sessions accepted by a WAN optimization profile with HTTP optimization

From the CLI, you can use the following command to configure how to process non-HTTP sessions when a rule configured to accept and optimize HTTP traffic accepts a non-HTTP session. This can occur if an application sends non-HTTP sessions using an HTTP destination port.

```
config wanopt profile
   edit default
      config http
         set status enable
         set tunnel-non-http {disable | enable}
      end
```

To drop non-HTTP sessions accepted by the rule set `tunnel-non-http` to `disable`, or set it to `enable` to pass non-HTTP sessions through the tunnel without applying protocol optimization, byte-caching, or web caching. In this case, the FortiGate unit applies TCP protocol optimization to non-HTTP sessions.

Processing unknown HTTP sessions

Unknown HTTP sessions are HTTP sessions that do not comply with HTTP 0.9, 1.0, or 1.1. From the CLI, use the following command to specify how a rule handles such HTTP sessions.

```
config wanopt profile
   edit default
      config http
         set status enable
         set unknown-http-version {best-effort | reject | tunnel}
      end
```

To assume that all HTTP sessions accepted by the rule comply with HTTP 0.9, 1.0, or 1.1, select `best-effort`. If a session uses a different HTTP version, WAN optimization may not parse it correctly. As a result, the

FortiGate unit may stop forwarding the session and the connection may be lost. To reject HTTP sessions that do not use HTTP 0.9, 1.0, or 1.1, select `reject`.

To pass HTTP sessions that do not use HTTP 0.9, 1.0, or 1.1, but without applying HTTP protocol optimization, byte-caching, or web caching, you can also select `tunnel`. TCP protocol optimization is applied to these HTTP sessions.

Protocol optimization

Protocol optimization techniques optimize bandwidth use across the WAN. These techniques can improve the efficiency of communication across the WAN optimization tunnel by reducing the amount of traffic required by communication protocols. You can apply protocol optimization to Common Internet File System (CIFS), FTP, HTTP, MAPI, and general TCP sessions. You can apply general TCP optimization to MAPI sessions.

For example, CIFS provides file access, record locking, read/write privileges, change notification, server name resolution, request batching, and server authentication. CIFS is a fairly “chatty” protocol, requiring many background transactions to successfully transfer a single file. This is usually not a problem across a LAN. However, across a WAN, latency and bandwidth reduction can slow down CIFS performance.

When you select the CIFS protocol in a WAN optimization profile, the FortiGate units at both ends of the WAN optimization tunnel use a number of techniques to reduce the number of background transactions that occur over the WAN for CIFS traffic.

If a policy accepts a range of different types of traffic, you can set **Protocol** to **TCP** to apply general optimization techniques to TCP traffic. However, applying this TCP optimization is not as effective as applying more protocol-specific optimization to specific types of traffic. TCP protocol optimization uses techniques such as TCP SACK support, TCP window scaling and window size adjustment, and TCP connection pooling to remove TCP bottlenecks.

Protocol optimization and MAPI

By default the MAPI service uses port number 135 for RPC port mapping and may use random ports for MAPI messages. The random ports are negotiated through sessions using port 135. The FortiOS DCE-RPC session helper learns these ports and opens pinholes for the messages. WAN optimization is also aware of these ports and attempts to apply protocol optimization to MAPI messages that use them. However, to configure protocol optimization for MAPI you should set the WAN optimization profile to a single port number (usually port 135). Specifying a range of ports may reduce performance.

Byte caching

Byte caching breaks large units of application data (for example, a file being downloaded from a web page) into small chunks of data, labelling each chunk of data with a hash of the chunk and storing those chunks and their hashes in a database. The database is stored on a WAN optimization storage device. Then, instead of sending the actual data over the WAN tunnel, the FortiGate unit sends the hashes. The FortiGate unit at the other end of the tunnel receives the hashes and compares them with the hashes in its local byte caching database. If any hashes match, that data does not have to be transmitted over the WAN optimization tunnel. The data for any hashes that does not match is transferred over the tunnel and added to that byte caching database. Then the unit of application data (the file being downloaded) is reassembled and sent to its destination.

The stored byte caches are not application specific. Byte caches from a file in an email can be used to optimize downloading that same file or a similar file from a web page.

The result is less data transmitted over the WAN. Initially, byte caching may reduce performance until a large enough byte caching database is built up.

To enable byte caching, you select **Byte Caching** in a WAN optimization profile.

Byte caching cannot determine whether or not a file is compressed (for example a zip file), and caches compressed and non-compressed versions of the same file separately.

Dynamic data chunking for byte caching

Dynamic data chunking can improve byte caching by improving detection of data chunks that are already cached in changed files or in data embedded in traffic using an unknown protocol. Dynamic data chunking is available for HTTP, CIFS and FTP.

Use the following command to enable dynamic data chunking for HTTP in the default WAN optimization profile.

```
config wanopt profile
   edit default
        config http
           set prefer-chunking dynamic
      end
```

By default dynamic data chunking is disabled and `prefer-chunking` is set to `fix`.

WAN optimization transparent mode

WAN optimization is transparent to users. This means that with WAN optimization in place, clients connect to servers in the same way as they would without WAN optimization. However, servers receiving packets after WAN optimization “see” different source addresses depending on whether or not transparent mode is selected for WAN optimization. If transparent mode is selected, WAN optimization keeps the original source address of the packets, so servers appear to receive traffic directly from clients. Routing on the server network should be configured to route traffic with client source IP addresses from the server-side FortiGate unit to the server and back to the server-side FortiGate unit.

Some protocols, for example CIFS, may not function as expected if transparent mode is **not** selected. In most cases, for CIFS WAN optimization you should select transparent mode and make sure the server network can route traffic as described to support transparent mode.

If transparent mode is not selected, the source address of the packets received by servers is changed to the address of the server-side FortiGate unit interface that sends the packets to the servers. So servers appear to receive packets from the server-side FortiGate unit. Routing on the server network is simpler in this case because client addresses are not involved. All traffic appears to come from the server-side FortiGate unit and not from individual clients.

Do not confuse WAN optimization transparent mode with FortiGate transparent mode. WAN optimization transparent mode is similar to source NAT. FortiGate Transparent mode is a system setting that controls how the FortiGate unit (or a VDOM) processes traffic.

Configuring Transparent mode

You can configure transparent mode by selecting **Transparent** in a WAN Optimization profile. The profile is added to an active WAN Optimization policy.

When you configure a passive WAN Optmization policy you can accept the active policy transparent setting or you can override the active policy transparent setting. From the GUI you can do this by setting the **Passive Option** as follows:

- **default** use the transparent setting in the WAN Optimization profile added to the active policy (client-side configuration).
- **transparent** impose transparent mode (override the active policy transparent mode setting). Packets exiting the FortiGate keep their original source addresses.
- **non-transparent** impose non-transparent mode (override the active policy transparent mode setting). Packets exiting the FortiGate have their source address changed to the address of the server-side FortiGate unit interface that sends the packets to the servers.

From the CLI you can use the following command:

```
config firewall policy
   set wanopt-passive-opt {default | transparent | non-transparent}
end
```

FortiClient WAN optimization

PCs running the FortiClient application are client-side peers that initiate WAN optimization tunnels with server-side peer FortiGate units. However, you can have an ever-changing number of FortiClient peers with IP addresses that also change regularly. To avoid maintaining a list of such peers, you can instead configure WAN optimization to accept any peer and use authentication to identify FortiClient peers.

Together, the WAN optimization peers apply the WAN optimization features to optimize the traffic flow over the WAN between the clients and servers. WAN optimization reduces bandwidth requirements, increases throughput, reduces latency, offloads SSL encryption/decryption and improves privacy for traffic on the WAN.

For more details, see FortiClient WAN optimization on page 3512.

Operating modes and VDOMs

To use WAN optimization, the FortiGate units can operate in either NAT/Route or Transparent mode. The client-side and server-side FortiGate units do not have to be operating in the same mode.

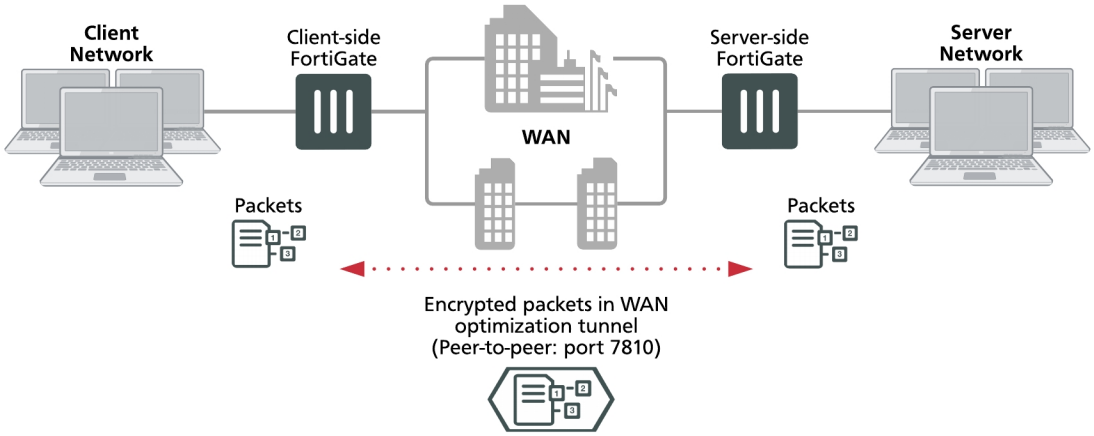
As well, the FortiGate units can be configured for multiple virtual domain (VDOM) operation. You configure WAN optimization for each VDOM and configure one or both of the units to operate with multiple VDOMs enabled.

If a FortiGate unit or VDOM is operating in Transparent mode with WAN optimization enabled, WAN optimization uses the management IP address as the peer IP address of the FortiGate unit instead of the address of an interface.

WAN optimization tunnels

All optimized traffic passes between the FortiGate units or between a FortiClient peer and a FortiGate unit over a WAN optimization tunnel. Traffic in the tunnel can be sent in plain text or encrypted using AES-128bit-CBC SSL.

WAN optimization tunnels



Both plain text and the encrypted tunnels use TCP destination port 7810.

Before a tunnel can be started, the peers must be configured to authenticate with each other. Then, the client-side peer attempts to start a WAN optimization tunnel with the server-side peer. Once the peers authenticate with each other, they bring up the tunnel and WAN optimization communication over the tunnel starts. After a tunnel has been established, multiple WAN optimization sessions can start and stop between peers without restarting the tunnel.

Tunnel sharing

You can use the `tunnel-sharing` WAN optimization profile CLI keyword to configure tunnel sharing for WAN optimization rules. Tunnel sharing means multiple WAN optimization sessions share the same tunnel. Tunnel sharing can improve performance by reducing the number of WAN optimization tunnels between FortiGate units. Having fewer tunnels means less data to manage. Also, tunnel setup requires more than one exchange of information between the ends of the tunnel. Once the tunnel is set up, each new session that shares the tunnel avoids tunnel setup delays.

Tunnel sharing also uses bandwidth more efficiently by reducing the chances that small packets will be sent down the tunnel. Processing small packets reduces network throughput, so reducing the number of small packets improves performance. A shared tunnel can combine all the data from the sessions being processed by the tunnel and send the data together. For example, suppose a FortiGate unit is processing five WAN optimization sessions and each session has 100 bytes to send. If these sessions use a shared tunnel, WAN optimization combines the packets from all five sessions into one 500-byte packet. If each session uses its own private tunnel, five 100-byte packets will be sent instead. Each packet also requires a TCP ACK reply. The combined packet in the shared tunnel requires one TCP ACK packet. The separate packets in the private tunnels require five.

Use the following command to configure tunnel sharing for HTTP traffic in a WAN optimization profile.

```
config wanopt profile
   edit default
      config http
         set tunnel-sharing {express-shared | private | shared}
      end
```

Tunnel sharing is not always recommended and may not always be the best practice. Aggressive and non-aggressive protocols should not share the same tunnel. An aggressive protocol can be defined as a protocol that is able to get more bandwidth than a non-aggressive protocol. (The aggressive protocols can “starve” the non-

aggressive protocols.) HTTP and FTP are considered aggressive protocols. If aggressive and non-aggressive protocols share the same tunnel, the aggressive protocols may take all of the available bandwidth. As a result, the performance of less aggressive protocols could be reduced. To avoid this problem, rules for HTTP and FTP traffic should have their own tunnel. To do this, set `tunnel-sharing` to `private` for WAN optimization rules that accept HTTP or FTP traffic.

It is also useful to set `tunnel-sharing` to `express-shared` for applications, such as Telnet, that are very interactive but not aggressive. Express sharing optimizes tunnel sharing for Telnet and other interactive applications where latency or delays would seriously affect the user's experience with the protocol.

Set `tunnel-sharing` to `shared` for applications that are not aggressive and are not sensitive to latency or delays. WAN optimization rules set to `sharing` and `express-shared` can share the same tunnel.

WAN optimization and user and device identity policies, load balancing and traffic shaping

Please note the following about WAN optimization and firewall policies:

- WAN optimization is not compatible with firewall load balancing.
- WAN optimization is compatible with source and destination NAT options in firewall policies (including firewall virtual IPs). If a virtual IP is added to a policy the traffic that exits the WAN optimization tunnel has its destination address changed to the virtual IPs mapped to IP address and port.
- WAN optimization is compatible with user identity-based and device identity security policies. If a session is allowed after authentication or device identification the session can be optimized.

Traffic shaping

Traffic shaping works for WAN optimization traffic that is not in a WAN optimization tunnel. So traffic accepted by a WAN optimization security policy on a client-side FortiGate unit can be shaped on ingress. However, when the traffic enters the WAN optimization tunnel, traffic shaping is not applied.

In manual mode:

- Traffic shaping works as expected on the client-side FortiGate unit.
- Traffic shaping cannot be applied to traffic on the server-side FortiGate unit.

In active-passive mode:

- Traffic shaping works as expected on the client-side FortiGate unit.
- If transparent mode is enabled in the WAN optimization profile, traffic shaping also works as expected on the server-side FortiGate unit.
- If transparent mode is not enabled, traffic shaping works partially on the server-side FortiGate unit.

WAN optimization and HA

You can configure WAN optimization on a FortiGate HA cluster. The recommended best practice HA configuration for WAN optimization is active-passive mode. When the cluster is operating, all WAN optimization sessions are processed by the primary unit only. Even if the cluster is operating in active-active mode, HA does not load-balance WAN optimization sessions.

You can also form a WAN optimization tunnel between a cluster and a standalone FortiGate unit or between two clusters.

In a cluster, only the primary unit stores the byte cache database. This database is not synchronized to the subordinate units. So, after a failover, the new primary unit must rebuild its byte cache. Rebuilding the byte cache can happen relatively quickly because the new primary unit gets byte cache data from the other FortiGate unit that it is participating with in WAN optimization tunnels.

WAN optimization, web caching and memory usage

To accelerate and optimize disk access and to provide better throughput and less latency FortiOS WAN optimization uses provisioned memory to reduce disk I/O and increase disk I/O efficiency. In addition, WAN optimization requires a small amount of additional memory per session for comprehensive flow control logic and efficient traffic forwarding.

When WAN optimization is enabled you will see a reduction in available memory. The reduction increases when more WAN optimization sessions are being processed. If you are thinking of enabling WAN optimization on an operating FortiGate unit, make sure its memory usage is not maxed out during high traffic periods.

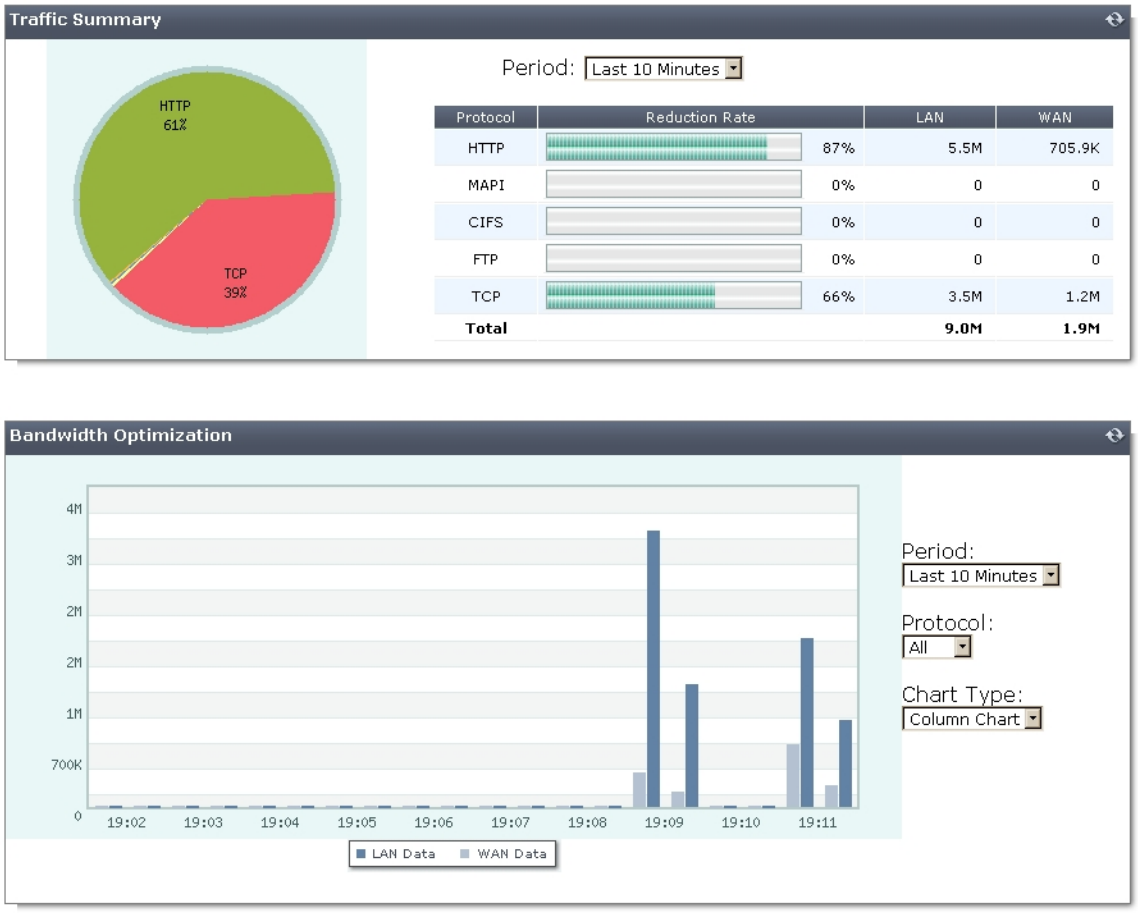
In addition to using the system dashboard to see the current memory usage you can use the `get test wad 2` command to see how much memory is currently being used by WAN optimization. See "get test {wad | wccpd} <test_level>" for more information.

Monitoring WAN optimization performance

Using WAN optimization monitoring, you can confirm that a FortiGate unit is optimizing traffic and view estimates of the amount of bandwidth saved. The WAN optimization monitor presents collected log information in a graphical format to show network traffic summary and bandwidth optimization information.

To view the WAN optimization monitor, go to **Monitor > WAN Opt. Monitor**.

WAN optimization monitor



Traffic Summary

The traffic summary shows how WAN optimization is reducing the amount of traffic on the WAN for each WAN optimization protocol by showing the traffic reduction rate as a percentage of the total traffic. The traffic summary also shows the amount of WAN and LAN traffic. If WAN optimization is being effective the amount of WAN traffic should be lower than the amount of LAN traffic.

You can use the refresh icon to update the traffic summary display at any time. You can also set the amount of time for which the traffic summary shows data. The time period can vary from the last 10 minutes to the last month.

Bandwidth Optimization

This section shows network bandwidth optimization per time period. A line or column chart compares an application's pre-optimized size (LAN data) with its optimized size (WAN data). You can select the chart type, the monitoring time period, and the protocol for which to display data. If WAN optimization is being effective the WAN bandwidth should be lower than the LAN bandwidth.

WAN optimization configuration summary

This section includes a client-side and a server-side WAN Optimization configuration summary.:

Client-side configuration summary

WAN optimization profile

Enter the following command to view WAN optimization profile CLI options:

```
tree wanopt profile
-- [profile] --*name (36)
      |- transparent
      |- comments
      |- auth-group (36)
      |- <http> -- status

            |- port
            |- ssl
            +- ssl-port (1,65535)
```

Local host ID and peer settings

```
config wanopt settings
   set host-id client
end
config wanopt peer
   edit server
   set ip 10.10.2.82
end
```

Security policies

Two client-side WAN optimization security policy configurations are possible. One for active-passive WAN optimization and one for manual WAN optimization.

Active/passive mode on the client-side

```
config firewall policy
   edit 2
      set srcintf internal
      set dstintf wan1
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
      set service ALL
      set wanopt enable <<< enable WAN optimization
      set wanopt-detection active <<< set the mode to active/passive
      set wanopt-profile "default" <<< select the wanopt profile
   next
end
```

Manual mode on the client-side

```
config firewall policy
   edit 2
      set srcintf internal
      set dstintf wan1
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
      set service ALL
      set wanopt enable <<< enable WAN optimization
      set wanopt-detection off <<< sets the mode to manual
      set wanopt-profile "default" <<< select the wanopt profile
      set wanopt-peer "server" <<< set the only peer to do wanopt
                                                                                with
          (required for manual mode)
   next
end
```

server-side configuration summary

Local host ID and peer settings

```
config wanopt settings
```

```
   set host-id server
end
config wanopt peer
   edit client
      set ip 10.10.2.81
end
```

Security policies

Two server-side WAN optimization security policy configurations are possible. One for active-passive WAN optimization and one for manual WAN optimization.

Active/passive mode on server-side

```
config firewall policy
edit 2 <<< the passive mode policy
      set srcintf wan1
      set dstintf internal
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
      set service ALL
      set wanopt enable
      set wanopt-detection passive
      set wanopt-passive-opt transparent
   end
config firewall explicit-proxy-policy
   edit 3 <<< policy that accepts wanopt tunnel connections from the       server
      set proxy wanopt <<< wanopt proxy type
      set dstintf internal
      set srcaddr all
      set dstaddr server-subnet
      set action accept
      set schedule always
      set service ALL
   next
end
```

Manual mode on server-side

```
config firewall explicit-proxy-policy
   edit 3 <<< policy that accepts wanopt tunnel connections from the       client
      set proxy wanopt <<< wanopt proxy type
      set dstintf internal
      set srcaddr all
      set dstaddr server-subnet
      set action accept
      set schedule always
      set service ALL
   next
end
```

Best practices

This is a short list of WAN optimization and explicit proxy best practices.

- WAN optimization tunnel sharing is recommended for similar types of WAN optimization traffic. However, tunnel sharing for different types of traffic is not recommended. For example, aggressive and non-aggressive protocols should not share the same tunnel. See Tunnel sharing on page 3460.
- Active-passive HA is the recommended HA configuration for WAN optimization. See WAN optimization and HA on page 3461.
- Configure WAN optimization authentication with specific peers. Accepting any peer is not recommended as this can be less secure. SeeAccepting any peers on page 3468.
- Set the explicit proxy **Default Firewall Policy Action** to **Deny**. This means that a security policy is required to use the explicit web proxy. See The FortiGate explicit web proxy on page 3515.
- Set the explicit FTP proxy **Default Firewall Policy Action** to **Deny**. This means that a security policy is required to use the explicit FTP proxy. See General explicit FTP proxy configuration steps on page 3548.
- Do not enable the explicit web or FTP proxy on an interface connected to the Internet. This is a security risk because anyone on the Internet who finds the proxy could use it to hide their source address. If you must enable the proxy on such an interface make sure authentication is required to use the proxy. See General explicit web proxy configuration steps on page 3516.

Peers and authentication groups

All communication between WAN optimization peers begins with one WAN optimization peer (or client-side FortiGate unit) sending a WAN optimization tunnel request to another peer (or server-side FortiGate unit). During this process, the WAN optimization peers identify and optionally authenticate each other.

Basic WAN optimization peer requirements

WAN optimization requires the following configuration on each peer. For information about configuring local and peer host IDs, see Configuring peers on page 3469.

- The peer must have a unique host ID.
- Unless authentication groups are used, peers authenticate each other using host ID values. Do not leave the local host ID at its default value.
- The peer must know the host IDs and IP addresses of all of the other peers that it can start WAN optimization tunnels with. This does not apply if you use authentication groups that accept all peers.
- All peers must have the same local certificate installed on their FortiGate units if the units authenticate by local certificate. Similarly, if the units authenticate by pre-shared key (password), administrators must know the password. The type of authentication is selected in the authentication group. This applies only if you use authentication groups.

Accepting any peers

Strictly speaking, you do not need to add peers. Instead you can configure authentication groups that accept any peer. However, for this to work, both peers must have the same authentication group (with the same name) and both peers must have the same certificate or pre-shared key.

Accepting any peer is useful if you have many peers or if peer IP addresses change. For example, you could have many travelling FortiClient peers with IP addresses that are always changing as the users travel to different customer sites. This configuration is also useful if you have FortiGate units with dynamic external IP addresses (using DHCP or PPPoE). For most other situations, this method is not recommended and is not a best practice as it is less secure than accepting defined peers or a single peer. For more information, see Configuring authentication groups on page 3470.

How FortiGate units process tunnel requests for peer authentication

When a client-side FortiGate unit attempts to start a WAN optimization tunnel with a peer server-side FortiGate unit, the tunnel request includes the following information:

- the client-side local host ID
- the name of an authentication group, if included in the rule that initiates the tunnel
- if an authentication group is used, the authentication method it specifies: pre-shared key or certificate
- the type of tunnel (secure or not).

For information about configuring the local host ID, peers and authentication groups, see Configuring peers on page 3469 and Configuring authentication groups on page 3470.

The authentication group is optional unless the tunnel is a secure tunnel. For more information, see Secure tunneling on page 3472.

If the tunnel request includes an authentication group, the authentication will be based on the settings of this group as follows:

- The server-side FortiGate unit searches its own configuration for the name of the authentication group in the tunnel request. If no match is found, the authentication fails.
- If a match is found, the server-side FortiGate unit compares the authentication method in the client and server authentication groups. If the methods do not match, the authentication fails.
- If the authentication methods match, the server-side FortiGate unit tests the peer acceptance settings in its copy of the authentication group.
- If the setting is **Accept Any Peer**, the authentication is successful.
- If the setting is **Specify Peer**, the server-side FortiGate unit compares the client-side local host ID in the tunnel request with the peer name in the server-side authentication group. If the names match, authentication is successful. If a match is not found, authentication fails.
- If the setting is **Accept Defined Peers**, the server-side FortiGate unit compares the client-side local host ID in the tunnel request with the server-side peer list. If a match is found, authentication is successful. If a match is not found, authentication fails.

If the tunnel request does not include an authentication group, authentication will be based on the client-side local host ID in the tunnel request. The server-side FortiGate unit searches its peer list to match the client-side local host ID in the tunnel request. If a match is found, authentication is successful. If a match is not found, authentication fails.

If the server-side FortiGate unit successfully authenticates the tunnel request, the server-side FortiGate unit sends back a tunnel setup response message. This message includes the server-side local host ID and the authentication group that matches the one in the tunnel request.

The client-side FortiGate unit then performs the same authentication procedure as the server-side FortiGate unit did. If both sides succeed, tunnel setup continues.

Configuring peers

When you configure peers, you first need to add the local host ID that identifies the FortiGate unit for WAN optimization and then add the peer host ID and IP address of each FortiGate unit with which a FortiGate unit can create WAN optimization tunnels.

To configure WAN optimization peers - web-based manager:

1. Go to **WAN Opt. & Cache > Peers**.
2. For **Local Host ID**, enter the local host ID of **this** FortiGate unit and select **Apply**. If you add this FortiGate unit as a peer to another FortiGate unit, use this ID as its **peer** host ID.

   The local or host ID can contain up to 25 characters and can include spaces.
3. Select **Create New** to add a new peer.
4. For **Peer Host ID**, enter the peer host ID of the peer FortiGate unit. This is the local host ID added to the peer FortiGate unit.
5. For **IP Address**, add the IP address of the peer FortiGate unit. This is the source IP address of tunnel requests sent by the peer, usually the IP address of the FortiGate interface connected to the WAN.
6. Select **OK**.

To configure WAN optimization peers - CLI:

In this example, the local host ID is named `HQ_Peer` and has an IP address of `172.20.120.100`. Three peers are added, but you can add any number of peers that are on the WAN.

1. Enter the following command to set the local host ID to `HQ_Peer`.

```
config wanopt settings
   set host-id HQ_peer
end
```

2. Enter the following commands to add three peers.

```
config wanopt peer
   edit Wan_opt_peer_1
      set ip 172.20.120.100
   next
   edit Wan_opt_peer_2
      set ip 172.30.120.100
   next
   edit Wan_opt_peer_3
      set ip 172.40.120.100
   end
```

Configuring authentication groups

You need to add authentication groups to support authentication and secure tunneling between WAN optimization peers.

To perform authentication, WAN optimization peers use a certificate or a pre-shared key added to an authentication group so they can identify each other before forming a WAN optimization tunnel. Both peers must have an authentication group with the same name and settings. You add the authentication group to a peer-to-peer or active rule on the client-side FortiGate unit. When the server-side FortiGate unit receives a tunnel start request from the client-side FortiGate unit that includes an authentication group, the server-side FortiGate unit finds an authentication group in its configuration with the same name. If both authentication groups have the same certificate or pre-shared key, the peers can authenticate and set up the tunnel.

Authentication groups are also required for secure tunneling.

To add authentication groups, go to **WAN Opt. & Cache > Authentication Groups**.

To add an authentication group - web-based manager:

Use the following steps to add any kind of authentication group. It is assumed that if you are using a local certificate to authenticate, it is already added to the FortiGate unit

1. Go to **WAN Opt. & Cache > Authentication Groups**.
2. Select **Create New**.
3. Add a **Name** for the authentication group.

   You will select this name when you add the authentication group to a WAN optimization rule.
4. Select the **Authentication Method**.

   Select **Certificate** if you want to use a certificate to authenticate and encrypt WAN optimization tunnels. You must select a local certificate that has been added to this FortiGate unit. (To add a local certificate, go to **System > Certificates**.) Other FortiGate units that participate in WAN optimization tunnels with this FortiGate unit must have an authentication group with the same name and certificate.

Select **Pre-shared key** if you want to use a pre-shared key or password to authenticate and encrypt WAN optimization tunnels. You must add the **Password** (or pre-shared key) used by the authentication group. Other FortiGate units that participate in WAN optimization tunnels with this FortiGate unit must have an authentication group with the same name and password. The password must contain at least 6 printable characters and should be known only by network administrators. For optimum protection against currently known attacks, the key should consist of a minimum of 16 randomly chosen alphanumeric characters.

5. Configure **Peer Acceptance** for the authentication group.

   Select **Accept Any Peer** if you do not know the peer host IDs or IP addresses of the peers that will use this authentication group. This setting is most often used for WAN optimization with the FortiClient application or with FortiGate units that do not have static IP addresses, for example units that use DHCP.

   Select **Accept Defined Peers** if you want to authenticate with peers added to the peer list only.

   Select **Specify Peer** and select one of the peers added to the peer list to authenticate with the selected peer only.

6. Select **OK**.
7. Add the authentication group to a WAN optimization rule to apply the authentication settings in the authentication group to the rule.

To add an authentication group that uses a certificate- CLI:

Enter the following command to add an authentication group that uses a certificate and can authenticate all peers added to the FortiGate unit configuration.

In this example, the authentication group is named `auth_grp_1` and uses a certificate named `Example_Cert`.

```
config wanopt auth-group
   edit auth_grp_1
      set auth-method cert
      set cert Example_Cert
      set peer-accept defined
   end
```

To add an authentication group that uses a pre-shared key - CLI:

Enter the following command to add an authentication group that uses a pre-shared key and can authenticate only the peer added to the authentication group.

In this example, the authentication group is named `auth_peer`, the peer that the group can authenticate is named `Server_net`, and the authentication group uses `123456` as the pre-shared key. In practice you should use a more secure pre-shared key.

```
config wanopt auth-group
   edit auth_peer
      set auth-method psk
      set psk 123456
      set peer-accept one
      set peer Server_net
   end
```

To add an authentication group that accepts WAN optimization connections from any peer - web-based manager

Add an authentication group that accepts any peer for situations where you do not have the **Peer Host IDs** or **IP Addresses** of the peers that you want to perform WAN optimization with. This setting is most often used for WAN optimization with the FortiClient application or with FortiGate units that do not have static IP addresses, for example units that use DHCP. An authentication group that accepts any peer is less secure than an authentication group that accepts defined peers or a single peer.

The example below sets the authentication method to **Pre-shared key**. You must add the same password to all FortiGate units using this authentication group.

1. Go to **WAN Opt. & Cache > Authentication Groups**.
2. Select **Create New** to add a new authentication group.
3. Configure the authentication group:

Name	Specify any name.
Authentication Method	Pre-shared key
Password	Enter a pre-shared key.
Peer Acceptance	Accept Any Peer

To add an authentication group that accepts WAN optimization connections from any peer - CLI:

In this example, the authentication group is named `auth_grp_1`. It uses a certificate named `WAN_Cert` and accepts any peer.

```
config wanopt auth-group
   edit auth_grp_1
      set auth-method cert
      set cert WAN_Cert
      set peer-accept any
   end
```

Secure tunneling

You can configure WAN optimization rules to use AES-128bit-CBC SSL to encrypt the traffic in the WAN optimization tunnel. WAN optimization uses FortiASIC acceleration to accelerate SSL decryption and encryption of the secure tunnel. Peer-to-peer secure tunnels use the same TCP port as non-secure peer-to-peer tunnels (TCP port 7810).

To use secure tunneling, you must select **Enable Secure Tunnel** in a WAN optimization rule and add an authentication group. The authentication group specifies the certificate or pre-shared key used to set up the secure tunnel. The **Peer Acceptance** setting of the authentication group does not affect secure tunneling.

The FortiGate units at each end of the secure tunnel must have the same authentication group with the same name and the same configuration, including the same pre-shared key or certificate. To use certificates you must install the same certificate on both FortiGate units.

For active-passive WAN optimization you can select **Enable Secure Tunnel** only in the active rule. In peer-to-peer WAN optimization you select **Enable Secure Tunnel** in the WAN optimization rule on both FortiGate units.

For information about active-passive and peer-to-peer WAN optimization, see Manual (peer-to-peer) and active-passive WAN optimization on page 3451

For a secure tunneling configuration example, see Example Adding secure tunneling to an active-passive WAN optimization configuration on page 3488.

Monitoring WAN optimization peer performance

The WAN optimization peer monitor lists all of the WAN optimization peers that a FortiGate unit can perform WAN optimization with. These include peers manually added to the configuration as well as discovered peers.

The monitor lists each peer's name, IP address, and peer type. The peer type indicates whether the peer was manually added or discovered. To show WAN optimization performance, for each peer the monitor lists the percent of traffic reduced by the peer in client-side WAN optimization configurations and in server-side configurations (also called gateway configurations).

To view the peer monitor, go to **WAN Opt. & Cache > Peer Monitor**.

Configuration examples

This chapter provides the basic examples to illustrate WAN optimization configurations introduced in the previous chapters.

Example Basic manual (peer-to-peer) WAN optimization configuration

In a manual (peer to peer) configuration the WAN optimization tunnel can be set up between one client-side FortiGate unit and one server-side FortiGate unit. The peer ID of the server-side FortiGate unit is added to the client-side WAN optimization policy. When the client-side FortiGate unit initiates a tunnel with the server-side FortiGate unit, the packets that initiate the tunnel include information that allows the server-side FortiGate unit to determine that it is a manual tunnel request. The server-side FortiGate unit does not require a WAN optimization profile; you just need to add the client peer host ID and IP address to the server-side FortiGate unit peer list and from the CLI an explicit proxy policy to accept WAN optimization tunnel connections.

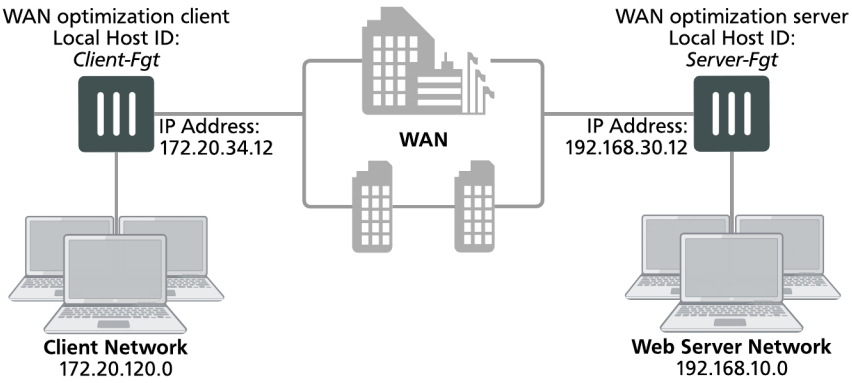
In a manual WAN optimization configuration, you create a manual WAN optimization security policy on the client-side FortiGate unit. To do this you must use the CLI to set `wanopt-detection` to `off` and to add the peer host ID of the server-side FortiGate unit to the WAN optimization security policy.

Network topology and assumptions

This example configuration includes a client-side FortiGate unit called Client-Fgt with a WAN IP address of 172.20.34.12. This unit is in front of a network with IP address 172.20.120.0. The server-side FortiGate unit is called Server_Fgt with a WAN IP address of 192.168.30.12. This unit is in front of a web server network with IP address 192.168.10.0.

This example customizes the default WAN optimization profile on the client-side FortiGate unit and adds it to the WAN optimization policy. You can also create a new WAN optimization profile.

Example manual (peer-to-peer) topology



General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1. Configure the client-side FortiGate unit:

- Add peers.
- Configure the default WAN optimization profile to optimize HTTP traffic.
- Add a manual WAN optimization security policy.

2. Configure the server-side FortiGate unit:
   - Add peers.
   - Add a WAN optimization tunnel policy.

Configuring basic peer-to-peer WAN optimization - web-based manager

Use the following steps to configure the example configuration from the web-based manager.

To configure the client-side FortiGate unit

1. Go to **WAN Opt. & Cache > Peers** and enter a **Local Host ID** for the client-side FortiGate unit:

Local Host ID	Client-Fgt

2. Select **Apply**.
3. Select **Create New** and add the server-side FortiGate unit **Peer Host ID** and **IP Address** for the server-side FortiGate:

Peer Host ID	Server-Fgt
IP Address	192.168.30.12

4. Select **OK**.
5. Go to **Policy & Objects > Addresses** and select **Create New** to add a firewall address for the client network.

Category	Address
Name	Client-Net
Type	Subnet
Subnet / IP Range	172.20.120.0/24
Interface	port1

6. Select **Create New** to add a firewall address for the web server network.

Category	Address
Name	Web-Server-Net
Type	Subnet
Subnet / IP Range	192.168.10.0/24
Interface	port2

7. Go to **WAN Opt. & Cache > Profiles** and edit the default profile.
8. Select **Transparent Mode**.
9. Under Protocol, select **HTTP** and for HTTP select **Byte Caching**. Leave the HTTP **Port** set to 80.
10. Select **Apply** to save your changes.
11. Go to **Policy & Objects > IPv4 Policy** and add a WAN optimization security policy to the client-side FortiGate unit that accepts traffic to be optimized:

Incoming Interface	port1
Source Address	all
Outgoing Interface	port2
Destination Address	all
Schedule	always
Service	ALL
Action	ACCEPT

12. Select **Enable WAN Optimization** and configure the following settings:

Enable WAN Optimization	active
Profile	default

13. Select **OK**.
14. Edit the policy from the CLI to turn off `wanopt-detection`, add the peer ID of the server-side FortiGate unit, and the default WAN optimization profile. The following example assumes the ID of the policy is 5:

```
config firewall policy
   edit 5
      set wanopt-detection off
      set wanopt-peer Server-Fgt
      set wanopt-profile default
   end
```

When you set the detection mode to `off` the policy becomes a manual mode WAN optimization policy. On the web-based manager the WAN optimization part of the policy changes to the following:

Enable WAN Optimization	Manual (Profile: default, Peer: Peer-Fgt-2)

To configure the server-side FortiGate unit

1. Go to **WAN Opt. & Cache > Peers** and enter a **Local Host ID** for the server-side FortiGate unit:

Local Host ID	Server-Fgt

2. Select **Apply**.
3. Select **Create New** and add a **Peer Host ID** and the **IP Address** for the client-side FortiGate unit:

Peer Host ID	Client-Fgt
IP Address	172.20.34.12

4. Select **OK**.
5. Enter the following CLI command to add an explicit proxy policy to accept WAN optimization tunnel connections.

```
configure firewall explicit-proxy-policy
   edit 0
      set proxy wanopt
      set dstintf port1
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
      set service ALL
   next
end
```

Configuring basic peer-to-peer WAN optimization - CLI

Use the following steps to configure the example WAN optimization configuration from the client-side and server-side FortiGate unit CLI.

To configure the client-side FortiGate unit

1. Add the Local Host ID to the client-side FortiGate configuration:

```
config wanopt settings
   set host-id Client-Fgt
end
```

2. Add the server-side Local Host ID to the client-side peer list:

```
config wanopt peer
   edit Server-Fgt
   set ip 192.168.30.12
end
```

3. Add a firewall address for the client network.

```
config firewall address
   edit Client-Net
      set type ipmask
      set subnet 172.20.120.0 255.255.255.0
      set associated-interface port1
   end
```

4. Add a firewall address for the web server network.

```
config firewall address
   edit Web-Server-Net
      set type ipmask
      set subnet 192.168.10.0 255.255.255.0
      set associated-interface port2
   end
```

5. Edit the default WAN optimization profile, select transparent mode, enable HTTP WAN optimization and enable byte caching for HTTP. Leave the HTTP Port set to 80.

```
config wanopt profile
   edit default
      set transparent enable
         config http
            set status enable
            set byte-caching enable
         end
   end
```

6. Add a WAN optimization security policy to the client-side FortiGate unit to accept the traffic to be optimized:

```
config firewall policy
   edit 0
      set srcintf port1
      set dstintf port2
      set srcaddr all
      set dstaddr all
      set action accept
      set service ALL
      set schedule always
      set wanopt enable
      set wanopt-profile default
      set wanopt-detection off
      set wanopt-peer Server-Fgt
   end
```

To configure the server-side FortiGate unit

1. Add the Local Host ID to the server-side FortiGate configuration:

```
config wanopt settings
   set host-id Server-Fgt
end
```

2. Add the client-side Local Host ID to the server-side peer list:

```
config wanopt peer
   edit Client-Fgt
   set ip 192.168.30.12
end
```

3. Add a WAN optimization tunnel explicit proxy policy.

```
configure firewall explicit-proxy-policy
   edit 0
      set proxy wanopt
      set dstintf port1
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
      set service ALL
   next
end
```

Testing and troubleshooting the configuration

To test the configuration attempt to start a web browsing session between the client network and the web server network. For example, from a PC on the client network browse to the IP address of a web server on the web server network, for example http://192.168.10.100. Even though this address is not on the client network you should be able to connect to this web server over the WAN optimization tunnel.

If you can connect, check WAN optimization monitoring. If WAN optimization has been forwarding the traffic the WAN optimization monitor should show the protocol that has been optimized (in this case HTTP) and the reduction rate in WAN bandwidth usage.

If you can't connect you can try the following to diagnose the problem:

- Review your configuration and make sure all details such as address ranges, peer names, and IP addresses are correct.
- Confirm that the security policy on the client-side FortiGate unit is accepting traffic for the 192.168.10.0 network. You can do this by checking the policy monitor (**Monitor > Firewall Monitor**). Look for sessions that use the policy ID of this policy.
- Check routing on the FortiGate units and on the client and web server networks to make sure packets can be forwarded as required. The FortiGate units must be able to communicate with each other, routing on the client network must allow packets destined for the web server network to be received by the client-side FortiGate unit, and packets from the server-side FortiGate unit must be able to reach the web servers.

You can use the following `get` and `diagnose` commands to display information about how WAN optimization is operating.

Enter the following command to list all of the running WAN optimization tunnels and display information about each one. The command output for the client-side FortiGate unit shows 10 tunnels all created by peer-to-peer WAN optimization rules (auto-detect set to off).

```
diagnose wad tunnel list

Tunnel: id=100 type=manual
   vd=0 shared=no uses=0 state=3
   peer name=Web-servers id=100 ip=192.168.30.12
   SSL-secured-tunnel=no auth-grp=
   bytes_in=348 bytes_out=384

Tunnel: id=99 type=manual

   bytes_in=1228 bytes_out=1264

Tunnels total=10 manual=10 auto=0
```

Example Active-passive WAN optimization

In active-passive WAN optimization you add an active WAN optimization policy to the client-side FortiGate unit and you add a WAN optimization tunnel policy and a passive WAN optimization policy to the server-side FortiGate unit.

The active policy accepts the traffic to be optimized and sends it down the WAN optimization tunnel to the server-side FortiGate unit. The active policy can also apply security profiles and other features to traffic before it exits the client-side FortiGate unit.

A tunnel explicit proxy policy on the sever-side FortiGate unit allows the server-side FortiGate unit to form a WAN optimization tunnel with the client-side FortiGate unit. The passive WAN optimization policy is required because of the active policy on the client-side FortiGate unit. You can also use the passive policy to apply WAN optimization transparent mode and features such as security profiles, logging, traffic shaping and web caching to the traffic before it exits the server-side FortiGate unit.

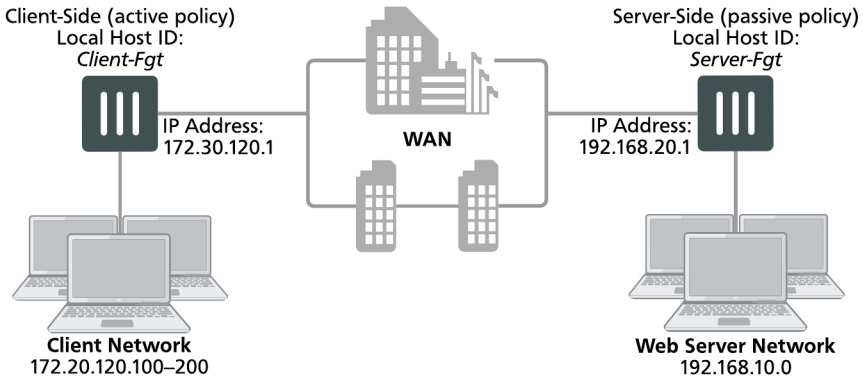
Network topology and assumptions

On the client-side FortiGate unit this example configuration includes a WAN optimization profile that optimizes CIFS, HTTP, and FTP traffic and an active WAN optimization policy. The active policy also applies virus scanning to the WAN optimization traffic.

On the server-side FortiGate unit, the passive policy applies application control to the WAN optimization traffic.

In this example, WAN optimization transparent mode is selected in the WAN optimization profile and the passive WAN optimization policy accepts this transparent mode setting. This means that the optimized packets maintain their original source and destination addresses. As a result, routing on the client network must be configured to route packets for the server network to the client-side FortiGate unit. Also the routing configuration on the server network must be able to route packets for the client network to the server-side FortiGate unit.

Example active-passive WAN optimization topology



General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1. Configure the client-side FortiGate unit:
   - Add peers.
   - Add a WAN optimization profile to optimize CIFS, FTP, and HTTP traffic.
   - Add firewall addresses for the client and web server networks.
   - Add an active WAN optimization policy.
2. Configure the server-side FortiGate unit by:
   - Add peers.
   - Add firewall addresses for the client and web server networks.
   - Add a passive WAN optimization policy.
   - Add a WAN optimization tunnel policy.

Configuring basic active-passive WAN optimization - web-based manager

Use the following steps to configure the example WAN optimization configuration from the client-side and server-side FortiGate unit web-based manager.

To configure the client-side FortiGate unit

1. Go to **WAN Opt. & Cache > Peers** and enter a **Local Host ID** for the client-side FortiGate unit:

Local Host ID	Client-Fgt

2. Select **Apply**.
3. Select **Create New** and add a Peer Host ID and the **IP Address** for the server-side FortiGate unit:

Peer Host ID	Server-Fgt
IP Address	192.168.20.1

4. Select **OK**.
5. Go to **WAN Opt. & Cache > Profiles** and select Create New to add a WAN optimization profile to optimize CIFS, HTTP, and FTP traffic:

Name	Custom-wan-opt-pro
Transparent Mode	Select

6. Select the **CIFS** protocol, select **Byte Caching** and set the **Port** to 445.
7. Select the **FTP** protocol, select **Byte Caching** and set the **Port** to 21.
8. Select the **HTTP** protocol, select **Byte Caching** and set the **Port** to 80.
9. Select **OK**.
10. Go to **Policy & Objects > Addresses** and select **Create New** to add an address for the client network.

Category	Address
Address Name	Client-Net
Type	IP Range
Subnet / IP Range	172.20.120.100-172.20.120.200
Interface	port1

11. Select **Create New** to add an address for the web server network.

Category	Address
Address Name	Web-Server-Net
Type	Subnet
Subnet / IP Range	192.168.10.0/24
Interface	port2

12. Go to **Policy & Objects > IPv4 Policy** and select **Create New** to add an active WAN optimization security policy:

Incoming Interface	port1
Source Address	Client-Net
Outgoing Interface	port2
Destination Address	Web-Server-Net
Schedule	always
Service	HTTP FTP SMB
Action	ACCEPT

13. Turn on **WAN Optimization** and configure the following settings:

WAN Optimization	active
Profile	Custom-wan-opt-pro

14. Turn on Antivirus and select the **default** antivirus profile.
15. Select **OK**.

To configure the server-side FortiGate unit

1. Go to **WAN Opt. & Cache > Peers** and enter a **Local Host ID** for the server-side FortiGate unit:

Local Host ID	Server-Fgt

2. Select **Apply**.
3. Select **Create New** and add a **Peer Host ID** and the **IP Address** for the client-side FortiGate unit:

Peer Host ID	Client-Fgt
IP Address	172.30.120.1

4. Select **OK**.
5. Go to **Policy & Objects > Addresses** and select **Create New** to add an address for the client network.

Category	Address
Address Name	Client-Net
Type	IP Range
Subnet / IP Range	172.20.120.100-172.20.120.200
Interface	port1

6. Select **Create New** to add a firewall address for the web server network.

Category	Address
Address Name	Web-Server-Net
Type	Subnet
Subnet / IP Range	192.168.10.0/24
Interface	port2

7. Select **OK**.
8. Select **Policy & Objects > IPv4 Policy** and select **Create New** to add a passive WAN optimization policy that applies application control.

Incoming Interface	port2
Source Address	Client-Net
Outgoing Interface	port1
Destination Address	Web-Server-Net
Schedule	always
Service	ALL
Action	ACCEPT

9. Turn on **WAN Optimization** and configure the following settings:

WAN Optimization	passive
Passive Option	default

10. Select **OK**.
11. From the CLI enter the following command to add a WAN optimization tunnel explicit proxy policy.

```
configure firewall explicit-proxy-policy
   edit 0
      set proxy wanopt
      set dstintf port1
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
      set service ALL
   next
end
```

Configuring basic active-passive WAN optimization - CLI

Use the following steps to configure the example WAN optimization configuration from the client-side and server-side FortiGate unit CLI.

To configure the client-side FortiGate unit

1. Add the Local Host ID to the client-side FortiGate configuration:

```
config wanopt settings
   set host-id Client-Fgt
end
```

2. Add the server-side Local Host ID to the client-side peer list:

```
config wanopt peer
   edit Server-Fgt
   set ip 192.168.20.1
end
```

3. Add a WAN optimization profile to optimize CIFS, HTTP, and FTP traffic.

```
config wanopt profile
   edit Custom-wan-opt-pro
      config cifs
         set status enable
         set byte-caching enable
         set port 445
      end
      config http
         set status enable
         set byte-caching enable
         set port 80
      end
      config ftp
         set status enable
         set byte-caching enable
         set port 21
      end
   end
```

4. Add a firewall address for the client network.

```
config firewall address
   edit Client-Net
      set type iprange
      set start-ip 172.20.120.100
      set end-ip 172.20.120.200
      set associated-interface port1
   end
```

5. Add a firewall address for the web server network.

```
config firewall address
   edit Web-Server-Net
      set type ipmask
      set subnet 192.168.10.0 255.255.255.0
      set associated-interface port2
   end
```

6. Add an active WAN optimization security policy that applies virus scanning:

```
config firewall policy
   edit 0
      set srcintf port1
      set dstintf port2
      set srcaddr Client-net
      set dstaddr Web-Server-Net
      set action accept
      set service HTTP FTP SMB
      set schedule always
```

```
      set wanopt enable
      set wanopt-detection active
      set wanopt-profile Custom-wan-opt-pro
   end
```

To configure the server-side FortiGate unit

1. Add the Local Host ID to the server-side FortiGate configuration:

```
config wanopt settings
   set host-id Server-Fgt
end
```

2. Add the client-side Local Host ID to the server-side peer list:

```
config wanopt peer
   edit Client-Fgt
   set ip 172.20.120.1
end
```

3. Add a firewall address for the client network.

```
config firewall address
   edit Client-Net
      set type iprange
      set start-ip 172.20.120.100
      set end-ip 172.20.120.200
      set associated-interface port1
   end
```

4. Add a firewall address for the web server network.

```
config firewall address
   edit Web-Server-Net
      set type ipmask
      set subnet 192.168.10.0 255.255.255.0
      set associated-interface port2
   end
```

5. Add a passive WAN optimization policy.

```
config firewall policy
   edit 0
      set srcintf port1
      set dstintf port2
      set srcaddr Client-Net
      set dstaddr Web-Server-Net
      set action accept
      set service ALL
      set schedule always
      set wanopt enable
      set wanopt-detection passive
      set wanopt-passive-opt default
   end
```

6. Add a WAN optimization tunnel explicit proxy policy.

```
configure firewall explicit-proxy-policy
   edit 0
      set proxy wanopt
      set dstintf port1
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
      set service ALL
```

```
    next
  end
```

Testing and troubleshooting the configuration

To test the configuration attempt to start a web browsing session between the client network and the web server network. For example, from a PC on the client network browse to the IP address of a web server on the web server network, for example http://192.168.10.100. Even though this address is not on the client network you should be able to connect to this web server over the WAN optimization tunnel.

If you can connect, check WAN optimization monitoring. If WAN optimization has been forwarding the traffic the WAN optimization monitor should show the protocol that has been optimized (in this case HTTP) and the reduction rate in WAN bandwidth usage.

If you can't connect you can try the following to diagnose the problem:

- Review your configuration and make sure all details such as address ranges, peer names, and IP addresses are correct.
- Confirm that the security policy on the Client-Side FortiGate unit is accepting traffic for the 192.168.10.0 network and that this security policy does not include security profiles. You can do this by checking the FortiGate session table from the dashboard. Look for sessions that use the policy ID of this policy.
- Check routing on the FortiGate units and on the client and web server networks to make sure packets can be forwarded as required. The FortiGate units must be able to communicate with each other, routing on the client network must allow packets destined for the web server network to be received by the client-side FortiGate unit, and packets from the server-side FortiGate unit must be able to reach the web servers etc.

You can use the following `get` and `diagnose` commands to display information about how WAN optimization is operating

Enter the following command to list all of the running WAN optimization tunnels and display information about each one. The command output shows 3 tunnels all created by peer-to-peer WAN optimization rules (auto-detect set to on).

```
diagnose wad tunnel list

Tunnel: id=139 type=auto
   vd=0 shared=no uses=0 state=1
   peer name= id=0 ip=unknown
   SSL-secured-tunnel=no auth-grp=test
   bytes_in=744 bytes_out=76

Tunnel: id=141 type=auto
   vd=0 shared=no uses=0 state=1
   peer name= id=0 ip=unknown
   SSL-secured-tunnel=no auth-grp=test
   bytes_in=727 bytes_out=76

Tunnel: id=142 type=auto
   vd=0 shared=no uses=0 state=1
   peer name= id=0 ip=unknown
   SSL-secured-tunnel=no auth-grp=test
   bytes_in=727 bytes_out=76

Tunnels total=3 manual=0 auto=3
```

Example Adding secure tunneling to an active-passive WAN optimization configuration

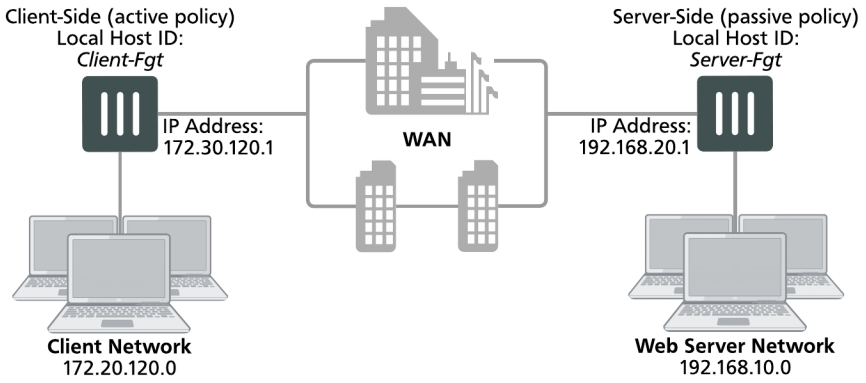
This example shows how to configure two FortiGate units for active-passive WAN optimization with secure tunneling. The same authentication group is added to both FortiGate units. The authentication group includes a password (or pre-shared key) and has **Peer Acceptance** set to **Accept any Peer**. An active policy is added to the client-side FortiGate unit and a passive policy to the server-side FortiGate unit. The active policy includes a profile that performs secure tunneling, optimizes HTTP traffic, and uses Transparent Mode and byte caching.

The authentication group is named **Auth-Secure-Tunnel** and the password for the pre-shared key is **2345678**. The topology for this example is shown below. This example includes web-based manager configuration steps followed by equivalent CLI configuration steps. For information about secure tunneling, see Secure tunneling on page 3472.

Network topology and assumptions

This example configuration includes a client-side FortiGate unit called Client-net with a WAN IP address of 172.30.120.1.This unit is in front of a network with IP address 172.20.120.0. The server-side FortiGate unit is called Web-servers and has a WAN IP address of 192.168.20.1. This unit is in front of a web server network with IP address 192.168.10.0.

Example active-passive WAN optimization and secure tunneling topology



General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1. Configure the client-side FortiGate unit:
   - Add peers.
   - Add an authentication group.
   - Add an active WAN optimization policy.
2. Configure the server-side FortiGate unit.
   - Add peers.
   - Add the same authentication group
   - Add a passive WAN optimization policy that applies application control.
   - Add a WAN optimization tunnel policy.

Also note that if you perform any additional actions between procedures, your configuration may have different results.

Configuring WAN optimization with secure tunneling - web-based manager

Use the following steps to configure the example WAN optimization configuration from the client-side and server-side FortiGate unit web-based manager. (CLI steps follow.)

To configure the client-side FortiGate unit

1. Go to **WAN Opt. & Cache > Peers** and enter a **Local Host ID** for the client-side FortiGate unit:

Local Host ID	Client-Fgt

2. Select **Apply** to save your setting.
3. Select **Create New** and add a **Peer Host ID** and the **IP Address** for the server-side FortiGate unit:

Peer Host ID	Server-Fgt
IP Address	192.168.20.1

4. Select **OK**.
5. Go to **WAN Opt. & Cache > Authentication Groups** and select **Create New** to add the authentication group to be used for secure tunneling:

Name	Auth-Secure-Tunnel
Authentication Method	Pre-shared key
Password	2345678
Peer Acceptance	Accept Any Peer

6. Select **OK**.
7. Go to **WAN Opt. & Cache > Profiles** and select **Create New** to add a WAN optimization profile that enables secure tunneling and includes the authentication group:

Name	Secure-wan-op-pro
Transparent Mode	Select
Authentication Group	Auth-Secure-tunnel

8. Select the **HTTP** protocol, select Secure Tunneling and **Byte Caching** and set the **Port** to 80.
9. Select **OK**.
10. Go to **Policy & Objects > Addresses** and select **Create New** to add a firewall address for the client network.

Category	Address

Name	Client-Net
Type	Subnet
Subnet / IP Range	172.20.120.0/24
Interface	port1

11. Select **Create New** to add a firewall address for the web server network.

Category	Address
Address Name	Web-Server-Net
Type	Subnet
Subnet / IP Range	192.168.10.0/24
Interface	port2

12. Go to **Policy & Objects > IPv4 Policy** and select **Create New** to add an active WAN optimization security policy:

Incoming Interface	port1
Source Address	Client-Net
Outgoing Interface	port2
Destination Address	Web-Server-Net
Schedule	always
Service	HTTP
Action	ACCEPT

13. Turn on **WAN Optimization** and configure the following settings:

WAN Optimization	active
Profile	Secure-wan-opt-pro

14. Select **OK**.

To configure the server-side FortiGate unit

1. Go to **WAN Opt. & Cache > Peers** and enter a **Local Host ID** for the server-side FortiGate unit:

Local Host ID	Server-Fgt

2. Select **Apply** to save your setting.
3. Select **Create New** and add a **Peer Host ID** and the **IP Address** for the client-side FortiGate unit:

Peer Host ID	Client-Fgt
IP Address	172.30.120.1

4. Select **OK**.
5. Go to **WAN Opt. & Cache > Authentication Groups** and select **Create New** and add an authentication group to be used for secure tunneling:

Name	Auth-Secure-Tunnel
Authentication Method	Pre-shared key
Password	2345678
Peer Acceptance	Accept Any Peer

6. Select **OK**.
7. Go to **Policy & Objects > Addresses** and select **Create New** to add a firewall address for the client network.

Category	Address
Name	Client-Net
Type	Subnet
Subnet / IP Range	172.20.120.0/24
Interface	port1

8. Select **Create New** to add a firewall address for the web server network.

Category	Address
Address Name	Web-Server-Net
Type	Subnet
Subnet / IP Range	192.168.10.0/24
Interface	port2

9. Select **OK**.
10. Select **Create New** to add a passive WAN optimization policy that applies application control.

Incoming Interface	port2
Source Address	Client-Net
Outgoing Interface	port1
Destination Address	Web-Server-Net

Schedule	always
Service	ALL
Action	ACCEPT

11. Turn on **WAN Optimization** and configure the following settings:

WAN Optimization	passive
Passive Option	default

12. Select **OK**.
13. From the CLI enter the following command to add a WAN optimization tunnel explicit proxy policy.

```
configure firewall explicit-proxy-policy
   edit 0
      set proxy wanopt
      set dstintf port1
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
      set service ALL
   next
end
```

Configuring WAN optimization with secure tunneling - CLI

Use the following steps to configure the example WAN optimization configuration from the client-side and server-side FortiGate unit CLI.

To the client-side FortiGate unit

1. Add the Local Host ID to the client-side FortiGate configuration:

```
config wanopt settings
   set host-id Client-Fgt
end
```

2. Add the server-side Local Host ID to the client-side peer list:

```
config wanopt peer
   edit Server-Fgt
   set ip 192.168.20.1
end
```

3. Add a new authentication group to be used for secure tunneling:

```
config wanopt auth-group
   edit Auth-Secure-Tunnel
      set auth-method psk
      set psk 2345678
end
```

Leave `peer-accept` at its default value.

4. Add a WAN optimization profile that enables secure tunneling and includes the authentication group, enables HTTP protocol optimization, and enables secure tunneling and byte caching for HTTP traffic:

```
config wanopt profile
   edit Secure-wan-op-pro
      set auth-group Auth-Secure-Tunnel
      config http
         set status enable
         set secure-tunnel enable
         set byte-caching enable
         set port 80
      end
   end
```

5. Add a firewall address for the client network.

```
config firewall address
   edit Client-Net
      set type ipmask
      set subnet 172.20.120.0 255.255.255.0
      set associated-interface port1
   end
```

6. Add a firewall address for the web server network.

```
config firewall address
   edit Web-Server-Net
      set type ipmask
      set subnet 192.168.10.0 255.255.255.0
      set associated-interface port2
   end
```

7. Add an active WAN optimization security policy that includes the WAN optimization profile that enables secure tunneling and that applies virus scanning:

```
config firewall policy
   edit 0
      set srcintf port1
      set dstintf port2
      set srcaddr Client-Net
      set dstaddr Web-Server-Net
      set action accept
      set service HTTP
      set schedule always
      set wanopt enable
      set wanopt-detection active
      set wanopt-profile Secure-wan-opt-pro
   end
```

To configure the server-side FortiGate unit

1. Add the Local Host ID to the server-side FortiGate configuration:

```
config wanopt settings
   set host-id Server-Fgt
end
```

2. Add the client-side Local Host ID to the server-side peer list:

```
config wanopt peer
   edit Client-Fgt
   set ip 172.20.120.1
```

```
end
```

3. Add an authentication group to be used for secure tunneling:

```
config wanopt auth-group
   edit Auth-Secure-Tunnel
      set auth-method psk
      set psk 2345678
   end
```

   Leave `peer-accept` at its default value.

4. Add a firewall address for the client network.

```
config firewall address
   edit Client-Net
      set type ipmask
      set subnet 172.20.120.0 255.255.255.0
      set associated-interface port1
   end
```

5. Add a firewall address for the web server network.

```
config firewall address
   edit Web-Server-Net
      set type ipmask
      set subnet 192.168.10.0 255.255.255.0
      set associated-interface port2
   end
```

6. Add a passive WAN optimization policy.

```
config firewall policy
   edit 0
      set srcintf port1
      set dstintf port2
      set srcaddr Client-Net
      set dstaddr Web-Server-Net
      set action accept
      set service ALL
      set schedule always
      set wanopt enable
      set wanopt-detection passive
      set wanopt-passive-opt default
   end
```

7. Add a WAN optimization tunnel explicit proxy policy.

```
configure firewall explicit-proxy-policy
   edit 0
      set proxy wanopt
      set dstintf port1
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
      set service ALL
   next
end
```

Web caching and SSL offloading

FortiGate web caching is a form of object caching that accelerates web applications and web servers by reducing bandwidth usage, server load, and perceived latency. Web caching supports caching of HTTP 1.0 and HTTP 1.1 web sites. See RFC 2616 for information about web caching for HTTP 1.1.

Web caching supports caching of Flash content over HTTP but does not cache audio and video streams including Flash videos and streaming content that use native streaming protocols such as RTMP.

The first time a file is received by web caching it is cached in the format it is received in, whether it be compressed or uncompressed. When the same file is requested by a client but in a different compression format, the cached file is converted to the new compressed format before being sent to the client.

There are three significant advantages to using web caching to improve HTTP and WAN performance:

- reduced bandwidth consumption because fewer requests and responses go over the WAN or Internet.
- reduced web server load because there are fewer requests for web servers to handle.
- reduced latency because responses for cached requests are available from a local FortiGate unit instead of from across the WAN or Internet.

You can use web caching to cache any web traffic that passes through the FortiGate unit, including web pages from web servers on a LAN, WAN or on the Internet. You apply web caching by enabling the web caching option in any security policy. When enabled in a security policy, web caching is applied to all HTTP sessions accepted by the security policy. If the security policy is an explicit web proxy security policy, the FortiGate unit caches explicit web proxy sessions.

Turning on web caching for HTTP and HTTPS traffic

Web caching can be applied to any HTTP or HTTPS traffic by enabling web caching in a security policy that accepts the traffic. This includes IPv4, IPv6, WAN optimization and explicit web proxy traffic. Web caching caches all HTTP traffic accepted by a policy on TCP port 80.

You can add web caching to a policy to:

- Cache Internet HTTP traffic for users on an internal network to reduce Internet bandwidth use. Do this by selecting the web cache option for security policies that allow users on the internal network to browse web sites on the Internet.
- Reduce the load on a public facing web server by caching objects on the FortiGate unit. This is a reverse proxy with web caching configuration. Do this by selecting the web cache option for a security policy that allows users on the Internet to connect to the web server.
- Cache outgoing explicit web proxy traffic when the explicit proxy is used to proxy users in an internal network who are connecting to the web servers on the Internet. Do this by selecting the web cache option for explicit web proxy security policies that allow users on the internal network to browse web sites on the Internet.
- Combine web caching with WAN optimization. You can enable web caching in any WAN optimization security policy. This includes manual, active, and passive WAN optimization policies and WAN optimization tunnel policies. You can enable web caching on both the client-side and the server-side FortiGate units or on just one or the other.

For optimum performance you can enable web caching on both the client-side and server-side FortiGate units. In this way only uncached content is transmitted through the WAN optimization tunnel. All cached content is access locally by clients from the client side FortiGate unit.

One important use for web caching is to cache software updates (for example, Windows Updates or iOS updates. When updates occur a large number of users may all be trying to download these updates at the same time. Caching these updates will be a major performance improvement and also have a potentially large impact on reducing Internet bandwidth use. You may want to adjust the maximum cache object size to make sure these updates are cached. See Max cache object size on page 3499.

Turning on web caching for HTTPS traffic

Web caching can also cache the content of HTTPS traffic on TCP port 443. With HTTPS web caching, the FortiGate unit receives the HTTPS traffic on behalf of the client, opens up the encrypted traffic and extracts content to be cached. Then FortiGate unit re-encrypts the traffic and sends it on to its intended recipient. It is very similar to a man-in-the-middle attack.

You enable HTTPS web caching from the CLI in a security policy or an explicit proxy policy that accepts the traffic to be cached using `webcache-https`. For a firewall policy:

```
config firewall policy
   edit 0
      .
      .
      .
      set webcache enable
      set webcache-https enable
      .
      .
      .
   end
```

For an explicit web proxy policy:

```
config firewall policy
   edit 0
      set proxy web
      .
      .
      .
      set webcache enable
      set webcache-https enable
      .
      .
      .
   end
```

The `webcache-https` field is available only if `webcache` is enabled.

Web caching for HTTPS traffic is not supported if WAN optimization or FTP proxy is enabled: i.e., if `srcintf` is `ftp-proxy` or `wanopt`.

The `any` setting causes the FortiGate unit to re-encrypt the traffic with the FortiGate unit's certificate rather than the original certificate. This configuration can cause errors for HTTPS clients because the name on the certificate does not match the name on the web site.

You can stop these errors from happening by configuring HTTPS web caching to use the web server's certificate by setting `webcache-https` to `ssl-server`. This option is available for both firewall policies and explicit web proxy policies.

```
config firewall policy
   edit 0
      .
      .
      .
      set webcache enable
      set webcache-https enable
      .
      .
      .
   end
```

The `ssl-server` option causes the FortiGate unit to re-encrypt the traffic with a certificate that you imported into the FortiGate unit. You can add certificates using the following command:

```
config firewall ssl-server
   edit corporate-server
      set ip <Web-Server-IP>
      set port 443
      set ssl-mode { full | half}
      set ssl-cert <Web-Server-Cert>
   end
```

Where:

`Web-Server-IP` is the web server's IP address.

`Web-Server-Cert` is a web server certificate imported into the FortiGate unit.

The SSL server configuration also determines whether the SSL server is operating in half or full mode and the port used for the HTTPS traffic.

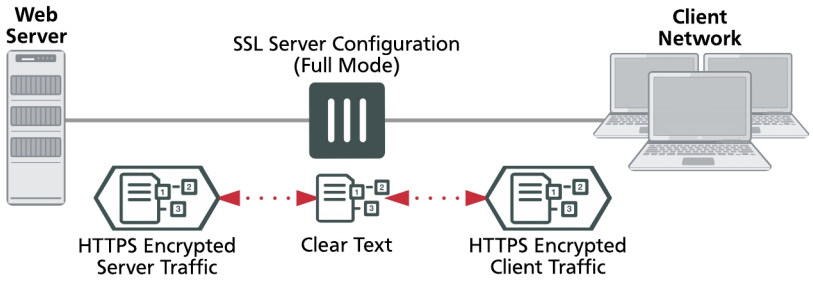
You can add multiple SSL server certificates in this way. When web caching processing an SSL stream if it can find a certificate that matches the web server IP address and port of one of the added SSL servers; that certificate is used to encrypt the SSL traffic before sending it to the client. As a result the client does not generate SSL certificate errors.

Web caching uses the FortiGate unit's FortiASIC to accelerate SSL decryption/encryption performance.

Full mode SSL server configuration

The `ssl-mode` option determines whether the SSL server operates in half or full mode. In full mode the FortiGate unit performs both decryption and encryption of the HTTPS traffic. The full mode sequence is shown below.

Full mode SSL server configuration



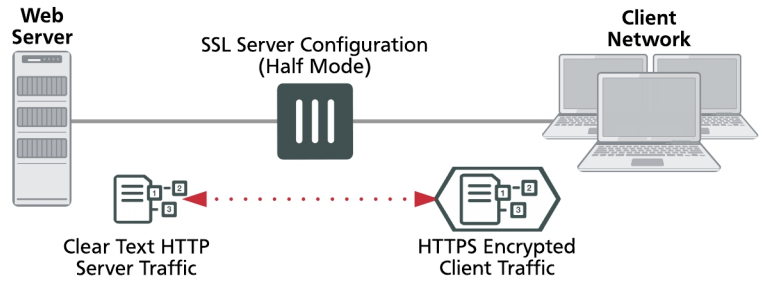
In full mode the FortiGate unit is acting as a man in the middle, decrypting and encrypting the traffic. So both the client and the web server see encrypted packets.

Usually the port of the encrypted HTTPS traffic is always 443. However, in the SSL server configuration you can set the port used for HTTPS traffic. This port is not altered by the SSL Server. So for example, if the SSL Server receives HTTPS traffic on port 443, the re-encrypted traffic forwarded to the FortiGate unit to the server or client will still use port 443.

Half mode SSL server configuration

In half mode, the FortiGate unit only performs one encryption or decryption action. If HTTP packets are received, the half mode SSL server encrypts them and converts them to HTTPS packets. If HTTPS packets are received, the SSL server decrypts them and converts them to HTTP packets.

Half mode SSL server configuration



In half mode, the FortiGate unit is acting like an SSL accelerator, offloading HTTPS decryption from the web server to the FortiGate unit. Since FortiGate units can accelerate SSL processing, the end result could be improved web site performance.

Usually the port of the encrypted traffic is always 443. However, in the SSL server configuration you can set the port used for HTTPS traffic. No matter what port is used for the HTTPS traffic, the decrypted HTTP traffic uses port 80.

Changing the ports on which to look for HTTP and HTTPS traffic to cache

By default FortiOS assumes HTTP traffic uses TCP port 80 and HTTPS traffic uses port 443. So web caching caches all HTTP traffic accepted by a policy on TCP port 80 and all HTTPS traffic on TCP port 443. If you want to cache HTTP or HTTPS traffic on other ports, you can enable security profiles for the security policy and configure

a proxy options profile to that looks for HTTP and HTTPS traffic on other TCP ports. To configure a proxy options profile go to **Network > Explicit Proxy**.

Setting the HTTP port to **Any** in a proxy options profile is not compatible with web caching. If you set the HTTP port to any, web caching only caches HTTP traffic on port 80.

Web caching and HA

You can configure web caching on a FortiGate HA cluster. The recommended best practice HA configuration for web caching is active-passive mode. When the cluster is operating, all web caching sessions are processed by the primary unit only. Even if the cluster is operating in active-active mode, HA does not load-balance web caching sessions.

In a cluster, only the primary unit stores the web cache database. The databases is not synchronized to the subordinate units. So, after a failover, the new primary unit must build its web cache.

Web caching and memory usage

To accelerate and optimize disk access and to provide better throughput and less latency, web caching uses provisioned memory to reduce disk I/O and increase disk I/O efficiency. In addition, web caching requires a small amount of additional memory per session for comprehensive flow control logic and efficient traffic forwarding.

When web caching is enabled you will see a reduction in available memory. The reduction increases when more web caching sessions are being processed. If you are thinking of enabling web caching on an operating FortiGate unit, make sure its memory usage is not maxed out during high traffic periods.

In addition to using the system dashboard to see the current memory usage you can use the `get test wad 2` command to see how much memory is currently being used by web caching. See get test {wad | wccpd} <test_level> on page 3569 for more information.

Changing web cache settings

In most cases, the default settings for the WAN optimization web cache are acceptable. However, you may want to change them to improve performance or optimize the cache for your configuration. To change these settings, go to **WAN Opt. & Cache > Settings.**

From the FortiGate CLI, you can use the `config wanopt webcache` command to change these WAN optimization web cache settings.

For more information about many of these web cache settings, see RFC 2616.

Always revalidate

Select to always revalidate requested cached objects with content on the server before serving them to the client.

Max cache object size

Set the maximum size of objects (files) that are cached. The default size is 512000 KB and the range is 1 to 4294967 KB. This setting determines the maximum object size to store in the web cache. Objects that are larger than this size are still delivered to the client but are not stored in the FortiGate web cache.

For most web traffic the default maximum cache object size is recommended. However, since web caching can also cache larger objects such as Windows updates, Mac OS updates, iOS updates or other updates delivered using HTTP you might want to increase the object size to make sure these updates are cached. Caching these updates can save a lot of Internet bandwidth and improve performance when major updates are released by these vendors.

Negative response duration

Set how long in minutes that the FortiGate unit caches error responses from web servers. If error responses are cached, then subsequent requests to the web cache from users will receive the error responses regardless of the actual object status.

The default is 0, meaning error responses are not cached. The content server might send a client error code (4xx HTTP response) or a server error code (5xx HTTP response) as a response to some requests. If the web cache is configured to cache these negative responses, it returns that response in subsequent requests for that page or image for the specified number of minutes.

Fresh factor

Set the fresh factor as a percentage. The default is 100, and the range is 1 to 100%. For cached objects that do not have an expiry time, the web cache periodically checks the server to see if the objects have expired. The higher the **Fresh Factor** the less often the checks occur.

For example, if you set the **Max TTL** value and **Default TTL** to 7200 minutes (5 days) and set the **Fresh Factor** to 20, the web cache check the cached objects 5 times before they expire, but if you set the **Fresh Factor** to 100, the web cache will check once.

Max TTL

The maximum amount of time (Time to Live) an object can stay in the web cache without the cache checking to see if it has expired on the server. The default is 7200 minutes (120 hours or 5 days) and the range is 1 to 5256000 minutes (5256000 minutes in a year).

Min TTL

The minimum amount of time an object can stay in the web cache before the web cache checks to see if it has expired on the server. The default is 5 minutes and the range is 1 to 5256000 minutes (5256000 minutes in a year).

Default TTL

The default expiry time for objects that do not have an expiry time set by the web server. The default expiry time is 1440 minutes (24 hours) and the range is 1 to 5256000 minutes (5256000 minutes in a year).

Proxy FQDN

The fully qualified domain name (FQDN) for the proxy server. This is the domain name to enter into browsers to access the proxy server. This field is for information only can be changed from the explicit web proxy configuration.

Max HTTP request length

The maximum length of an HTTP request that can be cached. Larger requests will be rejected. This field is for information only can be changed from the explicit web proxy configuration.

Max HTTP message length

The maximum length of an HTTP message that can be cached. Larger messages will be rejected. This field is for information only can be changed from the explicit web proxy configuration.

Ignore

Select the following options to ignore some web caching features.

If-modified-since	By default, if the time specified by the if-modified-since (IMS) header in the client's conditional request is greater than the last modified time of the object in the cache, it is a strong indication that the copy in the cache is stale. If so, HTTP does a conditional GET to the Overlay Caching Scheme (OCS), based on the last modified time of the cached object. Enable ignoring if-modified-since to override this behavior.
HTTP 1.1 conditionals	HTTP 1.1 provides additional controls to the client over the behavior of caches toward stale objects. Depending on various cache-control headers, the FortiGate unit can be forced to consult the OCS before serving the object from the cache. For more information about the behavior of cache-control header values, see RFC 2616.Enable ignoring HTTP 1.1 Conditionals to override this behavior.
Pragma-no-cache	Typically, if a client sends an HTTP GET request with a pragma no-cache (PNC) or cache-control no-cache header, a cache must consult the OCS before serving the content. This means that the FortiGate unit always re-fetches the entire object from the OCS, even if the cached copy of the object is fresh.Because of this behavior, PNC requests can degrade performance and increase server-side bandwidth utilization. However, if you enable ignoring Pragma-no-cache, then the PNC header from the client request is ignored. The FortiGate unit treats the request as if the PNC header is not present.
IE Reload	Some versions of Internet Explorer issue Accept / header instead of Pragma no-cache header when you select **Refresh**. When an Accept header has only the / value, the FortiGate unit treats it as a PNC header if it is a type-N object. Enable ignoring IE reload to cause the FortiGate unit to ignore the PNC interpretation of the Accept / header.

Cache Expired Objects

Applies only to type-1 objects. When this option is selected, expired type-1 objects are cached (if all other conditions make the object cacheable).

Revalidated Pragma-no-cache

The pragma-no-cache (PNC) header in a client's request can affect how efficiently the FortiGate unit uses bandwidth. If you do not want to completely ignore PNC in client requests (which you can do by selecting to ignore Pragma-no-cache, above), you can nonetheless lower the impact on bandwidth usage by selecting **Revalidate Pragma-no-cache**.

When you select **Revalidate Pragma-no-cache**, a client's non-conditional PNC-GET request results in a conditional GET request sent to the OCS if the object is already in the cache. This gives the OCS a chance to return the 304 Not Modified response, which consumes less server-side bandwidth, because the OCS has not been forced to otherwise return full content.

By default, **Revalidate Pragma-no-cache** is disabled and is not affected by changes in the top-level profile.

Most download managers make byte-range requests with a PNC header. To serve such requests from the cache, you should also configure byte-range support when you configure the **Revalidate pragma-no-cache** option.

Forwarding URLs to forwarding servers and exempting web sites from web caching

You can go to **Network > Explicit Proxy** and use the URL match list to forward URL patterns to forwarding servers and create a list of URLs that are exempt from web caching.

Forwarding URLs and URL patterns to forwarding servers

As part of configuring the explicit web proxy you can configure proxy chaining by adding web proxy forwarding servers. See "Proxy chaining (web proxy forwarding servers) ".

You can then use the URL match list to always forward explicit web proxy traffic destined for configured URLs or URL patterns to one of these forwarding servers. For example, you might want to forward all traffic for a specific country to a proxy server located in that country.

To forward traffic destined for a URL to a forwarding server that you have already added, go to **Network > Explicit Proxy** and select **Create New**. Add a name for the URL match entry and enter the URL or URL pattern. You can use wildcards such as * and ? and you can use a numeric IP address. Select **Forward to Server** and select a web proxy forwarding server from the list.

You can also exempt the URL or URL pattern from web caching.

Use the following command to forward all .ca traffic to a proxy server and all .com traffic to another proxy server.

```
config web-proxy url-match
   edit "com"
      set forward-server "server-commercial"
      set url-pattern "com"
   next
   edit "ca"
      set forward-server "server-canada"
      set url-pattern "ca"
   next
   edit "www.google.ca"
      set cache-exemption enable
      set url-pattern "www.google.ca"
   next
end
```

Exempting web sites from web caching

You may want to exempt some URLs from web caching for a number of reasons. For example, if your users access websites that are not compatible with FortiGate web caching you can add the URLs of these web sites to the web caching exempt list. You can add URLs and numeric IP addresses to the web cache exempt list.

You can also add URLs to the web cache exempt list by going to **Network > Explicit Proxy** and selecting **Create New**. Add a URL pattern to be exempt and select **Exempt from Cache**.

You can also add URLs and addresses to be exempt from caching using the CLI. Enter the following command to add www.example.com to the web cache exempt list:

```
config web-proxy url-match
   set cache-exemption enable
   set url-pattern www.example.com
end
```

Exempting specific files from caching

You can exempt files from being cached, so long as you specify its full URL. Enter the following command to add the URL, with the file extension (in this example, `.exe`), to the web cache exempt list:

```
config web-proxy url-match
   edit "exe"
      set url-pattern "iavs9x.u.avast.com/custom/iavs9x/20160613t1237z/avast_free_
          antivirus_setup_online.exe"
      set cache-exemption enable
   next
end
```

You cannot use wildcards to exempt file extensions in general from caching.

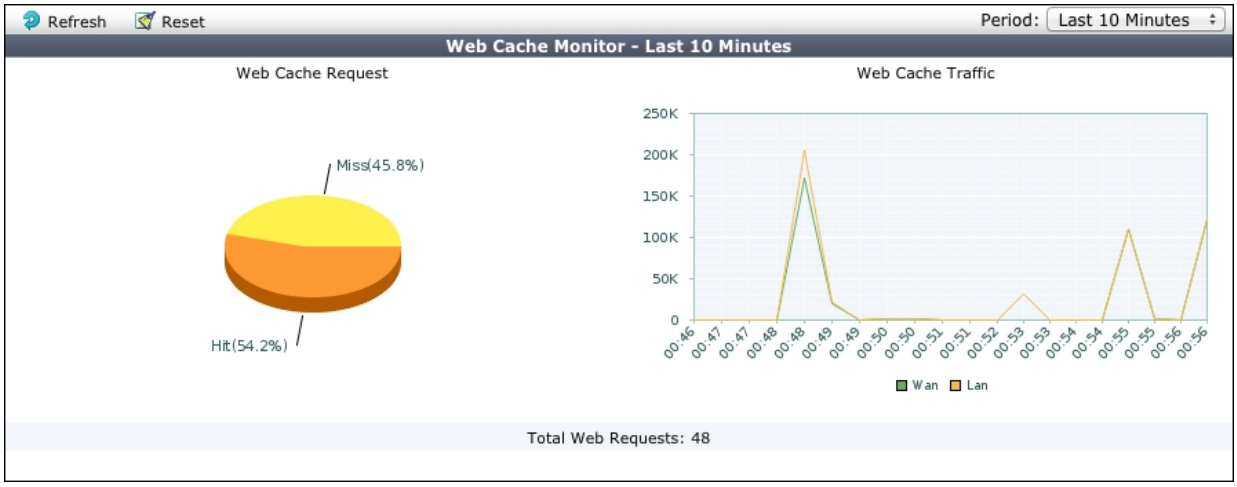
Monitoring Web caching performance

The web cache monitor shows the percentage of web cache requests that retrieved content from the cache (hits) and the percentage that did not receive content from the cache (misses). A higher the number of hits usually indicates that the web cache is being more effective at reducing WAN traffic.

The web cache monitor also shows a graph of web traffic on the WAN and LAN. A lower WAN line on the graph indicates the web cache is reducing traffic on the WAN. The web cache monitor also displays the total number of web requests processed by the web cache.

To view the web cache monitor, go to **Monitor > Cache Monitor**.

Web cache monitor



Example Web caching of HTTP and HTTPS Internet content for users on an internal network

This example describes how to configure web caching of HTTP and HTTPS for users on a private network connecting to the Internet.

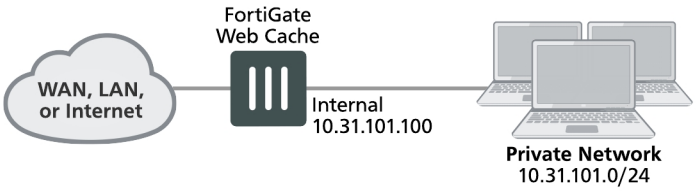
Network topology and assumptions

This example includes a client network with subnet address 10.31.101.0 connecting to web servers on the Internet. All of the users on the private network access the Internet though a single general security policy on the FortiGate unit that accepts all sessions connecting to the Internet. Web caching for HTTP and HTTPS traffic is added to this security policy.

Since users on the private network have unrestricted access to the Internet and can be accessing many web servers the `webcache-https` is set to `any` and users may see error messages on their web browsers when accessing HTTPS content.

Initially, security profiles are not selected so the example caches all HTTP traffic on TCP port 80 and HTTPS traffic on port 443. The example also describes how to configure the security policy to cache HTTP traffic on port 80 and 8080 by adding a proxy options profile that looks for HTTP traffic on TCP ports 80 and 8080. The example also describes how to configure the security policy to cache HTTPS traffic on port 443 and 8443 using the same proxy options profile.

Example web caching topology



General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1. Add HTTP web caching to the security policy that all users on the private network use to connect to the Internet.
2. Add HTTPS web caching.
3. Add a protocol options profile to look for HTTP traffic on ports 80 and 8080 and HTTPS traffic on ports 443 and 8443 and add this protocol options profile to the security policy.

If you perform any additional actions between procedures, your configuration may have different results.

Configuration Steps - web-based manager

Use the following steps to configure the example configuration from the FortiGate web-based manager.

To add HTTP web caching to a security policy

1. Go to **Policy & Objects > IPv4 Policy** and add a security policy that allows all users on the internal network to access the Internet.

Incoming Interface	Internal
Source Address	all
Outgoing Interface	wan1

Destination Address	all
Schedule	always
Service	ALL
Action	ACCEPT

2. Select **Enable NAT** and select **Use Destination Interface Address**.
3. Turn on **Web cache**.
4. Select **OK**.

To add HTTPS web caching

1. From the CLI enter the following command to add HTTPS web caching to the policy.

   Assume the index number of the policy is 5.

```
config firewall policy
   edit 5
      set webcache-https any
   end
```

To cache HTTP traffic on port 80 and 8080

1. Go to **Network > Explicit Proxy** and edit the **default** proxy options profile.

   You could also add a new profile.
2. Under **Protocol Port Mapping** enable **HTTP** and under **Inspection Ports** enter **80,8080**.
3. Go to **Policy & Objects > IPv4 Policy**, edit the security policy and

To cache HTTPS traffic on ports 443 and 8443

1. Go to **Security Profiles > SSL Inspection** and edit the **certificate-inspection** SSL/SSH inspection profile.

   You could also use the **deep-inspection** profile or add a new profile.
2. Under **SSL Inspection Options** select **Multiple Clients Connecting to Multiple Servers**.
3. Make sure **Inspect All Ports** is not selected.
4. Make sure **HTTPS** is turned on and enter **443,8443**.
5. From the CLI, enter the following command to add the **default** proxy options profile and the **certificate-inspection** SSL SSH profile to the firewall policy.

```
config firewall policy
   edit 5
      set utm-status enable
      set profile-protocol-options default
      set ssl-ssh-profile certificate-inspection
   end
```

You need to use the CLI to add the protocol options profile unless you also add a security profile that uses proxy-based inspection.

Configuration Steps - CLI

Use the following steps to configure the example configuration from the FortiGate CLI.

To add HTTP and HTTPS web caching to a security policy

1. Enter the following command to add a security policy that allows all users on the internal network to access the Internet and that includes web caching of HTTP and HTTPS traffic.

```
config firewall policy
   edit 0
      set srcintf internal
      set srcaddr all
      set dstintf wan1
      set distinf all
      set schedule always
      set service ANY
      set action accept
      set nat enable
      set webcache enable
      set webcache-https any
   end
```

To cache HTTP traffic on port 80 and 8080 and HTTPS traffic on ports 443 and 8443

1. Enter the following command to edit the **default** proxy options profile to configure it to look for HTTP traffic on ports 80 and 8080:

```
config firewall profile-protocol-options
   edit default
      config http
         set status enable
         set ports 80 8080
      end
```

2. Enter the following command to edit the **certification-inspection** SSL SSH options profile to configure it to look for HTTPS traffic on ports 443 and 8443:

```
config firewall ssl-ssh-profile
   edit certificate-inspection
      config https
         set status certificate-inspection
         set ports 443 8443
      end
```

3. Enter the following command to add the **default** proxy options profile and the **certificate-inspection** SSL SSH profile to the firewall policy.

```
config firewall policy
   edit 5
      set utm-status enable
      set profile-protocol-options default
      set ssl-ssh-profile certificate-inspection
   end
```

Example reverse proxy web caching and SSL offloading for an Internet web server using a static one-to-one virtual IP

This section describes configuring SSL offloading for a reverse proxy web caching configuration using a static one-to-one firewall virtual IP (VIP). While the static one-to-one configuration described in this example is valid, its also common to change the destination port of the unencrypted HTTPS traffic to a commonly used HTTP port such as 8080 using a port forwarding virtual IP.

Network topology and assumptions

In this configuration, clients on the Internet use HTTP and HTTPS to browse to a web server that is behind a FortiGate unit. A policy added to the FortiGate unit forwards the HTTP traffic to the web server. The policy also offloads HTTPS decryption and encryption from the web server so the web server only sees HTTP traffic.

The FortiGate unit also caches HTTP and HTTPS pages from the web server so when users access cached pages the web server does not see the traffic. Replies to HTTPS sessions are encrypted by the FortiGate unit before returning to the clients.

In this configuration, the FortiGate unit is operating as a web cache in reverse proxy mode. Reverse proxy caches can be placed directly in front of a web server. Web caching on the FortiGate unit reduces the number of requests that the web server must handle, therefore leaving it free to process new requests that it has not serviced before.

Using a reverse proxy configuration:

- avoids the capital expense of additional web servers by increasing the capacity of existing servers
- serves more requests for static content from web servers
- serves more requests for dynamic content from web servers
- reduces operating expenses including the cost of bandwidth required to serve content
- accelerates the response time of web servers and of page download times to end users.

When planning a reverse proxy implementation, the web server's content should be written so that it is “cache aware” to take full advantage of the reverse proxy cache.

In reverse proxy mode, the FortiGate unit functions more like a web server for clients on the Internet. Replicated content is delivered from the proxy cache to the external client without exposing the web server or the private network residing safely behind the firewall.

In this example, the site URL translates to IP address 192.168.10.1, which is the port2 IP address of the FortiGate unit. The port2 interface is connected to the Internet.

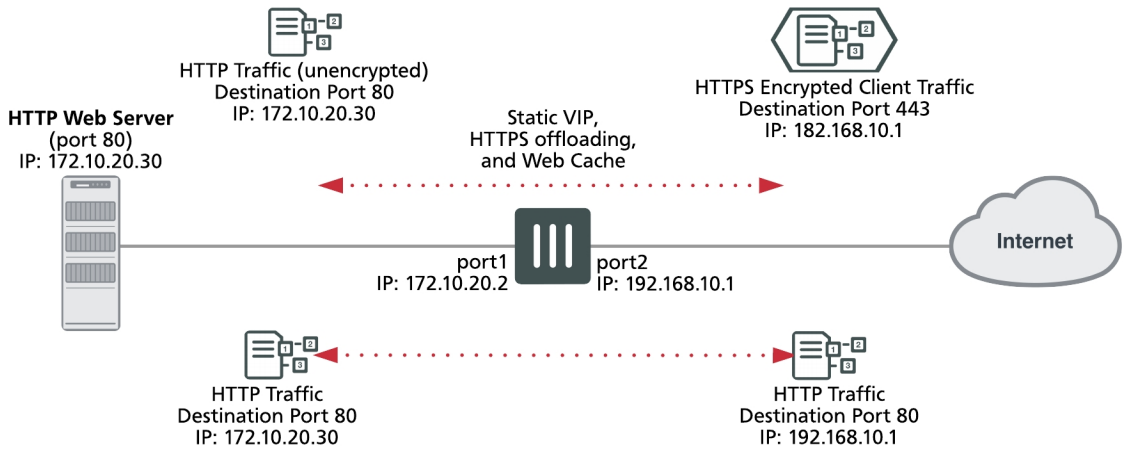
This example assumes that all HTTP traffic uses port 80 and all HTTPS traffic uses port 443.

The FortiGate unit includes the web server CA and an SSL server configuration for IP address 172.10.20.30 and port to 443. The name of the file containing the CA is Rev_Proxy_Cert_1.crt.

The destination address of incoming HTTP and HTTPS sessions is translated to the IP address of the web server using a static one-to-one virtual IP that performs destination address translation (DNAT) for the HTTP packets. The DNAT translates the destination address of the packets from 192.168.10.1 to 172.10.20.30 but does not change the destination port number.

When the SSL server on the FortiGate unit decrypts the HTTPS packets their destination port is changed to port 80.

Reverse proxy web caching and SSL offloading for an Internet web server using static one-to-one virtual IPs



General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1. Configure the FortiGate unit as a reverse proxy web cache server.
2. Configure the FortiGate unit for SSL offloading of HTTPS traffic.
3. Add an SSL server to offload SSL encryption and decryption for the web server.

Also note that if you perform any additional actions between procedures, your configuration may have different results.

Configuration steps - web-based manager

To configure the FortiGate unit as a reverse proxy web cache server

1. Go to **Policy & Objects > Virtual IPs** and select **Create New** to add a static NAT virtual IP that translates destination IP addresses from 192.168.10.1 to 172.10.20.30 (and does not translate destination ports):

VIP Type	IPv4 VIP
Name	Reverse_proxy_VIP
Interface	port2
Type	Static NAT
Source Address Filter	Do not select.
External IP Address/Range	192.168.10.1
Mapped IP Address/Range	172.10.20.30
Port Forwarding	Do not select.

2. Select **OK**.
3. Go to **Policy & Objects > IPv4 Policy** and select **Create New** to add a port2 to port1 security policy that accepts HTTP and HTTPS traffic from the Internet.

   Do not select security profiles. Set the destination address to the virtual IP. You do not have to enable NAT.

Incoming Interface	port2
Source Address	all
Outgoing Interface	port1
Destination Address	Reverse_proxy_VIP
Schedule	always
Service	HTTP HTTPS
Action	ACCEPT

4. Turn on **Web Cache**.
5. Select **OK**.
6. From the CLI enter the following command to add HTTPS web caching to the security policy

   Assume the index number of the policy is 5.

```
config firewall policy
   edit 5
      set webcache-https ssl-server
   end
```

To configure the FortiGate unit to offload SSL encryption and cache HTTPS content

1. Go to **System > Certificates** and select **Import** to import the web server's CA.

   For **Type**, select **Local Certificate**. Select the **Browse** button to locate the file (example file name: Rev_Proxy_Cert_1.crt).

   The certificate key size must be 1024 or 2048 bits. 4096-bit keys are not supported.
2. Select **OK** to import the certificate.
3. From the CLI, enter the following command to add the SSL server and to add the server's certificate to the SSL server.

   The SSL server `ip` must match the destination address of the SSL traffic after being translated by the virtual IP (172.10.20.30) and the SSL server `port` must match the destination port of the SSL traffic (443). The SSL server operates in half mode since it performs a single-step conversion (HTTPS to HTTP or HTTP to HTTPS).

```
config firewall ssl-server
   edit rev_proxy_server
      set ip 172.10.20.30
      set port 443
      set ssl-mode half
      set ssl-cert Rev_Proxy_Cert_1
```

```
end
```

Configuration steps - CLI

To configure the FortiGate unit as a reverse proxy web cache server

1. Enter the following command to add a static NAT virtual IP that translates destination IP addresses from 192.168.10.1 to 172.10.20.30 (and does not translate destination ports):

```
config firewall vip
   edit Reverse_proxy_VIP
      set extintf port2
      set type static-nat
      set extip 192.168.10.1
      set mappedip 172.10.20.30
   end
```

2. Enter the following command to add a port2 to port1 security policy that accepts HTTP and HTTPS traffic from the Internet. Enable web caching and HTTPS web caching.

   Do not select security profiles. Set the destination address to the virtual IP. You do not have to enable NAT.

```
config firewall policy
   edit 0
      set srcintf port2
      set srcaddr all
      set dstintf port1
      set dstaddr Reverse_proxy_VIP
      set schedule always
      set service HTTP HTTPS
      set action accept
      set webcache enable
      set webcache-https ssl-server
   end
```

To add an SSL server to offload SSL encryption and decryption for the web server

1. Place a copy of the web server's CA (file name Rev_Proxy_Cert_1.crt) in the root folder of a TFTP server.
2. Enter the following command to import the web server's CA from a TFTP server. The IP address of the TFTP server is 10.31.101.30:

```
execute vpn certificate local import tftp Rev_Proxy_Cert_1.crt 10.31.101.30
```

   The certificate key size must be 1024 or 2048 bits. 4096-bit keys are not supported.

3. From the CLI, enter the following command to add the SSL server.

   The SSL server `ip` must match the destination address of the SSL traffic after being translated by the virtual IP (172.10.20.30) and the SSL server `port` must match the destination port of the SSL traffic (443). The SSL server operates in half mode since it performs a single-step conversion (HTTPS to HTTP or HTTP to HTTPS).

```
config firewall ssl-server
   edit rev_proxy_server
      set ip 172.10.20.30
      set port 443
      set ssl-mode half
      set ssl-cert Rev_Proxy_Cert_1
   end
```

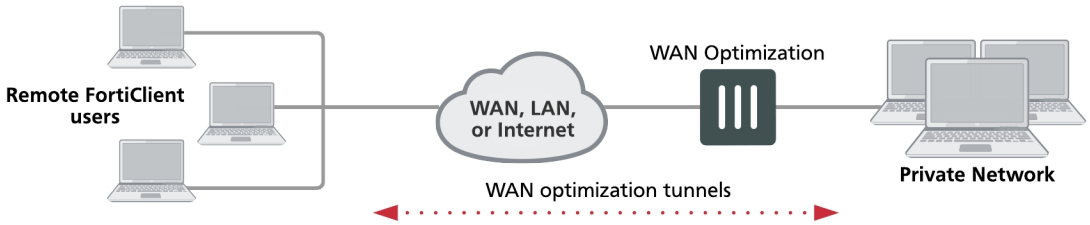
4. Configure other `ssl-server` settings that you may require for your configuration.

FortiClient WAN optimization

FortiClient WAN optimization supports protocol optimization and byte caching in IPsec VPN and SSL VPN tunnels between FortiClient and a FortiGate unit. To add WAN optimization to FortiClient, configure FortiClient Advanced settings and enable WAN optimization. This setting can then apply WAN optimization to any IPsec or SSL VPN tunnel between FortiClient and FortiGate, if the FortiGate IPsec or SSL VPN configuration also includes WAN optimization.

When FortiClient with WAN optimization enabled attempts to connect a server-side FortiGate unit, FortiClient automatically detects if WAN optimization has been added to the FortiGate tunnel configuration. If WAN optimization is detected and FortiClient can successfully negotiate with the FortiGate unit, WAN optimization starts.

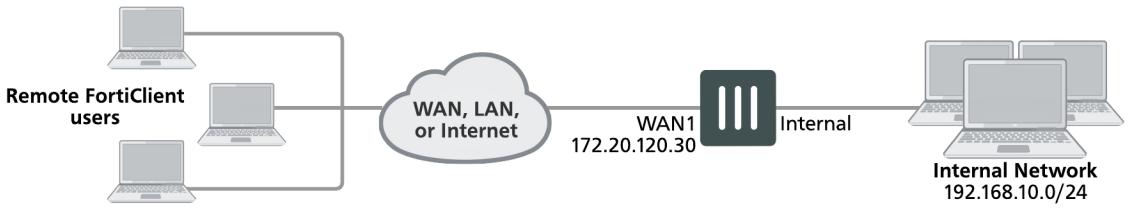
FortiClient WAN optimization topology



FortiClient WAN optimization over IPsec VPN configuration example

This example shows how to add WAN optimization to a FortiClient IPsec VPN. The IPsec VPN tunnel allows remote FortiClient users to connect to the internal network behind the FortiGate unit.

Example FortiClient WAN optimization configuration



To configure the FortiGate unit

Because computers running FortiClient can have IP addresses that change often, it is usually not practical to add FortiClient peers to the FortiGate WAN optimization peer list. Instead, a FortiGate unit that accepts WAN optimization tunnel requests from FortiClient is usually configured to accept any peer. This example does this by adding a WAN optimization authentication group with **Peer acceptance** set to **Accept Any Peer**.

In addition this example includes a **wanopt** to **internal** policy to allow WAN optimization traffic reach the internal network. Finally passive WAN optimization is added to the ssl.root policy because WAN optimization is accepting traffic from the IPsec VPN tunnel.

1. Go to **WAN Opt. & Cache > Authentication Groups** and select **Create New**.
2. Configure the WAN optimization authentication group:

Name	auth-fc
Authentication Method	Certificate
Certificate	Fortinet_Firmware
Peer Acceptance	Accept Any Peer

3. Select **OK**.
4. Go to **WAN Opt. & Cache > Profiles** and select **Create New** (select the + button).
5. Add a profile for FortiClient WAN optimization sessions:

Name	Fclient_Pro
Transparent Mode	Select
Authentication Group	auth-fc

6. Select any Protocols and any settings for each protocol.
7. Select **OK**.
8. Go to **Policy & Objects > Addresses** and select **Create New** to add a firewall address for the internal network that FortiClient users can access.

Category	Address
Address Name	Internal-Server-Net
Type	IP Range
Subnet / IP Range	192.168.10.0/24
Interface	internal

9. Enter the following CLI command to add an explicit proxy policy to accept WAN optimization tunnel connections.

```
configure firewall explicit-proxy-policy
   edit 0
      set proxy wanopt
      set dstintf internal
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
      set service ALL
   next
end
```

To set up IPsec VPN to support WAN optimization

1. Go to **VPN > IPsec Wizard**, enter a **Name** for the IPsec VPN and select **Dialup - FortiClient (Windows, Mac OS, Android)**.
2. Follow the wizard steps to configure the VPN. No special WAN optimization settings are required.
3. Go to **Policy & Objects > IPv4 Policy** and edit the policy created by the wizard.

   This policy has the IPsec VPN interface created by the wizard as the source interface.
4. Turn on **WAN Optimization** and configure the following settings:

Enable WAN Optimization	passive
Passive Option	default

5. Select **OK**.

To configure FortiClient and start the WAN optimization SSL VPN connection

1. Open FortiClient, configure **Advanced** settings, and select **Enable WAN optimization**.
2. Add a new IPsec VPN connection.

   Set the Server to the WAN1 IP address of the FortiGate unit (172.20.120.30 in this example).

   No other settings are required for this example. You can add authentication in the form of a user name and password if required by the FortiGate unit.
3. Start the IPsec VPN tunnel.

   You should be connected to the IPsec VPN tunnel and traffic in it should be optimized.

The FortiGate explicit web proxy

You can use the FortiGate explicit web proxy to enable explicit proxying of IPv4 and IPv6 HTTP, and HTTPS traffic on one or more FortiGate interfaces. The explicit web proxy also supports proxying FTP sessions from a web browser and proxy auto-config (PAC) to provide automatic proxy configurations for explicit web proxy users. From the CLI you can also configure the explicit web proxy to support SOCKS sessions from a web browser.

The explicit web and FTP proxies can be operating at the same time on the same or on different FortiGate interfaces.

If explicit web proxy options are not visible on the web-based manager, go to **System > Feature Select** and turn on **Explicit Proxy**.

In most cases you would configure the explicit web proxy for users on a network by enabling the explicit web proxy on the FortiGate interface connected to that network. Users on the network would configure their web browsers to use a proxy server for HTTP and HTTPS, FTP, or SOCKS and set the proxy server IP address to the IP address of the FortiGate interface connected to their network. Users could also enter the PAC URL into their web browser PAC configuration to automate their web proxy configuration using a PAC file stored on the FortiGate unit.

Enabling the explicit web proxy on an interface connected to the Internet is a security risk because anyone on the Internet who finds the proxy could use it to hide their source address.

If the FortiGate unit is operating in Transparent mode, users would configure their browsers to use a proxy server with the FortiGate management IP address.

If the FortiGate unit is operating with multiple VDOMs the explicit web proxy is configured for each VDOM.

The web proxy receives web browser sessions to be proxied at FortiGate interfaces with the explicit web proxy enabled. The web proxy uses FortiGate routing to route sessions through the FortiGate unit to a destination interface. Before a session leaves the exiting interface, the explicit web proxy changes the source addresses of the session packets to the IP address of the exiting interface. When the FortiGate unit is operating in Transparent mode the explicit web proxy changes the source addresses to the management IP address. You can configure the explicit web proxy to keep the original client IP address. See Preventing the explicit web proxy from changing source addresses on page 3532.

For more information about explicit web proxy sessions, see Explicit web proxy sessions and user limits on page 3538.

Example explicit web proxy topology

To allow all explicit web proxy traffic to pass through the FortiGate unit you can set the explicit web proxy default firewall policy action to accept. However, in most cases you would want to use security policies to control explicit web proxy traffic and apply security features such as access control/authentication, virus scanning, web filtering, application control, and traffic logging. You can do this by keeping the default explicit web proxy security policy action to deny and then adding web-proxy security policies.

You can also change the explicit web proxy default security policy action to accept and add explicit web proxy security policies. If you do this, sessions that match web-proxy security policies are processed according to the security policy settings. Connections to the explicit web proxy that do not match a web-proxy security policy are allowed with no restrictions or additional security processing. This configuration is not recommended and is not a best practice.

The explicit web-proxy can accept VIP addresses for destination address. If an external IP matches a VIP policy, the IP is changed to the mapped-IP of the VIP.

Web-proxy policies can selectively accept or deny traffic, apply authentication, enable traffic logging, and use security profiles to apply virus scanning, web filtering, IPS, application control, DLP, and SSL/SSH inspection to explicit web proxy traffic.

You cannot configure IPsec, SSL VPN, or Traffic shaping for explicit web proxy traffic. Web Proxy policies can only include firewall addresses not assigned to a FortiGate unit interface or with interface set to **Any**. (On the web-based manager you must set the interface to **Any**. In the CLI you must `unset` the `associated-interface`.)

Authentication of explicit web proxy sessions uses HTTP authentication and can be based on the user's source IP address or on cookies from the user's web browser. For more information, see Explicit web proxy authentication on page 3527.

To use the explicit web proxy, users must add the IP address of a FortiGate interface on which the explicit web proxy is enabled and the explicit web proxy port number (default 8080) to the proxy configuration settings of their web browsers.

On FortiGate units that support it, you can also enable web caching for explicit web proxy sessions.

For the time being, traffic shaping is not supported per policy for explicit proxy. For explicit proxy traffic, traffic shaping can be carried out per interface.

General explicit web proxy configuration steps

You can use the following general steps to configure the explicit web proxy.

To enable the explicit web proxy - web-based manager:

1. Go to **Network > Explicit Proxy** and enable **Explicit Web Proxy**. From here you can optionally change the HTTP port that the proxy listens on (the default is 8080) and optionally specify different ports for HTTPS, FTP, PAC, and other options.
2. Optionally enable **IPv6 Explicit Proxy** to turn on the explicit web proxy for IPv6 traffic.

If you enable both the IPv4 and the IPv6 explicit web proxy you can combine IPv4 and IPv6 addresses in a single explicit web proxy policy to allow both IPv4 and IPv6 traffic through the proxy.

3. Select **Apply**.

4. Go to **Network > Interfaces** and select one or more interfaces for which to enable the explicit web proxy. Edit the interface and select **Enable Explicit Web Proxy**.

Enabling the explicit web proxy on an interface connected to the Internet is a security risk because anyone on the Internet who finds the proxy could use it to hide their source address. If you enable the proxy on such an interface make sure authentication is required to use the proxy.

5. Go to **Policy & Objects > Addresses** and select **Create New** to add a firewall address that matches the source address of packets to be accepted by the explicit proxy.

Category	Address
Name	Internal_subnet
Type	IP Range
Subnet / IP Range	10.31.101.1 - 10.31.101.255
Interface	any*

*The **Interface** must be set to **Any**.

You can also set the **Type** to **URL Pattern (Explicit Proxy)** to add a destination URL that is only used by the explicit proxy. For example, to create an explicit policy that only allows access to Fortinet.com:

Category	Address
Name	Fortinet-web-sites
Type	URL Pattern (Explicit Proxy)
URL Pattern	fortinet.com
Interface	any

6. Go to **Policy & Objects > Explicit Proxy Policy** and select **Create New.** Configure the policy as required to accept the traffic that you want to be allowed to use the explicit web proxy.

The source address of the policy must match the client's source IP addresses. The interface of this firewall address must be set to **any**.

The destination address of the policy should match the IP addresses of web sites that clients are connecting to. Usually the destination address would be **all** if proxying Internet web browsing. You could also specify a URL firewall address to limit the policy to allowing access to this URL.

If **Default Firewall Policy Action** is set to **Deny** (under **Network > Explicit Proxy**), traffic sent to the explicit web proxy that is not accepted by a web-proxy policy is dropped. If **Default Firewall Policy Action** is set to **Allow** then all web-proxy sessions that don't match with a security policy are allowed.

For example, the following security policy allows users on an internal network to access fortinet.com websites through the wan1 interface of a FortiGate unit.

Explicit Proxy Type	Web
Source Address	Internal_subnet
Outgoing Interface	wan1
Destination Address	Fortinet-web-sites
Schedule	always
Action	ACCEPT

Add security profiles as required.

7. Select Create New to add another explicit web proxy and set the **Action** to **AUTHENTICATE** to require authentication to access the explicit web proxy. For example:

Explicit Proxy Type	Web
Source Address	Internal_subnet
Outgoing Interface	wan1
Destination Address	Fortinet-web-sites
Schedule	always
Action	AUTHENTICATE

Select **Create New** to add an **Authentication Rule** and configure the rule as follows:

Groups	Proxy-Group
Source User(s)	(optional)
Schedule	always

Add security profiles as required and select **OK**.

You can add multiple user identity policies to apply different authentication for different user groups and users and also apply different UTM and logging settings for different user groups.

You can change the **User Authentication Options** if required. In most cases you can accept the defaults.

8. Optionally enable Web Caching.
9. Select **OK**.

To enable the explicit web proxy - CLI:

1. Enter the following command to turn on the IPv4 and IPv6 explicit web proxy for HTTP and HTTPS traffic.

```
config web-proxy explicit
```

```
   set status enable
   set ipv6-status enable
end
```

You can also enter the following command to enable the web proxy for FTP sessions in a web browser.

```
config web-proxy explicit
   set ftp-over-http enable
end
```

The default explicit web proxy configuration has `sec-default-action` set to `deny` and requires you to add a security policy to allow access to the explicit web proxy.

2. Enter the following command to enable the explicit web proxy for the internal interface.

```
config system interface
   edit internal
      set explicit-web-proxy enable
   end
end
```

3. Use the following command to add a firewall address that matches the source address of users who connect to the explicit web proxy.

```
config firewall address
   edit Internal_subnet
      set type iprange
      set start-ip 10.31.101.1
      set end-ip 10.31.101.255
   end
```

The source address for a web-proxy security policy cannot be assigned to a FortiGate interface.

4. Optionally use the following command to add a destination URL that is only used by the explicit proxy. For example, to create an explicit policy that only allows access to Fortinet.com:

```
config firewall address
   edit Fortinet-web-sites
      set type url
      set url fortinet.com
   end
```

5. Use the following command to add an explicit web proxy policy that allows all users on the internal subnet to use the explicit web proxy for connections through the wan1 interface to the Internet.

```
config firewall explicit-proxy-policy
   edit 0
      set proxy web
      set dstintf wan1
      set scraddr Internal_subnet
      set dstaddr all
      set action accept
      set service webproxy
      set schedule always
end
```

6. Use the following command to add an explicit web proxy policy that allows authenticated users on the internal subnet to use the explicit web proxy for connections through the wan1 interface to the Internet.

```
config firewall explicit-proxy-policy
   edit 0
      set proxy web
      set dstintf wan1
      set scraddr Internal_subnet
      set dstaddr Fortinet-web-sites
      set action accept
      set service webproxy
      set schedule always
      set identity-based enable
         config identity-based-policy
            edit 1
               set groups Proxy-group
               set schedule always
      end
end
```

7. Use the following command to change global web proxy settings, for example to set the maximum request length for the explicit web proxy to 10:

```
config web-proxy global
   set max-request-length 10
end
```

Explicit proxy firewall address types

Explicit proxy firewall address types improve granularity over header matching for explicit web proxy policies. You can enable this option using the **Show in Address List** button on the Address and Address Group New/Edit forms under **Policy & Objects > Addresses**.

The following address types are available:

- **URL Pattern** - destination address
- **Host Regex Match** - destination address
- **URL Category** - destination address (URL filtering)
- **HTTP Method** - source address
- **User Agent** - source address
- **HTTP Header** - source address
- **Advanced (Source)** - source address (combines User Agent, HTTP Method, and HTTP Header)
- **Advanced (Destination)** - destination address (combines Host Regex Match and URL Category)

Proxy auto-config (PAC) configuration

A proxy auto-config (PAC) file defines how web browsers can choose a proxy server for receiving HTTP content. PAC files include the FindProxyForURL(url, host) JavaScript function that returns a string with one or more access method specifications. These specifications cause the web browser to use a particular proxy server or to connect directly.

To configure PAC for explicit web proxy users, you can use the port that PAC traffic from client web browsers use to connect to the explicit web proxy. explicit web proxy users must configure their web browser's PAC proxy settings to use the PAC port.

PAC File Content

You can edit the default PAC file from the web-based manager or use the following command to upload a custom PAC file:

```
config web-proxy explicit
   set pac-file-server-status enable
   set pac-file-data <pac_file_str>
end
```

Where `<pac_file_str>` is the contents of the PAC file. Enter the PAC file text in quotes. You can copy the contents of a PAC text file and paste the contents into the CLI using this option. Enter the command followed by two sets of quotes then place the cursor between the quotes and paste the file content.

The maximum PAC file size is 256 kbytes. If your FortiGate unit is operating with multiple VDOMs each VDOM has its own PAC file. The total amount of FortiGate memory available to store all of these PAC files 2 MBytes. If this limit is reached you will not be able to load any additional PAC files.

You can use any PAC file syntax that is supported by your users's browsers. The FortiGate unit does not parse the PAC file.

To use PAC, users must add an automatic proxy configuration URL (or PAC URL) to their web browser proxy configuration. The default FortiGate PAC file URL is:

```
http://<interface_ip>:<PAC_port_int>/<pac_file_str>
```

For example, if the interface with the explicit web proxy has IP address 172.20.120.122, the PAC port is the same as the default HTTP explicit web proxy port (8080) and the PAC file name is proxy.pac the PAC file URL would be:

```
http://172.20.120.122:8080/proxy.pac
```

From the CLI you can use the following command to display the PAC file URLs:

```
get web-proxy explicit
```

Unknown HTTP version

You can select the action to take when the proxy server must handle an unknown HTTP version request or message. Set unknown HTTP version to Reject or Best Effort. Best Effort attempts to handle the HTTP traffic as best as it can. Reject treats known HTTP traffic as malformed and drops it. The Reject option is more secure.

Authentication realm

You can enter an authentication realm to identify the explicit web proxy. The realm can be any text string of up to 63 characters. If the realm includes spaces enclose it in quotes. When a user authenticates with the explicit web proxy the HTTP authentication dialog includes the realm so you can use the realm to identify the explicitly web proxy for your users.

Implementing Botnet features

The option `scan-botnet-connections` can be added to an explicit proxy policy.

CLI Syntax:

```
config firewall explicit-proxy-policy
   edit <policy_id>
      set scan-botnet-connections [disable|block|monitor]
end
```

where:

- `disable` means do not scan connections to botnet servers.
- `block` means block connections to botnet servers.
- `monitor` means log connections to botnet servers.

Other explicit web proxy options

You can change the following explicit web proxy options as required by your configuration.

HTTP port, HTTPS port, FTP port, PAC port	The TCP port that web browsers use to connect to the explicit proxy for HTTP, HTTPS, FTP and PAC services. The default port is 8080 for all services. By default HTTPS, FTP. and PAC use the same port as HTTP. You can change any of these ports as required. Users configuring their web browsers to use the explicit web proxy should add the same port numbers to their browser configurations.
Proxy FQDN	Enter the fully qualified domain name (FQDN) for the proxy server. This is the domain name to enter into browsers to access the proxy server.
Max HTTP request length	Enter the maximum length of an HTTP request in Kbytes. Larger requests will be rejected.
Max HTTP message length	Enter the maximum length of an HTTP message in Kbytes. Larger messages will be rejected.

Configuring an external IP address for the IPv4 explicit web proxy

You can use the following command to set an external IP address (or pool) that will be used by the explicit web proxy policy.

```
config web-proxy explicit
   set status enable
   set outgoing-ip <ip1> <ip2> ... <ipN>
end
```

Configuring an external IP address for the IPv6 explicit web proxy

You can use the following command to set an external IP address (or pool) that will be used by the explicit web proxy policy.

```
config web-proxy explicit
   set status enable
   set outgoing-ipv6 <ip1> <ip2> ... <ipN>
end
```

Restricting the IP address of the IPv4 explicit web proxy

You can use the following command to restrict access to the explicit web proxy using only one IP address. The IP address that you specify must be the IP address of an interface that the explicit web proxy is enabled on. You might want to use this option if the explicit FTP proxy is enabled on an interface with multiple IP addresses.

For example, to require uses to connect to the IP address 10.31.101.100 to connect to the explicit web proxy:

```
config web-proxy explicit
   set incoming-ip 10.31.101.100
end
```

Restricting the outgoing source IP address of the IPv4 explicit web proxy

You can use the following command to restrict the source address of outgoing web proxy packets to a single IP address. The IP address that you specify must be the IP address of an interface that the explicit web proxy is enabled on. You might want to use this option if the explicit web proxy is enabled on an interface with multiple IP addresses.

For example, to restrict the outgoing packet source address to 172.20.120.100:

```
config web-proxy explicit
   set outgoing-ip 172.20.120.100
end
```

Restricting the IP address of the explicit IPv6 web proxy

You can use the following command to restrict access to the IPv6 explicit web proxy to use only one IP6 IP address. The IPv6 address that you specify must be the IPv6 address of an interface that the explicit web proxy is enabled on. You might want to use this option if the explicit web proxy is enabled on an interface with multiple IPv6 addresses.

For example, to require uses to connect to the IPv6 address 2001:db8:0:2::30 to connect to the explicit IPv6 web proxy:

```
config web-proxy explicit
   set incoming-ipv6 2001:db8:0:2::30
end
```

Restricting the outgoing source IP address of the IPv6 explicit web proxy

You can use the following command to restrict the source address of outgoing web proxy packets to a single IPv6 address. The IP address that you specify must be the IPv6 address of an interface that the explicit web proxy is enabled on. You might want to use this option if the explicit web proxy is enabled on an interface with multiple IPv6 addresses.

For example, to restrict the outgoing packet source address to 2001:db8:0:2::50:

```
config web-proxy explicit
   set outgoing-ipv6 2001:db8:0:2::50
end
```

Proxy chaining (web proxy forwarding servers)

For the explicit web proxy you can configure web proxy forwarding servers to use proxy chaining to redirect web proxy sessions to other proxy servers. Proxy chaining can be used to forward web proxy sessions from the FortiGate unit to one or more other proxy servers on your network or on a remote network. You can use proxy chaining to integrate the FortiGate explicit web proxy with an web proxy solution that you already have in place.

A FortiGate unit can forward sessions to most web proxy servers including a remote FortiGate unit with the explicit web proxy enabled. No special configuration of the explicit web proxy on the remote FortiGate unit is required.

You can deploy the explicit web proxy with proxy chaining in an enterprise environment consisting of small satellite offices and a main office. If each office has a FortiGate unit, users at each of the satellite offices can use their local FortiGate unit as an explicit web proxy server. The satellite office FortiGate units can forward explicit web proxy sessions to an explicit web proxy server at the central office. From here the sessions can connect to web servers on the Internet.

FortiGate proxy chaining does not support authenticating with the remote forwarding server.

Adding a web proxy forwarding server

To add a forwarding server, select **Create New** in the **Web Proxy Forwarding Servers** section of the **Explicit Proxy** page by going to **Network > Explicit Proxy**.

Server Name	Enter the name of the forwarding server.
Proxy Address	Enter the IP address of the forwarding server.
Proxy Address Type	Select the type of IP address of the forwarding server. A forwarding server can have an FQDN or IP address.
Port	Enter the port number on which the proxy receives connections. Traffic leaving the FortiGate explicit web proxy for this server has its destination port number changed to this number.
Server Down action	Select what action the explicit web proxy to take if the forwarding server is down. **Block** means if the remote server is down block traffic. **Use Original Server** means do not forward traffic to the forwarding sever but instead forward it from the FortiGate to its destination. In other words operate as if there is no forwarding server configured.
Enable Health Monitor	Select to enable health check monitoring and enter the address of a remote site. See "Web proxy forwarding server monitoring and health checking".
Health Check Monitor Site	

Use the following CLI command to add a web proxy forwarding server named `fwd-srv` at address `proxy.example.com` and port 8080.

```
config web-proxy forward-server
   edit fwd-srv
      set addr-type fqdn
      set fqdn proxy.example.com
      set port 8080
   end
```

Web proxy forwarding server monitoring and health checking

By default, a FortiGate unit monitors web proxy forwarding server by forwarding a connection to the remote server every 10 seconds. If the remote server does not respond it is assumed to be down. Checking continues and when the server does send a response the server is assumed to be back up. If you configure health checking, every 10

seconds the FortiGate unit attempts to get a response from a web server by connecting through the remote forwarding server.

You can configure health checking for each remote server and specify a different website to check for each one.

If the remote server is found to be down you can configure the FortiGate unit to block sessions until the server comes back up or to allow sessions to connect to their destination, bypassing the remote forwarding server. You cannot configure the FortiGate unit to fail over to another remote forwarding server.

Configure the server down action and enable health monitoring from the web-based manager by going to **Network > Explicit Proxy**, selecting a forwarding server, and changing the server down action and changing the health monitor settings.

Use the following CLI command to enable health checking for a web proxy forwarding server and set the server down option to bypass the forwarding server if it is down.

```
config web-proxy forward-server
   edit fwd-srv
      set healthcheck enable
      set monitor http://example.com
      set server-down-option pass
   end
```

Grouping forwarding servers and load balancing traffic to them

You can add multiple web proxy forwarding servers to a forwarding server group and then add the server group to an explicit web proxy policy instead of adding a single server. Forwarding server groups are created from the FortiGate CLI but can be added to policies from the web-based manager (or from the CLI).

When you create a forwarding server group you can select a load balancing method to control how sessions are load balanced to the forwarding servers in the server group. Two load balancing methods are available:

- **Weighted** load balancing sends more sessions to the servers with higher weights. You can configure the weight for each server when you add it to the group.
- **Least-session** load balancing sends new sessions to the forwarding server that is processing the fewest sessions.

When you create a forwarding server group you can also enable **affinity**. Enable affinity to have requests from the same client processed by the same server. This can reduce delays caused by using multiple servers for a single multi-step client operation. Affinity takes precedence over load balancing.

You can also configure the behavior of the group if all of the servers in the group are down. You can select to **block** traffic or you can select to have the traffic **pass** through the FortiGate explicit proxy directly to its destination instead of being sent to one of the forwarding servers.

Use the following command to add a forwarding server group that users weighted load balancing to load balance traffic to three forwarding servers. Server weights are configured to send most traffic to server2. The group has affinity enabled and blocks traffic if all of the forward servers are down:

```
config web-proxy forward-server
   edit server_1
      set ip 172.20.120.12
      set port 8080
   next
   edit server_2
      set ip 172.20.120.13
      set port 8000
   next
   edit server_3
```

```
      set ip 172.20.120.14
      set port 8090
   next
   end
config web-proxy forward-server-group
   edit New-fwd-group
      set affinity enable
      set ldb-method weight
      set group-down-option block
         config server-list
            edit server_1
               set weight 10
            next
            edit server_2
               set weight 40
            next
            edit server_3
               set weight 10
            next
   end
```

Adding proxy chaining to an explicit web proxy policy

You enable proxy chaining for web proxy sessions by adding a web proxy forwarding server or server group to an explicit web proxy policy. In a policy you can select one web proxy forwarding server or server group. All explicit web proxy traffic accepted by this security policy is forwarded to the specified web proxy forwarding server or server group.

To add an explicit web proxy forwarding server - web-based manager:

1. Go to **Policy & Objects > Explicit Proxy Policy** and select **Create New**.
2. Configure the policy:

Explicit Proxy Type	Web
Source Address	Internal_subnet
Outgoing Interface	wan1
Destination Address	all
Schedule	always
Action	ACCEPT
Web Proxy Forwarding Server	Select, fwd-srv

3. Select **OK** to save the security policy.

To add an explicit web proxy forwarding server - CLI:

1. Use the following command to add a security policy that allows all users on the 10.31.101.0 subnet to use the explicit web proxy for connections through the wan1 interface to the Internet. The policy forwards web proxy sessions to a remote forwarding server named `fwd-srv`

```
config firewall explicit-proxy-policy
   edit 0
      set proxy web
      set dstintf wan1
      set scraddr Internal_subnet
      set dstaddr all
      set action accept
      set schedule always
      set webproxy-forward-server fwd-srv
   end
```

Adding disclaimer messages to explicit proxy policies

This feature allows you to create user exceptions for specific URL categories (including warning messages) based on user groups. The **Disclaimer Options** are configured under **Policy & Objects > Explicit Proxy Policy**.

You can also configure a disclaimer for each Authentication Rule by setting **Action** to **Authenticate**.

Disclaimer explanations

- **Disable:** No disclaimer (default setting).
- **By Domain:** The disclaimer will be displayed on different domains. The explicit web proxy will check the referring header to mitigate the javascript/css/images/video/etc page.
- **By Policy:** The disclaimer will be displayed ifa the HTTP request matches a different explicit firewall policy.
- **By User:** The disclaimer will be displayed when a new user logs on.

Explicit web proxy authentication

You can add authentication to explicit web proxy policies to control access to the explicit web proxy and to identify users and apply different UTM features to different users.

Authentication of web proxy sessions uses HTTP basic and digest authentication as described in RFC 2617 (HTTP Authentication: Basic and Digest Access Authentication) and prompts the user for credentials from the browser allowing individual users to be identified by their web browser instead of IP address. HTTP authentication allows the FortiGate unit to distinguish between multiple users accessing services from a shared IP address.

You can also select IP-based authentication to authenticate users according to their source IP address in the same way as normal firewall policies.

IP-Based authentication

IP-based authentication applies authentication by source IP address. For the explicit web proxy, IP authentication is compatible with basic, digest, NTLM, FSSO, or RSSO authentication methods. Once a user authenticates, all sessions to the explicit web proxy from that user's IP address are assumed to be from that user and are accepted until the authentication timeout ends or the session times out.

This method of authentication is similar to standard (non-web proxy) firewall authentication and may not produce the desired results if multiple users share IP addresses (such as in a network that uses virtualization solutions or includes a NAT device between the users and the explicit web proxy).

To configure IP-based authentication, add an explicit web proxy security policy, set the **Action to AUTHENTICATION**, and select **Enable IP Based Authentication** is selected.

Use the following CLI command to add IP-based authentication to a web proxy security policy. IP-based authentication is selected by setting `ip-based` to `enable`.

```
config firewall explicit-proxy-policy
   edit 0
      set proxy web
      set scraddr User_network
      set dstintf port1
      set dstaddr all
      set action accept
      set identity-based enable
      set ip-based enable
         config identity-based-policy
            edit 0
               set groups Internal_users
               set users dwhite rlee
               set schedule always
            end
```

Per session authentication

If you don't select **IP Based** the explicit web proxy applies HTTP authentication per session. This authentication is browser-based. When a user enters a user name and password in their browser to authenticate with the explicit web proxy, this information is stored by the browser in a session cookie. Each new session started by the same web browser uses the session cookie for authentication. When the session cookie expires the user has to re-authenticate. If the user starts another browser on the same PC or closes and then re-opens their browser they have to authenticate again.

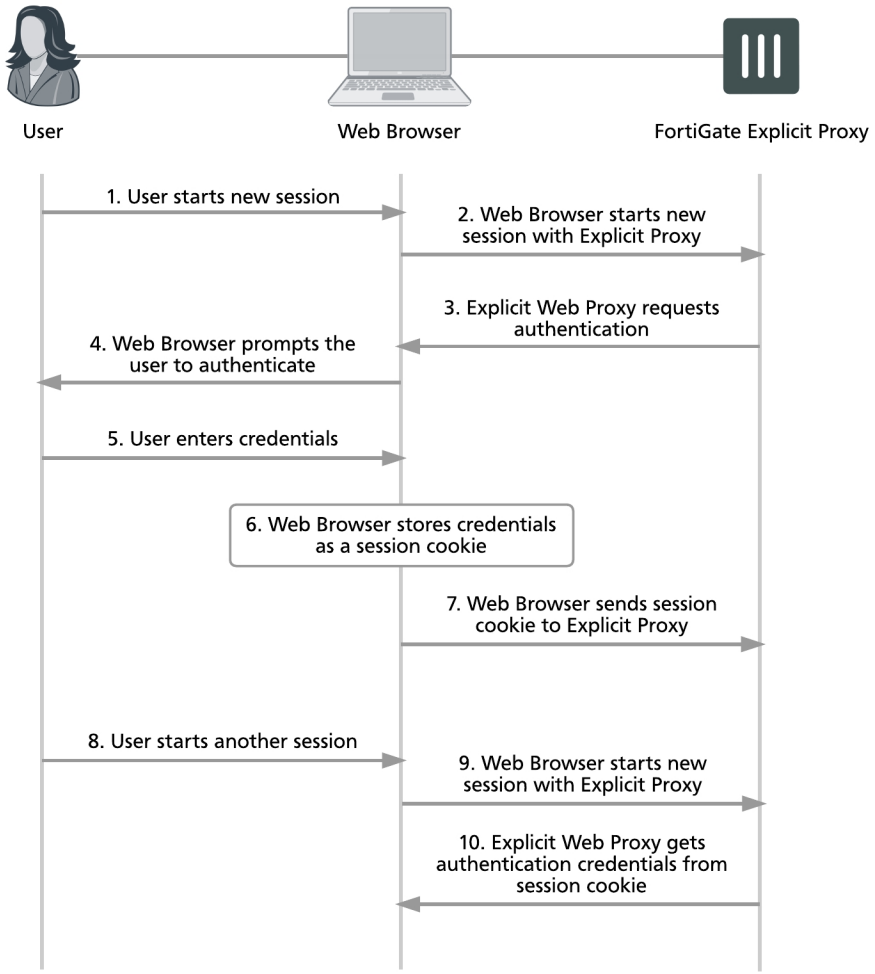
Since the authentication is browser-based, multiple clients with the same IP address can authenticate with the proxy using their own credentials. HTTP authentication provides authentication for multiple user sessions from the same source IP address. This can happen if there is a NAT device between the users and the FortiGate unit. HTTP authentication also supports authentication for other configurations that share one IP address among multiple users. These includes Citrix products and Windows Terminal Server and other similar virtualization solutions.

To configure per session authentication, add a explicit web proxy policy, set the **Action** to **AUTHENTICATE**, and make sure **Enable IP Based Authentication** is not selected.

Use the following CLI command to add per session authentication to a security policy. Per session authentication is selected by setting `ip-based` to `disable`.

```
config firewall explicit-proxy-policy
   edit 0
      set proxy web
      set scraddr User_network
      set dstintf port1
      set dstaddr all
      set action accept
      set identity-based enable
      set ip-based disable
         config identity-based-policy
            edit 0
               set groups Internal_users
               set users dwhite rlee
               set schedule always
            end
   end
```

Per session HTTP authentication



Transaction-based authentication

Multiple HTTP transactions (request/response) may be pipelined in the same TCP connection. Typically, all HTTP transactions of a TCP connection are considered as belonging to the same user. However, some devices (e.g., load balancers) may send HTTP transactions of different users to the same TCP connection and to explicit proxy. In order to support this deployment case, transaction-based authentication can be implemented to require each HTTP transaction to be authenticated separately.

To implement transaction-based authentication in the CLI:

```
config firewall explicit-proxy-policy
   edit <id>
      set transaction-based enable
   next
end
```

Security profiles, threat weight, device identification, and the explicit web proxy

You can apply all security profiles to explicit web proxy sessions. This includes antivirus, web filtering, intrusion protection (IPS), application control, data leak prevention (DLP), and SSL/SSH inspection. Security profiles are applied by selecting them in an explicit web proxy policy or in authentication rules added to web proxy policies.

Traffic accepted by explicit web proxy policies contributes to threat weight data.

The explicit web proxy is not compatible with device identification.

Since the traffic accepted by the explicit web proxy is known to be either HTTP, HTTPS, or FTP over HTTP and since the ports are already known by the proxy, the explicit web proxy does not use all of the SSL/SSH inspection options. The explicit web proxy does support the following proxy options:

- Enable chunked bypass
- HTTP oversized file action and threshold

The explicit web proxy does not support the following proxy options:

- Client comforting
- Server comforting
- Monitor content information from dashboard. URLs visited by explicit web proxy users are not added to dashboard usage and log and archive statistics widgets.

For explicit web proxy sessions, the FortiGate unit applies antivirus scanning to HTTP POST requests and HTTP responses. The FortiGate unit starts virus scanning a file in an HTTP session when it receives a file in the body of an HTML request. The explicit web proxy can receive HTTP responses from either the originating web server or the FortiGate web cache module.

Web Proxy firewall services and service groups

Configure web proxy services by selecting **Explicit Proxy** when configuring a service. Web proxy services can be selected in a explicit web proxy policy when adding one from the CLI. If you add a policy from the web-based manager the service is set to the **webproxy** service. The webproxy service should be used in most cases, it matches with any traffic with any port number. However, if you have special requirements, such as using a custom protocol type or a reduced port range or need to add an IP/FQDN to an explicit proxy service you can create custom explicit web proxy services.

Web proxy services are similar to standard firewall services. You can configure web proxy services to define one or more protocols and port numbers that are associated with each web proxy service. Web proxy services can also be grouped into web proxy service groups.

One way in which web proxy services differ from firewall services is the protocol type you can select. The following protocol types are available:

- ALL
- CONNECT
- FTP
- HTTP
- SOCKS-TCP
- SOCKS-UDP

To add a web proxy service go to **Policy & Objects > Services** and select **Create New**. Set **Service Type** to **Explicit Proxy** and configure the service as required.

To add a web proxy service from the CLI enter:

```
config firewall service custom
   edit my-socks-service
      set explicit-proxy enable
      set category Web Proxy
      set protocol SOCKS-TCP
      set tcp-portrange 3450-3490
   end
```

To add a web proxy service group go to **Policy & Objects > Services** and select **Create New > Service Group**. Set **Type** to **Explicit Proxy** and add web proxy services to the group as required.

To add a web proxy service group from the CLI enter:

```
config firewall service group
   edit web-group
      set explicit-proxy enable
      set member webproxy my-socks-service
   end
```

Explicit web proxy firewall address URL patterns

You can add URL pattern addresses and address groups to control the destination URLs that explicit proxy users can connect to. To add a URL pattern to go to **Policy & Objects > Addresses**, select **Create New** and set the Type to **URL Pattern (Explicit Proxy)**. Add a URL or URL pattern that defines the URL or URLs that explicit proxy users should be limited to. Set the **Interface** to **any**.

For example to limit access to a single website:

www.fortinet.com

To limit access to websites from the same domain:

google.com

To limit access to a part of a website:

www.apple.com/ipad/

To add a URL pattern group, create several URL pattern addresses then go to **Policy & Objects > Addresses**, select **Create New > Group** and add URL patterns to the address group.

Then when creating explicit web proxy policies, select the URL pattern addresses or groups as the destination address.

URL patterns and HTTPS scanning

For HTTPS traffic, URL patterns can only be matched up to the root path. For example, consider the following URL pattern:

www.apple.com/ipad/

If a proxy user browses using HTTP, this URL pattern limits their access the iPad pages of www.apple.com. However, if a proxy user browses using HTTPS, they will be able to access all pages on www.apple.com.

Changing HTTP headers

You can create explicit web proxy profiles that can add, remove and change HTTP headers. The explicit web proxy profile can be added to a web explicit proxy policy and will be applied to all of the HTTP traffic accepted by that policy.

You can change the following HTTP headers:

- client-ip
- via header for forwarded requests
- via header for forwarded responses
- x-forwarded-for
- front-end-https

For each of these headers you can set the action to:

- Pass to forward the traffic without changing the header
- Add to add the header
- Remove to remove the header

You can also configure how the explicit web proxy handles custom headers. The proxy can add or remove custom headers from requests or responses. If you are adding a header you can specify the content to be included in the added header.

Create web proxy profiles from the CLI:

```
config web-proxy profile
   edit <name>
      set header-client-ip {add | pass | remove}
      set header-via-request {add | pass | remove}
      set header-via-response {add | pass | remove}
      set header-x-forwarded-for {add | pass | remove}
      set header-front-end-https {add | pass | remove}
         config headers
            edit <id>
               set action {add-to-request | add-to-response | remove-from-request |
                   remove-from-response}
               set content <string>
               set name <name>
            end
   end
```

Use the following command to add a web proxy profile to an explicit proxy policy:

```
config firewall explicit-proxy-policy
   edit <id>
      set webproxy-profile <name>
   end
```

Preventing the explicit web proxy from changing source addresses

By default in NAT/Route mode the explicit web proxy changes the source address of packets leaving the FortiGate to the IP address of the FortiGate interface that the packets are exiting from. In Transparent mode the source address is changed to the management IP.

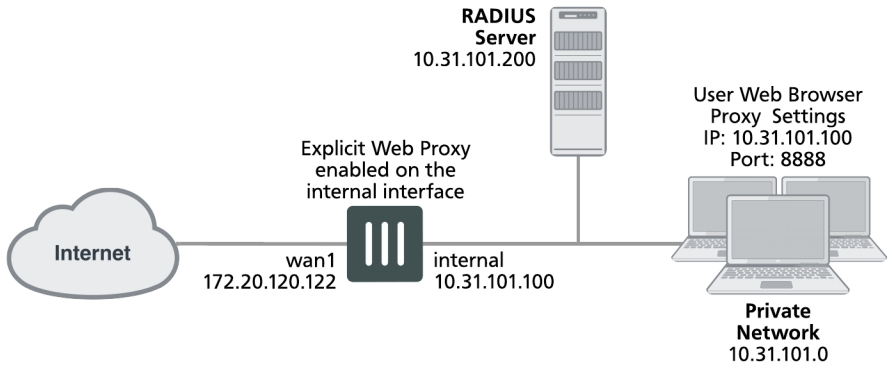
This configuration hides the IP addresses of clients and allows packets to return to the FortiGate unit interface without having to route packets from clients. You can use the following command to configure the explicit web proxy to keep the original client's source IP address:

```
config firewall explicit-proxy-policy
   edit 0
      set proxy web
      set transparent enable
   end
```

Example users on an internal network browsing the Internet through the explicit web proxy with web caching, RADIUS authentication, web filtering, and virus scanning

This example describes how to configure the explicit web proxy for the example network shown below. In this example, users on the internal network connect to the explicit web proxy through the Internal interface of the FortiGate unit. The explicit web proxy is configured to use port 8888 so users must configure their web browser proxy settings to use port 8888 and IP address 10.31.101.100.

Example explicit web proxy network topology



Explicit web proxy users must authenticate with a RADIUS server before getting access to the proxy. The explicit proxy policy that accepts explicit web proxy traffic applies per session authentication and includes a RADIUS server user group. The authentication rule also applies web filtering and virus scanning.

General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1. Enable the explicit web proxy for HTTP and HTTPS and change the HTTP and HTTPS ports to 8888.
2. Enable the explicit web proxy on the internal interface.
3. Add a RADIUS server and user group for the explicit web proxy.
4. Add an authentication explicit proxy policy. Enable web caching. Add an authentication rule and enable antivirus and web filtering.

Configuring the explicit web proxy - web-based manager

Use the following steps to configure the explicit web proxy.

To enable and configure the explicit web proxy

1. Go to **System > Feature Select** and turn on the **Explicit Proxy** feature.
2. Go to **Network > Explicit Proxy** and change the following settings:

Enable Explicit Web Proxy	Select **HTTP/HTTPS**.
Listen on Interfaces	No change. This field will eventually show that the explicit web proxy is enabled for the Internal interface.
HTTP Port	8888
HTTPS Port	0
Realm	You are authenticating with the explicit web proxy.
Default Firewall Policy Action	Deny

3. Select **Apply**.

To enable the explicit web proxy on the Internal interface

1. Go to **Network > Interfaces**.
2. Edit the internal interface.
3. Select **Enable Explicit Web Proxy.**
4. Select **OK**.

To add a RADIUS server and user group for the explicit web proxy

1. Go to **User & Device > RADIUS Servers** and select **Create New** to add a new RADIUS server:

Name	RADIUS_1
Primary Server Name/IP	10.31.101.200
Primary Server Secret	RADIUS_server_secret

2. Select **OK**.
3. Go to **User & Device > User Groups** and select **Create New** to add a new user group.

Name	Explict_proxy_user_group
Type	Firewall
Remote Groups	RADIUS_1
Group Name	Any

4. Select **OK**.

To add an explicit proxy policy

1. Go to **Policy & Objects > Addresses** and select **Create New**.
2. Add a firewall address for the internal network:

Category	Address
Name	Internal_subnet
Type	Subnet / IP Range
Subnet / IP Range	10.31.101.0
Interface	Any

3. Go to **Policy & Objects > Explicit Proxy Policy** and select **Create New**.
4. Configure the explicit web proxy policy.

Explicit Proxy Type	Web
Source Address	Internal_subnet
Outgoing Interface	wan1
Destination Address	all
Action	AUTHENTICATE

5. Under **Configure Authentication Rules** select **Create New** to add an authentication rule:

Groups	Explicit_policy
Source User(s)	Leave blank
Schedule	always

6. Turn on **Antivirus** and **Web Filter** and select the **default** profiles for both.
7. Select the **default** proxy options profile.
8. Select **OK**.
9. Make sure **Enable IP Based Authentication** is not selected.
10. Turn on **Web Cache**.
11. Select **OK**.

Configuring the explicit web proxy - CLI

Use the following steps to configure the example explicit web proxy configuration from the CLI.

To enable the explicit web proxy on the Internal interface

1. Enter the following command to enable the explicit web proxy on the internal interface.

```
config system interface
  edit internal
```

```
      set explicit-web-proxy enable
end
```

To enable and configure the explicit web proxy

1. Enter the following command to enable the explicit web proxy and set the TCP port that proxy accepts HTTP and HTTPS connections on to 8888.

```
config web-proxy explicit
   set status enable
   set http-incoming-port 8888
   set https-incoming-port 8888
   set realm "You are authenticating with the explicit web proxy"
   set sec-default-action deny
end
```

To add a RADIUS server and user group for the explicit web proxy

1. Enter the following command to add a RADIUS server:

```
config user radius
   edit RADIUS_1
      set server 10.31.101.200
      set secret RADIUS_server_secret
end
```

2. Enter the following command to add a user group for the RADIUS server.

```
config user group
   edit Explicit_proxy_user_group
      set group-type firewall
      set member RADIUS_1
end
```

To add a security policy for the explicit web proxy

1. Enter the following command to add a firewall address for the internal subnet:

```
config firewall address
   edit Internal_subnet
      set type iprange
      set start-ip 10.31.101.1
      set end-ip 10.31.101.255
end
```

2. Enter the following command to add the explicit web proxy security policy:

```
config firewall explicit-proxy-policy
   edit 0
      set proxy web
      set dstintf wan1
      set srcaddr Internal_subnet
      set dstaddr all
      set action accept
      set service webproxy
      set webcache enable
      set identity-based enable
      set ipbased disable
      set active-auth-method basic
         config identity-based-policy
```

```
            edit 0
               set groups Explicit_Proxy_user_group
               set schedule always
               set utm-status enable
               set av-profile default
               set webfilter-profile default
               set profile-protocol-options default
            end
end
```

Testing and troubleshooting the configuration

You can use the following steps to verify that the explicit web proxy configuration is working as expected:

To test the explicit web proxy configuration

1. Configure a web browser on the internal subnet to use a web proxy server at IP address 10.31.101.100 and port 8888.
2. Browse to an Internet web page.
   The web browser should pop up an authentication window that includes the phrase that you added to the Realm option.
3. Enter the username and password for an account on the RADIUS server.
   If the account is valid you should be allowed to browse web pages on the Internet.
4. Close the browser and clear its cache and cookies.
5. Restart the browser and connect to the Internet.
   You could also start a second web browser on the same PC. Or you could start a new instance of the same browser as long as the browser asks for a user name and password again.

   You should have to authenticate again because identity-based policies are set to session-based authentication.
6. If this basic functionality does not work, check your FortiGate and web browser configuration settings.
7. Browse to a URL on the URL filter list and confirm that the web page is blocked.
8. Browse to http://eicar.org and attempt to download an anti-malware test file.
   The antivirus configuration should block the file.
   Sessions for web-proxy security policies do not appear on the Top Sessions dashboard widget and the count column for security policies does not display a count for explicit web proxy security policies.
9. You can use the following command to display explicit web proxy sessions

   ```
   get test wad 60
   IP based users:

   Session based users:
      user:0x9c20778, username:User1, vf_id:0, ref_cnt:9

   Total allocated user:1

   Total user count:3, shared user quota:50, shared user count:3
   ```

   This command output shows one explicit proxy user with user name `User1` authenticated using session-based authentication.

Explicit web proxy sessions and user limits

Web browsers and web servers open and close multiple sessions with the explicit web proxy. Some sessions open and close very quickly. HTTP 1.1 keepalive sessions are persistent and can remain open for long periods of time. Sessions can remain on the explicit web proxy session list after a user has stopped using the proxy (and has, for example, closed their browser). If an explicit web proxy session is idle for more than 3600 seconds it is torn down by the explicit web proxy. See RFC 2616 for information about HTTP keepalive/persistent HTTP sessions.

This section describes proxy sessions and user limits for both the explicit web proxy and the explicit FTP proxy. Session and user limits for the two proxies are counted and calculated together. However, in most cases if both proxies are active there will be many more web proxy sessions than FTP proxy sessions.

The FortiGate unit adds two sessions to its session table for every explicit proxy session started by a web browser and every FTP session started by an FTP client. An entry is added to the session table for the session from the web browser or client to the explicit proxy. All of these sessions have the same destination port as the explicit web proxy port (usually 8080 for HTTP and 21 for FTP). An entry is also added to the session table for the session between the exiting FortiGate interface and the web or FTP server destination of the session. All of these sessions have a FortiGate interface IP address and the source address of the session and usually have a destination port of 80 for HTTP and 21 for FTP.

Proxy sessions that appear in FortiView do not include the Policy ID of the web-proxy or ftp-proxy security policy that accepted them. However, the explicit proxy sessions include a destination port that matches the explicit proxy port number (usually 8080 for the web proxy and 21 for the FTP proxy). The proxied sessions from the FortiGate unit have their source address set to the IP address of the FortiGate unit interface that the sessions use to connect to their destinations (for example, for connections to the Internet the source address would be the IP address of the FortiGate interface connected to the Internet).

FortiOS limits the number of explicit proxy users. This includes both explicit FTP proxy and explicit web proxy users. The number of users varies by FortiGate model from as low as 10 to up to 18000 for high end models. You cannot raise this limit.

If your FortiGate unit is configured for multiple VDOMs you can go to **System > Global Resources** to view the maximum number of **Concurrent explicit proxy users** and optionally reduce the limit. You can also use the following command:

```
config global
   config system resource-limits
      set proxy 50
   end
end
```

To limit the number of explicit proxy users for a VDOM, from the web-based manager enable multiple VDOMs and go to **System > VDOM** and edit a VDOM or use the following command to change the number of explicit web proxy users for VDOM_1:

```
config global
   config system vdom-property
      edit VDOM_1
         set proxy 25
   end
end
```

You can use the `diagnose wad user list` command to view the number of explicit web proxy users. Users may be displayed with this command even if they are no longer actively using the proxy. All idle sessions time out after 3600 seconds.

You can use the command `diagnose wad user clear` to clear current explicit proxy users. You can also use the command `diagnose wad user clear <user-name>` to clear individual users. This means delete information about all users and force them re-authenticate.

Users that authenticate with explicit web-proxy or ftp-proxy security policies do not appear in the **Monitor > Firewall Monitor** list and selecting **De-authenticate All Users** has no effect on explicit proxy users.

How the number of concurrent explicit proxy users is determined depends on their authentication method:

- For session-based authenticated users, each authenticated user is counted as a single user. Since multiple users can have the same user name, the proxy attempts to identify users according to their authentication membership (based upon whether they were authenticated using RADIUS, LADAP, FSAE, local database etc.). If a user of one session has the same name and membership as a user of another session, the explicit proxy assumes this is one user.
- For IP Based authentication, or no authentication, or if no web-proxy security policy has been added, the source IP address is used to determine a user. All sessions from a single source address are assumed to be from the same user.

The explicit proxy does not limit the number of active sessions for each user. As a result the actual explicit proxy session count is usually much higher than the number of explicit web proxy users. If an excessive number of explicit web proxy sessions is compromising system performance you can limit the amount of users if the FortiGate unit is operating with multiple VDOMs.

Kerberos authentication for explicit proxy users

Kerberos authentication is a new method for authenticating explicit proxy users. It has several advantages over NTLM challenge response:

- Does not require FSSO/AD agents to be deployed across domains.
- Requires fewer round-trips than NTLM SSO, making it less latency sensitive.
- Is (probably) more scalable than challenge response.
- Uses existing Windows domain components rather than added components.
- NTLM may still be used as a fallback for non-Kerberos clients.

1. General configuration

1.1 Kerberos environment - Windows server setup

1. Build a Windows 2008 Platform server.
2. Enable domain configuration in windows server (dcpromo).
3. Set the domain name TEST.COM (realm name).

1.2 Create users

- *testuser* is a normal user (could be any existing domain user account).
- *testfgt* is the service name. In this case it should be the FQDN for the explicit proxy Interface, For example the hostname in the client browser proxy config.
- Recommendation: create username all in lowercase (even if against corporate standards).
  - The account only requires “domain users” membership

- Password set to never expire
- Set a very strong password

1.3 Add FortiGate to DNS

Add the FortiGate FQDN in to the Windows DNS domain, as well as in-addr.arpa

For Lab/Testing add the FortiGate Domain name and IP mapping in the hosts file (windows/system32/drivers/etc/hosts). e.g., `TESTFGT.TEST.COM 10.10.1.10`

1.4 Generate the Kerberos keytab

Use the *ktpass* command (found on Windows Servers and many domain workstations) to generate the Kerberos keytab.

Example:

```
ktpass -princ HTTP/<domain name of test fgt>@realm -mapuser testfgt -pass <password> -
    crypto all -ptype KRB5_NT_PRINCIPAL -out fgt.keytab
```

The ktpass on older Windows servers (i.e. 2003) may not support the “all” crypto option.

Example:

```
ktpass -princ HTTP/testfgt.test.com@TEST.COM -mapuser testfgt -pass 12345678 -crypto all -
    ptype KRB5_NT_PRINCIPAL -out fgt.keytab
```

The realm name is always presented in uppercase, and prefixed with the “@” character.

1.5 Encode base64

Use the *base64* command (available in most Linux distros) command to encode the *fgt.keytab* file. Any LF (Line Feed) need to be deleted from the file.

Example:

```
base64 fgt.keytab > fgt.txt
```

Use Notepad++ or some native Linux text editor. Windows Notepad and Wordpad are likely to introduce errors.

2. FortiGate configuration

2.1 Create LDAP Server instance

```
config user ldap
   edit "ldap" <<< Required for authorization
      set server "10.10.1.1" <<< LDAP server IP, normally it should be same as KDC server
      set cnid "cn"
      set dn "dc=test,dc=com"
      set type regular
      set username "CN=admin,CN=Users,DC=test,DC=com" <<< Your domain may require STARTTLS
      set password <FOOS>
   next
end
```

2.2 Define Kerberos as an authentication service

```
config user krb-keytab
   edit "http_service"
      set principal "HTTP/testfgt.test.com@TEST.COM" <<< Same as the principal name in 1.4
      set ldap-server "ldap" <<< the defined ldap server for authoriztion
      set keytab
          "BQIAAABNAAIACkJFUkJFUi5DT00ABEhUVFAAGlRPTllfRkdUXzEwMERfQS5CRVJCRVIuQ09NAAAAAQA
          AAAAKABcAEJQl0MHqovwplu7XzfENJzw=" <<< base64 endoding keytab data, created in step 1.5
   next
end
```

2.3 Create user gorup(s)

```
config user group <<< the group is used for kerberos authentication
   edit "testgrp"
      set member "ldap"
      config match
         edit 1
            set server-name "ldap" <<< Same as ldap-server option in krb-keytab
            set group-name "CN=Domain Users,CN=Users,DC=TEST,DC=com"
         next
      end
   next
end
```

2.4 Create firewall policy

```
config firewall explicit-proxy-policy
   edit 1
      set uuid 5e5dd6c4-952c-51e5-b363-120ad77c1414
      set proxy web
      set dstintf "wan1"
      set srcaddr "all"
      set dstaddr "all"
      set service "webproxy"
      set action accept
      set identity-based enable
      set webcache enable
      set comments "test"
      set active-auth-method negotiate <<< Accepts both Kerberos and NTLM as fallback
      config identity-based-policy
```

```
            edit 1
               set schedule "always"
               set groups "testgrp"
            next
         end
      next
   end
```

2.5 Diagnostics

Once the keytab is imported, check that it has been properly decoded. The filename generated will be relatively random, but should be clearly visible.

```
Artoo-Deetoo (root) # fnsysctl ls -la /tmp/kt
drwxr--r-- 2  0   0 Fri Dec 2 10:06:43 2016    60 .
drwxrwxrwt 22 0   0 Tue Dec 6 14:28:29 2016    3280 ..
-rw-r--r-- 1  0   0 Fri Dec 2 10:06:43 2016    392 1.0.89.keytab
```

If there is no file present, then the file hasn't decoded. Check the file for line feeds and try again.

3. Client side walkthrough

3.1 Check Kerberos is working

Log on to the domain by using *testuser*, created in 1.2. Use the *klist* command to list ticket information. In the below example, the client has received *krbtgt*, *CIFS*, and *LDAP* tickets. As there has been no interaction with the FortiGate, there are no references to it.

```
C:\Users\glenk>klist Cached Tickets: (5)

C:\Users\glenk>klist
Cached Tickets: (5)
#0> Client: glenk @ home.local

      Server: krbtgt/HOME.LOCAL @ HOME.LOCAL

      Session Key Type: AES-256-CTS-HMAC-SHA1-96
```

3.2 Configure client

Set up web-proxy in browser through the FortiGate. This can be achieved via a PAC file or direct browser configuration.

Some Firefox documentation indicates that it is necessary to make manual advanced configuration changes to allow Kerberos authentication work. However, builds 48 (and possibly much earlier) require no additional configuration beyond setting of the proxy server.

3.3 Open a connection to the Internet

1. The client accesses the explicit proxy, but a *HTTP 407 Proxy Authentication Required* is returned.
2. As “Negotiate” is set, the client has knowledge of the KRBTGT, it requests a ticket from the KDC with a *krb-tgs-req* message. This includes the REALM (HOME.LOCAL) in the *reg-body* section, and the provided instances SNAME and service (in this case, HTTP/artoo-deetoo.home.local).
3. The KDC responds with a next KRB-TGS-REP.

   This ticket is then available on the client.

   In the example below, the ticket-granted-service has issued Ticket #2.

```
#2>  Client: glenk @ home.local
      Server: HTTP/artoo-deetoo.home.local @ HOME.LOCAL
      KerbTicket Encryption Type: RSADSI RC4-HMAC(NT)
      Ticket Flags 0x40a00000 -> forwardable renewable pre_authent
      Start Time: 12/6/2016 14:59:45 (local)
      End Time: 12/7/2016 0:58:04 (local)
      Renew Time: 12/13/2016 14:58:04 (local)
      Session Key Type: RSADSI RC4-HMAC(NT)
```

4. The conversation between the client and the proxy continues, as the client responds with the Kerberos ticket in the response.

   The whole process takes less than a second to complete. The user should be visible as a FSSO logon in the Web UI.

The FortiGate explicit FTP proxy

You can use the FortiGate explicit FTP proxy to enable explicit FTP proxying on one or more FortiGate interfaces. The explicit web and FTP proxies can be operating at the same time on the same or on different FortiGate interfaces.

Explicit FTP proxies are configured for each VDOM when multiple VDOMs are enabled.

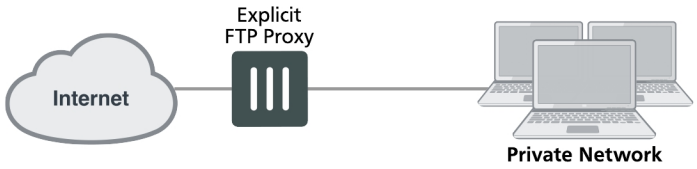
In most cases you would configure the explicit FTP proxy for users on a network by enabling the explicit FTP proxy on the FortiGate interface connected to that network. Users on the network would connect to and authenticate with the explicit FTP proxy before connecting to an FTP server. In this case the IP address of the explicit FTP proxy is the IP address of the FortiGate interface on which the explicit FTP proxy is enabled.

Enabling the explicit FTP proxy on an interface connected to the Internet is a security risk because anyone on the Internet who finds the proxy could use it to hide their source address.

If the FortiGate unit is operating in Transparent mode, users would configure their browsers to use a proxy server with the FortiGate unit management IP address.

The FTP proxy receives FTP sessions to be proxied at FortiGate interfaces with the explicit FTP proxy enabled. The FTP proxy uses FortiGate routing to route sessions through the FortiGate unit to a destination interface. Before a session leaves the exiting interface, the explicit FTP proxy changes the source addresses of the session packets to the IP address of the exiting interface. When the FortiGate unit is operating in Transparent mode the explicit web proxy changes the source addresses to the management IP address.

Example explicit FTP proxy topology



To allow anyone to anonymously log into explicit FTP proxy and connect to any FTP server you can set the explicit FTP proxy default firewall proxy action to accept. When you do this, users can log into the explicit FTP proxy with any username and password.

In most cases you would want to use explicit proxy policies to control explicit FTP proxy traffic and apply security features, access control/authentication, and logging. You can do this by keeping the default explicit FTP proxy firewall policy action to deny and then adding explicit FTP proxy policies. In most cases you would also want users to authenticate with the explicit FTP proxy. By default an anonymous FTP login is required. Usually you would add authentication to explicit FTP proxy policies. Users can then authenticate with the explicit FTP proxy according to users or user groups added to the policies. User groups added to explicit FTP proxy policies can use

any authentication method supported by FortiOS including the local user database and RADIUS and other remote servers.

If you leave the default firewall policy action set to deny and add explicit FTP proxy policies, all connections to the explicit FTP proxy must match an or else they will be dropped. Sessions that are accepted are processed according to the ftp-proxy security policy settings.

You can also change the explicit FTP proxy default firewall policy action to accept and add explicit FTP proxy policies. If you do this, sessions that match explicit FTP proxy policies are processed according to the policy settings. Connections to the explicit FTP proxy that do not match an explicit FTP proxy policy are allowed and the users can authenticate with the proxy anonymously.

There are some limitations to the security features that can be applied to explicit FTP proxy sessions. See Security profiles, threat weight, device identification, and the explicit FTP proxy on page 3551.

You cannot configure IPsec, SSL VPN, or Traffic shaping for explicit FTP proxy traffic. Explicit FTP proxy policies can only include firewall addresses not assigned to a FortiGate unit interface or with interface set to **any**. (On the web-based manager you must set the interface to **Any**. In the CLI you must `unset` the `associated-interface`.)

How to use the explicit FTP proxy to connect to an FTP server

To connect to an FTP server using the explicit FTP proxy, users must run an FTP client and connect to the IP address of a FortiGate interface on which the explicit FTP proxy is enabled. This connection attempt must use the configured explicit FTP proxy port number (default 21).

The explicit FTP proxy is not compatible with using a web browser as an FTP client. To use web browsers as FTP clients configure the explicit web proxy to accept FTP sessions.

The following steps occur when a user starts an FTP client to connect to an FTP server using the explicit FTP proxy. Any RFC-compliant FTP client can be used. This example describes using a command-line FTP client. Some FTP clients may require a custom FTP proxy connection script.

1. The user enters a command on the FTP client to connect to the explicit FTP proxy.

   For example, if the IP address of the FortiGate interface on which the explicit FTP proxy is enabled is 10.31.101.100, enter:

   ```
   ftp 10.31.101.100
   ```

2. The explicit FTP proxy responds with a welcome message and requests the user's FTP proxy user name and password and a username and address of the FTP server to connect to:

   ```
   Connected to 10.31.101.100.
   220 Welcome to Fortigate FTP proxy
   Name (10.31.101.100:user):
   ```

   You can change the message by editing the FTP Explicit Banner Message replacement message.

3. At the prompt the user enters their FTP proxy username and password and a username and address for the FTP server. The FTP server address can be a domain name or numeric IP address. This information is entered using the following syntax:

   ```
   <proxy-user>:<proxy-password>:<server-user>@<server-address>
   ```

   For example, if the proxy username and password are `p-name` and `p-pass` and a valid username for the FTP server is `s-name` and the server's IP address is `ftp.example.com` the syntax would be:

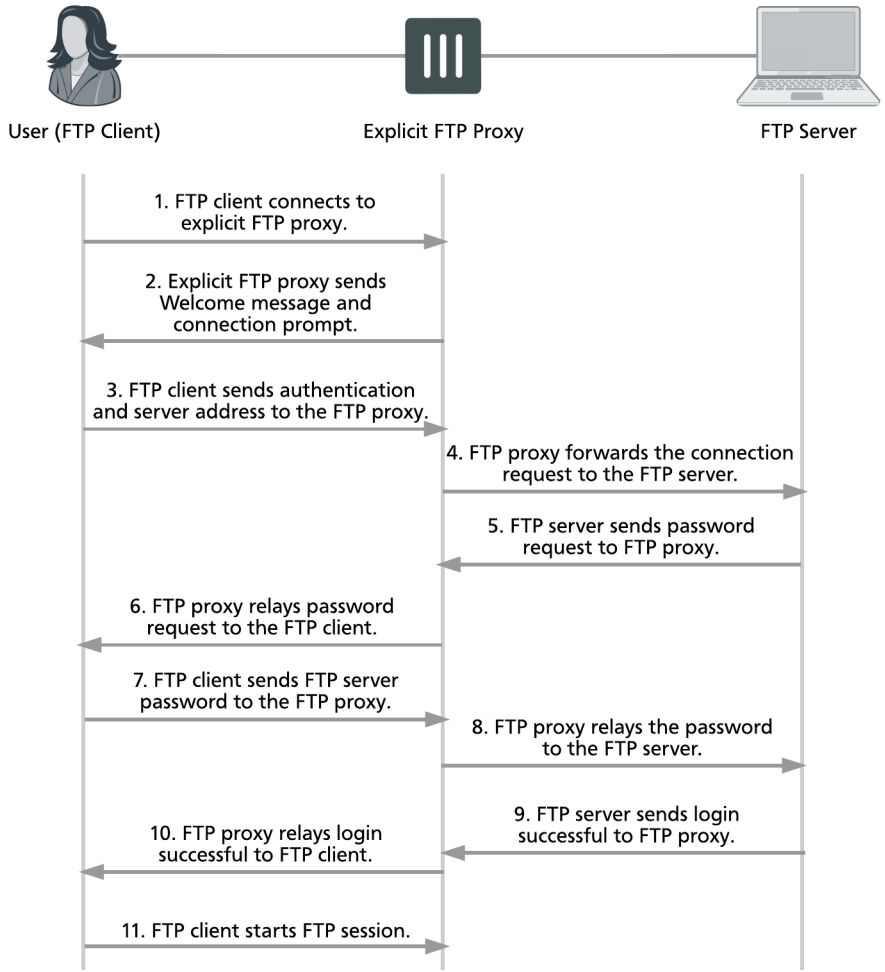
   ```
   p-name:p-pass:s-name@ftp.example.com
   ```

If the FTP proxy accepts anonymous logins `p-name` and `p-pass` can be any characters.

4. The FTP proxy forwards the connection request, including the user name, to the FTP server.
5. If the user name is valid for the FTP server it responds with a password request prompt.
6. The FTP proxy relays the password request to the FTP client.
7. The user enters the FTP server password and the client sends the password to the FTP proxy.
8. The FTP proxy relays the password to the FTP server.
9. The FTP server sends a login successful message to the FTP proxy.
10. The FTP proxy relays the login successful message to the FTP client.
11. The FTP client starts the FTP session.

    All commands entered by the client are relayed by the proxy to the server. Replies from the server are relayed back to the FTP client.

Explicit FTP proxy session



From a simple command line FTP client connecting to an the previous sequence could appear as follows:

```
ftp 10.31.101.100 21
Connected to 10.31.101.100.
220 Welcome to Fortigate FTP proxy
Name (10.31.101.100:user): p-name:p-pass:s-name@ftp.example.com
331 Please specify the password.
Password: s-pass
230 Login successful.
Remote system type is UNIX
Using binary mode to transfer files.
ftp>
```

General explicit FTP proxy configuration steps

You can use the following general steps to configure the explicit FTP proxy.

To enable the explicit FTP proxy - web-based manager:

1. Go to **Network > Explicit Proxy > Explicit FTP Proxy Options**. Select **Enable Explicit FTP Proxy** to turn on the explicit FTP proxy.
2. Select Apply.

   The **Default Firewall Policy Action** is set to **Deny** and requires you to add a explicit FTP proxy policy to allow access to the explicit FTP proxy. This configuration is recommended and is a best practice because you can use policies to control access to the explicit FTP proxy and also apply security features and authentication.
3. Go to **Network > Interfaces** and select one or more interfaces for which to enable the explicit web proxy. Edit the interface and select **Enable Explicit FTP Proxy**.

Enabling the explicit FTP proxy on an interface connected to the Internet is a security risk because anyone on the Internet who finds the proxy could use it to hide their source address. If you enable the proxy on such an interface make sure authentication is required to use the proxy.

4. Go to **Policy & Objects > Explicit Proxy Policy** and select **Create New** and set the **Explicit Proxy Type** to **FTP.**

   You can add multiple explicit FTP proxy policies.
5. Configure the policy as required to accept the traffic that you want to be processed by the explicit FTP proxy.

   The source address of the policy should match client source IP addresses. The firewall address selected as the source address cannot be assigned to a FortiGate interface. The Interface field of the firewall address must be blank or it must be set to **Any**.

   The destination address of the policy should match the IP addresses of FTP servers that clients are connecting to. The destination address could be **all** to allow connections to any FTP server.

   If **Default Firewall Policy Action** is set to Deny, traffic sent to the explicit FTP proxy that is not accepted by an explicit FTP proxy policy is dropped. If **Default Firewall Policy Action** is set to Allow then all FTP proxy sessions that don't match a policy are allowed.

For example the following explicit FTP proxy policy allows users on an internal network to access FTP servers on the Internet through the wan1 interface of a FortiGate unit.

Explicit Proxy Type	FTP
Source Address	Internal_subnet
Outgoing Interface	wan1
Destination Address	all
Schedule	always
Action	ACCEPT

The following explicit FTP proxy policy requires users on an internal network to authenticate with the FortiGate unit before accessing FTP servers on the Internet through the wan1 interface.

Explicit Proxy Type	FTP
Source Address	Internal_subnet
Outgoing Interface	wan1
Destination Address	all
Action	AUTHENTICATE

6. Select **Create New** to add an **Authentication Rule** and configure the rule as follows:

Groups	Proxy-Group
Source Users	(optional)
Schedule	always

7. Add security profiles as required and select **OK**.
8. You can add multiple authentication rules to apply different authentication for different user groups and users and also apply different security profiles and logging settings for different users.
9. Select **OK**.

To enable the explicit FTP proxy - CLI:

1. Enter the following command to turn on the explicit FTP proxy. This command also changes the explicit FTP proxy port to 2121.

```
config ftp-proxy explicit
   set status enable
   set incoming-port 2121
end
```

The default explicit FTP proxy configuration has `sec-default-action` set to `deny` and requires you to add a security policy to allow access to the explicit FTP proxy.

2. Enter the following command to enable the explicit FTP proxy for the internal interface.

```
config system interface
   edit internal
      set explicit-ftp-proxy enable
   end
end
```

3. Use the following command to add a firewall address that matches the source address of users who connect to the explicit FTP proxy.

```
config firewall address
   edit Internal_subnet
      set type iprange
      set start-ip 10.31.101.1
      set end-ip 10.31.101.255
   end
```

The source address for a ftp-proxy security policy cannot be assigned to a FortiGate unit interface.

4. Use the following command to add an explicit FTP proxy policy that allows all users on the internal subnet to use the explicit FTP proxy for connections through the wan1 interface to the Internet.

```
config firewall explicit-proxy-policy
   edit 0
      set proxy ftp
      set dstintf wan1
      set scraddr Internal_subnet
      set dstaddr all
      set action accept
      set schedule always
end
```

5. Use the following command to add an explicit FTP proxy policy that allows authenticated users on the internal subnet to use the explicit FTP proxy for connections through the wan1 interface to the Internet.

```
config firewall explicit-proxy-policy
   edit 0
      set proxy ftp
      set dstintf wan1
      set scraddr Internal_subnet
      set dstaddr Fortinet-web-sites
      set action accept
      set schedule always
      set identity-based enable
         config identity-based-policy
            edit 1
               set groups Proxy-group
               set schedule always
      end
end
```

Restricting the IP address of the explicit FTP proxy

You can use the following command to restrict access to the explicit FTP proxy using only one IP address. The IP address that you specify must be the IP address of an interface that the explicit FTP proxy is enabled on. You might want to use this option if the explicit FTP proxy is enabled on an interface with multiple IP addresses.

For example, to require uses to connect to the IP address 10.31.101.100 to connect to the explicit FTP proxy:

```
config ftp-proxy explicit
   set incoming-ip 10.31.101.100
```

```
end
```

Restricting the outgoing source IP address of the explicit FTP proxy

You can use the following command to restrict the source address of outgoing FTP proxy packets to a single IP address. The IP address that you specify must be the IP address of an interface that the explicit FTP proxy is enabled on. You might want to use this option if the explicit FTP proxy is enabled on an interface with multiple IP addresses.

For example, to restrict the outgoing packet source address to 172.20.120.100:

```
config ftp-proxy explicit
   set outgoing-ip 172.20.120.100
end
```

Security profiles, threat weight, device identification, and the explicit FTP proxy

You can apply antivirus, data leak prevention (DLP), and SSL/SSH inspection to explicit FTP proxy sessions. Security profiles are applied by selecting them in an explicit FTP proxy policy or an authentication rule in an FTP proxy security policy.

Traffic accepted by explicit FTP proxy policies contributes to threat weight data.

The explicit FTP proxy is not compatible with device identification.

Explicit FTP proxy options and SSL/SSH inspection

Since the traffic accepted by the explicit FTP proxy is known to be FTP and since the ports are already known by the proxy, the explicit FTP proxy does not use the FTP port proxy options settings.

When adding UTM features to an FTP proxy security policy, you must select a proxy options profile. In most cases you can select the default proxy options profile. You could also create a custom proxy options profile.

The explicit FTP proxy supports the following proxy options:

- Block Oversized File and oversized file limit

The explicit FTP proxy does not support the following protocol options:

- Client comforting

Explicit FTP proxy sessions and antivirus

For explicit FTP proxy sessions, the FortiGate unit applies antivirus scanning to FTP file GET and PUT requests. The FortiGate unit starts virus scanning a file in an FTP session when it receives a file in the body of an FTP request.

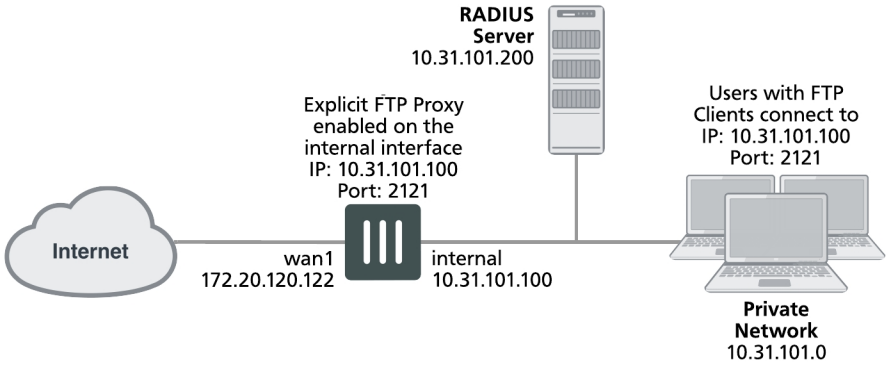
Flow-based virus scanning is not available for explicit FTP proxy sessions. Even if the FortiGate unit is configured to use flow-based antivirus, explicit FTP proxy sessions use the regular virus database.

Example users on an internal network connecting to FTP servers on the Internet through the explicit FTP with RADIUS authentication and virus scanning

This example describes how to configure the explicit FTP proxy for the example network shown below. In this example, users on the internal network connect to the explicit FTP proxy through the Internal interface with IP

address 10.31.101.100. The explicit web proxy is configured to use port 2121 so to connect to an FTP server on the Internet users must first connect to the explicit FTP proxy using IP address 10.31.101.100 and port 2121.

Example explicit FTP proxy network topology



In this example, explicit FTP proxy users must authenticate with a RADIUS server before getting access to the proxy. To apply authentication, the security policy that accepts explicit FTP proxy traffic includes an identity based policy that applies per session authentication to explicit FTP proxy users and includes a user group with the RADIUS server in it. The identity based policy also applies UTM virus scanning and DLP.

General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1. Enable the explicit FTP proxy and change the FTP port to 2121.
2. Enable the explicit FTP proxy on the internal interface.
3. Add a RADIUS server and user group for the explicit FTP proxy.
4. Add a user identity security policy for the explicit FTP proxy.
5. Enable antivirus and DLP features for the identity-based policy.

Configuring the explicit FTP proxy - web-based manager

Use the following steps to configure the explicit FTP proxy from FortiGate web-based manager.

To enable and configure the explicit FTP proxy

1. Go to **Network > Explicit Proxy > Explicit FTP Proxy Options** and change the following settings:

Enable Explicit FTP Proxy	Select.
Listen on Interface	No change. This field will eventually show that the explicit web proxy is enabled for the Internal interface.
FTP Port	2121
Default Firewall Policy Action	Deny

2. Select **Apply**.

To enable the explicit FTP proxy on the Internal interface

1. Go to **Network > Interfaces**, edit the Internal interface and select **Enable Explicit FTP Proxy**.

To add a RADIUS server and user group for the explicit FTP proxy

1. Go to **User & Device > RADIUS Servers**.
2. Select **Create New** to add a new RADIUS server:

Name	RADIUS_1
Primary Server Name/IP	10.31.101.200
Primary Server Secret	RADIUS_server_secret

3. Go to **User > User > User Groups** and select **Create New**.

Name	Explict_proxy_user_group
Type	Firewall
Remote groups	RADIUS_1
Group Name	ANY

4. Select **OK**.

To add a security policy for the explicit FTP proxy

1. Go to **Policy & Objects > Addresses** and select **Create New**.
2. Add a firewall address for the internal network:

Address Name	Internal_subnet
Type	Subnet
Subnet / IP Range	10.31.101.0
Interface	Any

3. Go to **Policy & Objects > Explicit Proxy Policy** and select **Create New**.
4. Configure the explicit FTP proxy security policy.

Explicit Proxy Type	FTP
Source Address	Internal_subnet
Outgoing Interface	wan1
Destination Address	all
Action	AUTHENTICATE

5. Under **Configure Authentication Rules** select **Create New** to add an authentication rule:

Groups	Explicit_policy
Users	Leave blank
Schedule	always

6. Turn on **Antivirus** and **Web Filter** and select the **default** profiles for both.
7. Select the **default** proxy options profile.
8. Select **OK**.
9. Make sure **Enable IP Based Authentication** is not selected and **Default Authentication Method** is set to **Basic**.
10. Select **OK**.

Configuring the explicit FTP proxy - CLI

Use the following steps to configure the example explicit web proxy configuration from the CLI.

To enable and configure the explicit FTP proxy

1. Enter the following command to enable the explicit FTP proxy and set the TCP port that proxy accepts FTP connections on to 2121.

```
config ftp-proxy explicit
   set status enable
   set incoming-port 2121
   set sec-default-action deny
end
```

To enable the explicit FTP proxy on the Internal interface

1. Enter the following command to enable the explicit FTP proxy on the internal interface.

```
config system interface
   edit internal
      set explicit-ftp-proxy enable
end
```

To add a RADIUS server and user group for the explicit FTP proxy

1. Enter the following command to add a RADIUS server:

```
config user radius
   edit RADIUS_1
      set server 10.31.101.200
      set secret RADIUS_server_secret
end
```

2. Enter the following command to add a user group for the RADIUS server.

```
config user group
   edit Explicit_proxy_user_group
      set group-type firewall
      set member RADIUS_1
end
```

To add a security policy for the explicit FTP proxy

1. Enter the following command to add a firewall address for the internal subnet:

```
config firewall address
   edit Internal_subnet
      set type iprange
      set start-ip 10.31.101.1
      set end-ip 10.31.101.255
end
```

2. Enter the following command to add the explicit FTP proxy security policy:

```
config firewall explicit-proxy-policy
   edit 0
      set proxy ftp
      set dstintf wan1
      set srcaddr Internal_subnet
      set dstaddr all
      set action accept
      set identity-based enable
      set ipbased disable
      set active-auth-method basic
         config identity-based-policy
            edit 0
               set groups Explicit_Proxy_user_group
               set schedule always
               set utm-status enable
               set av-profile default
               set profile-protocol-options default
            end
   end
```

Testing and troubleshooting the configuration

You can use the following steps to verify that the explicit FTP proxy configuration is working as expected. These steps use a command line FTP client.

To test the explicit web proxy configuration

1. From a system on the internal network start an FTP client and enter the following command to connect to the FTP proxy:

```
ftp 10.31.101.100
```

   The explicit FTP proxy should respond with a message similar to the following:

```
Connected to 10.31.101.100.
220 Welcome to Fortigate FTP proxy
Name (10.31.101.100:user):
```

2. At the prompt enter a valid username and password for the RADIUS server followed by a user name for an FTP server on the Internet and the address of the FTP server. For example, if a valid username and password on the RADIUS server is ex_name and ex_pass and you attempt to connect to an FTP server at ftp.example.com with user name s_name, enter the following at the prompt:

```
Name (10.31.101.100:user):ex_name:ex_pass:s_name@ftp.example.com
```

3. You should be prompted for the password for the account on the FTP server.
4. Enter the password and you should be able to connect to the FTP server.
5. Attempt to explore the FTP server file system and download or upload files.

6. To test UTM functionality, attempt to upload or download an ECAR test file. Or upload or download a tex file containing text that would be matched by the DLP sensor.

   For eicar test files, go to http://eicar.org.

Explicit FTP proxy sessions and user limits

FTP clients do not open large numbers of sessions with the explicit FTP proxy. Most sessions stay open for a short while depending on how long a user is connected to an FTP server and how large the file uploads or downloads are. So unless you have large numbers of FTP users, the explicit FTP proxy should not be adding large numbers of sessions to the session table.

Explicit FTP proxy sessions and user limits are combined with explicit web proxy session and user limits. For information about explicit proxy session and user limits, see Explicit web proxy sessions and user limits on page 3538.

FortiGate WCCP

The Web Cache Communication Protocol (WCCP) can be used to provide web caching with load balancing and fault tolerance. In a WCCP configuration, a WCCP server receives HTTP requests from user's web browsers and redirects the requests to one or more WCCP clients. The clients either return cached content or request new content from the destination web servers before caching it and returning it to the server which in turn returns the content to the original requestor. If a WCCP configuration includes multiple WCCP clients, the WCCP server load balances traffic among the clients and can detect when a client fails and failover sessions to still operating clients. WCCP is described by the Web Cache Communication Protocol Internet draft.

The sessions that are cached by WCCP depend on the configuration of the WCCP clients. If the client is a FortiGate unit, you can configure the port numbers and protocol number of the sessions to be cached. For example, to cache HTTPS traffic on port 443 the WCCP client port must be set to 443 and protocol must be set to 6. If the WCCP client should also cache HTTPS traffic on port 993 the client ports option should include both port 443 and 993.

On a FortiGate unit, WCCP sessions are accepted by a security policy before being cached. If the security policy that accepts sessions that do not match the port and protocol settings in the WCCP clients the traffic is dropped.

WCCP is configured per-VDOM. A single VDOM can operate as a WCCP server or client (not both at the same time). FortiGate units are compatible with third-party WCCP clients and servers. If a FortiGate unit is operating as an Internet firewall for a private network, you can configure it to cache and serve some or all of the web traffic on the private network using WCCP by adding one or more WCCP clients, configuring WCCP server settings on the FortiGate unit and adding WCCP security policies that accept HTTP session from the private network.

FortiGate units support WCCPv1 and WCCPv2. A FortiGate unit in NAT/Route or transparent mode can operate as a WCCP server. To operate as a WCCP client a FortiGate unit must be in NAT/Route mode. FortiGate units communicate between WCCP servers and clients over UDP port 2048. This communication can be encapsulated in a GRE tunnel or just use layer 2 forwarding.

A WCCP server can also be called a WCCP router. A WCCP client can also be called a WCCP cache engine.

WCCP service groups, service numbers, service IDs and well known services

A FortiGate unit configured as a WCCP server or client can include multiple server or client configurations. Each of these configurations is called a WCCP service group. A service group consists of one or more WCCP servers (or routers) and one or more WCCP clients working together to cache a specific type of traffic. The service group configuration includes information about the type of traffic to be cached, the addresses of the WCCP clients and servers and other information about the service.

A service group is identified with a numeric WCCP service ID (or service number) in the range 0 to 255. All of the servers and clients in the same WCCP service group must have service group configurations with the same WCCP service ID.

The value of the service ID provides some information about the type of traffic to be cached by the service group. Service IDs in the range 0 to 50 are reserved for well known services. A well known service is any service that is

defined by the WCCP standard as being well known. Since the service is well known, just the service ID is required to identify the traffic to be cached.

Even though the well known service ID range is 0 to 50, at this time only one well known service has been defined. Its service ID 0, which is used for caching HTTP (web) traffic.

So to configure WCCP to cache HTTP sessions you can add a service group to the WCCP router and WCCP clients with a service ID of 0. No other information about the type of traffic to cache needs to be added to the service group.

Since service IDs 1 to 50 are reserved for well know services and since these services are not defined yet, you should not add service groups with IDs in the range 1 to 50.

FortiOS does allow you to add service groups with IDs between 1 and 50. Since these service groups have not been assigned well known services, however, they will not cache any sessions. Service groups with IDs 51 to 255 allow you to set the port numbers and protocol number of the traffic to be cached. So you can use service groups with IDs 51 to 255 to cache different kinds of traffic based on port numbers and protocol number of the traffic. Service groups 1 to 50; however, do not allow you to set port numbers or protocol numbers so cannot be used to cache any traffic.

To cache traffic other than HTTP traffic you must add service groups with IDs in the range 51 to 255. These service group configurations must include the port numbers and protocol number of the traffic to be cached. It is the port and protocol number configuration in the service group that determines what traffic will be cached by WCCP.

Example WCCP server and client configuration for caching HTTP sessions (service ID = 0)

Enter the following command to add a WCCP service group to a WCCP server that caches HTTP sessions. The IP address of the server is 10.31.101.100 and the WCCP clients are on the 10.31.101.0 subnet. The service

ID of this service group is 0.

```
config system wccp
   edit 0
      set router-id 10.31.101.100
      set server-list 10.31.101.0 255.255.255.0
   end
```

Enter the following commands to configure a FortiGate unit to operate as a WCCP client and add a service group that configures the client to cache HTTP sessions. The IP address of the server is 10.31.101.100 and IP address of this WCCP clients is 10.31.101.1 subnet. The service ID of this service group is 0.

```
config system settings
   set wccp-cache-engine enable
end

config system wccp
   edit 0
      set cache-id 10.31.101.1
      set router-list 10.31.101.100
   end
```

You cannot enter the `wccp-cache-engine enable` command if you have already added a WCCP service group. When you enter this command an interface named w.<vdom_name> is added to the FortiGate configuration (for example w.root). All traffic redirected from a WCCP router is considered to be received at this interface of the FortiGate unit operating as a WCCP client. A default route to this interface with lowest priority is added.

Example WCCP server and client configuration for caching HTTPS sessions

Enter the following command to add a service group to a WCCP server that caches HTTPS content on port 443 and protocol 6. The IP address of the server is 10.31.101.100 and the WCCP clients are on the 10.31.101.0 subnet. The service ID of this service group is 80.

```
config system settings
   set wccp-cache-engine enable
end

config system wccp
   edit 80
      set router-id 10.31.101.100
      set server-list 10.31.101.0 255.255.255.0
      set ports 443
      set protocol 6
   end
```

Enter the following commands to configure a FortiGate unit to operate as a WCCP client and add a service group that configures client to cache HTTPS sessions on port 443 and protocol 6. The IP address of the server is 10.31.101.100 and IP address of this WCCP clients is 10.31.101.1 subnet. The service ID of this service group must be 80 to match the service ID added to the server.

```
config system settings
   set wccp-cache-engine enable
end

config system wccp
   edit 80
      set cache-id 10.31.101.1
      set router-list 10.31.101.100
      set ports 443
      set protocol 6
   end
```

Example WCCP server and client configuration for caching HTTP and HTTPS sessions

You could do this by configuring two WCCP service groups as described in the previous examples. Or you could use the following commands to configure one service group for both types of traffic. The example also caches HTTP sessions on port 8080.

Enter the following command to add a service group to a WCCP server that caches HTTP sessions on ports 80 and 8080 and HTTPS sessions on port 443. Both of these protocols use protocol number 6. The IP address of the server is 10.31.101.100 and the WCCP clients are on the 10.31.101.0 subnet. The service ID of this service group is 90.

```
config system wccp
   edit 90
      set router-id 10.31.101.100
      set server-list 10.31.101.0 255.255.255.0
```

```
      set ports 443 80 8080
      set protocol 6
   end
```

Enter the following commands to configure a FortiGate unit to operate as a WCCP client and add a service group that configures client to cache HTTP sessions on port 80 and 8080 and HTTPS sessions on port 443. The IP address of the server is 10.31.101.100 and IP address of this WCCP clients is 10.31.101.1 subnet. The service ID of this service group must be 90 to match the service ID added to the server.

```
config system settings
   set wccp-cache-engine enable
end
config system wccp
   edit 90
      set cache-id 10.31.101.1
      set router-list 10.31.101.100
      set ports 443 80 8080
      set protocol 6
   end
```

Other WCCP service group options

In addition to using WCCP service groups to define the types of traffic to be cached by WCCP the following options are available for servers and clients.

Server configuration options

The server configuration must include the `router-id`, which is the WCCP server IP address. This is the IP address of the interface that the server uses to communicate with WCCP clients.

The `group-address` is used for multicast WCCP configurations to specify the multicast addresses of the clients.

The `server-list` defines the IP addresses of the WCCP clients that the server can connect to. Often the server list can be the address of the subnet that contains the WCCP clients.

The `authentication` option enables or disables authentication for the WCCP service group. Authentication must be enabled on all servers and clients in a service group and members of the group must have the same `password`.

The `forward-method` option specifies the protocol used for communication between the server and clients. The default forwarding method is GRE encapsulation. If required by your network you can also select to use unencapsulated layer-2 packets instead of GRE or select any to allow both. The `return-method` allows you to specify the communication method from the client to the server. Both GRE and layer-2 are supported.

The `assignment-method` determines how the server load balances sessions to the clients if there are multiple clients. Load balancing can be done using hashing or masking.

Client configuration options

The client configuration includes the `cache-id` which is the IP address of the FortiGate interface of the client that communicates with WCCP server. The `router-list` option is the list of IP addresses of the WCCP servers in the WCCP service group.

The `ports` option lists the port numbers of the sessions to be cached by the client and the `protocol` sets the protocol number of the sessions to be cached. For TCP sessions the protocol is 6.

The `service-type` option can be auto, dynamic or standard. Usually you would not change this setting.

The client configuration also includes options to influence load balancing including the `primary-hash`, `priority`, `assignment-weight` and `assignment-bucket-format`.

WCCP configuration overview

To configure WCCP you must create a service group that includes WCCP servers and clients. WCCP servers intercept sessions to be cached (for example, sessions from users browsing the web from a private network). To intercept sessions to be cached the WCCP server must include a security policy that accepts sessions to be cached and WCCP must be enabled in this security policy.

The server must have an interface configured for WCCP communication with WCCP clients. That interface sends and receives encapsulated GRE traffic to and from WCCP clients. The server must also include a WCCP service group that includes a service ID and the addresses of the WCCP clients as well as other WCCP configuration options.

To use a FortiGate unit as a WCCP client, the FortiGate unit must be set to be a WCCP client (or cache engine). You must also configure an interface on the client for WCCP communication. The client sends and receives encapsulated GRE traffic to and from the WCCP server using this interface.

The client must also include a WCCP service group with a service ID that matches a service ID on the server. The client service group also includes the IP address of the servers in the service group and specifies the port numbers and protocol number of the sessions that will be cached on the client.

When the client receives sessions from the server on its WCCP interface, it either returns cached content over the WCCP interface or connects to the destination web servers using the appropriate interface depending on the client routing configuration. Content received from web servers is then cached by the client and returned to the WCCP server over the WCCP link. The server then returns the received content to the initial requesting user web browser.

Finally you may also need to configure routing on the server and client FortiGate units and additional security policies may have to be added to the server to accept sessions not cached by WCCP.

Example caching HTTP sessions on port 80 using WCCP

In this example configuration (shown below), a FortiGate unit with host name WCCP_srv is operating as an Internet firewall for a private network is also configured as a WCCP server. The port1 interface of WCCP_srv is connected to the Internet and the port2 interface is connected to the internal network.

All HTTP traffic on port 80 that is received at the port2 interface of WCCP_srv is accepted by a port2 to port1 security policy with WCCP enabled. All other traffic received at the port2 interface is allowed to connect to the Internet by adding a general port2 to port1 security policy below the HTTP on port 80 security policy.

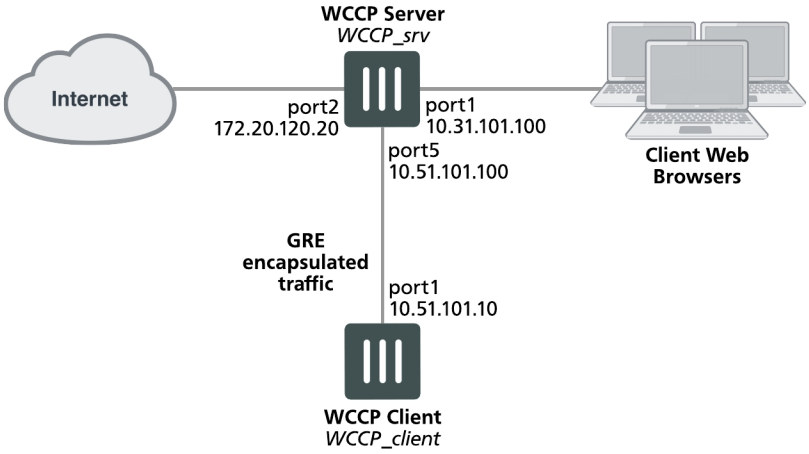
A WCCP service group is added to WCCP_srv with a service ID of 0 for caching HTTP traffic on port 80. The port5 interface of WCCP_srv is configured for WCCP communication.

A second FortiGate unit with host name WCCP_client is operating as a WCCP client. The port1 interface of WCCP_client is connected to port5 of WCCP_srv and is configured for WCCP communication.

WCCP_client is configured to cache HTTP traffic because it also has a WCCP service group with a service ID of 0.

WCCP_client connects to the Internet through WCCP_srv. To allow this, a port5 to port1 security policy is added to WCCP_srv.

FortiGate WCCP server and client configuration



Configuring the WCCP server (WCCP_srv)

Use the following steps to configure WCCP_srv as the WCCP server for the example network. The example steps only describe the WCCP-related configuration.

To configure WCCP_srv as a WCCP server

1. Add a port2 to port1 security policy that accepts HTTP traffic on port 80 and is configured for WCCP:

```
config firewall policy
   edit 0
      set srtintf port1
      set dstintf port2
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
      set service HTTP
      set wccp enable
      set nat enable
   end
```

2. Add another port2 to port1 security policy to allow all other traffic to connect to the Internet.

```
config firewall policy
   edit 0
      set srtintf port1
      set dstintf port2
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
      set service ANY
      set nat enable
   end
```

3. Move this policy below the WCCP policy in the port2 to port1 policy list.
4. Enable WCCP on the port5 interface.

```
config system interface
   edit port5
      set wccp enable
   end
```

5. Add a WCCP service group with service ID 0.

```
config system wccp
   edit 0
      set router-id 10.51.101.100
      set server-list 10.51.101.0 255.255.255.0
   end
```

6. Add a firewall address and security policy to allow the WCCP_client to connect to the internet.

```
config firewall address
   edit WCCP_client_addr
      set subnet 10.51.101.10
end
config firewall policy
   edit 0
      set srtintf port5
      set dstintf port1
      set srcaddr WCCP_client_addr
      set dstaddr all
      set action accept
      set schedule always
      set service ANY
      set nat enable
   end
```

Configuring the WCCP client (WCCP_client)

Use the following steps to configure WCCP_client as the WCCP client for the example network. The example steps only describe the WCCP-related configuration.

To configure WCCP_client as a WCCP client

1. Configure WCCP_client to operate as a WCCP client.

```
config system settings
   set wccp-cache-engine enable
end
```

You cannot enter the `wccp-cache-engine enable` command if you have already added a WCCP service group. When you enter this command an interface named w.<vdom_name> is added to the FortiGate configuration (for example w.root). All traffic redirected from a WCCP router is considered to be received at this interface of the FortiGate unit operating as a WCCP client. A default route to this interface with lowest priority is added.

2. Enable WCCP on the port1 interface.

```
config system interface
   edit port1
      set wccp enable
end
```

3. Add a WCCP service group with service ID 0.

```
config system wccp
   edit 0
      set cache-id 10.51.101.10
      set router-list 10.51.101.100
end
```

Example caching HTTP sessions on port 80 and HTTPS sessions on port 443 using WCCP

This example configuration is the same as thatdescribed in Example caching HTTP sessions on port 80 using WCCP on page 3561 except that WCCP now also cached HTTPS traffic on port 443. To cache HTTP and HTTPS traffic the WCCP service group must have a service ID in the range 51 to 255 and you must specify port 80 and 443 and protocol 6 in the service group configuration of the WCCP client.

Also the security policy on the WCCP_srv that accepts sessions from the internal network to be cached must accept HTTP and HTTPS sessions.

Configuring the WCCP server (WCCP_srv)

Use the following steps to configure WCCP_srv as the WCCP server for the example network. The example steps only describe the WCCP-related configuration.

To configure WCCP_srv as a WCCP server

1. Add a port2 to port1 security policy that accepts HTTP traffic on port 80 and HTTPS traffic on port 443 and is configured for WCCP:

```
config firewall policy
   edit 0
      set srtintf port2
      set dstintf port1
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
      set service HTTP HTTPS
      set wccp enable
      set nat enable
   end
```

2. Add another port2 to port1 security policy to allow all other traffic to connect to the Internet.

```
config firewall policy
   edit 0
      set srtintf port2
      set dstintf port1
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
      set service ANY

      set nat enable
   end
```

3. Move this policy below the WCCP policy in the port2 to port1 policy list.
4. Enable WCCP on the port5 interface.

```
config system interface
   edit port5
      set wccp enable
   end
```

5. Add a WCCP service group with service ID 90 (can be any number between 51 and 255).

```
config system wccp
   edit 90
      set router-id 10.51.101.100
      set server-list 10.51.101.0 255.255.255.0
   end
```

6. Add a firewall address and security policy to allow the WCCP_client to connect to the internet.

```
config firewall address
   edit WCCP_client_addr
      set subnet 10.51.101.10
   end
config firewall policy
   edit 0
      set srtintf port5
      set dstintf port1
      set srcaddr WCCP_client_addr
      set dstaddr all
      set action accept
      set schedule always
      set service ANY
      set nat enable
   end
```

Configuring the WCCP client (WCCP_client)

Use the following steps to configure WCCP_client as the WCCP client for the example network. The example steps only describe the WCCP-related configuration.

To configure WCCP_client as a WCCP client

1. Configure WCCP_client to operate as a WCCP client.

```
config system settings
   set wccp-cache-engine enable
end
```

You cannot enter the `wccp-cache-engine enable` command if you have already added a WCCP service group. When you enter this command an interface named w.<vdom_name> is added to the FortiGate configuration (for example w.root). All traffic redirected from a WCCP router is considered to be received at this interface of the FortiGate unit operating as a WCCP client. A default route to this interface with lowest priority is added.

2. Enable WCCP on the port1 interface.

```
config system interface
   edit port1
      set wccp enable
```

```
end
```

3. Add a WCCP service group with service ID 90. This service group also specifies to cache sessions on ports 80 and 443 (for HTTP and HTTPS) and protocol number 6.

```
config system wccp
   edit 90
      set cache-id 10.51.101.10
      set router-list 10.51.101.100
      ports 80 443
      set protocol 6
   end
```

WCCP packet flow

The following packet flow sequence assumes you have configured a FortiGate unit to be a WCCP server and one or more FortiGate units to be WCCP clients.

1. A user's web browser sends a request for web content.
2. The FortiGate unit configured as a WCCP server includes a security policy that intercepts the request and forwards it to a WCCP client.

   The security policy can apply UTM features to traffic accepted by the policy.
3. The WCCP client receives the WCCP session.
4. The client either returns requested content to the WCCP server if it is already cached, or connects to the destination web server, receives and caches the content and then returns it to the WCCP server.
5. The WCCP server returns the requested content to the user's web browser.
6. The WCCP router returns the request to the client web browser.

   The client we browser is not aware that all this is taking place and does not have to be configured to use a web proxy.

Configuring the forward and return methods and adding authentication

The WCCP forwarding method determines how intercepted traffic is transmitted from the WCCP router to the WCCP cache engine. There are two different forwarding methods:

- GRE forwarding (the default) encapsulates the intercepted packet in an IP GRE header with a source IP address of the WCCP router and a destination IP address of the target WCCP cache engine. The results is a tunnel that allows the WCCP router to be multiple hops away from the WCCP cache server.
- L2 forwarding rewrites the destination MAC address of the intercepted packet to match the MAC address of the target WCCP cache engine. L2 forwarding requires that the WCCP router is Layer 2 adjacent to the WCCP client.

You can use the following command on a FortiGate unit configured as a WCCP router to change the forward and return methods to L2:

```
config system wccp
   edit 1
      set forward-method L2
      set return-method L2
end
```

You can also set the forward and return methods to any in order to match the cache server configuration.

By default the WCCP communication between the router and cache servers is unencrypted. If you are concerned about attackers sniffing the information in the WCCP stream you can use the following command to enable hash-based authentication of the WCCP traffic. You must enable authentication on the router and the cache engines and all must have the same password.

```
config system wccp
   edit 1
      set authentication enable
      set password <password>
end
```

WCCP Messages

When the WCCP service is active on a web cache server it periodically sends a WCCP HERE I AM broadcast or unicast message to the FortiGate unit operating as a WCCP router. This message contains the following information:

- Web cache identity (the IP address of the web cache server).
- Service info (the service group to join).

If the information received in the previous message matches what is expected, the FortiGate unit replies with a WCCP I SEE YOU message that contains the following details:

- Router identity (the FortiGate unit's IP address.
- Sent to IP (the web cache IP addresses to which the packets are addressed)

When both ends receive these two messages the connection is established, the service group is formed and the designated web cache is elected.

Troubleshooting WCCP

Two types of debug commands are available for debugging or troubleshooting a WCCP connection between a FortiGate unit operating as a WCCP router and its WCCP cache engines.

Real time debugging

The following commands can capture live WCCP messages:

```
diag debug en
diag debug application wccpd <debug level>
```

Application debugging

The following commands display information about WCCP operations:

```
get test wccpd <integer>
diag test application wccpd <integer>
```

Where `<integer>` is a value between 1 and 6:

1. Display WCCP stats
2. Display WCCP config
3. Display WCCP cache servers
4. Display WCCP services
5. Display WCCP assignment
6. Display WCCP cache status

Enter the following command to view debugging output:

```
diag test application wccpd 3
```

Sample output from a successful WCCP connection:

```
service-0 in vdom-root: num=1, usable=1
cache server ID:
len=44, addr=172.16.78.8, weight=4135, status=0
rcv_id=6547, usable=1, fm=1, nq=0, dev=3(k3),
to=192.168.11.55
ch_no=0, num_router=1:
192.168.11.55
```

Sample output from the same command from an unsuccessful WCCP connection (because of a service group password mismatch):

```
service-0 in vdom-root: num=0, usable=0
diag debug application wccpd -1
Sample output:
wccp_on_recv()-98: vdom-root recv: num=160, dev=3(3),
172.16.78.8->192.168.11.55
wccp2_receive_pkt()-1124: len=160, type=10, ver=0200,
length=152
wccp2_receive_pkt()-1150: found component:t=0, len=20
wccp2_receive_pkt()-1150: found component:t=1, len=24
wccp2_receive_pkt()-1150: found component:t=3, len=44
wccp2_receive_pkt()-1150: found component:t=5, len=20
wccp2_receive_pkt()-1150: found component:t=8, len=24
wccp2_check_security_info()-326: MD5 check failed
```

Diagnose commands

The following get and diagnose commands are available for troubleshooting WAN optimization, web cache, explicit proxy and WCCP.

get test {wad | wccpd} <test_level>

Display usage information about WAN optimization, explicit proxy, web cache, and WCCP applications. Use `<test_level>` to display different information.

```
get test wad <test_level>
get test wccpd <test_level>
```

Variable	Description
`wad`	Display information about WAN optimization, web caching, the explicit web proxy, and the explicit FTP proxy.
`wccpd`	Display information about the WCCP application.

Examples

Enter the following command to display WAN optimization tunnel protocol statistics. The http tunnel and tcp tunnel parts of the command output below shows that WAN optimization has been processing HTTP and TCP packets.

```
get test wad 1
WAD manager process status: pid=113 n_workers=1 ndebug_workers=0
```

Enter the following command to display all test options:

```
get test wad

WAD process 82 test usage:
   1: display process status
   2: display total memory usage.
   99: restart all WAD processes
   1000: List all WAD processes.
   1001: dispaly debug level name and values
   1002: dispaly status of WANOpt storages
   1068: Enable debug for all WAD workers.
   1069: Disable debug for all WAD workers.
   2yxx: Set No. xx process of type y as diagnosis process.
   3: display all fix-sized advanced memory stats
   4: display all fix-sized advanced memory stats in details
   500000..599999: cmem bucket stats (599999 for usage)
   800..899: mem_diag commands (800 for help & usage)
   800000..899999: mem_diag commands with 1 arg (800 for help & usage)
   80000000..89999999: mem_diag commands with 2 args (800 for help & usage)
   60: show debug stats.
   61: discard all wad debug info that is currently pending
   62xxx: set xxxM maximum ouput buffer size for WAD debug. 0, set back to default.
   68: Enable process debug
```

```
69: Disable process debug
98: gracefully stopping WAD process
9xx: Set xx workers(0: default based on user configuration.)
```

diagnose wad

Display diagnostic information about the WAN optimization daemon (wad).

```
diagnose wad console-log {disable | enable)
diagnose wad debug-url {disable | enable)
diagnose wad filter {clear | dport | dst | list | negate | protocol | sport | src | vd}
diagnose wad history {clear | list}
diagnose wad session {clear | list}
diagnose wad stats {cache | cifs | clear | crypto | ftp | http | list | mapi | mem |
    scan | scripts | summary | tcp | tunnel}
diagnose wad user {clear | list}
diagnose wad tunnel {clear | list}1
diagnose wad webcache {clear | list} {10min | hour | day | 30days}
```

Variable	Description
`console-log`	Enable or disable displaying WAN optimization log messages on the CLI console.
`filter`	Set a filter for listing WAN optimization daemon sessions or tunnels. `clear` reset or clear the current log filter settings. `dport` enter the destination port range to filter by. `dst` enter the destination address range to filter by. `list` display the current log filter settings
`history`	Display statistics for one or more WAN optimization protocols for a specified period of time (the last 10 minutes, hour, day or 30 days).
`session`	Display diagnostics for WAN optimization sessions or clear active sessions.
`stats`	Display statistics for various parts of WAN optimization such as cache statistics, CIFS statistics, MAPI statistics, HTTP statistics, tunnel statistics etc. You can also clear WAN optimization statistics and display a summary.
`tunnel`	Display diagnostic information for one or all active WAN optimization tunnels. Clear all active tunnels. Clear all active tunnels.
`webcache`	Display web cache activity for the specified time period.

Example diagnose wad tunnel list

Enter the following command to list all of the running WAN optimization tunnels and display information about each one. The command output shows 10 tunnels all created by peer-to-peer WAN optimization rules (auto-detect set to off).

```
diagnose wad tunnel list

Tunnel: id=100 type=manual
   vd=0 shared=no uses=0 state=3
   peer name=Web_servers id=100 ip=172.20.120.141
   SSL-secured-tunnel=no auth-grp=
   bytes_in=348 bytes_out=384

Tunnel: id=99 type=manual
   vd=0 shared=no uses=0 state=3
   peer name=Web_servers id=99 ip=172.20.120.141
   SSL-secured-tunnel=no auth-grp=
   bytes_in=348 bytes_out=384

Tunnel: id=98 type=manual
   vd=0 shared=no uses=0 state=3
   peer name=Web_servers id=98 ip=172.20.120.141
   SSL-secured-tunnel=no auth-grp=
   bytes_in=348 bytes_out=384

Tunnel: id=39 type=manual
   vd=0 shared=no uses=0 state=3
   peer name=Web_servers id=39 ip=172.20.120.141
   SSL-secured-tunnel=no auth-grp=
   bytes_in=1068 bytes_out=1104

Tunnel: id=7 type=manual
   vd=0 shared=no uses=0 state=3
   peer name=Web_servers id=7 ip=172.20.120.141
   SSL-secured-tunnel=no auth-grp=
   bytes_in=1228 bytes_out=1264

Tunnel: id=8 type=manual
   vd=0 shared=no uses=0 state=3
   peer name=Web_servers id=8 ip=172.20.120.141
   SSL-secured-tunnel=no auth-grp=
   bytes_in=1228 bytes_out=1264

Tunnel: id=5 type=manual
   vd=0 shared=no uses=0 state=3
   peer name=Web_servers id=5 ip=172.20.120.141
   SSL-secured-tunnel=no auth-grp=
   bytes_in=1228 bytes_out=1264

Tunnel: id=4 type=manual
   vd=0 shared=no uses=0 state=3
   peer name=Web_servers id=4 ip=172.20.120.141
   SSL-secured-tunnel=no auth-grp=
   bytes_in=1228 bytes_out=1264

Tunnel: id=1 type=manual
   vd=0 shared=no uses=0 state=3
   peer name=Web_servers id=1 ip=172.20.120.141
   SSL-secured-tunnel=no auth-grp=
   bytes_in=1228 bytes_out=1264

Tunnel: id=2 type=manual
```

```
    vd=0 shared=no uses=0 state=3
    peer name=Web_servers id=2 ip=172.20.120.141
    SSL-secured-tunnel=no auth-grp=
    bytes_in=1228 bytes_out=1264

Tunnels total=10 manual=10 auto=0
```

Example diagnose wad webcache list

This following command displays the web caching stats for the last 10 minutes of activity. The information displayed is divided into 20 slots and each slot contains stats for 30 seconds:

20 * 30 seconds = 600 seconds = 10 minutes

```
diagnose wad webcache list 10min
web cache history vd=0 period=last 10min
```

The first 20 slots are for HTTP requests in the last 10 minutes. Each slot of stats has four numbers, which is the total number of HTTP requests, the number of cacheable HTTP requests, the number of HTTP requests that are processed by the web cache (hits), and the number of HTTP requests that are processed without checking the web cache (bypass). There are many reasons that a HTTP request may bypass web cache.

```
total        cacheable     hits         bypass
------------ ------------- ------------ -------------
36           10            3            1
128          92            1            10
168          97            2            3
79           56            0            3
106          64            5            3
180          118           6            11
88           53            7            3
80           43            4            4
107          44            9            2
84           12            0            2
228          139           52           10
32           2             0            5
191          88            13           7
135          25            40           3
48           10            0            8
193          13            7            7
67           31            1            2
109          35            24           6
117          36            10           5
22           0             0            4
```

The following slots are for video requests in the last 10 minutes. Each slot has two numbers for each 30 seconds: total number of video requests, and the number of video requests that are processing using cached data.

```
video total  video hit
------------ -------------
0            0
0            0
0            0
0            0
0            0
0            0
0            0
0            0
0            0
0            0
0            0
0            0
0            0
0            0
0            0
```

The following 20 slots are for traffic details in last 10 minutes. Each slot has four numbers for 30 seconds each.

```
--- LAN ---                --- WAN ---
bytes_in     bytes_out     bytes_in     bytes_out

59576        248734        164002       59448
```

diagnose wacs

Display diagnostic information for the web cache database daemon (wacs).

```
diagnose wacs clear
diagnose wacs recents
diagnose wacs restart
diagnose wacs stats
```

Variable	Description
clear	Remove all entries from the web cache database.
recents	Display recent web cache database activity.
restart	Restart the web cache daemon and reset statistics.
stats	Display web cache statistics.

diagnose wadbd

Display diagnostic information for the WAN optimization database daemon (waddb).

```
diagnose wadbd {check | clear | recents | restart | stats}
```

Variable	Description
check	Check WAN optimization database integrity.
clear	Remove all entries from the WAN optimization database.
recents	Display recent WAN optimization database activity.
restart	Restart the WAN optimization daemon and reset statistics.
stats	Display WAN optimization statistics.

diagnose debug application {wad | wccpd} [<debug_level>]

View or set the debug level for displaying WAN optimization and web cache-related daemon debug messages. Include a <debug_level> to change the debug level. Leave the <debug_level> out to display the current debug level. Default debug level is 0.

```
diagnose debug application wad [<debug_level>]
diagnose debug application wccpd [<debug_level>]
```

Variable	Description
wad	Set the debug level for the WAN optimization daemon.
wccpd	Set the debug level for the WCCP daemon.

diagnose test application wad 2200

The debug level 2200 switches the debug to explicit proxy mode. You have to enter this debug level first. After that you have to type the command again with a different debug level to check the different explicit proxy statistics. To list what each debug level shows, follow these steps in any FortiGate device:

1. Enable explicit proxy globally and in one interface, to start the wad process. If the wad process is *not* running, you *cannot* list the options.
2. Once the wad process starts, type:

```
diagnose test application wad 2200
diagnose test application wad  ///// Do not type any debug level value to list all the options.
```

This is the output you will get:

```
# diagnose test application wad 2200
Set diagnosis process: type=wanopt index=0 pid=114
# diagnose test application wad
WAD process 114 test usage:
1: display process status
2: display total memory usage
99: restart all WAD processes
1000: List all WAD processes
1001: dispaly debug level name and values
1002: dispaly status of WANOpt storages
1068: Enable debug for all WAD workers
1069: Disable debug for all WAD workers
2yxx: Set No. xx process of type y as diagnosis process
3: display all fix-sized advanced memory stats
4: display all fix-sized advanced memory stats in details
500000..599999: cmem bucket stats (599999 for usage)
800..899: mem_diag commands (800 for help & usage)
800000..899999: mem_diag commands with 1 arg (800 for help & usage)
80000000..89999999: mem_diag commands with 2 args (800 for help & usage)
60: show debug stats
61: discard all wad debug info that is currently pending
62xxx: set xxxM maximum ouput buffer size for WAD debug (0: set back to default)
68: Enable process debug
69: Disable process debug
98: gracefully stopping WAD process
20: display all listeners
21: display TCP port info
22: display SSL stats
23: flush SSL stats
24: display SSL mem stats
70: display av memory usage
71xxxx: set xxxxMiB maximum AV memory (0: set back to default)
72: toggle av memory protection
73: toggle AV conserve mode (for debug purpose)
90: set to test disk failure
91: unset to test disk failure
92: trigger a disk failure event
100: display explicit proxy settings
101: display firewall policies
102: display security profile mapping for regular firewall policy
103: display Web proxy forwarding server and group
104: display DNS stats
105: display proxy redirection scan stats
106: list all used fqdns
107: list all firewall address
110: display current web proxy users
111: flush current web proxy users
112: display current web proxy user summary
```
